Background: Endometrial cancer is one of the most common gynecologic malignancies in the world. however, the effects of systemic chemotherapy are limited. The combination of targeted therapy with immunotherapy is a new research field in the treatment of malignant tumors. Anlotinib is a novel tyrosine kinase inhibitor with highly selective inhibition effects on multi-targets, especially on vascular endothelial growth factor receptor, Platelet-derived growth factor receptor and Fibroblast growth factor receptor. Sintilimab is a highly selective, fully humanized, monoclonal antibody, which blocks the interaction between Programmed death 1 and its ligands. This research aimed to evaluate the efficacy and safety of the combination of anotinib and sintilimab in patients with recurrent advanced endometrial cancer. **Methods:** Patients who received at least one platinum-based systemic chemotherapy, had an Eastern Cooperative Oncology Group performance status of 0 or 1 were considered eligible for enrollment. Sintilimab was administered intravenously (200mg， q3w); anlotinib was taken orally (12mg qd, d1-14, 21 days per cycle). The treatment was continued until disease progression, death or intolerant toxicity. The primary endpoint was objective response rate (ORR) and the secondary endpoints included duration of response, disease control rate (DCR), progression-free survival (PFS), overall survival and safety. **Results:** From November 2019 to to September 2020, 23 patients with a median age of 56 years (range: 37-70), FIGO stage IA (21.7%), IB (8.7%), II (4.4%), IIIA (13.1%)， IIIC (30.4%), IVB (21.7%) were enrolled. Among these participants, 22 patients were evaluable. The therapeutic evaluation showed the incidence of complete response, partial response, stable disease and progression disease was 13.6%, 63.7%, 13.6% and 9.1% respectively, yielding the ORR of 77.3% (95%CI: 58.3%-96.3%) and the DCR of 91.7% (95%CI: 79.8%-100%). ≥1 and ＜ 1 Combined Positive Score of PD-L1 expression were observed in 66.7% (14/21) and 33.3% (7/21) patients respectively, and the ORR was 92.9% (95%CI: 77.4%-100%) and 57.1% (95%CI: 18.4%-90.1%) in the two groups. The median time of the first response was 1.5 months (range, 0.7-12.8). The median PFS was not reached. Most of the occurring adverse events (AEs) were grade 1 or 2. Grade 3 AEs included ileus (4.3%), immune myocarditis (4.3%) immune peritonitis (4.3%), hand-foot syndrome (8.7%), neutropenia (4.3%), neutrophils decrease (4.3%), and hypertension (4.3%); Grade 4 AE was lymphocytosis (4.3%). Neither unexpected safety signals nor treatment-related death occurred. **Conclusions:** Anlotinib plus sintilimab showed a promising antitumor activity with a favorable toxicity profile for patients with recurrent advanced endometrial cancer. We will report more data in the future. Clinical trial information: NCT04157491. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd., Pharmaceutical/Biotech Company.

Tumor-associated immune cells and progression-free survival in advanced endometrial cancer (EC), results from the PHAEDRA trial (ANZGOG 1601). *First Author: Deborah Smith, Mater Research Institute, The University of Queensland, Brisbane, QLD, Australia*

Background: Activity of durvalumab in patients with deficient mismatch repair (dMMR) advanced endometrial carcinoma (EC) was confirmed in the PHAEDRA trial (ANZGOG 1601). This study investigated the association between immune biomarkers and clinical outcomes in PHAEDRA. **Methods:** Formalin-fixed paraffin embedded sections immunohistochemically stained for PD-L1 using the Ventana platform, were with matched H&E slides scored independently by two pathologists according to the Ventana PD-L1 (SP263) algorithm for urothelial carcinoma (UC). Immune biomarkers assessed were PD-L1 staining of tumor cells (TCP) and immune cells (IC), and presence of tumor-associated immune cells (ICP). **Results:** Sixty-seven of the 71 patients had sufficient tumor for PD-L1 testing. AUC were 0.667, 0.726 and 0.644 for TCP, ICP and IC, respectively for predicting tumor response. Optimal cutpoints were TCP≥1%, ICP≥10% and IC≥35%. ICP≥10% achieved the highest sensitivity (53%) and specificity (82%) of the individual cutpoints. The optimal cutpoint algorithm was able to identify patients who would not respond, (sensitivity 88%, negative predictive value 92%), but had low specificity (48%) and positive predictive value (37%). Differences in PFS were found using ICP≥10% (logrank p = 0.01), compared to TCP (p = 0.25), IC (p = 0.48) and the UC algorithm (p = 0.08) (Figure 1). PFS was shorter in patients with pMMR than dMMR after adjusting for ICP (HR 2.99, 95%CI: 1.61-5.57, $p < 0.001$). Adjustment for MMR reduced the prognostic significance of ICP≥10% for PFS (HR 0.59, 95% CI: 0.28-1.23, p = 0.16). For OS, differences were seen for the UC algorithm (p = 0.02), but not ICP (p = 0.07), TCP (p = 0.18) or IC (p = 0.23). Similarly to PFS, adjustment for MMR reduced the prognostic significance of the UC algorithm for OS (HR: 0.53, 95% CI: 0.25-1.12, p = 0.10). **Conclusions:** In this exploratory analysis, ICP was more closely associated with tumor response and PFS than TCP or IC. ICP alone was better than the UC algorithm for predicting PFS. The optimum cutpoint algorithm was promising for identifying non-responders, but requires external validation. Clinical trial information: ACTRN12617000106336. Research Sponsor: Astra Zeneca.

Computational features of TIL architecture are differentially prognostic of uterine cancer between African and Caucasian American women. *First Author: Sepideh Azarianpour Esfahani, Case Western Reserve University, Cleveland Heights, OH*

Background: Although the vast majority of endometrial cancer (EC) is early-stage and thus, curable by surgery, chemotherapy, and radiotherapy (with at least 85% 5-year OS), a fraction of them are aggressive neoplasms such as high-grade or deeply invasive lesions and thus exhibit poor prognosis. African American (AA) women are disproportionately affected by high-grade EC and have 80% higher mortality rate compared with Caucasian American (CA) women. In this work, we evaluated the prognostic ability of computational measurements of architecture of tumor-infiltrating lymphocytes (ArcTIL) from H&E slide images for EC. We also investigated the presence of morphologic differences in terms of ArcTIL features between AA and CA women and whether ArcTIL based population-specific models were more prognostic of OS in AA women compared to a population-agnostic model. **Methods:** The study included digitized H&E tissue slides from 445 post-surgery EC patients from TCGA, with further chemotherapy, or radiotherapy, including only the AA and CA patients, patients without reported race or from other populations were excluded. The dataset was divided into discovery (D1, n = 300), and a validation set (D2, n = 145), while ensuring population balance between two splits (D1(AA) = 65, D1(CA) = 235, D2(AA) = 37, D2(CA) = 108). A machine learning approach was employed to identify tumor regions, and tumor-associated stroma on the diagnostic slides and then used to automatically identify TILs within these compartments. Graph network theory based computational algorithms were used to capture 85 quantitative descriptors of the architectural patterns of intratumoral and stromal TILs. A multivariable Cox regression model (MCRM) was used to create population specific-prognostic models (M_{AA}, M_{CA}) and a population-agnostic model (M_{AA+CA})) to predict OS. All 3 models were evaluated on D2(AA), D2(CA), and D2. **Results:** M_{AA} identified 4 prognostic features relating to interaction of TIL clusters with cancer nuclei in stromal compartment and was prognostic of OS on D2(AA) (see Table) but not prognostic in D2(CA) nor D2(AA+CA). M_{CA} and M_{AA+CA} identified respectively 7 and 6 prognostic features relating to interaction of TIL clusters with cancer nuclei (both in the epithelial and stromal regions) and were prognostic of OS on D2(CA) and D2, but not prognostic in D2(AA). **Conclusions:** Our findings suggest an important role of stromal TIL architecture in prognosticating OS in AA women with EC, while epithelial TIL features were more prognostic in CA women. These findings need to be validated in larger, multi-site validation sets. Research Sponsor: U.S. National Institutes of Health, US Department of Veterans Affairs, US Department of Defense.

Lurbinectedin (LUR) in combination with Irinotecan (IRI) in patients (pts) with advanced endometrial carcinoma. *First Author: Alejandro Falcon Gonzalez, Hospital Universitario Virgen del Rocio, Seville, Spain*

Background: LUR is a new agent that exerts antitumor activity through inhibition of trans-activated transcription and modulation of tumor microenvironment. Preclinical synergism/additivity in combination with IRI has been reported, thus prompting the conduct of this trial. This synergism had been evaluated and recently reported in patients with Small Cell Lung Cancer, with encouraging results (Ponce et al. WCLC, 2020). **Methods:** Phase I trial to evaluate escalating doses of LUR on Day (D) 1 plus a fixed dose of IRI 75 mg/m^2 on D1 and D8 every 3 weeks (q3w) in pts with advanced solid tumors, enrolled following a standard 3+3 dose escalation design. Phase II to expand in selected indications at the Recommended Dose (RD). In this abstract, the cohort of patients with endometrial carcinoma treated at the RD is presented. **Results:** 21 pts (all female) with endometrial carcinoma were treated at the RD (LUR 2 mg/m2 + IRI 75 mg/m2 + G-CSF); 57% had ECOG PS=1; median age was 64 years (range 34-74); subtype of tumour was split: 67% (14 pts) endometroid, 33% non-endometroid (3 pts serouspapilar, 3 pts clear-cell and 1 pt undifferentiated); median of 2 prior lines (range, 1−7) per pt. Common G1/2 toxicities were nausea, vomiting, fatigue, diarrhea and anorexia; G3/4 hematological toxicities comprised neutropenia (33%), thrombocytopenia (5%) and anemia (38%). Two episodes of febrile neutropenia occurred (9.5%). G3/4 non hematological toxicities consisted of diarrhea (24%), asthenia (19%), nausea (14%) and vomiting (5%), all were transient and manageable. 1 patient (5%) discontinued treatment due to toxicity drug-related (generalized muscular weakness), but no treatment-related deaths were reported. Objective RECIST responses were documented in 4/21 evaluable pts (19%). With 6 pts censored for progression, median PFS was 4.4 months (95% CI 2.1-9.6 months), and PFS at 6 months was 40.4%. The clinical benefit rate (% of pts with Complete Response (CR), Partial Response (PR) or Stable Disease > 4 months) was 43%, and the Disease Control Rate (% of pts with CR, PR or SD) 81%. 3/21 pts (14%) have been more than 12 months on treatment so far. **Conclusions:** The combination of Lurbinectedin and Irinotecan is active in heavily pretreated patients with endometrial carcinoma. The combination was well-tolerated and consistent with the known safety profile for this combination. Myelosuppression, diarrhea, nausea and asthenia were predictable and manageable. Updated results of this cohort will be presented at the meeting. Clinical trial information: NCT02611024. Research Sponsor: PharmaMar SA, CDTI.

Exploring molecular profiles of uterine carcinosarcoma with alterations in the chromatin remodeling pathway. *First Author: Annelise M. Wilhite, University of South Alabama, Mobile, AL*

Background: In a preliminary data analysis to identify prognostic molecular biomarkers in uterine carcinosarcoma (UCS), we found that alterations in KMT2C, a gene involved in the chromatin remodeling pathway, correlated with improved survival. We sought to explore relevant biomarkers of KMT2C-mutated (KMT2C-mut) tumors compared to wildtype (KMT2C-wt) tumors. **Methods:** Tumor samples were analyzed using next generation sequencing (NGS) of the DNA (NextSeq, 592 genes or NovaSeq, whole exome sequencing) and RNA (NovaSeq, whole transcriptome sequencing) and immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ).PD-L1 IHC used SP-142 (cut-off >1%). Microsatelite instability (MSI) was tested by FA, IHC and NGS. TMB was measured by totaling somatic mutations per tumor (high > 10 mutations per MB). Immune cell fraction was calculated by QuantiSeq. Overall survival (OS) information was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined patient cohorts. Statistical significance was determined using chi-square and Wilcoxon rank sum test and p values adjusted for multiple comparisons (q) to be <0.05. **Results:** Molecular analysis was performed on 1,144 UCS tumors. 7.7% were found to be KMT2C-mut. Patients with pathogenic alterations in KMT2C had longer median OS than patients without (OS not yet reached vs 19.0 months HR(95% CI): 0.37(0.19-0.72) p< 0.01). The most common mutations in KMT2C-mut tumors are shown in Table and resulted in more frequent dysregulation in the following pathways compared to KMT2C-wt tumors: chromatin remodeling (100% vs 28%; q<0.01), WNT (39% vs 12%; q=0.01), base/nucleotide excision repair (29% vs 5%; q<0.01), homologous recombination (26% vs 6%; q=0.02), DNA damage sensors (23% vs 4%; q=0.02) and Fanconi anemia (13% vs 1%; q=0.04). KMT2C-mut tumors were more frequently MSI-H (32% vs 6%; q<0.01) and TMB-H (42% vs 5%; q<0.01). Among MSS tumors, KMT2C-mut tumors had increased mutations in JAK1 and POLE (q<0.01) and higher frequency of TMB-H (24% vs 1%; q<0.01) than KMT2C-wt tumors. Additionally, MSS patients with KMT2C-mut had longer OS than patients with KMT2C-wt tumors (OS not yet reached vs 18.9 months; HR(95% CI): 0.33(0.15-0.75) p< 0.01). **Conclusions:** Mutations in KMT2C correlate with improved OS in UCS. KMT2C-mut tumors have distinct molecular profiles from wild type tumors. They exhibit greater immunogenicity, including more frequent MSI-H and TMB-H. This suggests a potential role for Immune-oncology (IO) therapy. Further study of the impact of IO therapies in the cohort is warranted as this may contribute to the improved survival of these patients. Research Sponsor: None.

Association of the presence of estrogen and progesterone receptors in uterine carcinosarcoma with improved survival and increased immunogenicity. *First Author: Nathaniel L. Jones, University of South Alabama, Mobile, AL*

Background: Recent data has shed light on molecular profiles of uterine carcinosarcoma (UCS), but few have correlated molecular profiles with prognosis. In a preliminary data analysis, we found that hormone receptors (HR)—estrogen receptor (ER) and progesterone receptor (PR)—expression was associated with improved OS. Here, we investigate the molecular profile differences between ER+/- and PR +/- tumors. **Methods:** Tumor samples were analyzed using Next-Generation sequencing of DNA (NextSeq, 592 genes or NovaSeq, whole exome sequencing) and RNA (NovaSeq, whole transcriptome sequencing) and immunohistochemistry (IHC) at the Caris Life Sciences Laboratory (Phoenix, AZ).ER and PR tested by IHC on whole tumor (cut-off: +1, 10%). PD-L1 IHC used SP-142 (cut-off >1%). MSI was tested by FA, IHC an NGS. TMB was measured by totaling somatic mutations per tumor (high > 10 mutations per MB). Immune cell fraction was calculated by QuantiSeq. Overall survival (OS) information was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined cohorts. Statistical significance was determined by chi-square and Wilcoxon rank sum test and p-values adjusted for multiple comparisons (q) to be <0.05. **Results:** 1,144 UCS tumors were included. (ER+, n=261; PR+, n=197; HR+ (ER+ and PR+), n=168). Median OS for patients with hormone receptor (HR)+ tumors was significantly longer than for patients with HR- tumors (months: 34.8 vs 17.4; HR(95% CI): 0.67 (0.53-0.84), p<0.01). This remained significant for ER (29.4 vs 17.3) and PR (25.3 vs 18.7) individually. ER+ tumors had fewer alterations in the TP53 pathway (71.4% vs 82.1%) in the WNT (19.5% vs 5.8%) pathway than ER- tumors (q<0.05). PR+ tumors had similar findings in the TP53 and WNT pathways, and also more alterations in the DNA damage sensor pathway. Both ER+ and PR+ UCS tumors had significantly increased MSI-H (ER: 10.9% vs 5.5%, PR: 12.9% vs 5.5%) and TMB-H (ER: 16.8% vs 6.0%; PR: 19.5% vs 6.1%) (all q<0.05) compared to ER- and PR- tumors. They also had increased T-reg cells in their immune micro-environment and increased expression of the immune checkpoint gene IDO1 (q<0.05; Table). **Conclusions:** HR+ tumors have distinct molecular profiles from HR- tumors. ER+ and PR+ UCS tumors appear more immunogenic with more frequent MSI-H status, TMB-H, increased infiltrating regulatory T-cells and IDO1 expression, suggesting possible benefit with immune-oncology (IO) therapy. This may contribute to the observed improved OS, but more data are needed to determine if HR status is a marker of response to IO therapy. Research Sponsor: None.

Use of Khorana score to predict VTE in patients undergoing chemotherapy for uterine cancer. *First Author: Vincent Wagner, The Ohio State University Wexner Medical Center and James Cancer Hospital, Columbus, OH*

Background: Gynecologic cancers are associated with a high risk of venous thromboembolism (VTE). The Khorana score is a clinically-validated tool to assess risk of VTE in cancer patients (using disease site, BMI and blood counts). Recent ASCO clinical practice guidelines have recommended patients with a Khorana score of 2 or greater be offered pharmacologic thromboprophylaxis during systemic chemotherapy. For women with uterine cancer, the utility of the Khorana score is still unknown. **Methods:** A retrospective cohort study was performed from January 2016 to January 2020. All patients with uterine cancer were screened. Patients receiving chemotherapy, both neoadjuvant (NACT) and adjuvant (ACT), were included. VTE was evaluated for 12 months following the first cycle of chemotherapy. The Khorana score was calculated for each patient using both a high risk score of ≥2 and ≥3 and the patients were stratified based on NACT vs ACT. Logistic regression and chi-square were used to evaluate the prognostic utility of the Khorana score as well as other clinico-pathologic criteria on development of VTE. **Results:** A total of 265 patients were included. The majority of patients were obese (160, 60.4%) and 60 years or older (188, 70.9%). The most common histology was endometrioid (107, 40.4%) followed by serous (71, 26.8%) and the majority were advanced-stage (169, 63.8%). Most women underwent hysterectomy during treatment (243, 91.7%) followed by ACT (228, 86.0%). 14% (37) had NACT. 24 patients developed VTE (9.1%), which was higher, but not statistically different, with NACT vs ACT (13.5% vs 8.3%, p = 0.35). Demographics including age, race and BMI nor pathologic data including histology, grade or stage significantly correlated with development of VTE. Similarly, treatment factors including undergoing hysterectomy and radiation treatment were not statistically significant in regards to VTE. The proportion of patients with high Khorana score (both ≥2 and ≥3) was similar between groups. In the whole cohort, high Khorana score (defined either as ≥2 or ≥3) did not significantly predict VTE; however, the model using ≥3 was more predictive (OR 1.154, 95%CI 0.402-2.907, p = 0.7326). In the NACT cohort, neither model was predictive of VTE (both with OR < 1). In the ACT group, Khorana ≥3 was a better prediction model, but was still not statistically significant (OR 1.557, 95%CI 0.480-4.343, p = 0.4213). **Conclusions:** Although validated in other cancer types, the Khorana score was found to be a poor predictor of VTE in this population. A defined high risk Khorana score of ≥3 (per the original validation study) better predicted VTE than a score of ≥2 (per guidelines). Independent of the Khorana score, demographic and pathologic data were poor predictors of VTE. At this time, use of the Khorana score to guide routine thromboprophylaxis in patients undergoing chemotherapy for uterine cancer should be used with caution. Research Sponsor: None.

Immune-response markers and actual response to immune-oncology therapy in uterine serous carcinoma. *First Author: Nathaniel L. Jones, University of South Alabama, Mobile, AL*

Background: Uterine serous carcinoma (USC) is an aggressive subtype of endometrial cancer with poor prognosis and limited treatment options. Immune-oncology (IO) agents have shown promise USC, however data is limited regarding which patients benefit most from IO therapy. In other malignancies, PD-L1, MSI-H status and high TMB have been predictive of IO response. We sought to characterize the immune profiles of USC and investigate treatment response to IO therapy. **Methods:** Tumor samples were analyzed using Nex-Gen sequencing of the DNA (NextSeq, 592 genes or NovaSeq, whole exome sequencing) and RNA (NovaSeq, whole transcriptome sequencing) and immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ).PD-L1 IHC used SP-142 (cut-off >1%). MSI was tested by FA, IHC and NGS. TMB was measured by totaling somatic mutations per tumor (high > 10 mutations per MB). Immune cell fraction was calculated by QuantiSeq. Real-world overall survival (OS) information was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined patient cohorts. Statistical significance was determined using chi-square and Wilcoxon rank sum test and p values adjusted for multiple comparisons (q) to be < 0.05. **Results:** Molecular analysis was performed on 2,806 USC tumors. The median age was 67 years. 65.3% were from primary tumors, 34.7% from metastatic sites. In total, 92 patients were treated with IO therapy and had a significantly longer median survival than those not treated with IO (months: 59.6 vs 31.2; HR(95% CI): 0.38(0.24-0.61) p < 0.001), resulting in a survival advantage of 867 days. PD-L1 expression was present in 19.1% of cases, but only 2.3% of tumors were MSI-H and 4.2% were TMB-H. Patients with these markers trended toward a better median survival, but this was not significant; PD-L1 (months: 34.4 vs 31.2; HR(95% CI): 0.90 (0.74-1.1), MSI-H (OS not yet reached vs 31.6 months; HR(95% CI): 0.69(0.38-1.25) and TMB-H (months: 36.4 vs 31.6; HR(95% CI): 0.84(0.50-1.39). Regarding the immune microenvironment, the most common infiltrating immune cells were M2 Macrophages (5.35%), B cells (4.71%), myeloid dendritic cells (3.45%), NK cells (2.94%) and regulatory T cells (1.59%). There were few CD8 T cells and non-regulatory CD4 T cells. **Conclusions:** IO therapy was associated with a median survival benefit of more than 2 years in USC. We did not identify any prognostic markers of IO-therapy response. MSI-H and TMB-H are rare in USC, but PD-L1 is present in nearly 20% of cases. Notably these markers did predict a significant survival benefit, which has important clinical implications. Further study is warranted. Research Sponsor: None.

Metabolic and bariatric surgery among endometrial cancer survivors: Are we missing an opportunity to help? *First Author: Justin Gray, UB MD Surgery, Buffalo, NY*

Background: Multiple studies have delineated a clear link between the estrogenic effects of obesity and the incidence of endometrial cancer (EC). Obese EC patients are less likely to receive guideline-recommended surgical treatment (ST) relying instead on chemotherapy and radiation therapy. Furthermore, EC patients are more likely to die from obesity-related complications than from cancer-related causes. Several small-scale studies have demonstrated that metabolic and bariatric surgery (MBS) could offer EC patients fast, safe and effective weight loss, which provides an opportunity to improve survival. This is the first population-based study that examines uptake and outcomes of MBS among EC survivors in New York State (NYS). **Methods:** This study was based on the all-payer longitudinal data from the NYS's Statewide Planning and Research Cooperative System and included inpatient and ambulatory surgeries performed between 2006 and 2012. Using ICD and CPT diagnostic and procedure codes, we identified patients diagnosed with EC for the first time, and we further examined whether they received ST within one year of their initial EC diagnosis. We followed EC patients with ST for 4 years to examine the rates of MBS, and we assessed long-term patient outcomes through 2019. We conducted bivariate and multivariate analyses to evaluate all-cause mortality and identify risk factors for poor surgical outcomes and readmissions. **Results:** Among 24,950 EC patients (2006-2012), 16,156 (65%) of them underwent ST within 1 year of EC diagnosis. Compared to those who did not receive ST, patients who underwent ST were younger, less likely to be White and more likely to be from urban counties, had private insurance, diagnosed with diabetes and hypertension, and had lower Elixhauser scores for readmission and mortality ($p < 0.01$ for all). Within 4 years following ST, 136 (0.8%) EC patients underwent MBS. Those who underwent MBS were younger ($p < 0.01$), predominantly white, privately insured, morbidly obese ($p < 0.01$) and diabetic ($p = 0.01$) compared to those who did not undergo MBS. **Conclusions:** Despite having higher risk of mortality from obesity-related complications such as diabetes and cardiovascular disease, the proportion of EC patients obtaining MBS (0.8%) was similar to that seen among the US population eligible for MBS (1.0%). More research is needed to understand barriers to MBS among eligible women with EC. Research Sponsor: Empire Clinical Research Investigator Program (ECRIP).

Photodynamic therapy for preinvasive vaginal cancer. *First Author: Viktoria A. Ivanova, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Photodynamic therapy (PDT) is an effective method for the treatment of various cancers resulting in apoptosis, autophagy and ischemic necrosis of irradiated tissues. The purpose of the study was to analyze the efficacy of PDT for pre-invasive vaginal cancer treatment. **Methods:** PDT results were studied in 20 patients aged 32-65 years with verified pre-invasive vaginal cancer. All patients received PDT with the Latus diode laser and Photolon or Photolan photosensitizers. The effect was evaluated with extended colposcopy. The criteria for efficiency included normalization of the colposcopic picture and the absence of atypical cells. The sizes of the irradiation fields varied from 1.5 to 2 cm, the number of fields - from 1 to 4, the power density - from 0.1 to 0.17 W/cm2, the light dose - from 40 to 100 J/cm2. The duration of a PDT session varied from 10 to 30 min, depending on the number of irradiation fields. The irradiation field necessarily included an area of normal tissue 3-5 mm surrounding the lesion. 4 to 6 sessions were required to restore the normal layer of stratified squamous epithelium. The antitumor efficacy of PDT was evaluated based on the results of visual observation of changes in the area of the treated pathological foci and information on the presence or absence of clinical symptoms of the disease 1 and 3 months after the treatment (WHO criteria). **Results:** Complete regression was registered in 100% of patients after 3 months. Repeated courses of PDT were required in cases with a wide spread of pathological foci and the impossibility of their simultaneous irradiation. At follow-up after 1 month, 3 of 20 patients (15%) showed local foci of atypical changes in the epithelium managed with repeated PDT courses. In 6 months, stable remission of the disease clinical symptoms in the treated pathological foci was registered. The results of the cytological study performed 3 months after PDT were normal in 100% patients; no negative changes were registered 6 and 12 months after PDT. **Conclusions:** The results of PDT in the treatment of patients with pre-invasive vaginal cancer demonstrated its high therapeutic efficacy and a minimal number of adverse reactions, which allows recommending PDT in the treatment of pre-invasive vaginal cancer. Does time to completion of radiation treatment in locally advanced vulvar cancer impact survival? *First Author: Nancy T. Nguyen, University of California Davis, Department of Obstetrics Gynecology, Division of Gynecologic Oncology, Sacramento, CA*

Background: Although well established in cervical cancer, it is unclear whether time from initiation to completion of radiation therapy for vulvar cancer affects survival outcomes. We seek to assess if completion of radiation, either alone (RT) or as concurrent chemoradiation (CRT), within a planned timeframe in locally advanced squamous cell vulvar cancer impacts overall survival (OS). **Methods:** Women 18 years or older with FIGO stage II to IVA vulvar cancer who received external beam RT or CRT as part of their initial treatment course were identified from the National Cancer Database from 2004-2017. Patients with non-squamous cell carcinoma histology or who received systemic cytotoxic therapies as primary treatment were excluded. Patients who received less than 20 fractions of radiation were also excluded. Time to radiation completion was the number of days from the initiation to completion of radiation. The delay of radiation completion was calculated as the difference between the actual time to radiation completion and predicted duration of radiation. Types of treatment (RT and CRT) were both stratified into groups based on the delay of radiation completion, less than 7 days or greater than 7 days. Chi-square, Fisher Exact ANOVA and Kruskal-Wallis tests were used for analysis. Kaplan-Meier curves with log-rank tests were fit for univariate time-to-event analysis. Multivariable Cox proportional hazard models were fit to assess effects after controlling for confounding. **Results:** There were 2378 patients identified for analysis (n = 856 RT and n = 1522 CRT). Median age was 67 (IQR 56-78) and the CRT group was younger ($p < 0.0001$) than the RT group. The majority were white (88.35%) with advanced FIGO stage III or IVA (72.29 %) disease. Median dose of total radiation was 5720 cGy (IQR 5040-6300) with higher doses observed in the greater than 7 days delay group versus less than 7 days, ($p < 0.0001$). Median follow up was 27.2 (IQR 11.8-57.9) months. For both cohorts, completion of treatment with delay less than 7 days resulted in significant improvement in median survival when compared to treatment completion delay of more than 7 days: RT (Median OS 34.9 versus 21.6 months, $p < 0.01$) and CRT (58 versus 41.3 months, $p < 0.01$). On multivariate subset analysis, both completion of CRT and RT were associated with improved OS when treatment was completed with less than 7 days delay vs greater than 7 days delay, CRT (HR 0.869 [95%CI 0.758-0.997]), RT (HR 0.820 [95%CI 0.698-0.964]). Advanced FIGO stage IVA was associated with the greatest increase in hazard of death, (HR 1.758 [95%CI 1.516-2.039]), compared to FIGO stage II. **Conclusions:** Completion of radiation with less than 7 days delay is associated with improved overall survival, which is independent of concurrent chemotherapy. These findings suggest that strategies to minimize delays in radiation treatment are crucial in treating locally advanced vulvar cancer. Potential impact of HPV vaccine on incidence of high-grade vulvar, vaginal, and anal precancers among females and males aged 15 to 39 years, United States 2000 to 2017. *First Author: Mona Saraiya, CDC/NCCDPHP/DCPC, Atlanta, GA*

Background: Since introduction of HPV vaccine, cervical precancers have decreased, but the vaccine's impact on non-cervical anogenital precancers is unknown. These precancers are identified opportunistically and are not routinely collected in most cancer registries. **Methods:** We examined high-grade vulvar (VIN3), vaginal (VAIN3), and anal (AIN3) precancers among persons aged 15-39 years using 2000-2017 data from select cancer registries covering 27.8% of the U.S. population. Incidence trends were evaluated with Joinpoint regression. **Results:** VIN3 rates declined 21% per year post-HPV vaccination introduction among women. VAIN3 rates declined 19.1% per year among women aged 15-29 years, also post-HPV vaccination introduction. Compared to the pre-vaccination period when AIN3 rates were increasing, AIN3 rates were stable among women aged 15-29 years and among men aged 30-39 years. **Conclusions:** Decreases in rates of VIN3 and VAIN3 after HPV vaccine introduction among younger age groups were similar to declines observed in cervical precancers, suggesting HPV vaccine impact. Research Sponsor: Funding support for the primary author was received from Oak Ridge Institute for Science and Education, an asset of the United States Department of Energy.

TPS5595 **Poster Session**

AdvanTIG-202: A phase 2 study investigating anti-TIGIT monoclonal antibody ociperlimab plus anti-PD-1 monoclonal antibody tislelizumab in patients with previously treated recurrent or metastatic cervical cancer. *First Author: Lingying Wu, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

Background: Women with recurrent/metastatic cervical cancer represent a poor prognostic group with high unmet clinical needs. T-cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibition motif domains (TIGIT) is a co-inhibitory, immune checkpoint receptor expressed on immune cells and upregulated on T-cells and natural killer cells in multiple solid tumors, inhibiting anticancer immune responses. Ociperlimab (BGB-A1217) is a novel, humanized, monoclonal antibody that binds TIGIT with high specificity and affinity, blocking the interaction with its ligands on tumor cells. Tislelizumab is an anti-PD-1 antibody engineered to minimize binding to FcγR on macrophages to abrogate antibody-dependent phagocytosis, a mechanism of T-cell clearance and potential resistance to anti-PD-1 therapy. Preclinical and clinical studies suggest that dual targeting with anti-TIGIT and anti-PD-1 antibodies produces synergistic immune cell activation and enhanced antitumor activity. **Methods:** AdvanTIG-202 is a Phase 2, randomized, multicenter, open-label study (NCT04693234). Approximately 167 pts with cervical squamous cell or adenosquamous carcinoma or adenocarcinoma, recruited from 100 centers, whose disease progressed on or after ≥ 1 prior line of chemotherapy for recurrent/metastatic disease will be included in this 2-Part study. In Part 1, approximately 80 pts will be randomized (1:1) to either ociperlimab 900 mg intravenously (IV) in combination with tislelizumab 200 mg IV every 3 weeks (Q3W) (Arm 1), or tislelizumab monotherapy 200 mg IV Q3W (Arm 2), until disease progression, unacceptable toxicity, or withdrawal of consent. In Part 2, Arm 1 will be expanded by approximately 87 additional pts whose tumors are evaluable for PD-L1 expression. The primary endpoint is overall response rate (ORR) (RECIST v1.1) assessed by Independent Review Committee (IRC) in Arm 1. Secondary endpoints are investigator-assessed ORR in Arm 2, IRC-assessed and investigator-assessed ORR in Arm 1, IRC-assessed and investigator-assessed duration of response, progression-free survival, time to response, disease control rate, clinical benefit rate and overall survival, cancer-specific health-related quality of life (HRQoL), safety, pharmacokinetics and immunogenicity in Arms 1 and 2. Exploratory endpoints are generic HRQoL and the association of biomarkers with patient prognosis, response or resistance. Clinical trial information: NCT04693234. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Jessica Jones, PhD, of Ashfield MedComms, an Ashfield Health company, and funded by BeiGene, Ltd.

TPS5596 **Poster Session**

Tisotumab vedotin versus investigator's choice chemotherapy in second- or third-line recurrent or metastatic cervical cancer (innovaTV 301/ENGOT-cx12/GOG 3057, trial in progress). *First Author: Ignace Vergote, Belgium and Luxembourg Gynaecological Oncology Group (BCOG), University of Leuven, Leuven Cancer Institute, Leuven, Belgium*

Background: Doublet chemotherapy (paclitaxel plus either platinum or topotecan) with bevacizumab (if eligible) is recommended for first-line treatment of recurrent (not amenable to curative therapy) or metastatic cervical cancer (r/mCC; Tewari 2014). In the second-line setting, there are limited data for currently available treatment options. Tisotumab vedotin (TV) is an investigational antibody-drug conjugate (ADC) composed of a tissue factor (TF)-directed human monoclonal antibody covalently linked to the microtubule-disrupting agent monomethyl auristatin E (MMAE) via a protease-cleavable linker. TV is directed to cells expressing TF and releases MMAE upon internalization, resulting in cell cycle arrest and apoptotic cell death. TV has anti-tumor activity on multiple tumor types and kills tumor cells by direct cytotoxicity, bystander cytotoxicity, antibody-dependent cellular cytotoxicity, antibody-dependent cellular phagocytosis , and in a manner consistent with immunogenic cell death. In a recent phase 2 pivotal trial (innovaTV 204), TV demonstrated a clinically meaningful objective response rate (ORR) of 24% and median duration of response (DOR) of 8.3 months, as well as a manageable and tolerable safety profile with most adverse events being mild to moderate, in r/mCC patients with disease progression on or after chemotherapy. These findings support further investigation of TV in patients with r/mCC who progress on available first-line treatment options. **Methods:** The innovaTV 301 trial (NCT04697628) is a global, randomized, open-label, phase 3 clinical trial evaluating the efficacy and safety of TV in patients with previously treated r/mCC. Eligible patients must be ≥18 years, have r/mCC, and have experienced disease progression after receiving 1-2 prior lines of therapy (either standard of care systemic chemotherapy doublet or platinum-based therapy [if eligible; paclitaxel+cisplatin+bevacizumab, paclitaxel+carboplatin+bevacizumab, or paclitaxel+topotecan/nogitecan+bevacizumab]). Approximately 482 patients will be randomized 1:1 to receive 21-day cycles of either TV (2.0 mg/kg IV once every 3 weeks) or investigator's choice of chemotherapy: topotecan (1 or 1.25 mg/m^2 IV; Day 1 [D1] to D5 of each cycle), vinorelbine (30 mg/m^2 IV; D1 and D8 of each cycle), gemcitabine (1000 mg/m^2 IV; D1 and D8 of each cycle), irinotecan (100 or 125 mg/m^2 IV; weekly for 28days, then every 42 days), or pemetrexed (500 mg/m^2 IV, D1 of each cycle). The primary endpoint of this trial is overall survival. Key secondary endpoints are progression-free survival, ORR, time to response, DOR, safety, and quality of life outcomes. The study is currently enrolling and will have sites open in the US, EU, Japan, Latin America, Taiwan, Singapore, and South Korea. Clinical trial information: NCT04697628. Research Sponsor: Seagen Inc.

TPS5597 **Poster Session**

Immunotherapy in combination with PARP inhibition in advanced cervical cancer patients functionally competent or deficient for the Fanconi anemia repair pathway. *First Author: John Paul Diaz, Miami Cancer Institute Baptist Health South Florida, Miami, FL*

Background: Immunotherapy has improved outcomes for patients with recurrent or metastatic cervical cancer whose tumors express PD-L1. Pembrolizumab (PEM), a monoclonal antibody that binds to programmed cell death 1 (PD 1) receptor, inhibits interaction with programmed cell death ligand 1 (PD-L1) and programmed cell death ligand 2 (PD-L2). It is approved for the treatment of recurrent or metastatic cervical cancer. Despite promising results, new strategies are being developed to improve immunotherapy responses. This includes DNA-damaging agents that have the potential to enhance the response to immunotherapy by promoting neo-antigen release, increasing tumor mutational burden, and enhancing PD-L1 expression. Poly-ADP-ribose polymerase (PARP) inhibitors, such as olaparib, have shown synergy with immunotherapy in preclinical and early clinical studies. PARP-based therapy is based on the inhibition of single-strand DNA repair, leading to DNA damage and increased tumor mutational burden. As a result, the tumor becomes a more attractive target for immunotherapy. Based on this, we are investigating the interplay between homologous recombination (HR) repair deficiency, another mechanism of DNA repair, and solid tumor response to ICI. Our approach uses an all-inclusive functional immunofluorescence assay of the Fanconi Anemia triple-staining immunofluorescence (FATSI) we developed and can be performed in paraffin-embedded tumors. **Methods:** This is a phase II open-label single center trial evaluating the role of PEM and olaparib in patients with metastatic cervical cancer who have progressed on first-line standard of care chemotherapy. FATSI will be performed in all patients. We hypothesize that FATSI negative tumors will be associated with improved responses. Other eligibility criteria include measurable disease by imaging, 18 years of age or older, and no previous exposure to ICI or PARP inhibitor. The primary objective is to evaluate the immune-related objective response rate (iORR) achieved in patients with FA Repair Pathway functionally competent and functionally deficient tumors. Secondary objectives include 20-week progression free survival and overall survival. Other exploratory objectives include evaluation of the mutation load and markers of neo-antigenicity, T cell receptor clonotype analyses (before and after treatment), and alterations in HR repair genes. We will utilize a two-stage phase II design to detect an iORR ≥ 20% in the whole population tested vs. the null hypothesis that the true iORR ≤5%, represents a response by chance alone or other infrequent unknown mechanisms. An interim analysis requires at least 2 of the first 20 evaluable patients enrolled have an objective response. If this occurs, we will accrue 28 additional patients to total 48. Enrollment is ongoing and two patients are currently on treatment. Clinical trial information: NCT04483544. Research Sponsor: Florida Department of Health, Pharmaceutical/Biotech Company.

ENGOT-ov54/Swiss-GO-2/MATAO including LOGOS (Low-Grade Ovarian cancer Sub-study): MAintenance Therapy with Aromatase inhibitor in epithelial Ovarian cancer—A randomized, double-blinded, placebo-controlled, multicenter phase III Trial. *First Author: Viola A. Heinzelmann-Schwarz, Swiss GO and University Hospital Basel, Basel, Switzerland*

Background: The prognosis of advanced epithelial ovarian cancer (OC) is poor with a relapse rate of 75% at 5 years. Some 80% of OC express estrogen receptor (ER). This is the first trial that wants to capitalize on this and prospectively evaluates letrozole, a potent aromatase inhibitor, as initial maintenance treatment for high and low grade OC. **Methods:** Eligible pts have primary OC, FIGO Stage II-IV with low or high grade serous or endometrioid histology, with (interval) debulking surgery, ECOG-status 0-2, Positivity (≥ 1%) for ER expression, and at least 4 cycles of platinum-based chemotherapy (neoadjuvant allowed). Pts are allowed to undergo concurrent maintenance treatment with bevacizumab and PARP inhibitors. Extensive quality of life (QoL) questionnaires via an App and physical activity measurements by a tracking device as well as G8 geriatric score, ESGO surgery questionnaire, and Charleson Comorbidity Index are routinely assessed. Primary objective is to evaluate the efficacy of letrozole maintenance therapy after standard surgical and chemotherapy treatment as measured by Progression Free Survival (PFS) compared to no maintenance therapy (placebo). Primary outcome is PFS, defined as time from date of first letrozole/placebo administration until date of progression or death by any cause. Stratification for high and low grade histologies and ER measurement is performed via a digital centralized pathology review process. Final analysis will be performed for the whole cohort and for the subgroup of low grade ovarian cancers (LOGOS subprotocol). Secondary objectives and outcomes are overall survival (OS), quality adjusted progression free survival (QAPFS), time to first subsequent treatment (TFST), quality adjusted time without symptoms (TWiST), and health related QoL. Study is designed as international, randomized (1:1 ratio), two-arm, multi-centric, double-blinded, placebo-controlled superiority phase III trial. In total, 528 pts will be randomly assigned to letrozole or placebo for 5 yrs or until unacceptable toxicity, progression of underlying disease, or study discontinuation. Final analysis is planned after 5 years without interval analysis and follow-up is collected for up to 10yr and for the low-grade cohort for up to 12yr. Clinical trial information: NCT04111978. Research Sponsor: Swiss GO Trial Group.

TPS5599 **Poster Session**

Clinical trial in progress: Pivotal study of VB-111 combined with paclitaxel versus paclitaxel for treatment of platinum-resistant ovarian cancer (OVAL, VB-111-701/GOG-3018). *First Author: Rebecca Christian Arend, University of Alabama at Birmingham, Birmingham, AL*

Background: Ofranergene obadenovec (VB-111) is a targeted anti-cancer gene therapy with a dual mechanism of action that includes a broad antiangiogenic effect and induction of a tumor directed immune response. A phase II trial in patients with platinum resistant ovarian cancer showed that VB-111 in combination with weekly paclitaxel was well tolerated and associated with a CA-125 Objective Response Rate (ORR) of 58% with a trend for improved survival. The favorable outcomes were associated with induction of an immunotherapeutic effect of tumor infiltration with CD-8 T cells. Based on these observations, a phase III study was initiated in collaboration with the GOG Foundation, Inc. **Methods:** Study NCT03398655 is an international, randomized, double-blind, placebo-controlled, phase III study. Eligible patients have recurrent platinum-resistant epithelial ovarian cancer with measurable disease (RECIST 1.1), and may have been previously treated with up to 5 prior lines of therapy. Patient are randomized 1:1 to receive VB-111 (1x10^{13} VPs) with weekly paclitaxel (80mg/m^2), or weekly paclitaxel with placebo. Randomization is stratified by number of prior treatment lines, prior antiangiogenic therapy and platinum refractory disease status. The efficacy endpoints are OS, PFS and ORR by RECIST 1.1 and by CA-125 (GCIG criteria). A pre-planned interim analysis was performed by the DSMC in the first 60 patients evaluable for CA-125 response. The analysis met the pre-defined criteria of a CA-125 ORR (GCIG) in the treatment arm at least 10% higher than in the control arm. Study enrolment is ongoing and over 220 patients were enrolled in the US, EU, and Israel. Enrolment of the full sample size of 400 patients is expected to complete by the end of 2021. Clinical trial information: NCT03398655. Research Sponsor: VBL therapeutics.

TPS5600 **Poster Session**

Trial in progress: A phase 1, multicenter, open-label, dose-exploration and dose-expansion study evaluating the safety, tolerability, pharmacokinetics, and efficacy of AMG650 in subjects with advanced solid tumors. *First Author: Ramaswamy Govindan, Washington University School of Medicine, St. Louis, MO*

Background: KIF18A is a mitotic kinesin motor protein that regulates chromosome positioning during cell division and is overexpressed in a subset of human cancers. *TP53* mutant unstable aneuploid cancer cells with chromosomal instability (CIN) features are dependent on KIF18A motor activity to prevent lethal multipolar cell division. Preclinical data demonstrate that treatment with AMG 650; an oral, first in class, selective small molecule inhibitor of KIF18A may be safe and tolerable. We are conducting a first-in-human phase 1 study with AMG 650 in adult subjects with locally advanced or metastatic solid tumors with *TP53MUT*, triple negative breast cancer (TNBC), high grade serous ovarian cancer (HGSOC) or serous like endometrial cancers and other solid tumors. **Methods:** In this phase 1, multicentric, dose escalation and dose expansion study we evaluate the safety and tolerability of AMG 650 monotherapy in patients with advanced/metastatic solid tumors (NCT04293094). The main objective is to determine the maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D) based on emerging safety, efficacy, and pharmacodynamics (PD) data prior to reaching the MTD. Key inclusion criteria include the presence of measurable disease and diagnosis of advanced/metastatic triple negative breast cancer (TNBC), high-grade serous ovarian cancer (HGSOC), serous-like endometrial cancer or other solid tumors with documented TP53 mutations. In the dose expansion phase, participants with locally advanced or metastatic TNBC or HGSOC will be treated with the preliminary RP2D identified from the dose exploration part of the study. Primary endpoints include the incidence of Dose Limiting Toxicities (DLTs),Treatment-Emergent Adverse Events (TEAEs), Serious Adverse Events (SAEs), Treatment-related Adverse Events and the evaluation of the number of participants who experience a clinically significant change from baseline in vital signs, electrocardiogram and laboratory tests parameters. Secondary endpoints include Objective Response Rate, Duration of Response, Progression-free Survival, Clinical Benefit Rate, Time to Response, Time to Progression, Overall Survival (OS), Maximum Plasma Concentration (Cmax) of AMG 650, Time to Maximum Plasma Concentration (Tmax) of AMG 650 as well as Area Under the Plasma Concentration-time Curve (AUC) Over the Dosing Interval for AMG 650. Continuous monitoring of toxicity is conducted. The study began enrolling pts in March 2020 and is ongoing. For more information, please contact Amgen Medical Information: medinfo@amgen.com Clinical trial information: NCT04293094. Research Sponsor: Amgen inc.

TPS5601 **Poster Session**

A randomized phase III, two-arm trial of paclitaxel, carboplatin, and maintenance letrozole versus letrozole monotherapy in patients with stage II-IV, primary low-grade serous carcinoma of the ovary or peritoneum. *First Author: Amanda Nickles Fader, The Johns Hopkins Hospital, Baltimore, MD*

Background: Low-grade serous carcinoma of the ovary or peritoneum (LGSOC) is a rare subtype of epithelial carcinoma. Differences in epidemiology, pathogenesis, disease presentation, and clinical outcomes have been characterized between women diagnosed with LGSOC and those with the p53-driven high-grade serous carcinoma (HGSOC). Ultimately, patients with LGSOC should be treated differently than those with HGSOC. Several studies suggest that LGSOC is relatively chemoresistant and that most tumors robustly express estrogen and progesterone receptors. Recently, retrospective reports suggest that utilization of the aromatase inhibitor, letrozole, as monotherapy or in addition to platinum/taxane-based chemotherapy in those with primary advanced-stage LGSOC results in preliminarily promising survival outcomes. **Methods:** This study is a two-arm, randomized, open-label, Phase III clinical trial. The primary objective is to assess whether letrozole monotherapy (2.5 mg po daily) is non-inferior to carboplatin (AUC 5-6) and paclitaxel (175 mg/m^2) followed by letrozole maintenance therapy with respect to progression free survival in women with primary, Stage II-IV LGSOC who have undergone an attempt at maximal surgical cytoreduction. Secondary endpoints include incidence of adverse events, objective response rate in those with measurable disease after surgery, response duration, overall survival, and adherence to letrozole maintenance therapy. Study subjects must have undergone a bilateral salpingo-oophorectomy, and p53 IHC testing of tumors is required to rule out those with aberrant p53 expression commonly observed in HGSOC tumors. Study strata include residual disease status and country of enrollment. Four hundred and fifty patients will be enrolled in the United States, Canada and South Korea through the NRG Oncology trials network. Correlative aims include analyzing the association of ER/PR tumoral expression with aromatase inhibitor therapy response and determining ESR1 mutational status in those who develop letrozole resistance. The study includes two interim analyses; at 20% information time, a futility analysis will be conducted, and at 40% information time, both efficacy and futility will be assessed. This is one of the first randomized trials performed in women with primary, advanced LGSOC, and the study is open with 71 patients enrolled at the time of abstract submission. Clinical trial information: NCT04095364. Research Sponsor: U.S. National Institutes of Health.

TPS5602 **Poster Session**

A phase I/II, multicenter, open-label study of REGN5668 (mucin [MUC]16 x CD28 bispecific antibody [bsAb]) with cemiplimab (programmed death [PD]-1 Ab) or REGN4018 (MUC16 x CD3 bsAb) in recurrent ovarian cancer (rOVCA). *First Author: Ira Seth Winer, Wayne State University/Karmanos Cancer Center, Detroit, MI*

Background: There is a high unmet need in rOVCA treatment, with 14,000 deaths/year in the US and a 30%–40% 5-year overall survival rate in patients (pts) with advanced disease. REGN5668 and REGN4018 are human IgG4-based bsAbs that bridge ovarian MUC16+ tumor cells to CD28 and CD3, respectively, on T-cells to stimulate cytotoxicity. Cemiplimab is a human monoclonal Ab that blocks PD-1 binding to PD-ligand(L)1 and PD-L2. REGN5668 demonstrated increased preclinical anti-tumor activity with PD-1 inhibition or REGN4018 relative to each monotherapy. A Phase I/II study of REGN4018 alone or with cemiplimab is ongoing. **Methods:** This first-in-human study (NCT04590326) will assess safety, tolerability, pharmacokinetics, and preliminary anti-tumor activity of REGN5668 with cemiplimab (Module 1) or REGN4018 (Module 2) in pts with rOVCA. Key inclusion criteria include histologically confirmed diagnosis of advanced epithelial ovarian (except carcinosarcoma), fallopian tube, or primary peritoneal cancer; serum CA-125 level $\geq$2x upper normal limit; $\geq$1 prior-line of platinum-based therapy; prior treatment with or intolerance to available standard-of-care therapy. Exclusion criteria include recent biologic therapy ($<$ 5 half-lives or 28 days, whichever is longer, except $<$ 3 half-lives for bevacizumab or other nonimmunomodulatory Abs with half-lives $>$ 7 days); approved conventional therapy (except biologics or immunotherapy) $<$ 3 weeks (wks) or investigational agents $<$ 4 wks prior to first study dose; and anti–PD-L1 therapy $<$ 5 half-lives prior to first study dose. This two-phase study includes dose escalation (a 4+3 design modified from 3+3) and expansion phases. In Module 1, $\leq$84 pts will receive 3–4 wks of REGN5668 monotherapy lead-in at assigned intravenous (IV) weekly (QW) dose levels, followed by REGN5668 QW combined with cemiplimab IV every 3 wks. In Module 2, $\leq$106 pts will receive 4–5 wks of REGN4018 QW IV lead-in, followed by REGN4018 full QW dose combined with REGN5668 at initial and full assigned QW doses. In expansion, REGN5668+cemiplimab and REGN5668+REGN4018 combination regimens will each recruit 20 pts in stage 1 and 30 pts in stage 2 using a Simon two-stage design. In escalation, primary endpoints are dose-limiting toxicities, serious and treatment-emergent adverse events (TEAEs), deaths, laboratory abnormalities (Grade $\geq$3), concentrations of REGN5668 in serum alone and in each combination regimen; key secondary endpoint is objective response rate (ORR) per Response Evaluation Criteria in Solid Tumors (RECIST) 1.1. In expansion, primary endpoint is ORR by RECIST 1.1 for each combination; key secondary endpoints are TEAEs, serious AEs, deaths. Key exploratory endpoints are correlation between clinical efficacy endpoints and baseline protein expression levels of MUC16 and PD-L1. Clinical trial information: NCT04590326. Research Sponsor: Regeneron Pharmaceutical, Inc.

TPS5603 **Poster Session**

ENGOT-ov60/GOG3052/RAMP 201: A phase 2 study of VS-6766 (dual RAF/MEK inhibitor) alone and in combination with defactinib (FAK inhibitor) in recurrent low-grade serous ovarian cancer (LGSOC). *First Author: Susana N. Banerjee, The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, London, United Kingdom*

Background: VS-6766 is a unique small molecule inhibitor that blocks MEK kinase activity and RAF phosphorylation of MEK. This mechanism of blockade has been shown to limit compensatory MEK activation, thereby potentially enhancing efficacy of MEK inhibition. Defactinib, (VS-6063), an orally active small molecule, is a potent adenosine 5'-triphosphate (ATP) competitive, reversible inhibitor of focal adhesion kinase (FAK). Defactinib has shown synergistic activity with BRAF and MEK inhibitors in both in vitro and in vivo solid tumor models. Prior molecularly unselected studies with single agent MEK inhibitors have shown response rates up to 26% in recurrent LGSOC. A third of patients with recurrent LGSOC harbor somatic KRAS mutations. FAK inhibition has been shown to induce tumor regression when combined with RAF, MEK or RAF/MEK inhibitors in in vivo models of KRAS mutant ovarian cancer. The combination of VS-6766 and defactinib is currently being evaluated in the ongoing Investigator Sponsored FRAME study (NCT03875820). In this proof of concept study, durable objective responses have been reported in recurrent LGSOC patients, particularly those with KRAS mutations including patients who have had a prior MEK inhibitor (Banerji et al AACR 2020). Based on preclinical studies demonstrating efficacy of both VS-6766 and the VS-6766/defactinib combination and preliminary results of the FRAME study, the phase II ENGOT-ov60/GOG3052 has been developed in recurrent LGSOC. **Methods:** This is a Phase II, adaptive, two-part, multicenter, parallel cohort, randomized, open label study designed to evaluate the efficacy and safety of VS-6766 versus VS-6766 in combination with defactinib (NCT04625270). The study will be conducted in two parts. Part A will determine the optimal regimen based on confirmed overall response rate (independent radiology review) in KRAS-mutated LGSOC. Part B will determine the efficacy of the optimal regimen identified in Part A in KRAS-mutated and KRAS wild-type LGSOC. The minimum expected enrollment is 52 subjects with KRAS-mutated tumors (32 subjects in Part A and 20 in Part B) and 36 with KRAS wild-type tumors in Part B. Patients will be randomized to receive VS-6766 (4.0 mg PO, twice weekly 3 weeks on, 1 week off) or VS6766 with defactinib (VS-6766 3.2 mg PO, twice weekly + defactinib 200 mg PO BID 3 weeks on, 1 week off) till progression. Key inclusion criteria include histologically confirmed LGSOC, presence of KRAS mutation (Part A), prior systemic therapy for metastatic disease and up to 1 prior line of MEK/RAF inhibitor therapy permitted. This international study is open to enrollment. Clinical trial information: NCT04625270. Research Sponsor: Verastem.

TPS5604 **Poster Session**

ROCSAN trial (GINECO-EN203b/ENGOT-EN8): A multicentric randomized phase II/III evaluating dostarlimab in combination with niraparib versus niraparib alone compared to chemotherapy in the treatment of endometrial/ovarian carcinosarcoma after at least one line of platinum based chemotherapy. *First Author: Isabelle Laure Ray-Coquard, Centre Léon Bérard and University Claude Bernard Lyon 1 and GINECO, Lyon, France*

Background: Gynecological carcinosarcomas (CS) are rare and highly aggressive tumors with a 5-year overall survival (OS) < 10%. After initial treatment majority of patients (pts) relapse and receive diverse chemotherapies (CT) producing modest benefits. The median PFS in relapse after platinum based CT is less than 4 months and median OS less than 1 year. New innovative strategies are urgently needed. Since CS showed high DNA damage response activity and potentially a high tumor mutation load resulting in neo-antigens, a synergy between PARPi and anti-PD1 is expected. **Methods:** ROCSAN is a multicentric, randomized, open-label, integrated Phase II/III study. In the Phase II, 63 pts with recurrent or progressing endometrial or ovarian CS after at least a first line of platinum-based CT will be randomized (2:2:1) to receive either niraparib in monotherapy, niraparib in combination with dostarlimab or standard CT (paclitaxel, doxorubicine, gemcitabine, topotecan). Stratification factors include the number of previous CT lines (1 vs 2-3), FIGO stage at diagnosis (I-II vs III-IV), CS localisation (ovarian vs endometrial), and performance status (0-1 vs 2). The primary objective of the Phase II is to select the best experimental strategy between niraparib and dostarlimab/niraparib combination based on Response Rate at 4 months (RR-4M by RECIST1.1). A single stage design with a 10% unacceptable RR-4M and a 30% targeted RR-4M was used to determine Phase II sample size, assuming a 10% one sided alpha for each comparison and more than 90% power. A pick-the-winner selection design could be used in case of promising efficacy in each experimental arm. At the interim analysis, an Independent Data Monitoring Committee will make recommendation for the selection of the optimal experimental arm. The Steering committee could then support to continue enrolment for the international Phase III which is calibrated to detect an improvement in median OS from 7 months (Standard CT) to 11.7 months (best experimental arm). Assuming a 5% alpha level and 80% power, 133 additional pts could be randomized (2:1). Secondary endpoints include safety, PFS, PFS2, TTST, ORR, duration of response, patient report outcomes (assessed via EORTC QLQ-C30 OV28, HADS, PRO-CTCAE). A translational program supported by European Community is associated to the clinical study to identify predictive biomarkers of response/resistance to study treatments, to correlate with immune environment, a special focus on genetic instability and the EMT process will be included. Trial is currently recruiting only in France for the phase II part, the first pt was randomized in July 2020. Clinical trial information: NCT 03651206. Research Sponsor: GSK, European Community.

TPS5605 **Poster Session**

A phase 3, randomized, double-blind, adaptive, placebo/paclitaxel-controlled study of AVB-S6-500 in combination with paclitaxel in patients with platinum-resistant recurrent ovarian cancer (GOG-3059/ENGOT OV-66/AVB500-OC-004). *First Author: Katherine Cynthia Fuh, Washington University in St. Louis, St. Louis, MO*

Background: The AXL receptor and its activating ligand, GAS6, are important drivers of metastasis and therapeutic resistance in human cancers. This signaling axis represents an attractive target for therapeutic intervention, but the strong picomolar binding affinity between endogenous GAS6 and AXL and the promiscuity of small molecule AXL inhibitors have presented a barrier to specific and potent inhibition of AXL. AVB-S6-500 is a highly sensitive and specific inhibitor of AXL, with ~200-fold higher affinity than wild-type (WT) AXL. AVB-S6-500 binds GAS6, the sole ligand of AXL, inhibiting its interaction with AXL thereby dramatically reducing AXL signaled invasion and migration of highly metastatic cells in vitro and inhibiting metastatic disease in nonclinical models of aggressive human cancers. A Phase 1b study in platinum resistant ovarian cancer showed no dose limiting toxicities and established a recommended Phase 2 dose of 15mg/kg administered every 2 weeks. Longer progression free survival (PFS) and overall survival (OS) times were observed in patients who had not been previously treated with bevacizumab. Furthermore, retrospective analyses demonstrated that serum soluble AXL to GAS6 ratio may identify patients more likely to respond to this therapy. **Methods:** Patients with high grade serous, platinum resistant ovarian cancer, who have received no more than 4 prior therapy regimens will be randomized 1:1 to AVB-500 + PAC or PAC + placebo. Patients will be stratified by recurrence after last platinum regimen (<3, 3-6 months), prior lines (1-2, 3-4), and prior bevacizumab (yes, no). The primary endpoint is PFS by RECIST v 1.1 as assessed by the investigator, with OS a key secondary endpoint. The study design is adaptive; with two interim analyses addressing conditional power in the bevacizumab treated subset, and in a serum soluble AXL, GAS6 biomarker subset, respectively, with interim results used to define the final target population. Simulations confirm a nominal one-sided type 1 error below 0.025, and show >90% statistical power for PFS under the following assumptions of PFS medians. Study recruitment began in Q1. Clinical trial information: NCT04729608. Research Sponsor: Aravive, Inc.

TPS5606 **Poster Session**

FLORA-5: Front-line chemoimmunotherapy (Paclitaxel-Carboplatin-Oregovomab [PCO] versus chemotherapy (Paclitaxel-Carboplatin-Placebo [PCP]) in patients with advanced epithelial ovarian cancer (EOC)—Phase III double-blind placebo controlled multinational study. *First Author: Angeles Alvarez Secord, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: Oregovomab binds tumor-associated CA125 rendering the target antigen CA125 more immunogenic or "neoantigen-like" through altered and enhanced antigen processing and presentation to specific T cells. This phenomenon is hypothesized to bypass tumor-associated immune suppression when administered in combination with chemotherapy. In a randomized phase II study, immunization with oregovomab in a schedule-dependent combination with paclitaxel and carboplatin induced tumor immunity and demonstrated significant improvement in PFS (median (months) 41.8 PCO vs 12.3 PCP, HR 0.44 p = 0.0027, and OS median N.E. PCO vs 43.2 PCP HR 0.34 (p = 0.0077)) in patients with previously untreated EOC. The FLORA-5, the definitive confirmatory global registration trial, is currently recruiting patients in the front-line setting. **Methods:** The study is a phase 3, multicenter, double-blind, placebo-controlled clinical trial. Optimally debulked patients with FIGO III/IV EOC and serum CA125 > 50 U/ml receiving adjuvant (Cohort 1) or neoadjuvant (Cohort 2) chemotherapy will be randomized post-surgery to paclitaxel and carboplatin with or without oregovomab. Patients with germline BRCA1/2 mutations will be excluded. Chemotherapy will be administered every 3 weeks in both cohorts. Oregovomab/placebo is administered simultaneously at cycles 1, 3, and 5 of chemotherapy with a single maintenance dose at 12 weeks following cycle 5 in Cohort 1. Neoadjuvant patients (Cohort 2) will be administered oregovomab/placebo post interval debulking surgery at cycles 4 and 6 with maintenance doses at 6- and 18-weeks following cycle 6. No other post front-line maintenance therapy is permitted. The primary objective is PFS determined by RECIST 1.1 criteria. Cohort 1 will recruit 372 patients with a 90% power to detect a difference with an alpha of 0.025 and a hazard ratio of 0.65 when 252 PFS events have been observed. Cohort 2 will be analyzed separately recruiting 232 patients with a 90% power to detect a difference with an alpha of 0.025 and a hazard ratio of 0.60 when 165 PFS events have been observed. An interim analysis for futility will be performed. Secondary objectives include OS, frequency and severity of adverse events, and quality of life. Exploratory objectives include iRECIST, TFST, TSST, PFS2, and evaluation of potential biomarkers. The study is actively enrolling in the US with 9 patients enrolled at time of submission. Centers in Europe, South America and Asia are expected to begin accruing shortly. Clinical trial information: NCT04498117. Research Sponsor: Oncoquest.

TPS5607 **Poster Session**

Uplift (ENGOT-ov67): A pivotal cohort to evaluate XMT-1536 (upifitamab rilsodotin), a NaPi2b-directed antibody drug conjugate for platinum-resistant ovarian cancer. *First Author: Debra L. Richardson, Stephenson Cancer Center at the University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: XMT-1536 (upifitamab rilsodotin), is a first-in-class Dolaflexin ADC targeting NaPi2b, a sodium-dependent phosphate transport protein, broadly expressed in solid tumors such as serous epithelial ovarian cancer (OC) and non-small cell lung adenocarcinoma. XMT-1536 uses the Dolaflexin platform to deliver approximately 10 DolaLock auristatin payload molecules per antibody and is being evaluated in a Phase I study (NCT03319628). Observation of preliminary antitumor activity was reported in the ovarian cancer expansion cohort, including in patients previously treated with bevacizumab and PARPi (Tolcher et al, ASCO 2019; Richardson et al, ASCO 2019; Hamilton et al, ESMO 2020). Updated data on the OC cohort included 31 patients with higher NaPi2b expression as of December 2020 (Mersana Therapeutics, 2021). In these patients, the ORR was 32% and the DCR was 74%. Complete responses were observed in 2 patients with platinum-resistant ovarian cancer, both of whom had received prior treatment with bevacizumab and PARP inhibitors. Platinum resistant ovarian cancer remains a serious unmet medical need as treatment options are limited and response rates to these treatments are low. Based on the favorable safety and efficacy profile of XMT-1536, UPLIFT was designed as a Phase 2 single-arm registrational cohort of patients with platinum resistant ovarian cancer as part of the ongoing Phase I FIH dose escalation and expansion study to accelerate development and provide a streamlined pathway to regulatory review. **Methods:** The UPLIFT cohort is enrolling patients with platinum resistant high grade serous ovarian, fallopian tube and primary peritoneal cancer with up to 4 prior lines of therapy. The RP2D of XMT-1536 was determined to be 43 mg/m^2 administered intravenously every 4 weeks (q4w) and will be the dose evaluated in the UPLIFT cohort. UPLIFT will enroll approximately 180 patients with platinum-resistant advanced ovarian cancer to obtain approximately 100 patients with higher NaPi2b expression. Prior bevacizumab is required for those patients with 1 or 2 prior lines of therapy. Tumor samples (fresh or archived) will be collected prior to enrollment for retrospective tumor tissue evaluation of NaPi2b expression. The primary objective is assessment of confirmed objective response rate to XMT-1536 as assessed by Investigator in patients with higher NaPi2b expression. Secondary endpoints include confirmed objective response rate regardless of NaPi2b expression, duration of response, and adverse events. Correlative aims include assessing blood and tissue biomarkers for association with clinical benefit. This study is being conducted in collaboration with ENGOT and GOG. Patients will be enrolled globally. Clinical trial information: NCT03319628. Research Sponsor: Mersana Therapeutics.

TPS5608 **Poster Session**

ENGOT-en11/GOG-3053/KEYNOTE-B21: Phase 3 study of pembrolizumab or placebo in combination with adjuvant chemotherapy with/without radiotherapy in patients with newly diagnosed high-risk endometrial cancer. *First Author: Toon Van Gorp, UZ Leuven, Leuven, Belgium*

Background: Pembrolizumab, a selective humanized anti–PD-1 monoclonal antibody, has demonstrated activity in patients with previously treated mismatch repair (MMR) deficient (dMMR; 57.1% ORR as monotherapy and 63.6% ORR as combination therapy with lenvatinib) and MMR proficient (pMMR; 36.2% ORR as combination therapy with lenvatinib) endometrial cancer (EC). ENGOT-en11/GOG-3053/KEYNOTE-B21 is a phase 3, randomized, double-blind study of pembrolizumab or placebo in combination with adjuvant chemotherapy with/without radiotherapy in patients with EC. **Methods:** Eligible patients are ≥18 years old with newly diagnosed, histologically confirmed high-risk (stage I/II non-endometrioid, stage III/IVa, p53 abnormality) EC (carcinoma or carcinosarcoma) following surgery with curative intent with no evidence of disease post-operatively or on imaging, and without prior systemic therapy/radiotherapy. In total, ~990 patients are randomized to receive pembrolizumab 200 mg or placebo Q3W for 6 cycles + chemotherapy (carboplatin area under the curve [AUC] 5 or 6 + paclitaxel 175 mg/m^2 Q3W or carboplatin AUC 2 or 2.7 + paclitaxel 60 mg/m^2 QW) in stage 1. Patients receive pembrolizumab 400 mg or placebo Q6W for 6 cycles in stage 2 per their treatment assignment. At the investigator's discretion, radiotherapy (external beam radiotherapy [EBRT] and/or brachytherapy) ± radiosensitizing cisplatin 50 mg/m^2 (days 1 and 29) may be administered after completion of chemotherapy. Randomization is stratified by MMR status (pMMR vs dMMR) and, within pMMR, by planned radiation therapy (cisplatin-EBRT vs EBRT vs no EBRT), histology (endometrioid vs non-endometrioid), and International Federation of Gynecology and Obstetrics (FIGO) surgical stage (I/II vs III/IVA). Dual primary endpoints are disease-free survival (DFS; per investigator assessment) and overall survival (OS), both estimated by the Kaplan-Meier method, with a stratified log-rank test to assess treatment differences and a Cox proportional hazard model with Efron's method of tie handling to assess the magnitude of treatment differences. Secondary endpoints include DFS (per blinded independent central review), DFS (per investigator assessment) and OS by biomarker status (PD-L1 and tumor mutational burden), safety (per National Cancer Institute Common Terminology Criteria for Adverse Events version 5.0) and quality of life (per European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 [EORTC QLQ-C30] and Endometrial Cancer Module [EORTC QLQ-EN24]). The study began enrollment in December 2020. Clinical trial information: NCT04634877. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS5609 **Poster Session**

A phase 2, two-stage study of avelumab and axitinib in patients with mismatch repair proficient (MMR-P) recurrent or persistent endometrial cancer (EC). *First Author: Elizabeth Katherine Lee, Dana-Farber Cancer Institute, Boston, MA*

Background: Despite significant strides in understanding the molecular pathogenesis of EC, there remain few effective therapies for recurrent disease. Deeper insight into the roles of disordered tumor vasculature and HIF1α- and VEGF-mediated immunosuppressive effects on myeloid-derived suppressor cells, T-cells, and PD-L1 expression contributed to the development of new targeted regimens. Activity of pembrolizumab and lenvatinib was demonstrated in a phase 2 trial in MMR-P EC (NCT02501096). By inhibiting VEGF receptor (VEGFR) and PD-L1 signaling, immunologically "cold" tumors may become inflamed. However, there are concerns regarding the toxicity of pembrolizumab/lenvatinib and alternatives are sought. The combination of the anti-PD-L1 antibody avelumab with axitinib, an inhibitor of VEGFR 1-3 and PDGFR with more potent IC_{50} inhibitory activity than lenvatinib, has also shown synergistic activity and is FDA approved as first line treatment for patients with renal cell cancer. We therefore hypothesized that this combination would be well tolerated and efficacious in recurrent MMR-P EC. **Methods:** This is an investigator-initiated, phase 2, two-stage single cohort trial evaluating avelumab with axitinib in recurrent or persistent EC. Participants must have MMR-P EC of any histology and have received at least one chemotherapeutic regimen, with no upper limit on the number of prior lines received. Prior use of immune checkpoint (IC) inhibitors is excluded. Treatment consists of avelumab 800mg IV every 2 weeks and axitinib 5mg orally twice daily. Co-primary endpoints are progression-free survival at 6 months (PFS6) and objective response rate by RECIST 1.1. Translational objectives include characterization of tumor-infiltrating lymphocytes, infiltrating myeloid cells, expression of IC markers, and whole exome sequencing to evaluate mutations in genes related to DNA repair and immunologic response. This is a two-stage design in the method of Sill et al, with 16 participants anticipated in stage 1 and 19 participants in stage 2, for a total of 35 participants. Accrual is ongoing. Clinical trial information: NCT02912572. Research Sponsor: Pfizer.

TPS5610 **Poster Session**

SIENDO/ENGOT-EN5/GOG-3055: A randomized phase 3 trial of maintenance selinexor versus placebo after combination platinum-based chemotherapy in advanced or recurrent endometrial cancer. *First Author: Ignace Vergote, Belgium and Luxembourg Gynaecological Oncology Group (BCOG), University of Leuven, Leuven Cancer Institute, Leuven, Belgium*

Background: Endometrial cancer (EC) is the most common gynecologic malignancy. Options for advanced or recurrent EC following platinum-based therapy and/or radiotherapy are limited and prognosis remains poor. Selinexor is a novel, oral selective inhibitor of nuclear export (SINE) which forces nuclear retention and activation of tumor suppressor proteins. Selinexor in combination with low dose dexamethasone is approved for relapsed/refractory multiple myeloma. In addition, selinexor monotherapy has demonstrated broad activity in other hematologic malignancies and solid tumors. In a phase 2 study, 50 mg/m^2 (~80 mg) selinexor administered twice weekly demonstrated a disease control rate (SD ≥ 12 weeks or a PR) of 35% with 2 confirmed partial responses among 23 heavily pretreated EC patients); similar results were observed in 60 pts with platinum resistant or refractory ovarian cancer (median 5 prior regimens, ORR 8%, DCR 30%) (Vergote I et al. Gynecol Oncol 2020). In the absence of approved maintenance therapies, we conducted this study to evaluate the efficacy of selinexor compared with placebo as maintenance therapy in patients with advanced or recurrent EC following platinum-based chemotherapy. **Methods:** This is a multicenter, double-blind, placebo-controlled, randomized phase 3 study in patients in partial (PR) or complete remission (CR) after completing at least 12 weeks of taxane-platinum combination therapy for primary Stage IV disease and recurrent disease (i.e., relapse after primary therapy for early stage disease including surgery and/or adjuvant therapy). A total of 248 patients will be enrolled at 80 sites in Europe, North America, and Israel. Patients will be randomized in a 2:1 ratio to either maintenance therapy with 80 mg oral selinexor once weekly or placebo. Stratification factors include primary Stage IV versus first recurrence at the time of taxane-platinum therapy and disease status after chemotherapy (PR vs CR). Treatment will continue until disease progression. The primary endpoint is progression free survival (PFS) per RECIST v1.1. Secondary endpoints include disease-specific survival, overall survival, time to first subsequent therapy, time to second subsequent therapy, PFS on subsequent therapy and safety and tolerability. The study is currently open and enrolling patients. Clinical trial information: NCT03555422. Research Sponsor: Karyopharm Therapeutics Inc.

TPS5611 **Poster Session**

A phase 2, two-stage study of mirvetuximab soravtansine (IMGN853) in combination with pembrolizumab in patients with microsatellite stable (MSS) endometrial cancer (EC). *First Author: Rebecca L. Porter, Dana Farber Cancer Institute, Boston, MA*

Background: Folate receptor-alpha (FRα) is expressed on endometrial cancer (EC) cells and is associated with poor prognosis. Mirvetuximab soravtansine (ImmunoGen), an antibody drug conjugate (ADC) comprising a FRα-binding antibody, cleavable linker, and the tubulin-disrupting maytansinoid DM4, showed tolerability and single agent activity in a Phase 1 study with dose expansion in FRα+ advanced/recurrent EC (NCT01609556) and also when combined with chemotherapy, bevacizumab as well as pembrolizumab (NCT02606305). In addition to having direct target-mediated cytotoxicity, ADCs also stimulate the local tumor immune microenvironment. Mirvetuximab soravtansine has been shown to activate monocytes and promote phagocytosis of mirvetuximab-treated FRα-positive tumor cells through a mechanism of Fc-FcγR interaction. Further, the combination of ADCs with immune checkpoint inhibitors (ICI) can overcome primary resistance to immunotherapy in murine models. Given the low response of MSS endometrial cancers to PD-1 blockade, we hypothesized that addition of mirvetuximab may enhance response of these tumors to immunotherapy. **Methods:** This is a Phase 2, single cohort study of mirvetuximab soravtansine with pembrolizumab in recurrent or persistent EC. Patients must have advanced or recurrent MSS serous endometrial cancer with at least 1 and up to 3 prior lines of therapy. Confirmation of FRα expression (with PS2+ staining intensity in ≥ 50% of cells, performed centrally at Ventana Medical Systems, Inc) is required. Prior receipt of ICI is excluded. Patients will receive the combination of mirvetuximab soravtansine 6 mg/kg AIBW IV and pembrolizumab 200 mg IV administered every 21 days. The co-primary endpoint is progression-free survival at 6 months (PFS6) and objective response rate (ORR) by RECIST 1.1. Translational objectives include assessment of tumor infiltrating lymphocytes (TILs), expression of immune checkpoint markers, and whole exome sequencing (WES) for DNA repair pathway mutations, neoantigens, and polymorphisms in immunologically relevant genes. Statistical considerations are for a Simon two-stage optimal design with 16 patients in Stage 1 and 19 patients in Stage 2, to a total of 35. Prespecified activity for the first stage of accrual was met, and second stage accrual began November 2020. Clinical trial information: NCT03835819. Research Sponsor: ImmunoGen, Merck.

TPS5612 **Poster Session**

ADAGIO: A phase IIb, open-label, single-arm, multicenter study assessing the efficacy and safety of adavosertib (AZD1775) as treatment for recurrent or persistent uterine serous carcinoma. *First Author: Joyce F. Liu, Dana-Farber Cancer Institute, Boston, MA*

Background: There is a high unmet medical need for therapies treating uterine serous carcinoma (USC), an aggressive type of endometrial carcinoma with an increased likelihood of recurrence and limited therapeutic options. 5-year overall survival (OS) for USC is estimated to be 35–50% for women with stage I–II disease and 0–15% for women with stage III–IV disease (Acharya *et al. Lancet Oncol* 2005). USC exhibits high rates of mutation in *TP53* ($>$ 90% of cases), as well as mutations or amplifications in other cell-cycle regulators or oncogenes, including *CCNE1*, *FBXW7*, *MYC*, *RB1*, and *KRAS*/*NRAS* (Zhao *et al. PNAS* 2013; Levine DA *et al. Nature* 2013), which may contribute to increased replication stress and susceptibility to inhibition of the tyrosine kinase WEE1. WEE1 inhibition is expected to release a tumor cell from DNA-damage-induced arrest at the G2/M boundary, so that unrepaired DNA damage may be taken into mitosis, leading to cell death. A Phase II study of the WEE1 inhibitor adavosertib in 34 women with recurrent or persistent USC reported an objective response rate (ORR) of 29.4% and a median duration of response (DoR) of 9.0 months; further correlative analysis and a translational biopsy cohort are planned (Liu *et al. J Clin Oncol* 2020). This Phase IIb study, ADAGIO, a single-arm, multicenter, global study (NCT04590248), aims to expand on these findings and will evaluate the efficacy and safety of adavosertib in women with recurrent or persistent USC who have previously received platinum-based chemotherapy. **Methods:** Women aged $\geq$18 years with histologically confirmed recurrent or persistent USC who have previously received at least one platinum-based chemotherapy regimen for the management of USC and have evidence of measurable disease according to RECIST v1.1 are eligible for this study. Participants with carcinosarcomas are not eligible. Prior receipt of immune checkpoint inhibitors, vascular endothelial growth factor inhibitors and human epidermal growth factor receptor 2 targeted therapy is permitted, with no restriction on the number of prior lines of systemic therapy a participant may have previously received. Approximately 120 eligible participants will receive oral adavosertib 300 mg qd on days 1–5 and 8–12 of a 21-day treatment cycle until disease progression, unacceptable toxicity, withdrawal of consent, or another discontinuation criterion is met. The primary outcome measure is ORR, defined as the percentage of patients with measurable disease at baseline who have a confirmed complete or partial response, as determined by blinded independent central review (RECIST v1.1 assessment every 6 weeks for the first 48 weeks, then every 9 weeks). Secondary outcome measures include DoR, depth of response, progression-free survival, OS, disease control rate, biomarkers, safety, tolerability, and pharmacokinetics. Clinical trial information: NCT04590248. Research Sponsor: AstraZeneca.

6000 **Oral Abstract Session**

Camrelizumab versus placebo combined with gemcitabine and cisplatin for recurrent or metastatic nasopharyngeal carcinoma: A randomized, double-blind, phase 3 trial. *First Author: Li Zhang, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Camrelizumab plus gemcitabine and cisplatin (GP) showed promising preliminary anticancer activity as first line (1L) therapy in patients (pts) with recurrent or metastatic nasopharyngeal carcinoma (R/M NPC) in a phase 1 trial (*W Fang et al; Lancet Oncol 2018*). Here, we compared the efficacy and safety of camrelizumab with placebo plus GP as 1L therapy for pts with R/M NPC in a phase 3 trial. **Methods:** Eligible pts with previously untreated R/M NPC were randomized (1:1) to receive either camrelizumab (200 mg on day 1) plus gemcitabine (1000 mg/m^2 on days 1, 8) and cisplatin (80 mg/m^2 on day 1) or placebo plus the same chemotherapy regimens intravenously Q3W for a maximum of 6 cycles, followed by maintenance therapy with camrelizumab or placebo. The primary end point was progression-free survival (PFS) per independent review committee (IRC). Secondary end points included investigator-assessed PFS, objective response rate (ORR), disease control rate (DCR), duration of response (DOR), overall survival (OS) and tolerability. This trial is registered with ClinicalTrials.gov, number NCT03707509. **Results:** From Nov 2018 to Nov 2019, 263 pts from 28 centers were randomized to camrelizumab plus GP (n = 134, camrelizumab arm) or placebo plus GP (n = 129, placebo arm). At data cutoff on Dec 31, 2020 (67.7% maturity), 178 IRC-assessed PFS events occurred, and the median follow-up was 15.6 months (range 1.3-25.5). The median PFS per IRC was 10.8 months (95% CI 8.5-13.6) in the camrelizumab arm and 6.9 (95% CI 5.9-7.9) in the placebo arm (HR 0.51 [95% CI 0.37-0.69]; one-sided $P < 0.0001$). Investigator-assessed PFS showed similar results. IRC-assessed ORR was 88.1% (95% CI 81.3-93.0) in the camrelizumab arm and 80.6% (95% CI 72.7-87.1) in the placebo arm, with a median DOR of 9.9 (95% CI 7.7-12.5) and 5.7 months (95% CI 5.2-6.9; HR 0.48 [95% CI 0.34-0.68]), respectively. The DCR was 96.3% (95% CI 91.5-98.8) in the camrelizumab arm and 94.6% (95% CI 89.1-97.8) in the placebo arm. 18-month PFS rate was 34.8% (95% CI 25.7-44.1) vs 12.7% (95% CI 6.8-20.5), respectively. OS benefit was observed in the camrelizumab arm vs placebo arm (median not reached vs 22.6 months; HR 0.67 [95% CI 0.41-1.11]). Grade ≥3 treatment-related adverse events (TRAEs) occurred in 93% of pts in the camrelizumab arm and 90% in the placebo arm. The most common grade ≥3 TRAEs were decreased white blood cell count (66% vs 70%), decreased neutrophil count (64% vs 65%), decreased platelet count (40% vs 40%), and anemia (39% vs 43%). None of the differences were statistically significant. The safety profile was as expected, with no new signals observed. **Conclusions:** Addition of camrelizumab to GP significantly prolonged PFS as 1L therapy for R/M NPC, with a manageable safety profile. These data suggest that first line treatment with camrelizumab plus GP could be a standard of care for R/M NPC. Clinical trial information: NCT03707509. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

6001 **Oral Abstract Session**

Cabozantinib versus placebo in patients with radioiodine-refractory differentiated thyroid cancer who have progressed after prior VEGFR-targeted therapy: Results from the phase 3 COSMIC-311 trial. *First Author: Marcia S. Brose, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Cabozantinib (C), an inhibitor of VEGFR2, MET, AXL, and RET, showed clinical activity in patients (pts) with radioiodine (RAI)-refractory differentiated thyroid cancer (DTC) in phase 1/2 studies (Cabanillas 2017; Brose 2018). This phase 3 study (NCT03690388) evaluated the efficacy and safety of C vs placebo (P) in pts with RAI-refractory DTC who had progressed during/after prior VEGFR-targeted therapy for whom there is no standard of care. **Methods:** In this double-blind, phase 3 trial, pts were randomized 2:1 to receive C (60 mg QD) or P, stratified by prior lenvatinib treatment (L; yes, no) and age (≤65, > 65 yr). Pts with RAI-refractory DTC must have received L or sorafenib for DTC and progressed during or following treatment with ≤ 2 prior VEGFR inhibitors. Pts randomized to P could cross over to open-label C upon disease progression per blinded independent radiology committee (BIRC). The primary endpoints were objective response rate (ORR) in the first 100 randomized pts and progression-free survival (PFS) in all randomized pts. PFS and ORR were assessed by BIRC per RECIST v1.1. The study was designed to detect an ORR for C vs P (2-sided $\alpha = 0.01$) and a hazard ratio (HR) for PFS of 0.61 (90% power, 2-sided $\alpha = 0.04$). A prespecified interim PFS analysis was planned for the ITT population at the time of the primary ORR analysis. **Results:** As of 19 Aug 2020,125 vs 62 pts had been randomized to the C and P arms, respectively; median age was 66 yr, 55% were female and 63% received prior L. Median (m) follow-up was 6.2 months (mo). At the planned interim analysis, the trial met the primary endpoint of PFS with C demonstrating significant improvement over P (HR 0.22, 96% CI 0.13–0.36; p < 0.0001). mPFS was not reached for C vs 1.9 mo for P; PFS benefit was observed in all prespecified subgroups including prior L (yes, HR 0.26; no, HR 0.11) and age (≤65 yr, HR 0.16; > 65 yr, HR 0.31). ORR was 15% for C vs 0% for P (p = 0.0281) but did not meet the prespecified criteria for statistical significance (p < 0.01). A favorable OS trend was observed for C vs P (HR 0.54, 95% CI 0.27–1.11). Treatment-emergent adverse events (AEs) of any grade with higher occurrences in the C vs P arm included diarrhea (51% vs 3%), hand-foot skin reaction (46% vs 0%), hypertension (28% vs 5%), fatigue (27% vs 8%), and nausea (24% vs 2%); grade 3/4 AEs were experienced by 57% of pts with C vs 26% with P. Dose reductions due to any grade AEs occurred in 57% of pts with C vs 5% with P. Treatment discontinuations due to AEs not related to disease progression occurred in 5% of pts with C vs 0% with P. No treatment-related deaths occurred in either arm. **Conclusions:** C showed a clinically and statistically significant improvement in PFS over P in pts with RAI-refractory DTC after prior VEGFR-targeted therapy with no unexpected toxicities. C may represent a new standard of care in pts with previously treated DTC. Clinical trial information: NCT03690388. Research Sponsor: Exelixis.

6002 **Oral Abstract Session**

A phase II trial cohort of nivolumab plus ipilimumab in patients (Pts) with recurrent/metastatic salivary gland cancers (R/M SGCs). *First Author: Bharat Burman, Tufts Univ. School of Medcn., Washington, DC*

Background: R/M SGCs are a diverse group of malignant neoplasms arising from the major or minor salivary glands and have no standard treatment. The impact of combining PD-1/CTLA-4 checkpoint blockade in R/M SGCs is unknown. **Methods:** In a Simon's two-stage minimax phase II trial, pts with progressive R/M SGCs (any histology except adenoid cystic carcinoma (ACC)) were enrolled and treated with nivolumab 3 mg/kg every 2 weeks plus ipilimumab 1 mg/kg every 6 weeks (1 cycle = 6 weeks). Imaging, using RECIST v1.1 response assessment, was scheduled to be performed approximately every 12 weeks. The primary endpoint was best overall response (BOR = complete response [CR]+partial response [PR]) per RECIST v1.1. To detect a difference between an unacceptable BOR of 5% and a desirable BOR of 20% (one-sided type I error of 10%, power of 90%), at least 1 in the first 18 pts required an observed response. At least 4 responses of 32 total pts were needed to meet the primary endpoint. Treatment beyond progression of disease (PD) was allowed at the discretion of the investigator. A second cohort of pts with ACC was analyzed and reported separately. **Results:** From 7/25/2017-7/16/2020, 32 pts were enrolled and evaluable for the primary endpoint. There was 3 confirmed PRs in the first 18 pts, therefore enrollment of the second stage continued. BOR rate was 16% (5/32). Seven pts never reached a first disease assessment and were classified as non-responders: 5 due to clinical PD, 1 due to toxicity, and 1 pt withdrew. Four pts discontinued the trial for toxicities: pancytopenia (1), blurry vision (1), cardiomyopathy/hyperglycemia (1), and neutropenic sepsis (1), and mucositis (1). The 5 confirmed responders had regressions ranging from -66% to -100% in target lesions, with a duration of therapy ranging from 15.7 to 29.5 months (treatment ongoing for one as of 2/6/20). **Conclusions:** This cohort met its primary endpoint, and the responses observed were dramatic and durable. Paired biopsy and peripheral blood samples will be analyzed to elucidate insights into mechanisms of response and resistance to dual checkpoint blockade. Clinical trial information: NCT03172624. Research Sponsor: U.S. National Institutes of Health, Geoffrey Beene Cancer Research Center, Cycle for Survival, and the Overman Fund.

6003 **Oral Abstract Session**

Metronomic capecitabine as adjuvant therapy in locoregionally advanced nasopharyngeal carcinoma: A phase 3, multicenter, randomized controlled trial. *First Author: Jun Ma, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Patients suffering from locoregionally advanced nasopharyngeal carcinoma (NPC) commonly develop disease recurrence, despite a high rate of complete clinical remission after standard of care (concurrent cisplatin-radiotherapy, with or without induction chemotherapy). The benefit of additional adjuvant chemotherapy remains unclear. **Methods:** Patients with high-risk locoregionally advanced NPC (stage III to IVA, excluding T3-4N0 and T3N1), and with no locoregional disease or distant metastasis after definitive chemoradiotherapy, were eligible. They were randomly assigned (1:1) within 12 to 16 weeks after the last radiation dose to receive either capecitabine at a dose of 650 mg/m^2 twice daily for 1 year (metronomic capecitabine group) or observation (standard-therapy group). The primary end point was recurrence-free survival (RFS). The calculated sample size was 201 per group, with an 80% power (two-sided α 0.05) to detect a target hazard ratio (HR) of 0.52. **Results:** A total of 406 patients underwent randomization, comprising 204 in the metronomic capecitabine group and 202 in the standard-therapy group. After a median follow-up of 36 months (corresponding to 43 months when calculated from the start of standard therapy), the estimated 3-year RFS was 85.9% in the metronomic capecitabine group, as compared with 76.5% in the standard-therapy group (intention-to-treat population; HR 0.51, 95% confidence interval 0.32–0.81; $P = 0.003$). The incidence of grade 3 adverse events was 17.4% in the metronomic capecitabine group and 5.5% in the standard-therapy group; hand-foot syndrome was the most common adverse event related to capecitabine (9.0%). One grade 4 neutropenia occurred in the metronomic capecitabine group. Neither group sufferd from treatment-related deaths. During treatment, there was no clinically meaningful deterioration of health-related quality of life associated with the use of metronomic adjuvant capecitabine. **Conclusions:** The addition of metronomic capecitabine as adjuvant therapy to chemoradiotherapy significantly improved RFS in locoregionally advanced NPC, with a manageable safety profile and no compromise to quality of life. Clinical trial information: NCT02958111. Research Sponsor: Sun Yat-sen University Clinical Research 5010 Program, Pharmaceutical/Biotech Company.

Adjuvant capecitabine in locoregionally advanced nasopharyngeal carcinoma: A multicenter randomized controlled phase III trial. *First Author: Jingjing Miao, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China*

Background: We conducted a multicenter, randomized controlled phase III clinical trial (NCT02143388) to investigate the efficacy and toxicity of adjuvant capecitabine (AC) in addition to concurrent cisplatin and radiotherapy (CCRT) compared to CCRT alone in high-risk locoregionally advanced nasopharyngeal carcinoma (LANPC) patients. **Methods:** Eligibility criteria included AJCC/UICC 7th ed TNM stage III-IVb and one of the following features: T3-4N2 or T1-4N3 or pre-treatment plasma EBV DNA concentration of >20,000 copy/ml or gross primary tumor volume (GTVnx) of >30 cm^3 or a maximum standard uptake value (SUVmax) of >10.0 by ^{18}FDG PET-CT within the primary tumor or multiple neck node metastases, with any larger than 4 cm. All patients were randomly assigned in a 1:1 ratio to receive CCRT (3-weekly cisplatin at 100 mg/m^2 for 2-3 cycles) followed by AC (1000 mg/m^2 bi-daily for 14 days every 21-day cycle for 8 cycles), or CCRT alone. The prescribed radiation doses were 68-72 Gy/30-32 fractions to the PTVnx, 60-68 Gy/30-32 fractions to PTVnd, 60-64Gy/30-32 fractions to $PTV_{high\text{-}risk}$, 54-58Gy/30-32 fractions to $PTV_{low\text{-}risk}$. Primary end point was failure-free survival (FFS). **Results:** Between Mar 2014 to Jul 2018, 180 patients were recruited (90 patients in CCRT+AC arm and 90 in CCRT alone arm). All patients completed RT and ≥2 cycles of concurrent cisplatin in both treatment arms (cumulative dose intensities for cisplatin were 200 mg/m^2 in both arms). 85 (94.4%) patients went on to receive AC, with 71 (78.9%) patients completing 8 cycles; 19 (22.4%) patients had dose reduction of AC. With a median follow-up of 44.8 mo, the 3-y FFS was significantly superior in the CCRT+AC arm than the CCRT arm for the intention-to-treat cohort (87.7% *vs* 73.3%; HR: 0.52 [95% CI: 0.29-0.77], $P = 0.037$). 3-year overall, distant metastasis-free and locoregional relapse-free survival were 92.6% *vs* 88.9% (HR [95% CI]: 0.66 [0.28-1.59]), 88.8% vs. 81.1% (HR: 0.67 [0.33-1.33]) and 91.5% *vs* 80.0% (HR: 0.50 [0.25-1.00]), respectively. Incidences of G3-4 acute toxicities were 57.8% (52 of 90) in CCRT+AC arm and 51.1% (46 of 90) in CCRT alone arm, with a higher incidence of hand foot syndrome (3.5% *vs* 0%), xerostomia (11.1% *vs* 3.3%), mucositis (23.3% *vs* 16.7%), and anemia (5.6% *vs* 2.2%) in the CCRT+AC arm. G3-4 late toxicities occurred in 13.3% (12 of 90) and 9.0% (8 of 89), respectively. **Conclusions:** The addition of capecitabine to CCRT conferred a superior disease control than CCRT alone in high-risk LANPC. Survivals in ITT and PP set. Clinical trial information: NCT02143388. Research Sponsor: National Natural Science Foundation of China [No. 81872469 and 82073330]; Wu Jieping Medical Foundation [No. 320.6750.19089 and 320.6750.17108]; Sun Yat-sen University Cancer Center 308 Program.

6006 **Oral Abstract Session**

Association of pathological response to neoadjuvant pembrolizumab with tumor PD-L1 expression and high disease-free survival (DFS) in patients with resectable, local-regionally advanced, head and neck squamous cell carcinoma (HNSCC). *First Author: Trisha Michel Wise-Draper, University of Cincinnati Cancer Center, Cincinnati, OH*

Background: Patients with resected HNSCC, with high-risk (positive margins, extracapsular spread [ECE]) or intermediate-risk pathological features have an estimated 1-year DFS of 65% and 69%, respectively. Immune checkpoint blockade improved survival of patients with recurrent/metastatic HNSCC, and preclinical models indicate radiotherapy (RT) synergizes with anti-PD-1. Therefore, we administered the PD-1 inhibitor pembrolizumab (pembro) pre- and post-surgery with adjuvant RT +/- cisplatin in patients with resectable, locoregionally advanced (clinical T3/4 and/or ≥2 nodal metastases) HNSCC (NCT02641093). **Methods:** Eligible patients received pembro (200 mg I.V. x 1) 1-3 weeks before resection. Adjuvant pembro (q3 wks x 6 doses) was administered with RT (60-66Gy) with or without weekly cisplatin (40mg/m2 X 6) for patients with high-risk and intermediate-risk features, respectively. The primary endpoint was 1-year DFS estimated by Kaplan Meier curves. Safety was evaluated by CTCAE v5.0. Pathological response (PR) to neoadjuvant pembro was evaluated by comparing pre- and post-surgical tumor specimens for treatment effect (TE), defined as tumor necrosis and/or histiocytic inflammation and giant cell reaction to keratinaceous debris. PR was classified as no (NPR, < 20%), partial (PPR, ≥20% and < 90%) and major (MPR, ≥90%). Tumor PD-L1 immunohistochemistry was performed with 22c3 antibody and reported as combined positive score (CPS). **Results:** Ninety-two patients were enrolled. Seventy-six patients received adjuvant pembro and were evaluable for DFS. Patient characteristics included: median age 58 (range 27 – 80) years; 32% female; 88% oral cavity, 8% larynx, and 3% human papillomavirus negative oropharynx; 86% clinical T3/4 and 65% ≥2N; 49 (53%) high-risk (positive margins, 45%; ECE, 78%); 64% (44/69 available) had PD-L1 CPS ≥1. At a median follow-up of 20 months, 1-year DFS was 67% (95%CI 0.52-0.85) in the high-risk group and 93% (95%CI 0.84-1) in the intermediate-risk group. Among 80 patients evaluable for PR, TE scoring resulted in 48 NPR, 26 PPR and 6 MPR. Patients with PPR/MPR had significantly improved 1-year DFS when compared with those with NPR (100% versus 68%, p = 0.01; HR = 0.23). PD-L1 CPS ≥ 1 was not independently associated with 1-year DFS, but was highly associated with MPR/PPR (p = 0.0007). PPR/MPR in PD-L1 CPS < 1, ≥1 and ≥20, were estimated as 20, 55 and 90%, respectively. Grade ≥ 3 adverse events occurred in 62% patients with most common including dysphagia (15%), neutropenia (15%), skin/wound infections (10%), and mucositis (9%). **Conclusions:** PR to neoadjuvant pembro is associated with PD-L1 CPS≥1 and high DFS in patients with resectable, local-regionally advanced, HNSCC. Clinical trial information: NCT02641093. Research Sponsor: Merck & Co., Startup funds, internal pilot grants.

6007 **Oral Abstract Session**

Primary results of the phase II CheckRad-CD8 trial: First-line treatment of locally advanced head and neck squamous cell carcinoma (HNSCC) with double checkpoint blockade and radiotherapy dependent on intratumoral CD8+ T-cell infiltration. *First Author: Markus Hecht, Department of Radiation Oncology, Universitatsklinikum Erlangen, Friedrich-Alexander-Universitat Erlangen-Nürnberg, Erlangen, Germany*

Background: Inhibition of the PD-1/PD-L1 pathway is efficient in recurrent/metastatic HNSCC. Targeting the immune checkpoint CTLA-4 may be synergistic to radiotherapy. This trial studies feasibility and efficacy of combined PD-L1/CTLA-4 blockade concomitant to induction chemotherapy and radiotherapy. **Methods:** Patients with previously untreated stage III-IVB (AJCC 8th edition) HNSCC were eligible for this multicenter phase II trial. Treatment consisted of a single cycle of cisplatin 30mg/m^2 d1-3, docetaxel 75mg/m^2 d1, durvalumab 1500mg fix dose d5 and tremelimumab 75mg fix dose d5. Patients with at least 20% increase of intratumoral CD8+ immune cell density or pathological complete response (pCR) in the re-biopsy (performed on d22-26) entered radioimmunotherapy (RIT) up to a total dose of 70Gy. Patients received further three cycles of durvalumab/tremelimumab (q4w, two concomitant and one subsequent) followed by eight cycles of durvalumab mono (q4w). Primary endpoint was a feasibility rate of patients entering RIT to receive treatment until at least cycle 6 of immunotherapy of ≥80% (i.e. dose limiting toxicity/DLT ≤20%; exclusion of patients with other reasons than DLT for treatment discontinuation; feasibility unacceptable if ≤65%). The calculated sample size was 57 patients to enter RIT. Main secondary endpoints were progression-free survival (PFS) and overall survival (OS). **Results:** Between Sep 2018 and Mai 2020, 80 patients were enrolled (one excluded). Median age was 60 years, 33 patients (42%) were current smokers, 43 patients (54%) had oropharyngeal tumors (53% p16 positive), 44 patients (56%) were stage IV. Median follow up was 12.5 months. After induction chemo-immunotherapy 41 patients had pCR and 31 an intratumoral CD8+ immune cell increase. Of 60 patients entering RIT (primary endpoint cohort), 10 received DLT and 4 discontinued for other reasons. The feasibility rate of the RIT cohort until cycle 6 was 82%, meeting the primary endpoint of ≥80% (95% confidence interval (CI), one-sided (lower boundary): 72%). The RIT cohort had a PFS rate at 1 year of 79% (CI 69-90%) and at 2 years of 73% (CI 61-87%) and an OS rate at 1 year of 89% (CI 81-98%) and at 2 years of 86% (CI 77-97%). The entire study cohort had a PFS rate at 1 year of 75% (CI 65-85%) and at 2 years of 68% (CI 58-81%) and an OS rate at 1 year of 86% (CI 78-95%) and at 2 years of 80% (CI 70-91%). Toxicity (treatment-related or un-related) ≥grade 3 appeared in 75 patients (95%) and mainly consisted of dysphagia (53%), leucopenia (48%) and infections (29%). DLT mainly consisted of hepatitis (10%). **Conclusions:** The trial met the primary endpoint feasibility. CD8+ T cell-based pathological patient selection after induction therapy identifies patients with promising PFS rates after chemotherapy-free RIT. Clinical trial information: nct03426657. Research Sponsor: AstraZeneca.

6008 **Oral Abstract Session**

Enhanced pathologic tumor response with two cycles of neoadjuvant pembrolizumab in surgically resectable, locally advanced HPV-negative head and neck squamous cell carcinoma (HNSCC). *First Author: Ravindra Uppaluri, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: We reported that one cycle of neoadjuvant pembrolizumab induced pathologic tumor response in >10% (pTR-any) and in >50% (pTR-2) of the resection bed in 44% and 22% of patients (pts) with surgically resectable HPV-negative, Stage III/IV HNSCC (*Clin Cancer Res* 2020). We hypothesized that two cycles of neoadjuvant pembrolizumab would induce pTR-2 in 50% of pts. Increasing the pathologic response rate may favorably impact clinical outcomes. **Methods:** Multi-institutional phase 2 trial where pts with locally advanced, HPV-negative HNSCC received two cycles of pembrolizumab (200 mg), given 42 and 21 days prior to surgery. Resected tumor was analyzed by two independent pathologists for pTR (tumor necrosis and/or giant cell/histiocytic reaction to keratinous debris) in the resection bed (primary tumor and/or lymph nodes). Additional definitions: pTR-1 (>10-49%) and major pathologic response (> 90%). The primary endpoint was pTR-2. A sample size of 26 pts was needed to detect a significantly higher pTR-2 rate of 50%, with 80% power using a one-sided alpha level of 0.05. Pts were followed for serious adverse events (AEs) for 30 days after surgery and for AEs of clinical interest for 90 days following the last dose of pembrolizumab. Pts underwent baseline blood collection and tumor biopsies to match with blood and surgical specimens obtained post-pembrolizumab. Planned correlatives included PD-L1 expression, immune function, and molecular signatures of activation in the pre- and post-treatment blood and tumor tissue. **Results:** Characteristics of 29 enrolled and treated pts were median age 62 (30-82) yrs, smoking history 62% (18 pts); clinical stage T_2 (n = 6), T_3 (n = 5), T_4 (n = 18) and $N_{0/1}$ (n = 17), N_2 (n = 12). All treated patients received two cycles of neoadjuvant pembrolizumab, which was tolerated well with only one (3%) grade 3 AE (rash) and no grade 4 AEs. The primary endpoint was evaluable in 25 pts, and not evaluable in 4 pts (one pt withdrew before surgery and in three pts, pTR review was pending). pTR-2 occurred in 44% (11 of 25 pts), and 4 (16%) of these pts had a major pathologic response including 1 (4%) pathologic CR at the primary site. **Conclusions:** Two (vs one) cycles of neoadjuvant pembrolizumab resulted in a two-fold increase in the frequency of pTR-2 (44% vs 22%). These data imply that the frequency of pTR to neoadjuvant pembrolizumab can be improved by increasing the number of cycles and the treatment interval. Clinical trial information: NCT02296684. Research Sponsor: Merck Inc.

6010 **Poster Discussion Session**

Updated report of a phase II randomized trial of transoral surgical resection followed by low-dose or standard postoperative therapy in resectable p16+ locally advanced oropharynx cancer: A trial of the ECOG-ACRIN cancer research group (E3311). *First Author: Robert L. Ferris, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: Definitive or postoperative chemoradiation (CRT) is highly curative for human papillomavirus-associated (HPV+) oropharynx cancer (OPC) but induces significant toxicity. As a potential deintensification strategy, we studied primary transoral surgery (TOS) and, in intermediate pathologic risk patients, reduced dose postoperative RT (PORT). **Methods:** E3311 is a phase II trial with randomization to reduced- or standard-dose PORT for resected stage III-IVa (AJCC7) intermediate pathologic risk HPV+ OPC, stratified by smoking history. Primary endpoints have been reported; we now present updated 3-year PFS and patient-reported outcomes (PRO), including head and neck-cancer specific quality of life (FACT-H&N) and swallowing perception and performance (MDADI). **Results:** Of 519 enrolled patients, 495 underwent TOS. The primary oncologic endpoint was 2-year PFS for 50 Gy (Arm B) or 60Gy (Arm C). Among 360 eligible and treated patients (ETP), Arm A (observation, N = 38) enrolled 11%, Arms B (N = 100) or C (N = 109) randomized 58%, and Arm D (66Gy + weekly cisplatin, N = 113) enrolled 31%. With 35.1 months median follow-up, 3-year PFS Kaplan-Meier estimate is 96.9% (90% CI [91.9%, 100%]) for Arm A; 94.9% (90% CI [91.3%, 98.6%]) for Arm B; 93.5% (90% CI [89.4%, 97.9%]) for Arm C; and 90.7% (90% CI [86.2%, 95.4%]) for Arm D. Recurrences and death without recurrence were 4 and 1 in Arm B, and 5 and one in Arm C. Smokers ($>$ 10 pack-years) did not have worse 3-year PFS in Arms B or C. Treatment arm distribution and outcome for ineligible patients who started adjuvant therapy mirrored the 360 ETP. A comparison combining arms B/C versus arm D in the proportion of patients stable/improved in FACT-H&N total score, from baseline to 6 months post-treatment as a pre-specified endpoint, was 56% vs. 38% (p value = 0.011, one-sided Fisher's exact test); however, underlying differences in treatment and risk may be confounding. An exploratory comparison between Arms B and C revealed improvement in FACT H&N (63% in Arm B vs. 49% in Arm C had a stable/improved score, p-value = 0.056). **Conclusions:** Primary TOS and reduced PORT retained outstanding oncologic outcome at 35 months follow up, with favorable QOL and functional outcomes, in intermediate risk HPV+ OPC. Clinical trial information: NCT 01898494. Research Sponsor: U10CA180820, U10CA180794, UG1CA189953, UG1CA232760, UG1CA233184, UG1CA233196, UG1CA233247, UG1CA233329, UG1CA233331, UG1CA233337, U10CA180863, Canadian Cancer Society #704970.

6011 **Poster Discussion Session**

Nivolumab, nabpaclitaxel, and carboplatin followed by risk/response adaptive de-escalated locoregional therapy for HPV-associated oropharyngeal cancer: OPTIMA II trial. *First Author: Ari Rosenberg, University of Chicago, Chicago, IL*

Background: Despite the success of anti-PD-1 in recurrent/metastatic head and neck cancer, incorporation in the curative setting with induction therapy has yet to be investigated. Favorable prognosis of human papillomavirus associated (HPV+) oropharyngeal cancer (OPC) has led to interest in treatment de-escalation. OPTIMA 2 evaluated nivolumab (nivo) with nab-paclitaxel and carboplatin followed by risk/response adaptive de-intensified treatment for locoregionally advanced HPV+ OPC. We report the primary analysis and outcomes. **Methods:** OPTIMA 2 enrolled locoregionally advanced HPV+ OPC. Nivo, nab-paclitaxel, and carboplatin were administered for 3 cycles. High-risk (HR) included any of the following: T4, N2c-N3 (AJCC 7th edition), $>$ 20 pack year smoking history, non-HPV16 subtype; All others were low-risk (LR). Arm A included LR with $\geq$50% post-induction shrinkage by RECIST received single-modality de-escalation with low-dose radiation (RT) alone (50 Gy) or transoral robotic surgery (TORS). Arm B included HR with $\geq$50% shrinkage or LR with $<$50% received intermediate-dose chemoradiation (CRT) to 45-50Gy. Arm C included all others and received regular dose CRT to 70-75Gy. Adjuvant nivo was administered for 6 months. The primary endpoint was deep response rate (DRR) $\geq$50% shrinkage to induction therapy. **Results:** From September 2017 until March 2020, 73 patients (pts) were eligible and started treatment. One pt died during induction. The DRR following induction was 70.8% (95% CI 60.3%, 81.3%). Median follow-up 23.1 months. Median age 61 (range 39-85), T4 12.3%, N2c/N3 19.2%, LR 47.9%, and HR 52.1%. De-escalated treatment was administered in 84.9%. Arm A N = 28, Arm B N = 34, and Arm C N = 10. 2-year progression free survival (PFS) for full cohort was 90.4% (95% CI = 79.3%, 95.7%). 2-year PFS for Arms A, B, and C were 96.3%, 85.8%, and 100.0% respectively. 2-year overall survival (OS) for full cohort was 93.3% (95% CI = 82.4%, 97.5%). 2-year OS for Arm A, B, and C were 96.0%, 91.9%, and 100.0% respectively. Among TORS (N = 9), pathologic complete response (pCR) rate was 66.7%. G-tube rates in Arms A, B, and C were 7.1%, 44.1%, and 75.0% respectively (p = 0.0001). Grade 4 toxicity in arms A, B, and C, were observed in 7.1%, 8.8%, and 10.0% of pts respectively. There were 3 local failures and no distant failures. **Conclusions:** Nivo/nab-paclitaxel/carboplatin followed by risk/response adaptive de-escalated treatment in locoregionally advanced HPV+ OPC demonstrates excellent survival outcomes with reduced toxicity and enteral feeding rates, including high risk disease. Induction chemoimmunotherapy demonstrates a high rate of deep clinical response and represents a promising de-escalation approach that incorporates anti-PD1 in the definitive setting. High pCR rate was observed following nivo/nab-paclitaxel/carboplatin. Clinical trial information: NCT03107182. Research Sponsor: Bristol Myers Squibb.

6012 **Poster Discussion Session**

Randomized trial of radiotherapy with weekly cisplatin or cetuximab in low risk HPV associated oropharyngeal cancer (TROG 12.01): A Trans-Tasman Radiation Oncology Group study. *First Author: Danny Rischin, Department of Medical Oncology, Peter MacCallum Cancer Centre and the Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia*

Background: The excellent prognosis of patients with low risk HPV associated oropharyngeal squamous cell carcinoma has led to concerns about overtreatment and excessive toxicity with radiotherapy and cisplatin, leading to interest in de-intensification trials. We investigated whether cetuximab, an EGFR targeting antibody, when combined with radiotherapy would result in a decrease in symptom burden and toxicity with similar efficacy when compared to weekly cisplatin. **Methods:** TROG 12.01, a randomised, multicentre trial involving 15 sites in Australia and New Zealand enrolled patients with HPV associated oropharyngeal squamous cell carcinoma, AJCC 7th edition Stage III (excluding T1-2N1) or stage IV (excluding T4 and/or N3 and/or N2b-c if smoking history $>$10 pack years and/or distant metastases). Patients were randomised (1:1) to receive radiotherapy (70Gy in 35 fractions) with either weekly cisplatin, 7 doses of 40mg/m^2 or cetuximab, loading dose of 400mg/m^2 followed by 7 weekly doses of 250 mg/m^2. The primary outcome was symptom severity assessed by the MD Anderson Symptom Inventory Head and Neck Symptom Severity Scale from baseline to 13 weeks post completion of radiotherapy using the area under the time-severity curve (AUC). Sample size was 170 evaluable patients to provide at least 90% power to detect an effect size of 0.5, using a 2-sided test at 0.05 level of significance. Trial was registered on ClinicalTrials.gov: NCT01855451. **Results:** Between 17th June 2013 and 7th June 2018, 189 patients were enrolled and 182 were evaluable, with 92 on cisplatin arm and 90 on cetuximab included in the main analysis. The median follow-up was 4.1 years (0.4 - 5.3). Analyses were performed in all eligible randomised patients that commenced treatment (modified intention-to-treat population). There was no difference in the primary endpoint of symptom severity; difference in AUC cetuximab – cisplatin was 0.05 (95%CI: -0.19, 0.30), p= 0.66. The T-score (mean number of $>$ grade 3 acute adverse events) was 4.35 (SD 2.48) in the cisplatin arm and 3.82 (SD 1.8) in the cetuximab arm, p= 0.108. The 3 -year failure-free survival rates were 93% (95% CI: 86-97%) in the cisplatin arm and 80% (95% CI: 70-87%) in the cetuximab arm (hazard ratio = 3.0 (95% CI: 1.2-7.7); p=0.015. The increase in failures in the cetuximab arm was evenly split between distant and locoregional failures. **Conclusions:** For patients with low risk HPV associated oropharyngeal cancer, radiotherapy and cetuximab had inferior failure-free survival without improvement in symptom burden or toxicity compared to radiotherapy and weekly cisplatin. Radiotherapy and cisplatin remains the standard of care. Clinical trial information: NCT01855451. Research Sponsor: National Health and Medical Research Council (Project Grant 1047673), Pharmaceutical/Biotech Company.

6014 **Poster Discussion Session**

TRYHARD, a randomized phase II trial (RTOG Foundation 3501) of concurrent accelerated radiation plus cisplatin (cis) with or without lapatinib (Lap) for stage III- IV Non-HPV head and neck carcinoma (HNC). *First Author: Stuart J. Wong, Medical College of Wisconsin, Milwaukee, WI*

Background: Chemoradiation (CRT) with cis or anti-EGFR Ab has been shown to improve survival of patients with stage III-IV HNC. Since Lap, a dual EGFR and HER2 inhibitor, has shown effectiveness with CRT in a pilot non-HPV HNC cohort, the RTOG Foundation launched a phase II trial to test the hypothesis that adding Lap to the RT-cis for frontline therapy of stage III-IV Non-HPV HNC improves progression-free survival (PFS). **Methods:** Patients with stage III-IV carcinoma of the oropharynx (p16-negative), larynx, and hypopharynx, having Zubrod performance of 0-1, and meeting predefined blood chemistry criteria were enrolled after providing consent. Patients were randomized (1:1) to 70 Gy (6 weeks) + 2 cycles of CDDP (q3 weeks) plus either Lap (1500 mg daily, Arm A) or placebo (Arm B) starting 1 week prior to RT and concurrent with RT and for 3 months post RT. PFS was the primary endpoint. The protocol specified 69 PFS events (142 patients) for the final analysis based on HR = 0.65, 80% power, 1-sided alpha 0.20, and one interim efficacy and futility analysis at 50% information. PFS rates between arms for all randomized patients were compared by 1-sided log-rank test (1-sided alpha 0.1803). Overall survival (OS) was a secondary endpoint. **Results:** From 10/'12 to 04/'17, 142 patients were enrolled, of whom 127 were randomized, 63 to Arm A and 64 to Arm B. Arms A vs B, respectively, were similar in baseline patient characteristics, radiation delivery, completing $\geq$ 70 Gy (85.7% vs. 82.8%) and cisplatin delivery, completing 200 (±5%) mg/m^2 (65.1% vs 70.3%), but dissimilar in Lap/placebo delivery (median dose, 87000 mg vs. 125250 mg). Median follow-up was 4.1 years for surviving patients. The final analysis suggests no improvement in PFS of adding Lap to CRT (HR [A/B]: 0.91, 95% confidence interval CI 0.56-1.46; *P*= 0.34; 2-year rates: 50.6%, CI 37.5-63.7% vs. 56.2% CI 43.0-69.4%), or in OS (HR: 1.06, CI 0.61-1.86; P = 0.58; 2-year rates: 71.8% CI 60.1-83.5% vs. 76% CI 64.5-87.4%), death within 30 days of therapy (3.3% vs. 3.4%), and overall treatment-related grade 3-5 adverse event rate (86.7% vs. 84.7%). Grade 3-4 mucositis rates on Arm A and Arm B were 21.7% vs. 23.7%, all grade dysphagia and rash rates were 43.3% vs. 59.3%, and 13.3% vs. 6.8%, respectively. **Conclusions:** The addition of Lap to the radiation-cisplatin platform did not improve progression-free or overall survival in unselected non-HPV HN. Thus, dual EGFR, HER-2 inhibition does not appear to enhance the effects of chemoradiation. Although we showed that accrual to a non-HPV HN specific trial is feasible, new strategies must be investigated to improve the outcome for this poor prognosis HN population. Research Sponsor: Novartis.

6015 **Poster Discussion Session**

Randomized phase II trial of ficlatuzumab with or without cetuximab in pan-refractory, advanced head and neck squamous cell carcinoma (HNSCC). *First Author: Julie E. Bauman, Department of Medicine, Division of Hematology/Oncology, University of Arizona Cancer Center, Tucson, AZ*

Background: Cetuximab (C), an anti-EGFR monoclonal antibody (mAb), is approved for advanced HNSCC but benefits a minority. Crosstalk between the EGFR and hepatocyte growth factor (HGF)/cMet pathways is a known resistance mechanism. HGF is also immunosuppressive within the tumor microenvironment. A Phase I study confirmed the safety of C and ficlatuzumab (F), an IgG1 anti-HGF mAb, with preliminary efficacy and biomarker data suggesting that dual pathway inhibition may overcome tumor-intrinsic or immune cetuximab resistance. **Methods:** The primary objective of this phase II randomized, non-comparative trial was to evaluate the efficacy of F (20 mg/kg every 2 wks), with or without C (500 mg/m^2 every 2 wks), in pan-refractory, advanced HNSCC. Eligibility criteria included recurrent/metastatic HNSCC, performance status (PS) 0-1, C resistance (defined as progression on or within 6 months of exposure), and resistance to or ineligibility for platinum and anti-PD1 mAb. Randomization was stratified by HPV status and center. The primary endpoint was median progression-free survival (mPFS). An arm was deemed worthy of further study if the lower bound of the 90% 1-sided confidence interval (CI) excluded the historical control of 2 months. Secondary objectives included overall response rate (ORR) in the overall and HPV-stratified populations. A Bayesian continuous monitoring rule for futility was applied. **Results:** 60 patients were randomized and 58 treated between Jan 2018 and Dec 2020 (27 to F; 33 to FC). Baseline characteristics were balanced across major prognostic variables including age, PS, HPV status, platinum resistance, and PD1 mAb exposure. Median time since prior cetuximab was 3.5 months (range 0-48 months). Grade ≥3 adverse events attributed to F included: pneumonitis (2); edema (3); diarrhea (1); LFT elevation (1); rash (2); electrolyte abnormality (2). The Table presents efficacy data. The F arm stopped for futility after 26 evaluable subjects accrued. The FC arm completed accrual and met the primary endpoint; 32 evaluable subjects had mPFS of 3.6 months (lower bound 90% 1-sided CI: 2.3 months) and ORR of 19% (6/32). All responses were in HPV- subjects, including 2 complete (CR) and 4 partial responses (PR) to the FC combination and 1 PR to F monotherapy. The mPFS and ORR for the HPV- population (n = 16) on FC were 3.8 months and 38% (6/16). Mechanistic signaling and immune biomarkers are under analysis. **Conclusions:** The well-tolerated FC combination met the primary PFS endpoint in pan-refractory, advanced HNSCC with notable activity in HPV- HNSCC, warranting phase III investigation. Clinical trial information: NCT03422536. Research Sponsor: Aveo, U.S. National Institutes of Health.

Phase II trial of soluble EphB4-albumin in combination with PD-1 antibody (pembrolizumab) in relapsed/refractory head neck squamous cell carcinoma. *First Author: Alexandra Jackovich, University of Southern California, Los Angeles, CA*

Background: EphB4 receptor tyrosine kinase and its ligand EphrinB2 are highly induced in head neck squamous cell carcinoma (HN SCC) tumor cells and vessels, particularly in HPV negative tumors. Each are predictors for poor survival with worse prognosis when both are induced. EphB4 provides tumor cell survival and EphrinB2 inhibits immune cell invasion. Soluble EphB4-Alb blocks bidirectional signaling, enhances immune cell recruitment alone and when combined with PD-1 antibody. **Methods**: A phase II trial of sEphB4-Alb combined with pembrolizumab accrued HN SCC patients after failure of one or more prior regimens. IHC positivity for p16 was used as a surrogate for HPV infection. Treatment regimen was sEphB4-Alb 10 mg/kg weekly IV infusion with pembrolizumab 200 mg IV infusion every three weeks. Study endpoints were toxicity, overall response rates (ORR) and overall survival (OS). Response to therapy was based on RECIST 1.1 criteria. Patient tumor samples were collected at baseline with a 2nd biopsy at week 8 on therapy, for tissue analysis of PD-L1, EphrinB2 and other biomarkers. **Results**: Twenty-four patients were accrued to the phase II trial combination of sEphB4-Alb and pembrolizumab. Age, sex, prior treatment, HPV status, and response data are summarized in the table below. The most common toxicity was hypertension with 8 patients experiencing grade 3 HTN. No grade 4 or above toxicities were observed. Among HPV negative cases, partial and complete responses were observed in 6 of 14 patients (43%) with complete response (CR) observed in 3 of 6 responders. Additionally, rapid response was observed in 3 of 14 HPV negative patients. Response was associated with increase in immune markers on 2nd biopsy. Median overall and progression-free survival in all patients was 12.6 months and 8.6 months, respectively. **Conclusions:** 1. sEphB4-Alb was well tolerated in combination with PD-1 antibody. 2. sEphB4-Alb was associated with increased immune response to tumor, when combined with PD-1 antibody. 3. sEphB4-Alb appears to have substantial activity (including complete remission) when combined with PD-1 antibody in relapsed/refractory HPV negative HN SCC. Clinical trial information: NCT03049618. Research Sponsor: Merck.

Efficacy of concurrent cetuximab (CTX) and nivolumab (NIVO) in previously untreated recurrent and/or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). *First Author: Christine H. Chung, Moffit Cancer Center, Tampa, FL*

Background: Current standard of care for patients (pts) with previously untreated R/M HNSCC that are incurable is either pembrolizumab (pembro) with/without chemotherapy depending on the Programmed Death-Ligand 1 (PD-L1) combined positive score (CPS). We evaluated the combination of CTX and NIVO for its efficacy. **Methods:** Pts were treated with CTX 500 mg/m2 IV on Day (D) -14 as a lead-in followed by CTX 500 mg/m2 IV and NIVO 240 mg/m2 IV on D1 and D15 every 28-D cycle (C). Pts with CTX infusion reaction or who did not receive C1D1 for any reason were non-evaluable and replaced. NIVO dose reduction was not allowed. **Results**: Fifty-four evaluable pts were analyzed. Median age was 62 (42-85). ECOG performance status at baseline was 0 (20, 37%), 1 (30, 56%), and 2 (4, 7%). Primary sites were oral cavity 19 (35%), oropharynx 22 (41%), hypopharynx 3 (6%), larynx 9 (17%), and unknown primary 1 (2%). p16 status is positive 22 (41%), negative 29 (54%), and unknown 3 (6%). PD-L1 CPS is <1 in 6 (11%), >1 in 26 (48%), and unknown 22 (41%). Median follow up time for overall survival (OS) was 12.2 months. The most common grade 3 treatment-related adverse events (TRAEs) occurring in ≥2 pts were hypomagnesemia 2 (4%), hypophosphatemia 2 (4%), fatigue 4 (7%), and rash-acneiform 4 (7%). The only grade 4 TRAEs were hypomagnesemia in 1 (2%) and CTX infusion reaction in 1 (2%). The most common grade 3 immune-related adverse event (IRAE) occurring in ≥2 was fatigue 2 (4%). No grade 4 IRAEs is observed. Median progression-free survival (PFS) and OS were 7.8 and 14.5 months, while 1-year PFS and 1-year OS were 39% and 61%, respectively. There were no statistically significant differences in either PFS and OS based on tumor p16 or PD-L1 status. **Conclusions**: The clinical trial met its primary endpoint of 1-year OS. Our data indicate the combination of CTX and NIVO is safe and effective in pts with previously untreated incurable R/M HNSCC. Clinical trial information: NCT03370276. Research Sponsor: Lilly, Florida Health Department.

6018 **Poster Discussion Session**

A randomized phase II trial of diffusion-weighted MR imaging-guided radiotherapy plus chemotherapy versus standard chemoradiotherapy in locoregional advanced nasopharyngeal carcinoma. *First Author: Feng Liu, Hunan Cancer Hospital and The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China*

Background: We hypothesized that diffusion-weighted MR imaging (DWI) guided dose-painting radiotherapy (DP-RT) was associated with improved tumor control and survival compared with standard CT-based radiotherapy in locoregionally advanced nasopharyngeal carcinoma (NPC). The purpose of this randomized phase II trial was to compare the efficacy and toxicity of DWI guided DP-RT plus chemotherapy versus standard CT-based radiotherapy plus chemotherapy in locoregionally advanced NPC. **Methods:** Two hundred and fifty-six patients with stage III-IVa (8th AJCC) NPC were randomly assigned to receive DWI-guided dose-painting radiotherapy plus chemotherapy (DP-RT group, n = 128) or standard CT-based radiotherapy plus chemotherapy (CT-based RT group, n = 128). Patients in both groups received 3 cycles of induction chemotherapy followed by cisplatin-based concurrent chemoradiotherapy. In DP-RT group, subvolume GTVnx-DWI (gross tumor volume of nasopharynx in DWI) was defined as the areas within the GTVnx (gross tumor volume of nasopharynx) with an apparent diffusion coefficient (ADC) below the mean ADC (ADC $<$ mean). The dose to GTVnx-DWI was escalated to DT 75.2 Gy/32 Fx in patients with T1-2 disease, and DT 77.55 Gy/33 Fx in those with T3-4 disease, in 2.35 Gy per fraction. In CT-based RT group (n = 128), PGTVnx was irradiated at DT 70.4-72.6 Gy/32-33 Fx in 2.2 Gy per fraction. This trial is registered with chictr.org.cn, number ChiCTR1800015779. **Results:** Compared with standard CT-based radiotherapy, DWI-guided DP-RT significantly improved 2-year local recurrence-free survival (LRFS, 100% vs. 95.4%; P = 0.024), distant metastasis-free survival (DMFS, 97.9% vs. 90.6%; P = 0.006), disease free survival (DFS, 93.2% vs. 86.8%; P = 0.021), and overall survival (OS, 100% vs. 95.2%; P = 0.038). No statistically significant differences in acute and late toxic effects were observed. Multivariate analysis showed that dose painting (DWI-guided DP-RT vs CT-based RT without DP) was a significant independent prognostic factor for DMFS and DFS (P = 0.021 and P = 0.020, respectively). **Conclusions:** Diffusion-weighted MR imaging guided dose-painting radiotherapy plus chemotherapy is associated with a considerable survival benefit, without increasing toxicity, as compared with standard CT-based radiotherapy plus chemotherapy, among patients with locoregionally advanced nasopharyngeal carcinoma. Clinical trial information: ChiCTR1800015779. Research Sponsor: Cancer Foundation of China, and China Hunan Provincial Science and Technology Department.

The 30 ROC trial: Precision intra-treatment imaging guiding major radiation reduction in human papillomavirus related oropharyngeal cancer. *First Author: Nancy Y. Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Our previously published proof-of-concept trial using functional imaging to select patient with human papillomavirus (HPV) oropharyngeal carcinoma (OPC) for radiation de-escalation showed promising results. Here we report the outcome of a larger validation trial using the same paradigm where select HPV+ OPC patients received a definitive dose of 30Gy concurrently with chemotherapy and were subsequently observed. **Methods:** The trial enrolled patients who had p16+, T0-2, N1-N2c, M0 OPC by AJCC 7th TNM. Patients were required to have resection of the primary site (negative margin not required) or core biopsy of lymph node if unknown primary. In addition to standard positron emission tomography (PET), a pre-radiation dynamic ^{18}F-FMISO (fluoromisonidazole) PET was performed to identify hypoxia in gross nodal disease. Patients with evidence of hypoxia ($>$ 1.2 tumor to muscle standard uptake value on ^{18}F-FMISO) underwent repeat^{18}F-FMISO PET around 2 weeks into radiation. Patients without pre-radiation hypoxia or with resolution of hypoxia on ^{18}F-FMISO PET received 30Gy with 2 cycles of concurrent chemotherapy (cisplatin 100mg/m^2 or carboplatin AUC 1.25 x 4 with 5-fluorouracil 2400 mg/m^2). **Results:** From 11/2/17-1/4/21, 158 HPV+ OPC patients consented and were enrolled on trial. Patient characteristics were as follows: male (90%); ages 36-80 years; T-stage T0(26), T1(77), T2(55); N stage N1(19), N2a(15), N2b(95), N2c(29). Of the 114 patients with pre-treatment hypoxia, 24 had persistent hypoxia and received 70Gy. 128 patients were de-escalated to 30Gy and chemotherapy (86% cisplatin). 6 patients withdrew from trial [3 decided to receive standard of care; 3 refused ^{18}F-FMISO PET]. Acute mucositis rates were 11% grade 0, 59% grade 1, and 30% grade 2, respectively. Acute xerostomia rates were 92% grade 1 and 8% grade 2, respectively. Weight loss was infrequent and only 19% complained of grade 1 and 5% complained of grade 2 weight loss. Six patients experienced grade 3 adverse events (diarrhea (2), syncope (2), vasovagal (1), dysphagia (1)). No patients required PEG tubes. With a median follow-up is 12 months (range: 2 months to 40 months), the 1-year locoregional control, distant metastasis-free overall survival rates were 94%, 100%, and 100%, respectively. Among the 30Gy de-escalated patients, none failed in the primary site. 8 patients had recurrent nodal disease underwent successful salvage surgery of which no additional therapy was given to 4 patients. **Conclusions:** Major de-escalation to 30Gy using patient specific treatment response based on hypoxia resolution resulted in excellent locoregional control with significant toxicity reduction. Updated results along with detailed correlative analysis will be presented. Clinical trial information: NCT03323463. Research Sponsor: U.S. National Institutes of Health, Serra Mucositis Funds.

6020 **Poster Session**

Long-term follow-up of bintrafusp alfa, a bifunctional fusion protein targeting TGF-β and PD-L1, in advanced squamous cell carcinoma of the head and neck (SCCHN). *First Author: Byoung Chul Cho, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Bintrafusp alfa is a first-in-class bifunctional fusion protein composed of the extracellular domain of the TGF-βRII receptor (a TGF-β "trap") fused to a human IgG1 mAb blocking PD-L1. A previous report of an expansion cohort from a phase 1 study (NCT02517398) suggested that bintrafusp alfa had a manageable safety profile and early signs of clinical activity in patients with heavily pretreated, advanced SCCHN after a median follow-up of 86.4 weeks. Here we report long-term efficacy and safety for this cohort. **Methods:** Patients with advanced SCCHN that progressed/recurred after platinum therapy in the recurrent/metastatic setting, or $<$ 6 months after platinum therapy in the locally advanced setting, received bintrafusp alfa 1200 mg every 2 weeks until confirmed progressive disease, unacceptable toxicity, or trial withdrawal. The primary endpoint was confirmed best overall response assessed per RECIST 1.1 assessed by independent review committee (IRC); safety was a secondary endpoint. **Results:** As of May 15, 2020, 32 patients had received bintrafusp alfa for a median of 2.8 months (range, 0.5-29.9 months), no patient remained on treatment, and median follow-up to data cutoff was 41.7 months (range, 39.8-43.5 months). The objective response rate (ORR; 13%) was unchanged since the previous report; median duration of response (DOR) was increased at 21.4 months (95% CI, 5.5 months to not reached [NR]). While the clinical activity of bintrafusp alfa may be improved in patients with HPV-positive tumors (Table), outcomes were generally similar between PD-L1 subgroups ($\geq$1% vs $<$ 1% tumor cells). The overall safety profile was consistent with the previous report for this cohort, without grade 4 nor 5 treatment-related adverse events (TRAEs); no new TRAEs of grade 3 or that led to discontinuation of bintrafusp alfa were reported. **Conclusions:** With a median follow-up of over 3 years in patients with heavily pretreated advanced SCCHN, bintrafusp alfa showed sustained clinical activity and 3-year OS of 24.0%, which compares favorably to historical data. Clinical activity appeared to be greater in patients with HPV-positive tumors than those with HPV-negative tumors. The safety profile was manageable and consistent with earlier analysis. Further investigation of bintrafusp alfa in SCCHN and other HPV-associated cancers is ongoing. Clinical trial information: NCT02517398. Research Sponsor: Merck KGaA, Darmstadt, Germany, and GlaxoSmithKline.

The association of skeletal muscle mass and cisplatin pharmacokinetics in head and neck cancer patients: The prospective PLATISMA study. *First Author: Laura Molenaar-Kuijsten, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Locally advanced head and neck squamous cell carcinoma (HNSCC) is commonly treated with cisplatin-based chemoradiotherapy (CRT). Cisplatin is associated with severe toxicity, which negatively affects survival. In recent years, a relationship between low skeletal muscle mass (SMM) and toxicity has been described. This increased toxicity may be related to an altered cisplatin distribution and binding in the fat-free body mass, of which SMM is the largest contributor. This study aims to investigate the association between cisplatin pharmacokinetics and SMM in HNSCC patients. **Methods:** We performed a prospective observational study in HNSCC patients treated with CRT with cisplatin. Patients received standard-of-care chemotherapy with three cycles of cisplatin, at a dose level of 100 mg/m^2 per cycle. Quantitative data on body size descriptors including SMM, measured on computed tomography scans, and cisplatin pharmacokinetics (total and ultrafilterable plasma concentration) were collected, as well as data on toxicity. **Results:** 45 evaluable patients were included in the study. A large proportion of the study population had a low SMM (46.7%). The majority of patients (57.8%) experienced cisplatin dose limiting toxicities. Pharmacokinetic analysis showed a significant relationship between cisplatin pharmacokinetics and the body size descriptors SMM, weight, fat-free mass, and body surface area ($p<$ 0.005). In a simulation, patients with a low SMM were predicted to reach higher bound cisplatin concentrations. The higher concentration of bound cisplatin could be seen as a reflection of the smaller volume of distribution, and could thereby explain the increased toxicity in patients with a low SMM. **Conclusions:** We found an association between cisplatin pharmacokinetics and SMM. Patients with a low SMM were predicted to reach higher bound cisplatin concentrations, which could be an explanation for the increased toxicity in this patient group. Clinical trial information: Trial NL7469 (NTR7711). Research Sponsor: Dutch Cancer Society.

Anlotinib in radioiodine-refractory differentiated thyroid carcinoma: A subanalysis based on ALTER01032 study for patients with poor baseline characteristics. *First Author: Yihebali Chi, National Cancer Center/ National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Anlotinib (anlo), a multikinase inhibitor, has demonstrated a significant survival benefit in treating locally advanced or metastatic radioiodine-refractory differentiated thyroid carcinoma (RAIR-DTC) with a nearly 4 folds prolongation in median progression-free survival (mPFS) (HR = 0.21, $p < 0.0001$) compared with placebo in a randomized, placebo-controlled phase 2 study (ALTER01032, NCT02586337). Older age, bone metastasis, structural progression within a short time are generally indicated as negative prognostic factors for thyroid cancer. This subanalysis explored the outcomes of patients (pts) enrolled in ALTER01032 study with these poor baseline characteristics. **Methods:** 113 pts were enrolled, 76 in anlo arm and 37 in placbo arm. The primary endpoint is PFS. Pts with older age ($\geq$ 55), bone metastasis or radiographic documented disease progression within 3 months (mo) before enrollment were selected. The PFS and overall survival (OS) for these pts were estimated and compared. Since 64.9% pts in placebo arm received crossover treatment with open label anlo after progression while only 3 pts in anlo arm received post-study treatment, the penitential bias for OS from imbalance of subsequent treatment was adjusted by a two-stage estimation method. **Results:** The results of subanalysis were summarized in the table below. Pts with poor baseline characteristics showed higher risk of progression and death. Significant PFS prolongation was shown across all subgroups in pts received anlo compared with their counterparts who received placebo ($P < 0.05$). In pts with bone metastasis or structural progression within 3 mo, anlo treatment achieved significant OS benefit ($P < 0.05$). Also, in older pts, a trend of OS improvement was observed (HR = 0.85 (95% CI 0.37, 1.97)). Most pts in placebo arm received crossover anlo. After adjustment, a near-significant decrease of death risk was observed in older pts received anlo compared with those received placebo (HR = 0.48 (95% CI 0.20, 1.13)). **Conclusions:** This subanalysis showed anlo effectively improved both PFS and OS of pts with RAIR-DTC who have poor baseline characteristics above. Interestingly, although most pts in placebo arm received crossover anlo, they still have higher risk of death, indicating the importance of earlier treatment for these pts. Clinical trial information: NCT02586337. Research Sponsor: None.

Toripalimab plus intensity-modulated radiotherapy for recurrent nasopharyngeal carcinoma: An open-label single-arm, phase II trial. *First Author: Mingyuan Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Toripalimab is a humanized immunoglobulin G_4 monoclonal antibody against programmed death 1 (PD-1). We aimed to investigate the efficacy and safety of toripalimab in combination with intensity-modulated radiotherapy (IMRT) for recurrent nasopharyngeal carcinoma (rNPC). **Methods:** We conducted a single-arm, phase II trial with rNPC patients who had biopsy-proven disease and were unsuitable for local surgery. Eligible patients received IMRT in combination with toripalimab administered via intravenous infusion of 240 mg once every 3 weeks for a maximum of seven cycles. The primary endpoint was the objective response rate (ORR). The secondary endpoints included safety profiles, progression-free survival (PFS). **Results:** Between May 2019 and January 2020, a total of 25 rNPC patients were enrolled (18 men [72.0%] and 7 women [28.0%]; median [IQR] age, 49.0 [43.5-52.5] years). With a median (IQR) follow-up duration of 14.6 months (13.1-16.2) months, 19 patients (79.2%) achieved an overall response, and disease control was achieved in 23 (95.8%) patients at 3 months post radiotherapy. The 12-month progression-free survival was 91.8% (95% CI 91.7% - 91.9%). The incidences of acute (grade ≥3) blood triglyceride elevation, creatine phosphokinase elevation, skin reaction, and mucositis were 1 (4.0%), 1 (4.0%), 2 (8.0%), and 1 (4.0%), respectively. The incidences of late severe (grade ≥3) nasopharyngeal wall necrosis, nasal bleeding, and trismus were 28.0%, 12.0%, and 4.0%, respectively. **Conclusions:** Toripalimab combined with IMRT was tolerable and showed promising antitumor activity in rNPC patients. Clinical trial information: NCT03854838. Research Sponsor: the Key-Area Research and Development of Guangdong Province.

6024 **Poster Session**

Afatinib and pembrolizumab for recurrent or metastatic head and neck squamous cell carcinoma (ALPHA Study): A phase II study with biomarker analysis. *First Author: Hsiang-fong Kao, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan*

Background: Epidermal growth factor receptor (EGFR) pathway inhibition may synergize with anti-PD1 activity by inhibiting macrophage function, increasing antigen presentation, and augmenting T cell responses. Afatinib, an irreversible EGFR tyrosine kinase inhibitor (TKI), has been shown to enhance anti-PD1 activity in in vitro and animal studies. We thus hypothesized that adding afatinib to pembrolizumab may improve the treatment outcomes for patients with recurrent or metastatic head and neck squamous cell carcinoma (HNSCC). **Methods:** The ALPHA study (NCT03695510) is a single-arm, phase II study with a Simon 2-stage design. Patients with platinum-refractory, recurrent, or metastatic HNSCC are eligible for the study. Afatinib (40mg, oral, daily) and pembrolizumab (200mg, every 3 weeks) are administered to eligible patients. The primary endpoint is the objective response rate (ORR). PD-L1 IHC testing (22C3), comprehensive genomic profiling (CGP, Roche Foundation Medicine One CDx), and targeted multiplexed gene expression profiling (Nanostring nCounter PanCancer Immune Profiling Panel) were applied for biomarker analysis. **Results:** From JAN 2019 to MAR 2020, 29 patients were enrolled in the study. Age: mean = 53.4 years old; M/F = 27/2. Tumor type: oral cavity: 19; oropharynx: 6, hypopharynx: 2, larynx: 2. PD-L1 TPS > = 50: 7/29 (24.1%), CPS > = 20: 8/29 (27.6%), TMB > 10: 0/25 (0%). The common treatment-related adverse events (AEs; all grades, grade > = 3) were skin rash (22/29, 4/29), diarrhea (17/29, 3/29), paronychia (13/29, 0/29), mucositis (9/29, 1/29), and weight loss (2/29, 0/29). One patient experienced grade 2 pneumonitis. Twelve patients had partial responses to the treatment (12/29, ORR: 41.4%). The data cut-off date was 11FEB2021. The median progression free survival (PFS) was 4.1 (95% confidence interval [CI], 1.9-6.3) months. The median overall survival (OS) was 8.4 (95% CI, 4.1-10.8) months. Patients with high PD-L1 expression had a higher response rate (TPS > = 50: ORR = 0.71, CPS > = 20: ORR = 0.63). EGFR amplification might also predict a higher response rate (ORR: 3/3, 100%). MTAP loss or mutation may predict a poor response to the treatment (ORR: 0/5, 0%), shorter PFS (HR: 4.21, [95% CI: 1.34-13.24], p = 0.014), and shorter OS (HR: 4.20 [95% CI: 1.32-13.41], p = 0.015). Nine patients underwent paired pre-treatment and post-treatment biopsies for gene expression analysis. The mRNA of HLA-A, HLA-B, CXCL13, CXCL9, and CD8A were elevated in the post-treatment biopsies. Three patients underwent post-progression biopsies for CGP study. One patient had a new MTAP mutation. **Conclusions:** Afatinib can modify tumor microenvironment and increase the clinical response rate in pembrolizumab-based therapy in HNSCC patients. PD-L1, EGFR amplification, and MTAP loss/mutation could be biomarkers for cancer immunotherapy. Clinical trial information: NCT03695510. Research Sponsor: Boehringer Ingelheim, Merck.

A phase 2 study of liposomal irinotecan with 5-fluorouracil and leucovorin in squamous cell carcinoma of head and neck or esophagus after prior platinum-based chemotherapy or chemoradiotherapy. *First Author: Li-Yuan Bai, Department of Hematology and Oncology, China Medical University Hospital, Taichung, Taiwan*

Background: Liposomal irinotecan (nal-IRI) + 5-FU/LV has been approved and used in treating patients with metastatic pancreatic cancer after gemcitabine-based therapy through the NAPOLI-1 study result. This phase 2 trial evaluated the activity of NAPOLI-1 regimen in patients with squamous cell carcinoma (SCC) of head and neck (H&N) or esophagus that progressed on or recur after platinum-based chemotherapy or concurrent chemoradiotherapy. **Methods:** Patients with histologically confirmed SCC of H&N or esophagus whose disease progressed while on or progressed/recurred within 6 months after platinum-based chemotherapy or chemoradiotherapy, and unsuitable for further surgical or radiation intervention were eligible. Prior anti-EGFR or anti-PD1/anti-PDL1 treatment was allowed. The regimen consisted of nal-IRI 70 mg/m^2 (irinotecan free base) followed by LV 400 mg/m^2 and 5-FU 2400 mg/m^2, every 2 weeks. A Simon's 2-stage design was used with planned 30 evaluable patients in the first stage and 52 evaluable patients in total. The primary endpoint is objective tumor response. **Results:** From December 2018 to April 2020, 59 subjects were enrolled, including 16 with esophagus cancer and 43 with H&N cancer. Thirty-seven (63%) patients had metastatic disease at enrollment. The mean of treatment cycles were 5 (range, 1-21). Among the total 59 enrolled subjects, 53 subjects (14 esophagus cancer, 39 H&N cancer) were evaluable for objective tumor response. The disease control rate in esophagus cancer was 50% (7 SD, intent-to-treat (ITT) population 43.8%). For H&N patients, 1 CR, 4 PR, and 23 SD resulted in the response rate 12.8% (11.6% in ITT population) and disease control rate 72% (65% in ITT population). The median progression free survival (N = 59) was 2.5 months (esophagus/H&N: 1.5/2.7 months) and the median overall survival was 5.9 months (esophagus/H&N: 4.2/7.3 months). Seventy-eight percent of patients had ≥grade 3 treatment-related adverse events. The most frequent ≥grade 3 toxicities were decreased lymphocyte count (50.8%), decreased neutrophil count (42.4%), and decreased white blood count (33.9%). Only 3 patients (5%) had grade 3 diarrhea during the treatment period. **Conclusions:** This study showed the modest efficacy and manageable toxicity profile of nal-IRI+5-FU/LV in platinum-refractory locally advanced or metastatic H&N or esophagus cancer patients. Clinical benefits including complete tumor response were noted in H&N patients. The role of this regimen in selective patients and the efficacy of combination with immunotherapeutic agents warrant further explorations. Clinical trial information: NCT03712397. Research Sponsor: None.

Preliminary results of the efficacy and safety of all-trans retinoic acid combined with low-dose apatinib in the treatment of patients with recurrent/metastatic adenoid cystic carcinoma of the head and neck. *First Author: Lulu Ye, Radiotherapy Division, Department of Oral and Maxillofacial-Head Neck Oncology, Shanghai Ninth People's Hospital, College of Stomatology, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: There is no standard treatment for recurrent/metastatic adenoid cystic carcinoma of the head and neck (R/M ACCHN). Moreover, MYB and/or NOTCH1 mutation can lead to worse prognosis. Currently, anti-angiogenic targeted therapy is a relatively effective treatment option, but the accompanied toxicities may hinder the continuous medication. All-trans retinoic acid (ATRA) induces differentiation and promotes apoptosis, enhancing the cytotoxicity of anti-tumor agents; on the other hand, inhibits c-MYB and/or NOTCH1 expression. Apatinib is an oral tyrosine kinase inhibitor that selectively inhibits vascular endothelial growth factor receptor 2. We reported the preliminary results of the efficacy and safety of ATRA combined with low-dose apatinib in patients with R/M ACC. **Methods:** In this exploratory study, patients with pathologically or histologically confirmed advanced, R/M ACC with measurable disease were screened. Patients who previously received anti-angiogenic therapy then withdrew due to toxicities could be recruited. ATRA was administered orally at a dose of 20 mg twice a day, and apatinib was administered orally at a dose of 250 mg once a day. The primary endpoint was objective response rate (ORR), as assessed according to the Response Evaluation Criteria In Solid Tumors v1.1. **Results:** Between March 2019 and April 2020, a total of 16 patients were enrolled. The median age was 53 years (range: 35-69), and 7 (44%) patients were male. Four (25%) patients received ATRA plus apatinib as the third-line therapy, while 12 (75%) received as the second-line therapy. Of 16 patients, 3 (19%) achieved partial response and 13 (81%) achieved stable disease (SD), with ORR of 19% and disease control rate of 100%, respectively. Among patients with SD, 12 (75%) showed tumor shrinkage (3%-28%) and 1 (6%) showed minor tumor enlargement (2%). The median follow-up time was 14.5 months (range: 8.1-22.1). Throughout the period, 5 (42%) patients developed disease progression. The 6-month and 12-month progression-free survival rates were 100% and 80%, respectively. Grade 3 adverse events included hand-foot syndrome (1 [6%]) and proteinuria (1 [6%]). No grade ≥4 adverse events occurred. **Conclusions:** ATRA combined with low-dose anti-angiogenic drug apatinib could be a potential treatment option for patients with R/M ACC, including those with pretreated advanced ACC after progression on or intolerance to other therapies. These encouraging results were worth further investigations, and a randomized phase 2 trial in ongoing (the Aplus study, NCT04433169). Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Mathematical predication models to optimize post-treatment surveillance in HPV-associated oropharyngeal cancer. *First Author: Vivek Nair, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: In this study we develop post-treatment imaging surveillance schedules for locally advanced oropharyngeal carcinoma (OPC) specific to the unique recurrence patterns of tumor stage and HPV status, using mathematical models. Current post-treatment imaging surveillance recommendations for OPC are not evidence based. The exception is the use of a positron emission tomography (PET) scan at 3 months post-treatment, after which practice across institutions diverge. An optimized and personalized surveillance schedule for OPC patients can minimize costs and diagnostic delays. **Methods:** A Markov multi-state model defining local and distant recurrences was trained using 2159 patients from the National Cancer Database. Patients from 2010-2015 treated at an academic or major cancer center with curative radiotherapy were included. Tumors must have been stage III to IVB (AJCC 7th edition) with known p16/HPV status. Model performance was then successfully externally validated using the 2016 International Collaboration on Oropharyngeal cancer Network for Staging (ICON-S) study. Optimized radiographic surveillance schedules were created using this model, assuming a PET at month 3 and including 0 to 6 additional computed tomography (CT) scans of the neck and chest. Optimization was done for minimization of latency, defined as time between disease recurrence and radiographic discovery. **Results:** Model-selected schedules varied significantly from commonly utilized-surveillance schedules (such as imaging every 3 months within the first year from treatment) and showed lower mean diagnostic latency for every stage and HPV status (shown in Table). In the lowest risk cohort (Stage III HPV+), the optimized schedule had a sensitivity of 65% and latency of 3.1 months. In the highest risk group (Stage IVB HPV-), the optimized schedule had a sensitivity of 76% and latency of 1.9 months. **Conclusions:** Mathematical model optimization for HPV status and stage is feasible and produces non-intuitive results. These results could be used to inform surveillance if payors reimburse for fewer total scans. Across all cohorts, each added CT scan increases surveillance sensitivity and decreases latency. Incorporation of physical exam and direct visualization results into the model are still needed. Future steps include cost effectiveness research and prospective clinical trials. Research Sponsor: None.

Performance of optimized PET+6 additional CT scan surveillance strategies, divided by stage and HPV-status.

Cohort	Optimized Post-PET CT Scan Months	Sensitivity	Latency (months)	Latency (months) for Non-Optimized Post-PET CT Scans at Months 6,9,12,18,24,36
Stage III HPV+	8,13,18,23,28,33	.65	3.1	3.9
Stage III HPV-	6,9,12,15,19,23	.70	1.8	2.6
Stage IVA HPV+	7,11,15,19,23,31	.68	2.9	3.2
Stage IVA HPV-	6,10,14,18,23,30	.71	2.4	2.8
Stage IVB HPV+	6,9,13,18,23,30	.70	2.8	3.3
Stage IVB HPV-	6,9,12,16,20,24	.76	1.9	2.2

Results from a phase II study of eftilagimod alpha (soluble LAG-3 protein) and pembrolizumab in patients with PD-L1 unselected metastatic second-line squamous head and neck carcinoma. *First Author: Irene Brana, Vall d'Hebron University Hospital, Vall d'Hebrón Institute of Oncology, Barcelona, Spain*

Background: Eftilagimod alpha (efti) is a soluble LAG-3 protein that binds to a subset of MHC class II molecules to mediate antigen presenting cell (APC) activation and CD8 T-cell activation. The stimulation of the dendritic cell network and subsequent T cell recruitment with efti may lead to stronger anti-tumor responses in combination than observed with pembrolizumab alone. We hereby report results of the 2nd line metastatic squamous head and neck carcinoma (HNSCC) cohort (part C) of phase II trial (NCT03625323). **Methods:** Patients (pts) with HNSCC progressed on or after 1st line platinum-based therapy and unselected for PD-L1 expression were recruited into part C. The study used a Simon's 2-stage design (18 pts planned for stage 1 and 19 for stage 2), with objective response rate (ORR) by iRECIST as the primary endpoint (EP). Secondary EPs include tolerability, disease control rate (DCR), progression free survival (PFS), overall survival (OS), pharmacokinetics, pharmacodynamics and immunogenicity. Efti was administered as 30 mg subcutaneous injection every 2 wks for 8 cycles and then every 3 wks for 9 cycles with pembrolizumab (200 mg intravenous infusion every 3 wks for up to 2 yrs). Imaging was performed every 8 weeks. PD-L1 was assessed centrally (22C3 clone). The study was approved by ethics committees and institutional review boards. **Results:** In total 38 pts were enrolled. The median age was 62 yrs (range 37-84) and 89 % were male. The ECOG PS was 0 and 1 in 34% and 66%, respectively. Primary location at diagnosis was the oral cavity (29%), oropharynx (37%), hypopharynx (18%) and the larynx (16%). All PD-L1 subgroups (CPS $<$ 1 %, $\geq$ 1 to $\leq$19; $\geq$20) were included. All pts were pre-treated with platinum-based chemotherapy. Pts received a median of 3.0 (range 1 – 21) pembrolizumab and 5.0 (range 1-31) efti administrations. Thirty-five (35) pts were evaluated for response (cut-off Jan 2021) with 4 (11 %) pts showing CR, 7 (20 %) pts PR, 3 (9 %) pts SD, 16 (46 %) pts PD with 5 (14 %) pts being not evaluable as per iRECIST. ORR was reported with 31.4 % (95 % CI 16.9 % - 49.3 %) and DCR 40 %Median PFS was 2.1 months and 35 % were progression free at 6 months. Median OS (46 % events) was 12.6 months. There were no adverse reactions leading to treatment discontinuation. The most common ($>$ 10 %) treatment emergent adverse events were cough (18 %), asthenia (16 %), dyspnea (11 %), fatigue (13 %), diarrhea (11 %), hypothyroidism (11%), upper respiratory tract infection (11%) and back pain (11%). **Conclusions:** Efti in combination with pembrolizumab is safe and shows encouraging antitumor activity in platinum pre-treated 2nd line HNSCC patients. Clinical trial information: NCT03625323. Research Sponsor: Immutep S.A.

6029 **Poster Session**

Update on safety and efficacy of a phase 1/2 of SNS-301 added to pembrolizumab in patients with advanced squamous cell carcinoma of the head and neck (SCCHN). *First Author: Alain Patrick Algazi, Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA*

Background: The absence of infiltrating antigen-specific CD8+ T-cells at baseline is associated with low response rates to PD-1 blockade. SCCHN tumors often exclude effector T cells, and 2nd line response rates are low (13-18%). Highly immunogenic, antigen specific antitumor vaccines may expand intratumoral CD8+ T cells, potentially increasing durable response rates to PD-1 blockade. SNS-301 is a first-in-class, bacteriophage-based immune activating agent targeting human aspartate β-hydroxylase (ASPH), a tumor associated antigen overexpressed in multiple tumor types. SNS-301 is a self-adjuvanted vaccine consisting of λ-bacteriophage engineered to express an immunogenic fragment of ASPH fused to the phage gpD coat protein. The study objectives are to evaluate safety, immunogenicity and preliminary efficacy of SNS-301 added to pembrolizumab in patients (pts) not achieving tumor reductions on PD-1 blockade alone. **Methods:** Intradermal SNS-301 was combined with pembrolizumab in pts with locally advanced unresectable (LA) or metastatic/recurrent (met) SCCHN with a best response of stable disease (SD) or unconfirmed progressive disease (uPD) on ongoing PD-1 blockade $>$ 12 weeks. Pts provided pre and on-treatment biopsies to characterize the tumor microenvironment using Nanostring and multiplex immunohistochemistry (mIHC). Blood samples were collected to evaluate B and T cell responses using ELISA/ELISPOT assays. **Results:** As of February 4, 2021, 13 pts were enrolled. Median duration of PD-1 blockade was 48 weeks (range 14-114) at study entry. There were no DLTs & mostly Grade 1-2 unrelated adverse events. Only two related Grade 3 events were reported: rash & dehydration (also a serious adverse event). Ten pts were evaluable for efficacy: 1 pt with PD-L1 negative (neg) disease & SD on pembrolizumab monotherapy achieved a partial response (PR; -52% at 8 months), 4 pts achieved SD & 5 pts had progressive disease. Two of the pts with SD had long-lasting duration (8 & 10 months) of which the latter had PD-L1 neg disease. One pt with uPD at enrollment achieved SD for 4 months. Analyses of pre- & on-treatment biopsies from the PR pt demonstrated an increase in infiltrating CD8+ T cells, PD-L1 expression & PD-1/PD-L1 proximity measures. Nanostring analysis demonstrated increased gene expression signatures for immune cells in the PR pt that was concordant with the mIHC & clinical outcome. **Conclusions:** The combination of SNS-301 and pembrolizumab was well-tolerated and resulted in encouraging clinical efficacy in pts not expected to respond to PD-1 blockade alone. Translational data suggest cellular response to SNS-301 and transformation of a poorly inflamed tumor to an immunologically active tumor in a responding pt (PR). Based on these data, an additional cohort will start enrolling PD-1 blockade naïve pts with LA/met SCHNN in the front-line setting. Clinical trial information: NCT04034225. Research Sponsor: None.

6030 **Poster Session**

Expansion cohort validation of a clinical predictive model for head and neck cancer survival in patients treated with immune checkpoint inhibitors. *First Author: Georgios Laliotis, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: Immune checkpoint inhibitors (ICI) therapy is approved for patients (pts) with recurrent-metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). The majority of pts will die within two years of diagnosis. We have shown that pretreatment clinical characteristics may predict overall survival (OS). Here, we expand our analysis to a total of 201 pts. **Methods:** Between January 15,2016 and April 9, 2020, 201 pts with R/M HNSCC were treated with ICI as first, second line and beyond. Data on p16 status, hemoglobin (Hb), albumin, lactate dehydrogenase (LDH), neutrophil, platelet and lymphocyte count was recorded initially. OS was defined from the start of ICI to death. Progression Free Survival (PFS) was defined from the start of ICI to disease progression (PD) or death. A nomogram was created using the rms package to generate individualized survival prediction. **Results:** 201 pts were analyzed, sex: 154 male (77%), 47 female (23%), median age 61 (IQR: 55-68). ICI drug: pembrolizumab 100 (50%), nivolumab 91 (45%), ipilimumab+-nivolumab 10 (5%). Line of therapy: First: 98 (49%), second and beyond: 103 (51%). Tumor site: oropharynx 84 (42%), oral cavity 45 (22%), others 72 (36%). p16 status: negative 132 (66%), positive 69 (34%). Laboratory values: Median neutrophil count: 4.58 (IQR: 3.43-6.47), Median lymphocyte count: 0.69 (IQR: 0.47-1.08), Median Platelet count: 229 (IQR: 187-300), hemoglobin (Hb) normal/low 101/100 (50%/50%), albumin: normal/low 156/45 (78%/22%), LDH: normal/high 124/77 (62%/38%). Overall response rate: 36 (18%). Median OS: 12 months (CI: 9.4-14.8), median PFS: 4 months (CI: 3.5-5.7). The variables associated with OS were neutrophil count (high) [HR 1.28 (1.08 – 1.51), *p=0.004*], lymphocyte count (high) [HR 0.75 (0.60 – 0.95), *p=0.015*], albumin (low) [HR 2.06 (1.37 – 3.10), *p$<$0.001*], hemoglobin (low) [HR 1.64 (1.14 – 2.35), *p=0.007*], LDH (high) [HR 1.78 (1.23 – 2.56), *p=0.002*] and p16 status (positive) [HR 0.58 (0.39-0.87), *p=0.009*]. Using the prognostic index of the chosen model, we stratified patients into three risk groups at the 33rd and 66th percentile. Median OS in the good risk group was 24 months (CI: 18.5-NR), average risk group 13.8 months (CI: 11-20), poor risk group 2.3 months (CI: 1.7-4.4). The discrimination of the model after internal validation was c-index of 0.72. **Conclusions:** A small percentage of R/M HNSCC pts treated with ICI have good long-term survival outcomes. In a larger cohort, we internally validated the utilization of a simple, inexpensive and widely accessible nomogram based on clinical and laboratory variables which can predict OS in this patient population. Research Sponsor: None.

Adjuvant nivolumab following salvage resection in head and neck squamous cell carcinoma patients previously treated with definitive therapy: A single-arm phase II multi-institutional study. *First Author: Jennifer Leddon, University of Cincinnati Medical Center, Cincinnati, OH*

Background: Salvage surgery for locally recurrent head and neck squamous cell carcinoma (rHNSCC) results in local control rates of 33-50% but only 20-40% of patients achieve long-term survival necessitating additional therapy (Haque et al., Oral Oncol. 2019). Many patients are ineligible for re-irradiation and chemotherapy alone after salvage surgeryhas shown no survival benefit. The clinical activity and tolerability of immune checkpoint inhibitors has been demonstrated in metastatic HNSCC, but the benefit after salvage surgery (SS) has not been studied. Here we report the results of a multi-center phase II investigation of nivolumab, a PD-1 inhibitor, after SS in recurrent HNSCC (NCT03355560). **Methods:** HNSCC patients undergoing curative-intent SS were enrolled to receive 6 months of nivolumab beginning 4-11 weeks after surgery. All received radiation with or without chemotherapy as prior definitive therapy and had no other curative treatment options at the time of surgery. Key exclusion criteria included: distant metastatic disease, gross residual disease, or a history of immunodeficiency, autoimmunity, or pneumonitis. The primary endpoint was 2-year disease-free survival (DFS) measured by Kaplan Meier curves. Safety was evaluated by CTCAE v5.0. **Results:** 39 patients were enrolled. Median age was 68 years (range, 49-85). 12/39 (31%) were female. 34/39 (87%) were white. Disease sites included oropharynx 9/39 (23%), oral cavity 14/39 (36%), and larynx 16/39 (41%). P16 status was 26% (+), 48% (-), and 26% (unknown). 17/39 (44%) had high risk pathologic features (positive margins or extranodal spread) at time of SS. 28/39 (72%) patients experienced treatment-related adverse events (TRAE), the most common of which were fatigue (26%), hypothyroidism (10%) and acneiform rash (13%). Grade 3-4 TRAEs were rare, occurring in 3/39 (8%) patients and included diarrhea, oral pain, neck pain, productive cough, stridor, and COPD exacerbation. 3/39 (8%) required treatment discontinuation and there were no grade 5 events. The 2-year DFS was 60% (95%CI 0.39-0.91). 2-year overall survival was 74% (95% CI 0.54-1). In single-cell multiplex cytokine analysis, patients who relapsed following adjuvant nivolumab had a significantly higher proportion of peripheral blood CD8 T cells which displayed a polyfunctional cytokine profile. IFN-γ and Granzyme were the dominant CD8 cytokines in both responders and non-responders, however CD8 expression of MIP1a and TNF-α were significantly higher in patients who ultimately relapsed. **Conclusions:** Nivolumab after salvage surgery in rHNSCC is well tolerated and shows promising antitumor activity in this high-risk patient population with unmet need. Immunotherapy after salvage surgery should be studied in randomized clinical trials. Clinical trial information: NCT03355560. Research Sponsor: BMS.

A phase III multicenter randomized clinical trial to compare cisplatin plus fluorouracil with or without docetaxel as the first-line induction chemotherapy for locoregionally advanced nasopharyngeal carcinoma: Long-term outcomes update. *First Author: Wang Fang FangZheng, Zhejiang Cancer Hospital, Hangzhou, China*

Background: A phase III multicenter prospective randomized controlled trial was conducted to compare cisplatin plus 5-fluorourcil with or without docetaxel as first-line induction chemotherapy in the patients with locoregionally advanced nasopharyngeal carcinoma (LANPC). Here, we report on the long-term outcomes and late toxicities of the trial (NCT01536223). **Methods:** Patients with newly diagnosed LANPC, stage III-IV disease, Karnofsky performance score$\geq$70, without metastasis were eligible and randomly assigned 1:1 to TPF versus PF for three cycles. The primary end point was progression-free survival; local control, OS and advent events were important key secondary end points. The Kaplan-Meier method and the log-rank test were used to conduct and compare the survival curves in this study. **Results:** Two hundred ninety-nine patients were enrolled. 276 patients (138 TPF and 138 PF) were evaluable. Baseline characteristics were well-balanced between two groups, and the median age was 48 (range, 18-60 years). The ORR rates after induction chemotherapy and chemoradiotherapy were 90.6% and 9797.8% in TPF group and 87.0% ($P > 0.05$) and 97.8% ($P > 0.05$), respectively. The median follow-up was 99 months. For all patients, the 5- and 8-year OS and PFS were 76.9% and 74.9%, 72.3% and 69.1%, respectively. PF was associated with a similar PFS versus TPF (5-year PFS of 72.4% versus 73.2%, P = .747), and an equivalent OS at 5 years (79.2% and 79.1%, P = 0.519). Treatment-related grade 3 to 4 advent events were less frequent with PF compared with TPF. **Conclusions:** With prolonged follow-up, the survival outcomes in the PF group were not noninferiority to those in the TPF group, but grade 3 to 4 advent events were less frequent. Clinical trial information: NCT01536223. Research Sponsor: None.

Effect of neoadjuvant systemic therapy given during window trials on quality metrics in resectable head and neck squamous cell carcinoma. *First Author: Marco A. Mascarella, University of Pittsburgh Medical Center Cancer Center, Pittsburgh, PA*

Background: Quality oncologic care, including negative surgical margin status, adequate lymph node yield and prompt initiation of adjuvant treatment, impacts disease control and overall survival in patients with mucosal head and neck squamous cell carcinoma (HNSCC). The aim of this study was to ascertain the effect of neoadjuvant systemic therapy given during window trials on oncologic quality metrics in patients with delayed definitive surgery for a HNSCC. **Methods:** Treatment-naïve patients with HNSCC participating in one of two window of opportunity clinical trials at UPMC from 2009-2019 were included. Neoadjuvant regimens consisted of one dose of cetuximab (n = 33) or anti-ErbB3 antibody (n = 9) within 28 days of surgery. Sociodemographic, clinical and tumor staging were recorded. The primary outcome was overall oncologic quality, as defined as a composite measure of negative margin status, adequate lymph node yield, completion of adjuvant therapy (if indicated) and time to initiation of adjuvant therapy within 6 weeks of surgery. Secondary outcomes were difference in clinical and pathologic stages and overall survival (OS). **Results:** A total of 42 patients with a mean age of 57.1 ($\pm$10.2) years and median follow-up of 58 months were analyzed. 29 patients had clinical stage IVA disease with 43% (18/42) oral cavity, 36% (15/42) larynx/hypopharynx and 21% (9/42) oropharynx primaries. All patients underwent surgery following neoadjuvant systemic therapy. In 30 patients (71%), all oncologic quality markers were achieved. Pathological downstaging occurred in 21% (9/42) of patients with 4 patients no longer meeting criteria for adjuvant treatment and were observed. 3 patients showed pathological upstaging. The 3-year OS were 76% (95% CI of 63.6-88.4), respectively. Patients with a pathologic downstage migration (64.9%, 95% CI of 49.9-79.8) had higher 5-year OS compared to those without (57.8%, 95% CI of 40.1-76.4, P = 0.046). **Conclusions:** Most patients receiving neoadjuvant systemic therapy on window trials prior to surgery met all oncologic quality markers. Importantly, even with brief window trial therapy pathologic downstaging was achieved and associated with significantly better overall survival. Research Sponsor: None.

6034 **Poster Session**

Phase II trial of combined durvalumab plus tremelimumab with proton therapy to boost the abscopal effect for recurrent or metastatic head and neck squamous cell carcinoma. *First Author: Hana Kim, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: This phase 2 study investigated whether durvalumab plus tremelimumab with proton therapy improves objective response rate (ORR), overall survival (OS), and progression-free survival (PFS) in heavily treated recurrent or metastatic head and neck squamous cell carcinoma (HNSCC) via boosting abscopal effect. **Methods:** Thirty-one patients who have previously received more than one chemotherapy regimen, including at least one platinum-based regimen and have at least two measurable lesions enrolled at Samsung medical center. Patients received durvalumab 1500mg intravenously (IV) in combined with tremelimumab 75 mg IV every four weeks for four cycles followed by durvalumab 1500mg every four weeks. After one cycle of durvalumab and tremelimumab combination, proton therapy was performed with a total dose of 25 Gy in 5-Gy daily fractions to one of the measurable lesions. We assessed the target lesion response outside the radiation field by RECIST criteria 1.1 to evaluate the abscopal effect. **Results:** Between March 2018 and July 2020, 31 patients were enrolled. The median age was 59 years, and median two prior chemotherapy regimens were administered. With 24.8 months of follow-up, the median number of cycles of immunotherapy was three. The ORR was 27.3%, including one complete response and five partial responses. Median OS was 6.4 months (95% CI, 1.0 to 11.8), and median PFS was 2.4 months (95% CI, 0.6 to 4.2). Median duration of response was 15.9 months (range 3.7 – 21.2). Grade 3 or higher adverse events were observed in 6 (27.3%) patients; anemia (n = 1), constipation (n = 1), electrolyte imbalance (n = 2), hyperglycemia (n = 1), pneumonia (n = 1). **Conclusions:** Combination of durvalumab/tremelimuab with proton therapy is well tolerable and shows encouraging anti-tumor efficacy in non-irradiated tumor lesions of heavily treated HNSCC patients. These results suggest that the combination of immunotherapy with proton therapy might enhance the abscopal effect. Clinical trial information: NCT03450967. Research Sponsor: AstraZeneca.

Maintenance intervention to improve survival in patients with metastatic nasopharyngeal carcinoma who benefit from first-line treatment: A prospective multicenter randomized controlled clinical study. *First Author: Ying Lu, The Fourth Affiliated Hospital of Guangxi Medical University, Liuzhou, China*

Background: The role of drug maintenance intervention in improving survival outcomes remains controversial.To investigate the safety and effect of Tegafur(S1) maintenance intervention in patients with metastatic nasopharyngeal carcinoma who benefit from the first-line treatment in a multicenter randomized controlled study, and to identify the related biological prognostic factors and guide the individualized treatment choice. **Methods:** Patients with metastatic nasopharyngeal carcinoma in the Fourth Affiliated Hospital of Guangxi Medical University and other cancer centers who met the inclusion criteria were randomly divided into maintenance therapy group: S1 maintenance therapy until disease progression or intolerance; Observation group: follow-up to disease progression. PFS, overall survival (OS) and adverse reactions of S1 maintenance therapy were compared between the two groups. The correlation between EBV-DNA, human serum amyloid A (SAA) and prognosis was evaluated. **Results:** Follow-up was conducted to May 2020, with a median follow-up of 19.8 months (6.1-51.3 months), 183 cases were evaluable (88 cases in S1 maintenance treatment group, 95 cases in observation group). Compared with the observation group, the S1 maintenance treatment group significantly increased patients' median PFS (16.2 months vs. 8.7 months, $P < 0.001$) and median OS (32.1 months vs. 18.2 months, $P < 0.001$). Reduced the risk of poor prognosis for PFS and OS (PFS: HR 0.305, 95%CI 0.211-0.441, < 0.001; OS: HR 0.363, 95%CI 0.238-0.553, $P < 0.001$). In the maintenance treatment group, the median S1 treatment lasted for 14 courses (4-58 courses), and the main adverse reactions were grade 1 skin pigmentation, oral mucositis, hand-foot syndrome, nausea, etc. No grade 4 toxic reaction occurred, and it was well tolerated. Compared with observation patients with negative EBV-DNA, observation patients with positive EBV-DNA had a higher risk of poor prognosis for PFS (HR 1.764, 95%CI 1.078-2.887, P = 0.024). The risk of poor prognosis in patients with positive EBV-NDA was significantly reduced by 61.1% (< 0.001) for PFS and 65.5% (P = 0.001) for OS (P = 0.001). Compared with the observation group with stable SAA expression, S1 maintenance therapy significantly improved the prognosis of patients. Patients with continuous decline in SAA had a 61.9% lower risk of poor prognosis in PFS ($P < 0.001$) and a 60.2% lower risk of poor prognosis in OS (P = 0.007). **Conclusions:** For patients with metastatic nasopharyngeal carcinoma who benefit from first-line treatment, maintenance therapy of S1 can significantly improve the survival prognosis and is well tolerated. Patients with positive EBV-DNA and continuous decline in SAA may benefit more from maintenance intervention. Clinical trial information: ChiCTR-IOR-16007939. Research Sponsor: Guangxi Natural Science Foundation(China)Liuzhou City Science and technology research projects (China).

Final analysis of a phase 1b, randomized, multicenter study of talimogene laherparepvec (T-VEC) plus pembrolizumab (pembro) combination for the treatment (Tx) of recurrent/metastatic squamous cell carcinoma of the head and neck (R/M HNSCC): MASTERKEY-232. *First Author: Kevin Joseph Harrington, The Royal Marsden//The Institute of Cancer Research NIHR Biomedical Research Centre, London, United Kingdom*

Background: T-VEC, a genetically modified herpes simplex virus-1, is the first FDA- and EMA-approved oncolytic viral immunotherapy designed to enhance systemic antitumor immune responses. R/M HNSCC is a disease with considerable clinical complexity and poor prognosis. Pembro is a PD-1-specific humanized monoclonal antibody currently approved as first-line Tx for this disease, but there is an unmet need among many patients (pts). To meet this gap, the safety and preliminary efficacy of T-VEC plus pembro in pts with R/M HNSCC was evaluated in a phase 1b study (Harrington et al. *Clin Cancer Res.* 2020). Here, we present results of the final analysis of this study (NCT02626000). **Methods:** Eligible pts (≥18 yrs) had ECOG-PS of 0 or 1; histologically confirmed R/M HNSCC of the oral cavity, oropharynx, hypopharynx, or larynx unsuitable for curative surgical resection or radiotherapy; platinum-refractory and with injectable tumors. Pts with known active CNS metastases and any systemic or local therapy 28 days before enrollment were excluded. T-VEC was injected intralesionally up to 8.0 mL of 10^6 PFU/mL according to lesion sizes on day 1; after 3 weeks, subsequent doses of ≤8.0 mL of 10^8 PFU/mL were given Q3W. Pembro was given intravenously at 200 mg Q3W. Pts were followed-up for 36 mos after the last patient was enrolled in the study. Key endpoints (irRECIST per investigator assessment) were objective response rate (ORR), best overall response (BOR), disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** A total of 36 pts (80.6% male) were enrolled and treated: 28 (77.8%) had confirmed PD-L1-positive tumor (CPS ≥1), 5 (13.9%) were HPV-positive, 13 (36.1%) had metastatic disease, and 19 (52.8%) had prior lines of therapy in the R/M setting. At the final analysis, 7 pts (19.4%) completed the study, and 29 (80.6%) discontinued the study due to death. Safety profile was consistent with that at 1-yr analysis (Harrington et al. *Clin Cancer Res.* 2020). Confirmed ORR was seen in 16.7% (95% CI, 6.4–32.8). No patient had a complete response as their BOR, 6 (16.7%) had a partial response, 8 (22.2%) had stable disease, 6 (16.7%) had progressive disease, 6 (16.7%) were unevaluable, and 10 (27.8%) died before the first response assessment. The DCR was 38.9% (95% CI, 23.1–56.5). The median DOR was 45.9 mos (95% CI, 8.5–NE). The median PFS was 3.0 mos (95% CI, 2.0–5.8), and the median OS was 5.8 mos (95% CI, 2.9–11.4). **Conclusions:** The safety results at 3 yrs for T-VEC plus pembro in pts with R/M HNSCC were consistent with those of the 1-yr analysis. Although the response rate was consistent with that observed with pembro alone in historical HNSCC studies, the extended DOR in responding patients warrants further investigation. Clinical trial information: NCT02626000. Research Sponsor: Amgen.

6037 **Poster Session**

Interim analysis of IMMUNEBOOST-HPV: A multicenter, randomized, open label, phase II study evaluating the feasibility, and tolerance of neoadjuvant nivolumab in high-risk HPV driven oropharynx cancer. *First Author: Haitham Mirghani, Hôpital Européen Georges Pompidou HEGP, Paris, France*

Background: Among HPV-positive Oropharyngeal Cancer (OPC) patients (pts), some has a less favorable prognosis (T4, N2/N3, smokers >10 pack-year [p/y]). We assume that neoadjuvant immunotherapy might improve their oncological outcomes, so we tested nivolumab (N) prior to ChemoRadiaTion (CRT). **Methods**: The study population is restricted to HPV positive OPC pts (both p16+ & HPV-DNA+) with advanced disease (T4, N2/N3) or a smoking history >10 p/y. Pts were randomly allocated 1:2 to receive either cisplatin-based CRT (n=20) or 2 cycles of N 240 mg followed by CRT (n=41). The Primary Endpoint (PE) is the rate of pts who can receive Full Treatment in Due Time (FTDT), according to these criteria: a) 2 N infusions on day 1 and on day 14-16 b) CRT started between days 28-37 after the 1st N infusion c) No RT break ≥1 week d) RT dose received >95% of theoretical dose e) Cisplatin dose received ≥200 mg/m^2 To achieve FTDT, all criteria are required in the Experimental Arm (EA) while only criteria c), d), and e) are required in the Control Arm (CA). In the EA, the trial was designed in 2 steps, with FTDT rate of 88% considered as inacceptable versus an alternative of 98%, a type I error of 0.10, and a type 2 error of 0.08. As per protocol, patient accrual was temporarily suspended after inclusion of 19 pts in the EA (1st step) and results were reviewed by an Independent Data Monitoring Committee (IDMC). To resume pts' inclusion, FTDT had to be achieved in 18 pts in the EA. **Results**: From 07/2019 to 09/2020, 30 pts were enrolled including 11 in the CA (demographics are summarized in table). 2 pts in the EA did not reach the PE. For the 1st patient, the cisplatin dose was <200 mg/m^2 due to grade 1 hearing loss and grade 2 tinnitus (1st cycle: 100 mg/m^2, 2nd cycle: 80 mg/m^2, no 3rd cycle). For the 2nd patient, CRT began at D38 due to logistical issues (maintenance of RT devices). As this delay was unrelated to N or to patient's condition, the IDMC considered that the inclusions could resume for the 2nd step. 7 N-related Adverse Events (AE) were reported in 4 pts including 3 serious AE (ankylosing spondylitis flare-up, colitis, diabetic ketoacidosis). **Conclusions**: Neoadjuvant N before CRT seems feasible for the treatment of OPC pts. The trial has reopened to inclusion as recommended by the IDMC. Clinical trial information: NCT03838263. Research Sponsor: Programme Hospitalier de Recherche Clinique en Cancérologie (PHRC-K) financé par le ministère de la Santé (Direction générale de l'offre de soins (DGOS)), Pharmaceutical/Biotech Company.

Use of cetuximab added to weekly chemotherapy to improve progression-free survival in patients with recurrent metastatic head and neck squamous cell carcinoma after progression on immune checkpoint inhibitors. *First Author: Majd Issa, Ohio State University-James Cancer Hospital Solove Research Institute, Columbus, OH*

Background: Immune checkpoint inhibitors (ICI) are currently approved in the treatment of patients (pts) with recurrent-metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). The majority of pts will progress on ICI. Little is known regarding the best treatment approach for this patient population. We previously showed that the combination of weekly carboplatin, paclitaxel and cetuximab was associated with reduced risk of grade 3/4 toxicities, which makes it an ideal regimen in this setting. Here; we report the outcomes of pts with R/M HNSCC who were treated with chemotherapy alone vs weekly chemotherapy plus cetuximab after progression on ICI. **Methods:** Between January 15th 2016 and April 9th 2020, 154 pts who progressed on ICI were analyzed. Among these pts, 64 had received subsequent systemic therapy and met the inclusion criteria. Progression Free Survival (PFS) was defined as the time elapsed between initiation of subsequent chemotherapy and tumor progression or death. Overall Survival (OS) was defined as the time elapsed between initiation of subsequent chemotherapy to death. Descriptive statistics and Cox regression were used to explore study variables. **Results:** 64 pts received subsequent chemotherapy after progression on ICI. 28 pts (44%) received a combination of weekly chemotherapy plus cetuximab. This regimen included carboplatin AUC 1.5, paclitaxel 45 mg/m^2, and cetuximab loading dose of 400mg/m^2 followed by weekly dose of 250 mg/m^2. 36 pts (56%) received chemotherapy alone without cetuximab. These regimens included capecitabine, afatinib, and gemcitabine, among others. Sex: 51 males (80%), 13 females (20%), age (median): 61 (IQR: 53-66), tumor site: oropharynx 32 (50%), oral cavity 11 (17%), larynx 8 (12%), other sites 13 (21%). P16 status: negative 36 (56%), positive 28 (44%). Prior ICI drug: pembrolizumab 34 (53%), nivolumab 26 (41%), ipilimumab + nivolumab 4 (6%). Median follow up: 9 months (IQR: 5-13). Overall response rate: weekly chemotherapy plus cetuximab 32%, chemotherapy alone 22% (p = 0.4). Pts who received chemotherapy alone had a median PFS of 3.2 months (CI: 2-5) vs 5.6 months (CI: 4.3-10.1) in the weekly chemotherapy plus cetuximab group. After adjusting for p16 status and prior ICI drug, PFS was improved in the group that received weekly chemotherapy plus cetuximab vs. chemotherapy alone (HR: 0.52; CI: 0.28-0.98; p = 0.042). Median OS was 10 months (CI: 8.5-NR) in the weekly chemotherapy plus cetuximab group vs 8.7 months (CI: 5.7-13.8) in the chemotherapy alone group (HR: 0.84; CI: 0.4-1.8; p = 0.8). **Conclusions:** Pts with R/M HNSCC who progressed on ICI experience longer PFS with the addition of cetuximab to weekly chemotherapy. Further investigation in a larger cohort of pts is needed to fully assess the impact on survival for this treatment combination. Research Sponsor: None.

Adjuvant toripalimab or combined with S-1 in recurrent, previously irradiated head and neck squamous cell carcinoma treated with salvage surgery: A phase II clinical trial (The RePASS study). *First Author: Shengjin Dou, Radiotherapy Division, Department of Oral and Maxillofacial-Head Neck Oncology, Shanghai Ninth People's Hospital, College of Stomatology, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: The predominant pattern of failure for Head and Neck Squamous Cell Carcinoma (HNSCC) is locoregional disease. Salvage surgery remains the standard of care for operable disease. Re-irradiation after previous full course radiotherapy generally has been considered contraindicated. Since anti-PD-1 antibodies were efficacious and safety in recurrent/metastatic HNSCC, this study aimed to evaluate the efficacy and safety of adjuvant toripalimab (anti-PD-1 antibody) in recurrent, previously irradiated HNSCC treated with salvage surgery. **Methods:** This study was a single-arm, phase II study. Patients with HNSCC occurring in an area of previously irradiated and with at least one high risk factors after salvage surgery (1- positive margin; 2- extranodal extension; 3-rStaging T3-4/N2-3/T2N1) were enrolled. In the Stage I of 12 patients, patients received toripalimab 240mg once every 3 weeks until confirmed disease progression or unacceptable toxicity, for 12 months. In the stage II of 8 patients with PD-L1 CPS≥1, patients received toripalimab combined with S-1, which was given orally at 25 mg/m^2, twice daily, on day 1 to 14, repeated every 21 days for 4-6 cycles. The primary endpoint was 1-year progression-free survival (PFS). We hypothesized a 1-year PFS of at least 56% and assumed a null hypothesis of 34%. A retrospective cohort of 16 patients was compared. **Results:** Between May 2019 and December 2020, 20 patients were enrolled. High-risk factors included ENE (35%), positive margin (25%), T3-4(30%) and T2N+(10%). Seventeen patients have PD-L1 CPS≥1 and 3 patients have CPS < 1. With a median follow-up of 11.2 months, estimated 1-year PFS and overall survival was 57.0% (95% confidence interval, 32%– 77%) and 79.2% (51%–91%). The primary PFS endpoint has exceeded the hypothesis and its median has not been reached. When compared to the retrospective cohort, the PFS was significantly better(p=0.001), even for Stage I patients(Median PFS: 5.1 vs 3.7 months, p=0.03). Stage II patients resulted a better PFS and OS compare to stage I (p=0.02 and p=0.002). For patients with CPS≥1, 1-year PFS and OS was 79.1% (95% confidence interval, 51%–91%) and 91.7%(68%–99%), which were significantly better than patients with CPS < 1 (p=0.001 and p=0.05). Adjuvant Toripalimab or combine with S-1 was well-tolerated with no grade 3-4 toxicity and dose interruption as a result of treatment-related adverse event only occurred in 2 patients. Flow cytometry revealed that patients with short PFS had fewer baseline overall count of B cells(p=0.09). **Conclusions:** Adjuvant Toripalimab or combined with S-1 after salvage surgery is efficacious and safety in recurrent, previously irradiated HNSCC, and a better PFS was observed in patients treated with combined therapy and with CPS≥1. Further randomized trials are warranted. Clinical trial information: NCT04126460. Research Sponsor: Shanghai Junshi Biosciences.

Update and external validation of a multivariable prediction model for tube feeding dependency for at least four weeks during chemoradiotherapy for head and neck cancer. *First Author: Anna C. H. Willemsen, Department of Internal Medicine, Division of Medical Oncology; GROW-School of Oncology and Developmental Biology; Department of Respiratory Medicine, NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht University Medical Center, Maastricht, Netherlands*

Background: Patients who receive chemoradiation or bioradiation (CRT/BRT) for locally advanced head and neck squamous cell carcinoma (LAHNSCC) often experience high toxicity rates, which may interfere with oral intake, leading to (temporary) tube feeding (TF) dependency. International guidelines recommend gastrostomy insertion when the expected use of TF exceeds four weeks. In this study we aimed to update and externally validate a prediction model to identify patients in need for TF for at least four weeks, meeting the international criteria for prophylactic gastrostomy insertion. **Methods**: This retrospective multicenter cohort study was performed in four tertiary referral head and neck cancer centers in the Netherlands. The prediction model was developed using data from the University Medical Center Utrecht and the Netherlands Cancer Institute. The model was externally validated in patients from the Maastricht University Medical Center and Radboud University Medical Center. The primary endpoint was TF, initiated during or within 30 days after completion of CRT/BRT, and administered for at least four weeks. Potential predictors were retrieved from patient medical records and radiotherapy dose-volume parameters were calculated. **Results**: The developmental and validation cohort included 409 and 334 patients respectively. Multivariable analysis showed significant predictive value ($p < 0.05$) for adjusted diet at start of CRT/BRT, percentage weight change prior to treatment initiation, WHO performance status, tumor-site, nodal stage, mean radiation dose to the contralateral parotid gland, and mean radiation dose to the oral cavity. The area under the receiver operating characteristics curve for the updated model was 0.73 and after external validation 0.64. Positive and negative predictive value at 90% cut off were 80.0% and 48.2% respectively. **Conclusions**: This externally validated prediction model to estimate TF-dependency for at least four weeks in LAHNSCC patients performs well. This model, which will be presented, can be used in clinical practice to guide personalized decision making on prophylactic gastrostomy insertion. Research Sponsor: NUTRIM Graduate Programme.

Racial and regional differences in incidence of oropharyngeal cancer in the United States during 2001 to 2017. *First Author: Fangjian Guo, University of Texas Medical Branch at Galveston, Galveston, TX*

Background: The incidence of human papillomavirus (HPV)-related oropharyngeal squamous cell carcinoma (OPSCC) has been reported to be increasing among both middle-aged and elderly adults in the United States. This study was to assess racial and regional differences in the incidence of OPSCC among adults in the US. **Methods:** We included 271,037 adult patients ≥ 20 years old diagnosed with potentially HPV-related OPSCC from the US Cancer Statistics 2001–2017 database which essentially covered the entire US population. Incidence of OPSCC was age- adjusted to the US standard population. Annual percentage change (APC) in the incidence was assessed across races/ethnicities and regions of residence. **Results:** Among these adults with potentially HPV-related OPSCC from 2001-2017, 5.3% were Hispanics, 83.0% were non-Hispanic Whites, and 9.2% were non-Hispanic Blacks, and 79.1% were male. Incidence of OPSCC increased from 3.9 per 100,000 in 2001 to 4.0 per 100,000 in 2017 (APC 0.43, 95% confidence interval (CI) 0.01, 0.85) in Hispanics, increased from 5.3 per 100,000 in 2001 to 8.6 per 100,000 in 2017 (APC 2.97, 95% confidence interval (CI) 2.71, 3.24) in non-Hispanic Whites, and decreased from 6.3 per 100,000 in 2001 to 5.1 per 100,000 in 2017 (APC -1.27, 95% confidence interval (CI) -1.56, -0.99) in non-Hispanic Blacks. The incidence increased from 5.8 per 100,000 in 2001 to 7.8 per 100,000 in 2017 (APC 1.94, 95% confidence interval (CI) 1.67, 2.21) in the South, increased from 5.0 per 100,000 in 2001 to 7.1 per 100,000 in 2017 (APC 2.13, 95% confidence interval (CI) 1.92, 2.34) in the Northeast, increased from 4.9 per 100,000 in 2001 to 6.3 per 100,000 in 2017 (APC 1.85, 95% confidence interval (CI) 1.53, 2.17) in the West, and increased from 4.9 per 100,000 in 2001 to 7.7 per 100,000 in 2017 (APC 2.79, 95% confidence interval (CI) -2.52, 3.07) in the Midwest. The incidence decreased from 0.9 per 100,000 in 2001 to 0.8 per 100,000 in 2017 (APC -0.81, 95% confidence interval (CI) -1.41, -0.20) among adults 20-44 years old, increased from 9.0 per 100,000 in 2001 to 12.7 per 100,000 in 2017 (APC 2.01, 95% confidence interval (CI) 1.66, 2.36) among adults 45-64 years old, and increased from 10.9 per 100,000 in 2001 to 16.7 per 100,000 in 2017 (APC 2.96, 95% confidence interval (CI) 2.75, 3.16) among adults 65+ years old. **Conclusions:** OPSCC incidence increased across racial/ethnic groups, regions, and age groups from 2001 to 2017, except that the incidence decreased among non-Hispanic Blacks and young people. Underlying causes for the decreasing trend in the incidence of OPSCC among certain groups need further investigation. Efficacy and toxicity of weekly paclitaxel, carboplatin, and cetuximab as induction chemotherapy or in cases of metastases or relapse for head and neck cancer in elderly or frail patients. *First Author: Rebecca Forman, Yale New Haven Hospital, New Haven, CT*

Background: Standard of care treatments for locally advanced and metastatic head and neck squamous cell carcinoma (HNSCC) are not well tolerated, particularly in elderly or frail patients. One combination that has been studied in recent years is paclitaxel, carboplatin and cetuximab (PCC). Studies have shown this regimen yields promising results when used as an induction chemotherapy for locally advanced disease. PCC has also been studied in patients with metastatic or recurrent incurable disease, and has shown good response with tolerable toxicity rates, but there is a relative dearth of evidence surrounding its use. **Methods:** This retrospective observational study utilized EMR data analysis software to generate the cohort of adult patients that received PCC for HNSCC in 2014-2019 as well as demographic data. Chart review was used to gather details about the patients' tumors and clinical course. Modified RECIST response rates (MRRR), progression free survival (PFS) and overall survival (OS) were the primary end points calculated for the metastatic/recurrent group, and percentage of successful inductions (e.g., patients went on to definitive treatment, avoided surgery) and MRRR were used for the induction group. **Results:** There were 80 patients in the cohort. The average age was 65 (range 33-84) and the patients were 81% male. The most common tumor site was the tongue (25 patients), followed by tonsil (15), oropharynx (9), and larynx (7). 13 patients had p16 positive disease. Most patients had Stage IVA (36 patients), followed by IVB (20), and IVC (15); the remainder had stage III or below or unknown stage. The most common reasons patients did not receive cisplatin were performance status (13 patients), hearing loss (11), concern for nephrotoxicity (6) and age (5). 97.5% of patients experienced at least one adverse effect. The most common adverse effect was dermatologic (69%), followed by hematologic (51%), fatigue (41%) and gastrointestinal symptoms (41%). 53 patients (66%) experienced at least one dose interruption due to adverse effects. 11 patients (14%) stopped treatment due to toxicities. 58 patients received PCC for metastatic or recurrent disease. They had received a median of 1 line of systemic treatment prior; 72% had prior radiation, and 26% had prior salvage surgery. The MRRR was 22% (5 patients with complete response, 8 partial response, 15 stable, 27 progression). There was a 7.0 month mean PFS, and 17.3 month mean OS. Of the 22 patients who received PCC as induction, 86% (19) successfully reached their induction endpoint. The MRRR was 64% (8 patients with complete response, 6 partial response). **Conclusions:** PCC is a relatively well-tolerated combination with a very good induction success rate. More research is needed around alternate options for frail and elderly patients with HNSCC. Research Sponsor: None.

Palbociclib (P) in patients (pts) with head and neck cancer (HNC) with *CDKN2A* loss or mutation: Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Evan P. Pisick, Cancer Treatment Centers of America, Zion, IL*

Background: TAPUR is a phase II basket study evaluating anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in a cohort of HNC pts with *CDKN2A* loss or mutation treated with P are reported. **Methods:** Eligible pts had advanced HNC, no standard treatment options, measurable disease, ECOG PS 0-2, and adequate organ function. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts received P at 125 mg orally once daily for 21 days, followed by 7 days off until disease progression. Pts matched to P had *CDKN2A* loss or mutation and no *RB*mutations. Simon 2-stage design tested the null disease control (DC) - defined as partial (PR), complete response (CR) or stable disease at 16+ weeks (SD 16+) - rate of 15% vs. 35% (power = 0.85; $\alpha = 0.10$). If ≥2 of 10 pts in stage 1 have DC, 18 more pts are enrolled. If ≥7 of 28 pts have DC, the null DC rate is rejected. Secondary endpoints are progression-free survival (PFS), overall survival (OS) and safety. **Results:** 28 pts (64% male) with HNC with *CDKN2A*loss (20 pts) or mutation (8 pts) were enrolled from June 2016 to Sept 2019. All were eligible for efficacy and toxicity. Demographics and outcomes are summarized in Table. No objective response (OR) and 10 pts with SD16+ (9 with *CDKN2A* loss, 1 with mutation) were observed for a DC rate of 37% (95% CI: 21%, 50%); the null DC rate of 15% was rejected (p=0.005). 14 pts had at least one grade 3-5 adverse or serious adverse event (AE/SAE) at least possibly related to P with the most common being low WBC/platelets. Other grade 3-4 AEs included anemia, fatigue, hypocalcemia, and syncope. There was one pt with grade 5 respiratory failure likely due to extensive lung metastases and aspiration but P-related pneumonitis could not be ruled out. **Conclusions:** Monotherapy P demonstrated modest anti-tumor activity and clinically significant AEs in heavily pretreated pts with HNC with *CDKN2A*loss or mutation. Additional study is warranted to confirm the efficacy of P in pts with HNC with *CDKN2A*loss or mutation. Clinical trial information: NCT02693535. Research Sponsor: Pfizer.

Capecitabine maintenance therapy after induction chemotherapy in newly diagnosed metastatic nasopharyngeal carcinoma: An open-label, randomized, controlled, phase trial. *First Author: Guo-Ying Liu, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Capecitabine maintenance therapy improves outcomes in various tumor types, but minimal data are available on the effect of capecitabine maintenance therapy in metastatic nasopharyngeal carcinoma (NPC). We aimed to investigate whether capecitabine maintenance therapy would prolong the progression-free survival (PFS) of newly diagnosed metastatic NPC, in comparison to best supportive care (BSC). **Methods:** This was an open-label, randomized, controlled, phase trial. Eligible patients for maintenance randomisation were aged 18-65 years old with newly diagnosed metastatic NPC at the Sun Yat-Sun University Cancer Center (SYSUCC), had completed 4 to 6 cycles of induction chemotherapy as per protocol and had achieved disease control to protocol treatment, including capecitabine. Patients were randomly assigned 1:1 to capecitabine maintenance (oral 1,250 mg/m^2/day on days 1-14 every 21 days) for up to 24 months with BSC or BSC alone. The primary endpoint was PFS. The secondary endpoints included overall survival, duration of response, objective response rate and adverse effects. Analyses were done by intention to treat. This trial is registered with ClinicalTrials.gov, number NCT02460419 and is ongoing and no longer recruiting new patients. **Results:** Between May 16th, 2015, and January 9th, 2020, 140 metastatic NPC patients were screened, and 104 eligible patients were randomly assigned to capecitabine maintenance plus BSC (n = 52) or BSC alone (n = 52). After a median follow-up of 33.1 months (IQR, 21.5-50.7 months), median PFS was 35.2 months in the capecitabine maintenance group and 9.1 months in the BSC group (HR: 0.426; 95%CI: 0.248-0.731, P = 0.001). The most commongrade 3 or 4 adverse events during maintenance therapy were hand-foot syndrome (10.0%), nausea/vomiting (6.0%), fatigue (4.0%), and mucositis (4.0%). Totally 37 deaths occurred during follow-up, 14 (26.9%) in the capecitabine maintenance group and 23 (44.2%) in the BSC group. Overall survival data was immature. No deaths in the capecitabine maintenance group were deemed treatment related. **Conclusions:** Capecitabine maintenance significantly improved PFS in patients with newly diagnosed metastatic NPC who achieved disease control after induction chemotherapy compared to BSC and exhibited low grade and manageable toxicities. Clinical trial information: NCT02460419. Research Sponsor: None.

Evaluation of radiomics as a predictor of tumor hypoxia and response to anti-PD-1 mab treatment (IO) in recurrent/metastatic HNSCC patients (R/M). *First Author: Dan Paul Zandberg, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: There is a great need for non-invasive predictors of the tumor microenvironment and the efficacy of anti-PD-1 mAb treatment (IO) in R/M HNSCC patients. We previously showed that lower tumor hypoxia was associated with increased efficacy with IO (*Journal of Clinical Oncol*. 38, no. 15_suppl (May 20, 2020) 6546) and now we evaluate the predictive value of radiomics in this same patient cohort. **Methods:** We studied radiomic signatures in a cohort of 36 patients with R/M HNSCC treated with IO. Treatment response was evaluated using RECIST 1.1. Patients were categorized as: Responders (R) ie CR, PR, SD and non-Responders (NR) i.e PD. As per our previous analysis (ref above) hypoxia was evaluated on archival FFPE samples via immunofluorescent imaging and defined by the ratio of percent area (% CAIX) / the mean intensity (Int) of carbonic anhydrase IX in tumor (%CAIX/Int). ImageJ software was used to determine %CAIX and Int. Feature extraction was performed on the pre-immunotherapy baseline CT scans. The lesions were segmented using 3D slicer v4.10.2 to create a volume of interest (VOI) for radiomic texture analysis (TA). A total of 400 features (10 histogram-based and 390 second-order texture features) were calculated from each extracted volume of interest (VOI). Radiomic features were obtained using a feature selection approach based on Least Absolute Shrinkage and Selection Operator (LASSO). Selected features were used to build a classification model, using XGboost, for prediction of tumor response to immunotherapy. Cross-validation was performed using the Leave One Out Cross Validation (LOOCV) approach for the XGBoost method to evaluate the robustness of the estimates and calculated accuracy, sensitivity, specificity and p-value. **Results:** Our patient cohort had a median age of 59, 69% male, 58% smokers. 61% received IO for platinum failure, 39% frontline. Primary site included 39% OC, 22% OPC (38% HPV positive), 17% Larynx, 5% hypopharynx, and 17% other. Radiomics applied to the primary HNSCC tumor highly predicted tumor hypoxia status with a sensitivity, specificity, and accuracy of 78%, 83%, and 81%, respectively, p = 0.0001. To predict response, we applied radiomics to both the primary HNSCC tumor and pathological lymph nodes; radiomics was also able to predict whether a patient would be a responder (N = 8) versus a non-responder (N = 28) to IO based on the pre-immunotherapy baseline CT scan. The sensitivity, specificity, and accuracy were 93%, 88%, and 92%, respectively, p = 0.02. **Conclusions:** Even in a small cohort, radiomics could predict response to IO and tumor hypoxia in R/M HNSCC patients. To our knowledge this is the first evaluation of this kind in this patient population. Further evaluation of radiomics as a predictor of efficacy with IO and the tumor microenvironment is warranted. Refining TNM-8 M1 categories with anatomic subgroups for previously untreated de novo metastatic nasopharyngeal carcinoma. *First Author: Sik-Kwan Chan, Department of Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong*

Background: The eighth edition TNM (TNM-8) classified de novo metastatic (metastatic disease at presentation) nasopharyngeal carcinoma (NPC) as M1 without further subdivision. However, survival heterogeneity exists and long-term survival has been observed in a subset of this population. We hypothesize that certain metastatic characteristics could further segregate survival for de novo M1 NPC. **Methods:** Patients with previously untreated de novo M1 NPC prospectively treated in two academic institutions (The University of Hong Kong [n = 69] and Provincial Clinical College of Fujian Medical University [n = 114] between 2007 and 2016 were recruited and re-staged based on TNM-8 in this study. They were randomized in 2:1 ratio to generate a training cohort (n = 120) and validation cohort (n = 63) respectively. Univariable and multivariable analyses (MVA) were performed for the training cohort to identify the anatomic prognostic factors of overall survival (OS). We then performed recursive partitioning analysis (RPA) which incorporated the anatomic prognostic factors identified in multivariable analyses and derived a new set of RPA stage groups (Anatomic-RPA groups) which predicted OS in the training cohort. The significance of Anatomic-RPA groups in the training cohort was then validated in the validation cohort. UVA and MVA were performed again on the validation cohorts to identify significant OS prognosticators. **Results:** The training and the validation cohorts had a median follow-up of 27.2 months and 30.2 months, respectively, with the 3-year OS of 51.6% and 51.1%, respectively. Univariable analysis (UVA) and multivariable analysis (MVA) revealed that co-existing liver and bone metastases was the only factor prognostic of OS. Anatomic-RPA groups based on the anatomic prognostic factors identified in UVA and MVA yielded good segregation (M1a: no co-existing liver and bone metastases and M1b: co-existing both liver and bone metastases; median OS 39.5 and 23.7 months respectively; $P = .004$). RPA for the validation set also confirmed good segregation with co-existing liver and bone metastases (M1a: no co-existing liver and bone metastases and M1b: co-existing liver and bone metastases), with median OS 47.7 and 16.0 months, respectively; $P = .008$). It was also the only prognostic factor in UVA and MVA in the validation cohort. **Conclusions:** Our Anatomic-RPA M1 stage groups with anatomical factors provided better subgroup segregation for de novo M1 NPC. The study results provide a robust justification to refine M1 categories in future editions of TNM staging classification. Research Sponsor: None.

Outcomes and prediction of lethal recurrence after transoral robotic surgery for HPV+ head and neck cancer. *First Author: Devraj Basu, The University of Pennsylvania, Philadelphia, PA*

Background: Increasing use of transoral robotic surgery (TORS) for human papilloma virus-related (HPV+) head and neck squamous cell carcinomas (HNSCCs) is likely to impact recurrence patterns and outcomes. Profiling HPV+ HNSCC recurrences after TORS and identifying features predictive of lethal outcome would facilitate tailoring adjuvant therapy and guide surveillance post-therapy. This study uses long term follow-up of patients at the first institution to bring TORS into clinical use to describe the recurrence patterns, distinguish outcomes associated with distinct patterns, and create a risk model for lethal recurrence. **Methods:** This retrospective cohort study at a single academic tertiary center analyzed 634 consecutive, treatment-naïve HPV+ HNSCC patients receiving TORS and neck dissection for clinical features at presentation and pathologic traits identified by surgical resection. The main outcomes were distant metastatic recurrence (DMR) and locoregional recurrence (LRR). Multivariate logistic regression with backward stepwise elimination was used to identify features associated with recurrence. **Results:** 6.5% of patients developed DMR at a median of 12.4 months after surgery and had a 5-year overall survival (OS) of 52.5% (95% CI, 33.9%-68.2%), whereas the 6.2% patients developing LRR alone had 5-year OS of 83.3% (95% CI, 66.2%-92.2%; P = .01). After recurrence, 5-year progression-free survival was 24.7% (95% CI, 11.4%-40.7%) for DMR cases and 85.7% (95% CI, 65.1-94.6%) for cases with LRR alone (P < .001). Comparing recurrent cases to recurrence-free controls showed DMR to be independently associated with positive surgical margins (AOR 5.7; 95% CI, 2.1-15.7) and advanced clinical stage at presentation (AOR 6.5; 95% CI, 1.9-23.0). Positive margins increased DMR risk by 4.2-fold and reduced 5-year disease-free survival (P < .001) in early-stage cases (Table), which comprised 95% of the cohort. By contrast, isolated LRR was associated with failure to receive indicated adjuvant therapy and was usually controllable by salvage therapy. **Conclusions:** Based on the largest single institution cohort reported to date, long term oncologic outcomes for HPV+ HNSCCs after TORS are excellent overall. While DMR is often fatal, LRR is salvageable with durable disease control. In addition to standard staging criteria, positive margins indicate substantially higher risk of DMR but not LRR. A risk model for DMR that incorporates margin status after TORS is relevant for guiding clinical trial design and whole-body surveillance. Research Sponsor: U.S. National Institutes of Health.

Ultra-sensitive detection and quantification of HPV DNA in the plasma of patients with oropharyngeal squamous cell carcinoma (OPSCC) enrolled in the OPTIMA 2 treatment de-escalation trial. *First Author: Hillary Sloane, Sysmex Inostics, Baltimore, MD*

Background: Human papillomavirus (HPV) infection is a primary factor driving the increasing incidence of OPSCC. As patients with HPV+ OPSCC show significantly improved treatment response and prognosis, there is an urgent need to de-escalate treatment of HPV+ OPSCC that optimizes oncologic control while minimizing treatment-related toxicity. Cell-free HPV DNA (cfHPV-DNA) from plasma specimens represents a promising noninvasive surrogate of disease burden in these patients. To enable cfHPV-DNA analysis as a strategy to monitor response to therapy and guide treatment de-escalation, we developed a highly sensitive assay for HPV16/18 detection and quantification in plasma, based on the SafeSEQ next-generation sequencing (NGS) technology. **Methods:** Longitudinal plasma samples were collected from patients with locoregional HPV+ OPSCC treated on our institutional de-escalation protocol of induction chemoimmunotherapy followed by risk/response stratified de-escalated locoregional therapy, OPTIMA 2 (NCT03107182). Neck CT or MRI was obtained for all patients at baseline and following induction chemoimmunotherapy; radiographic response to induction therapy was assessed per RECIST 1.1 criteria. cfHPV-DNA was quantified in plasma samples collected at baseline and at the end of induction therapy. Changes in cfHPV-DNA levels were correlated with radiographic response. **Results:** The SafeSEQ HPV assay demonstrates high analytical sensitivity, with ability to detect a single copy of HPV DNA. Replicate testing of contrived samples containing HPV 16/18 DNA at defined levels revealed robust quantitative detection across a dynamic range over 5 orders of magnitude. The assay showed a low level of background signal (< 0.04 copies per sample) across 20 healthy donor samples, indicating high specificity. In plasma samples collected at baseline from patients enrolled in OPTIMA 2, cfHPV-DNA was detected at levels ranging from 1 to > 30,000 copies/ml. A high correlation was observed between dynamic changes in patients' cfHPV-DNA levels and radiographic responses following induction therapy. Furthermore, in samples collected longitudinally during induction therapy, changes in cfHPV-DNA levels accurately tracked radiographic responses to therapy. **Conclusions:** We have developed a highly sensitive and specific cfHPV-DNA detection assay based on SafeSEQ NGS technology and have successfully applied it to monitor therapeutic response in HPV+ OPSCC patients. The assay exhibits robust quantitative detection of HPV across a broad range of levels, even when only a few copies are present, enabling high-resolution molecular monitoring. Prospective studies are underway to further evaluate the kinetics of cfHPV-DNA as a predictor of response to therapy in order to more precisely guide the management of patients with HPV+ OPSCC. Research Sponsor: Sysmex.

The impact of tumor infiltrating lymphocytes (TILs) on disease progression in human papillomavirus (HPV)-related oropharyngeal squamous cell carcinoma. *First Author: Linda X Yin, Department of Otorhinolaryngology, Mayo Clinic, Rochester, MN*

Background: In the head and neck, human papillomavirus-related oropharyngeal squamous cell carcinoma (HPV(+)OPSCC) has a better prognosis and more tumor infiltrating lymphocytes (TILs) compared to its HPV(-) counterpart. Within HPV(+)OPSCC, the prognostic value of TILs in the primary tumor and in metastatic lymph nodes is not well understood. **Methods:** This is a matched case-control study at a tertiary care center of HPV(+)OPSCC patients who underwent primary surgery between 05/2007–12/2016. Cases developed locoregional recurrence or distant metastases during follow-up, while controls did not during a similar duration of follow-up. Pairs were matched on age, American Joint Committee on Cancer (AJCC) 8th edition pathologic stage, sex, year of surgery, degree of adjuvant treatment, comorbidities, and smoking status. One representative H&E slide of the primary tumor and lymph node (when nodal disease was present) from each patient was independently reviewed by two pathologists (JG, MR) blinded to outcome, for tumor TILs (tTILs) density (defined as % TILs), presence/absence of desmoplastic stroma, and when stroma was present, for stromal TILs (sTILs) density (defined as relative crowding of TILs). The Brandwein-Gensler pattern of invasion (POI) score was used to grade the primary tumor. Interrater agreement was assessed using Cohen's *kappa*. Associations between TILs and time to disease progression were assessed using Cox proportional hazards regression models. **Results:** 41 case-control pairs (N=82) were included in the study: 38 (46%) were AJCC pStage I, 37 (45%) were pStage II, and 7 (9%) were pStage III; 22 (27%) underwent surgery alone, 15 (18%) underwent surgery with adjuvant radiotherapy, and 45 (55%) underwent surgery with adjuvant chemoradiation. Interrater agreement was fair for tTILs density in the primary tumor (k=0.24) and lymph node (k=0.23), moderate for desmoplastic stroma in the primary tumor (k=0.58) and lymph node (k=0.64), moderate for sTILs density in the primary tumor (k=0.58) and lymph node (k=0.48), and fair for the POI score (k=0.17). tTILs density ≥10% (HR 0.35, 95% CI 0.14-0.90, p=0.028) and a moderate/dense sTILs density (HR 0.15, 95% CI 0.04-0.68, p=0.014) in the primary tumor were significantly associated with decreased risk of disease progression. An aggressive POI score of III or IV was significantly associated with increased risk of disease progression (HR 4.00, 95% CI 1.34-11.96, p=0.013). None of the study measures in the lymph node were significantly associated with disease progression. **Conclusions:** In HPV(+)OPSCC, a higher density of tumor and stromal TILs and non-aggressive POI in the primary tumor specimen may indicate a lower risk of disease progression. TILs may serve as a powerful prognostic marker for the adaptive immune response to this disease. Research Sponsor: None.

Endostar combined with intensity-modulated radiotherapy in low-risk local advanced nasopharyngeal carcinoma: A phase II, randomized, multicentric clinical trial. *First Author: Min Kang, Department of Radiation Oncology, The First Affiliated Hospital of Guangxi Medical University, Nanning, China*

Background: A Phase II, randomized, prospective, multicentric trial was conducted to evaluate the efficacy and safety of Endostar plus radiotherapy in patients with low-risk local advanced nasopharyngeal carcinoma (NPC). This study reported the preliminary results of NCT02237924. **Methods:** From 09/2014 to 08/2016, patients with low-risk local advanced NPC were randomly treated with Endostar plus radiotherapy (ERT group, n=60) and concurrent chemoradiotherapy (CCRT group, n=60). Primary endpoint was the 5-year overall survival (OS) rate. The secondary endpoints were 3-year OS rate, progression free survival (PFS) rate, loco-regional recurrence free survival (LRRFS) rate and distance metastasis free survival (DMFS) rate. **Results:** After a median follow-up of 47 months, 3-year OS rate were 93.2% and 79.3% (p=0.032), 3-year PFS rate were 89.8% and 70.6% (p=0.011), 3-year DMFS rate were 93.2% and 80.7%, in two groups, respectively (P=0.042). 3-year LRRFS rate were 96.6% and 92.0% in two groups, respectively (but P=0.565). For short-term curative effects, CR rate were 71.2% and 60.0% for primary tumor, 74.6%and 63.3%for cervical lymph nodes, in two groups, respectively (P < 0.05). Moreover, the incidences of adverse events were significantly lower in ERT group compared with in CCRT group. The grade 3/4 Hyponatraemia (0 [0%] vs 3 [5%] , p=0·04), the grade 1/2 vomiting (10 [16.7%] vs 52 [86.7%], p=0.000), dry mouth (45 [75.0%] vs 56 [93.3%], p=0.012), leukopenia (22 [36.7%] vs 42 [70.0%], p=0.000) and weight loss (30 [50.0%] vs 45 [75.0%], p=0.005). No patients died of treatment-related causes. **Conclusions:** OS, PFS, and DMFS rates can be improved, adverse events be reduced, with better tolerability, by Endostar plus radiotherapy, when compared to concurrent chemoradiotherapy for local advanced low-risk NPC. Clinical trial information: NCT02237924. Research Sponsor: National Natural Science Foundation of China.

Phase I study of functionalized hafnium oxide nanoparticles (NBTXR3) activated by radiotherapy in cisplatin-ineligible locally advanced HNSCC patients. *First Author: Christophe Le Tourneau, Institut Curie, Saint-Cloud, France*

Background: The non-surgical standard of care (SOC) for the treatment of locally advanced head and neck squamous cell carcinoma (LA HNSCC) patients is concurrent chemoradiation with high dose cisplatin or cetuximab in case of contra-indication to cisplatin. However elderly patients, and those with poor performance status, comorbidities, and/or intolerance, may not benefit from these SOC treatments and represent a high unmet need. New approaches are thus needed to improve clinical outcomes without adding toxicity. NBTXR3, a novel radioenhancer, composed of functionalized hafnium oxide nanoparticles**,** is injected once intratumorally and activated by radiotherapy (RT).NBTXR3 increases the RT energy deposit inside tumor cells and subsequently increases tumor cell death compared to RT alone, while sparing healthy tissues. We present here the results of the dose expansion part of the phase I study evaluating NBTXR3 plus intensity modulated radiation therapy (IMRT) in this population. **Methods:** Patients with stage III-IVA or T3/T4 (AJCC/UICC TNM staging system 8th ed.) HNSCC of the oropharynx or oral cavity, ineligible to cisplatin or cetuximab and amenable for RT, received a single intratumoral injection of NBTXR3 and IMRT (70 Gy in 35 fractions /7 weeks). A classical 3 + 3 dose escalation design has tested four doses of NBTXR3, equivalent to 5, 10, 15, and 22% of baseline theoretical tumor volume. The RP2D established as 22% of baseline tumor volume is further tested in the dose expansion part. The primary endpoints of the dose expansion part are objective response rate (ORR) and complete response rate (CRR) of the primary tumor, by imaging according to RECIST 1.1. Safety is also evaluated. **Results:** As of August 13, 2020, 43 patients have been treated in the phase I dose expansion part. The median age was 70.7 years old (range: 50.7- 89.9), 70% of patients had cardiac disorder risk, 44% had gastrointestinal disorder risk and 44% metabolic and nutrition disorder risk. The median tumor volume was 42.8 mL (range: 1.3 - 222.3). At a median time of 7.8 months after NBTXR3 injection, the ORR of the primary lesion was 83.9% and the CRR 67.7% in the evaluable population for efficacy (N = 31). Three patients (7%) experienced at least one serious adverse event (AE) related to the injection procedure and/or NBTXR3 which represented less than 1% of all reported AEs. RT-related toxicity was as expected with IMRT. Three deaths due to AEs related to RT and other causes were reported. The recruitment is ongoing and updated efficacy and safety results will be presented. **Conclusions:** NBTXR3 intratumoral administration followed by IMRT may represent an option in elderly patients or patients with multiple comorbidities with LA-HNSCC who have limited therapeutic options. NBTXR3 activated by RT showed promising anti-tumor efficacy, supporting further evaluation in a phase III randomized trial. Clinical trial information: NCT01946867. Research Sponsor: Nanobiotix, SA.

Inductive camrelizumab and apatinib for patients with locally advanced and resectable oral squamous cell carcinoma: A single-arm trial (Icemelting trial). *First Author: Lai-Ping Zhong, Department of Oral & Maxillofacial-Head & Neck Oncology, Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: In patients with locally advanced oral squamous cell carcinoma (LAOSCC), major pathologic response (MPR) to induction therapy may translate into improved survival. The induction therapy using chemo-free drugs, such as the combination of anti-PD1 and anti-VEGFR drugs, has not been well issued in LAOSCC. **Methods:** A prospective single arm trial (NCT04393506) has been performed to evaluate the induction therapy of anti-PD1 and anti-VEGFR protocol in LAOSCC patients at clinical stage III and IVA. The patients received three cycles of intravenous Camrelizumab (PD-1 antibody, 200mg) on d1, d15, d29; and oral Apatinib (anti-VEGFR inhibitor, 250mg) daily, initiating on d1, ending on the 5th day before surgery. Radical surgery was planned on d42-d45. Post-operative radiotherapy was planned within 1.5 months after surgery, based on clinical and pathological stage. The primary endpoints were MPR and safety; primary tumors were assessed for the percentage of residual viable tumor that was identified on HE staining, and tumors with no more than 10% viable tumor cells were considered as MPR. This study has been approved by institutional ethics committee at Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine. **Results:** From April to December 2020, 21 patients were enrolled in this trial, and one patient withdraw from the trial at the beginning of treatment. The induction therapy was well-tolerated with no grade 3-4 toxicity or serve induction therapy-related AEs. One patient required surgery delay for 7 days due to unexplainable cTnI elevation. One patient put off Camrelizumab for 14 days due to grade 2 thrombocytopenia. One patient suspended Apatinib for 21 days due to grade 2 Hyperbilirubinemia. The induction therapy did not effect on the subsequent standard treatment. MPR rate was 40% (8/20), including 5% (1/20) pCR. Radiological evaluation of response to induction therapy showed 3 PR, 10 SD, 5 PD and 2 NA. Weak correlation was found between pathologic and radiological evaluation on induction therapy. Combined positive score (CPS) of PD-L1 expression in biopsy was evaluated in 19 patients; all 4 patients with CPS$\geq$ 20 had MPR, 3 out of 11 patients with 1$\leq$CPS $<$ 20 had MPR, and 1 out of 4 patients with CPS $<$ 1 had MPR. **Conclusions:** The chemo-free protocol of induction therapy using Camrelizumab and Apatinib is safe and well-tolerated for the patients with LAOSCC. The MPR rate is much higher using the anti-PD1 and anti-VEGFR protocol than the traditional induction chemotherapy protocol in LAOSCC. Clinical trial information: NCT04393506. 6053 **Poster Session**

Neoadjuvant and adjuvant nivolumab and lirilumab in patients with recurrent, resectable squamous cell carcinoma of the head and neck. *First Author: Glenn J. Hanna, Dana-Farber Cancer Institute, Boston, MA*

Background: Locoregional recurrence (LRR) is a major cause of death for patients (pts) with squamous cell carcinoma of the head and neck (SCCHN). With therapy options limited by prior treatment, surgery often represents the best chance for disease control. Emerging data suggests a role for neoadjuvant immunotherapy in upfront resectable SCCHN and the importance of NK cells in the tumor microenvironment. We hypothesized that dual immune checkpoint inhibition (anti-PD-1, nivolumab [N] and anti-KIR, lirilumab [L]) before and after salvage surgery would improve 1-year disease-free survival (DFS). **Methods:** Pts with operable LRR of SCCHN (any HPV or smoking status) with a disease-free interval of $>$ 8 weeks after curative intent therapy were eligible for this phase II trial. Pts received a single dose of pre-op N (240 mg) + L (240 mg) 7-21 days before surgery, followed by 6-cycles of adjuvant N+L on days 1, 15 (N alone) of a 28-day cycle (C) for C1-3; and on day 1 for C4-6. Primary endpoint was 1-year DFS; 37 DFS events among N = 54 pts provided 81% power to detect improvement in 1-year DFS from 57% to 67.5% (one-sided 10% Wald's test). Secondary endpoints: safety, radiologic response (RECIST v1.1) to pre-op N+L, and overall survival (OS). Correlatives included tumor sequencing, PD-L1 status, and immunoprofiling. **Results:** Between 3/15/18 and 5/29/20, N = 29 enrolled (stopped due to expiration of drug supply). Among 28 treated pts, median age: 66, 18% (5/28) women, 83% smokers; primary site: 10 oral cavity, 8 oropharynx (5/8 HPV+), and 10 larynx/hypopharynx. 96% (27/28) had prior HN radiation; 71% (20/28) prior chemotherapy. There were no delays to surgery. Grade 3+ adverse events: 11% (3/28); no deaths from treatment. At time of surgery, 96% (27/28) had stable disease radiologically with 3 showing regression, 4% (1/28) had disease progression. Pathologic response to N+L was observed in 43% (12/28): 4/28 (14%) major (tumor viability, TV $\leq$10%); 8/28 (29%) partial (TV $\leq$50%). PD-L1 CPS at surgery was similar regardless of pathologic response (p = 0.63). 68% (19/28) completed all 6-cycles of adjuvant N+L; N = 1 came off for toxicity. Ten pts (36%) recurred (local = 8, distant = 2). 5/28 (18%) had positive margins, of which 4 (80%) recurred; 4/28 (14%) declined to start adjuvant N+L, of which 3 (75%) later recurred. At median follow-up of 20.2 months, 1-year DFS70% (95%CI, 48-84%) and 1-year OS: 85% (95%CI, 65-94%). Median tumor mutational burden was 4 (range, 1-11). *TP53* was the most frequent alteration (78%, 21/27). CD39 expression by TILs and CD38 expression by circulating CD4/8+ T cells increased after N+L exposure ($p < 0.05$). **Conclusions:** Neoadjuvant and adjuvant N+L was safe and well tolerated. We observed a 43% pathologic response rate prior to salvage surgery, with a favorable 1-year DFS of 70% and 1-year OS $>$ 80% among previously irradiated pts. Further evaluation of this strategy is warranted (NCT03341936). Research Sponsor: Bristol Myers Squibb.

Transoral robotic surgery for human papillomavirus-associated oropharynx squamous cell carcinoma: Recurrence and survival in the Veterans Affairs health system. *First Author: Abhishek Kumar, University of California, San Diego, La Jolla, CA*

Background: Most transoral robotic surgery (TORS) literature comes from single and multi-institutional studies at tertiary-care academic intuitions. Long-term outcomes for patients with HPV-mediated oropharyngeal squamous cell carcinoma (HPV-OPSCC) treated with upfront TORS in other hospital settings across the United States are largely unknown. We present long-term recurrence and survival outcomes from a novel Veterans Health Administration (VHA) longitudinal dataset that includes patient-level data. **Methods:** Retrospective analysis of national VHA patients with p16-positive OPSCC diagnosed between January 2010 and December 2016, treated with TORS primary tumor resection with neck dissection. Outcome measures included: Cancer-specific survival (CSS), progression free survival (PFS), overall survival (OS), recurrence, extranodal extension (ENE), positive surgical margin (PSM), and adjuvant therapy regimen. **Results:** One hundred sixty-one patients were included of whom 29 (18%) were low-risk [0-1 metastatic lymph nodes, negative margins]; 45 (28%) intermediate-risk [close surgical margins, 2 to 4 metastatic nodes, LVI or PNI, pathologic T3 or T4 tumor]; and 87 (54%) high-risk [PSM, ENE, and/or $\geq$ 5 metastatic nodes]. ENE was present in 41% of cases and 24% of cases had positive surgical margins. Median follow-up was 5.6 years (95% CI 3.0-9.3). The 5-year CSS rates for low, intermediate, and high-risk groups were: 100%, 90.0% (95% CI 75.4-96.1%), and 88.7% (78.3-94.2%). On univariable analysis, pathologic factors associated with inferior CSS were: pT3-T4 tumor category (HR 3.81, 95% CI 1.31-11; p = 0.01), presence of more than four metastatic lymph nodes (HR 3.41, 95% CI 1.20-11; p = 0.02), and ENE (HR 3.53, 95% CI 1.06-12; p = 0.04). Close or PSM were not associated with CSS (HR 0.67, 95% CI 0.21 – 2.14; p = 0.50). In the low-risk group, 48% avoided adjuvant therapy and although there were five recurrences, none died from cancer. The intermediate-risk group was treated with adjuvant radiation in 64% of cases, and chemoradiation in 29% of cases; and there were five locoregional recurrences and three distant recurrences. Adjuvant chemoradiation was used in 68% of high-risk cases. Of the seven total patients with distant recurrences, six died of their disease. **Conclusions:** Our findings in this national cohort of Veterans with HPV-OPSCC demonstrate that TORS followed by adjuvant therapy yields favorable survival outcomes. Tumor-category, ENE, and more than four nodal metastases were the strongest adverse features in our data, and surgical margins did not have a significant impact on survival. Further investigations with large cohorts and prospective clinical trials are needed to elucidate the true oncologic implications of high-risk features and to identify patients best suited for de-intensified treatment. Research Sponsor: U.S. Department of Defense. Grant Number: W81XWH-17-PCRP-PRA.

Survival outcomes in primary head and neck adult sarcoma: A systematic review and meta-analysis. *First Author: Sondos Zayed, Department of Radiation Oncology, London Health Sciences Centre, London, ON, Canada*

Background: Head and neck sarcomas (HNS) are rare entities and confer substantial morbidity and mortality. Yet, the optimal management of HNS remains unclear. This study aimed to describe the epidemiology of HNS and to identify the most favorable treatment approach. **Methods:** We performed a systematic review and meta-analysis based on the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines, using the PubMed (Medline), EMBASE, and Cochrane Library databases, queried from 1990 until present. Articles in the English language reporting on survival outcomes of adult primary HNS patients treated with curative-intent were included. All estimates were weighted based on sample size. Analysis of variance (ANOVA) and two-sample t-tests were used as appropriate. Meta-analyses were performed using random effects models. This study was registered with PROSPERO, CRD42021220970. **Results:** A total of 3652 articles were identified, with 42 articles reporting on 21228 patients, meeting inclusion criteria. Mean ± SD age was 56.7 ± 14.6 years with 14170 (67.0%) men and 6991 (33.0%) women. The most common locations included skin and soft tissues (n = 12749, 63.3%), bones of skull and face (n = 2256, 11.2%), and oral cavity (n = 1775, 8.8%). The most common histologies included undifferentiated pleomorphic sarcoma (n = 5065, 24.8%), osteosarcoma (n = 2578, 12.6%), Kaposi sarcoma (n = 2316, 11.3%), chondrosarcoma (n = 2141, 10.5%), and hemangiosarcoma (n = 2072, 10.1%). 5459 patients had early stage I-II disease (76.9%) whereas 1643 had late stage III-IV disease (23.1%). Most received surgery alone (n = 10968, 61.0%), 3917 (21.8%) received surgery and radiotherapy (RT), 2173 (12.1%) received definitive RT/chemoradiotherapy (CRT), 811 (4.5%) received surgery and CRT, and 98 (0.5%) received surgery and chemotherapy. Negative margins were achieved in 6081 (76.5%). Mean ± SD follow-up was 55.3 ± 42.8 months. Weighted mean, 2-, 5-, and 10-year overall survival (OS) were 78.5 months, 75.9%, 63.2%, and 54.9% respectively. There was no significant difference in mean OS (P = 0.674) or 5-year OS (P = 0.965) between patients who received surgery alone, multimodality treatment with surgery and RT/CRT, or definitive RT/CRT. Mean ± SD 5-year OS was significantly higher with negative margins (62.7 ± 20.8%) compared with positive margins (22.7 ± 19.1%; P = 0.001). Mean ± SD local recurrence rate (LRR) was 32.0 ± 13.0%. LRRs were 41.8% for definitive RT/CRT, 39.3% for surgery and CRT, 33.6% for surgery alone, 24.7% for surgery and chemotherapy, and 20.1% for surgery and RT (P = 0.126). **Conclusions:** In the largest HNS study to date, negative margins were associated with an improvement in OS. Multimodality treatment did not confer an OS benefit. Definitive RT/CRT may be associated with a higher LRR. Randomized trials are needed to establish the optimal treatment approach for HNS. Research Sponsor: None.

A phase II study of PRV111 nanoengineered cisplatin patch as a neoadjuvant therapy for early-stage oral squamous cell carcinoma (OSCC). *First Author: Nishant Agrawal, The University of Chicago, Chicago, IL*

Background: OSCC is a devastating disease causing substantial morbidity and mortality. Despite advancements in the conventional therapeutic approaches, surgical resection often leads to permanent disfigurement, while radiotherapies and systemic platinum-based chemotherapy result in significant toxicities, affecting patient wellbeing and quality of life. Thus, development of novel therapeutic approaches is paramount to improve health outcomes and survival of patients with OSCC. Systemic toxicity is often dose limiting, but could be tentatively reduced by locoregional administration. We have developed PRV111, a nanotechnology based patch for local and regional delivery of highly concentrated potent cisplatin, designed to penetrate tumor tissue, reach and enter regional lymph nodes and avoid systemic circulation. Here we present the results of phase 1/2 CLN-001 trial, designed to improve efficacy and reduce toxicity by neoadjuvant treatment with PRV111. **Methods:** A phase 1/2, single arm, open-label CLN-001 (NCT03502148) study has enrolled 12 patients with confirmed OSCC; unknown nodal involvement, no distant metastasis, and tumor size $\leq$ 4.0 cm. Three weeks prior to surgery, patients were administered 1 cycle of standalone neoadjuvant PRV111, consisting of up to 4 treatment visits (each visit dose: $\leq$12mg of cisplatin, each patch loading dose: 2mg of cisplatin). The primary endpoints were safety, efficacy and tumor reduction in ~ 7 days by greater than 30%. Secondary endpoints included nanoengineered patch consistent and complete adhesion to mucosal surfaces and uniform drug release. Exploratory endpoints included immunogenesis/immunomodulation. **Results:** PRV111 successfully met all clinical primary endpoints, as well as safety and efficacy objectives. It caused over 70% tumor reduction in ~7 days with over 87% response rate across 10 subjects. No dose-limiting toxicities, serious adverse event, or systemic toxicities were reported and no locoregional recurrences were evident in 6 months. PRV111 induced ~15 times increase in tumor infiltrating lymphocytes compared with the initial biopsy. Concentrations of cisplatin found in the tumor and regional lymph nodes were over 300 and 100 times higher respectively as compared with IV cisplatin, with only negligible amount of cisplatin found in the blood. Grade 1 or 2 oral and tongue pain induced by the treatment were the most common adverse events. Furthermore, 97.5% successful patch performance was achieved across 182 patches used in the study. **Conclusions:** Adding neoadjuvent PRV111 to the care for patients with OSCC may improve the surgical outcome and increase event free survival. Given these encouraging results, future studies are needed to establish the application of this non-invasive platform in head and neck SCC and other epithelial cancers, including anal, colorectal, genitourinary, nasal, and skin. Clinical trial information: NCT03502148. Research Sponsor: U.S. National Institutes of Health, Other Government Agency, Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

Impact of comprehensive geriatric assesment (CGA) in the treatment decision and outcome of older patients with locally advanced head and neck squamous cell carcinoma (LA-HNSCC). *First Author: Sandra Llop Serna, Institut Català d'Oncologia, Barcelona, Spain*

Background: Up to 24% of patients (pts) newly-diagnosed with LA-HNSCC are 70 years old (yo). NCCN guidelines recommend a geriatric assessment to guide treatment decisions in this pts population. Comprehensive geriatric assessment (CGA) of older HNSCC pts was implemented at our institution in 2018. We evaluated the impact of CGA in treatment decision and outcome and compare it to a control cohort with no CGA treated within the same institution. **Methods:** Retrospective single-institution analysis of two consecutively-treated cohorts of newly-diagnosed elderly LA-HNSCC pts treated at the Catalan Institute of Oncology: a cohort treated based on CGA between 2018-2020; and a control cohort with no CGA treated based on physician criteria following tumor board decision between 2016-2018. Pts demographics and disease characteristics were obtained from our in-site prospective database. Treatment received (standard, adjusted, palliative-intent, best supportive care [BSC]), treatment completion rate (TCR) an overall response rate (ORR) after conservative treatment were collected and compared for both cohorts using chi-square. **Results:** A total of 197 pts were included: CGA cohort =81; Control cohort=96. Baseline characteristics were similar between cohorts (Table). Pts in CGA cohort were classified as fit (F) 35 (34.7%), medium-fit (MF) 51 (50.5%) and unfit (UF) 15 (14.9%) according to CGA results. CGA changed final treatment decision following tumor board in 31 % of the cases. Pts were more likely to receive standard treatment in the CGA cohort when compared control (36 vs 21%; *p = 0.048*), with no differences observed in TCR (84% vs 86%; *p = 0.805*). In pts who underwent conservative treatment, ORR was similar between CGA and control cohort (73.9% vs 66.7 %; *p = 0.082*), respectively. Tumor progression was the major cause of death in both groups. **Conclusions:** Older pts with LA-HNSCC who underwent CGA were more likely to receive standard treatment than those who did not, supporting the relevance of CGA for clinical decision-making in this pt population. No differences were observed in CRR, TCR or death cause. In-deep survival analysis are on-going. Research Sponsor: None.

Survival (OS) and progression-free survival (PFS) results after induction chemotherapy (IC) followed by de-escalated chemoradiotherapy (RDCRT) for locally advanced (LA) HPV positive oropharynx cancer (HPVOPC. *First Author: Marshall R. Posner, Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: HPVOPC has a significantly better prognosis and survival than HPV negative cancer resulting in overtreatment with significant acute and late toxicities and mortality. Radiation therapy is the single greatest determinant of toxicity. Studies to support reduction of radiation dose are a high priority. IC improves local regional control, reduces distant metastases, and may support radiotherapy de-escalation. Patients with T4, ECE, and N2c disease have poorer local regional control (LRC) and a higher rate of distant metastases (DM) and may be suitable for this option. **Methods:** Data was combined for the experimental arm of a previously reported Phase 3 trial (12 subjects, NCT01706939) and a continuation Phase 2 trial (20 subjects, NCT02945631). After informed consent subjects who were PCR+ HPVOPC, smoked $<$ 20 py, and were LA or functionally unresectable were treated with Taxotere, cisplatin and reduced 5-fluorouracil (mTPF) for 3 cycles and then assessed for response. Responders were treated with 5600 cGy and weekly carboplatin, and then followed for LRC, DM, PFS, OAS and toxicity. Data was analyzed as of 2/1/21. 85% LRC at 3 years was considered non inferior to standard of care chemoradiotherapy. An acceptable end point was predetermined to be 80% PFS and 85% LRC at 3 years in this LA population. **Results:** 32 subjects were entered and included in the analysis, all responded to IC and had RDCRT. 2 patients with non-HPV16 subtypes were initially entered, treated with IC, responded, and then were taken off study and excluded from the analysis due to non-HPV 16 subtype. They were treated with 7000 cGy and are alive and well. Poor risk factors (ECE, T4, N2c, Non-HPV16 subtype) were present in 72% of 32 subjects; 22 (69%) never smoked. At data cutoff with a median follow up of 50m (21-95m), 28/32 (87.5%) have LRC, 1/32 DM (3.1%), OS is 28/32 (87.5%) and PFS is 27/32 (84.4%). All 5 patients who recurred did so in the first 12m (median 8m); all had 1 or more poor risk factors and 1 is alive with disease 42m post recurrence. 2 year LRC, PFS and OS are 87.4% [95% CI: 69.8%, 95.1%], 84.4% [95% CI: 66.5%, 93.2%] and 90.6% [95% CI: 73.7%, 96.9%] respectively. There was no therapy-related mortality, generally rapid recovery from CRT and minimal long term consequences (to be reported). **Conclusions:** Induction with mTPF followed by RDCRT resulted in excellent LRC, PFS and OS in patients with LA HPV OPC and significant risk factors. These results compare favorably to standard of care and other dose de-escalation trials in high and low risk categories. This treatment paradigm is highly effective in a LA, high risk HPVOPC patients and is a reasonable treatment option to be compared to other de-escalation treatment plans in Phase 3 trials for this higher risk population. Clinical trial information: NCT02945631, NCT01706939. Research Sponsor: None.

Prospective manipulation of the gut microbiome with Microbial Ecosystem Therapeutic 4 (MET4) in locoregionally advanced oropharyngeal squamous cell carcinoma (LA-OPSCC) undergoing primary chemoradiation (ROMA2). *First Author: Geoffrey Alan Watson, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Therapeutic manipulation of the gut microbiome in cancer patients (pts) is an area of active investigation. MET4 (NuBiyota) is an oral alternative to fecal transplant consisting of a mixture of human gut bacteria associated with immunotherapy (IO) response. We previously reported variation in IO-responsive taxa across stages in human papilloma virus related (HPV+) LA-OPSCC pts treated with chemoradiotherapy (CRT) (Oliva et al., ASCO 2020). ROMA-2 is the first interventional study evaluating the safety, feasibility and ecological effect of MET4, in combination with definitive CRT in HPV+ LA-OPSCC (NCT03838601). **Methods:** This is an investigator-initiated study of pts with HPV+ LA-OPSCC treated with standard of care CRT. MET4 is administered daily until week 4 of CRT or unacceptable toxicity. Stool samples are collected at baseline, week 4, week 8-10, and 2-months post CRT. Bacterial V4 16S rDNA was extracted from stool and sequenced. Microbiome analyses were conducted in R using DADA2, phyloseq and DESeq2. **Results:** As of February 11 2021, 25 pts have been enrolled. A total of 50 stool samples from the first 14 pts were collected (98% adherence) and analyzed. Baseline cohort characteristics: median age = 62.5 (range, 48-69); Stage I/II/III = 5/1/8; use of antibiotics = 1pt. 3 pts did not complete the 3-week course of MET4 treatment due to non-compliance (n = 1), withdrawal of consent (n = 1) and grade 2 diarrhea (n = 1). Other reported MET4-related adverse events (all grade 1) included bloating (n = 2), flatulence (n = 1) and belching (n = 1). No longitudinal changes in alpha-diversity were seen from baseline through follow up. Administration of MET4 resulted in a transient trend towards increased cumulative MET4 taxa relative abundance (RA) by week 4. Stage III patients demonstrated the lowest MET4 taxa RA at baseline, and the greatest increase in MET4 taxa RA from baseline to week 4. By week 4 the following taxa in all pts were increased compared to baseline: *Eubacterium hallii* (21.71 Log2-Fold change[L2FC], padj < 0.001) and *Parabacteroides johnsonii (*23.67 L2FC, padj $<$ 0.001). An increase in the following taxa was observed by weeks 8-10 compared to baseline: *Akkermansia muciniphilla* (3.75 L2FC, padj = 0.027), *Bacteroides fragilis* (6.73 L2FC, padj = 0.010), *Alistipes onderdonkii* (3.30 L2FC, padj = 0.049) and *Parabacteroides distasonis* (24.43 L2FC, padj < 0.001). **Conclusions:** Manipulation of the gut microbiota in these pts was feasible and safe. MET4-induced ecological changes are heterogenous and vary by taxa. MET4 taxa implicated in IO-response were increased by week 4 and week 8-10. This increase was higher in pts with stage III disease. These data suggest that specific subgroups may benefit from combination IO therapy and may guide pt selection for further interventional clinical trial design. Clinical trial information: NCT03838601. Research Sponsor: Tumor Immunotherapy Program, Princess Margaret Cancer Center.

Postoperative PET/CT for detection of early recurrence (ER) after surgery for squamous cell carcinomas (SCC) of the oral cavity (OC). *First Author: Yao Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients with ER after surgery and prior to postoperative radiation (RT) for SCC of the OC have aggressive biology and poor prognosis. After the introduction of a PET/CT simulator in our department, we incorporated post-operative PET/CT as part of RT planning. We hypothesized PET/CT would improve detection of macroscopic disease before postoperative RT. **Methods:** We reviewed the medical records of patients treated with postoperative radiotherapy between 2005 and 2019 for OC SCC. Clinicopathologic risk factors were recorded. Intermediate risk factors (IRFs) included pT3-4 disease, nodal disease, perineural invasion (PNI), lymphovascular invasion (LVI), and close ($<$ 5mm) surgical margins (SM); extranodal extension (ENE) and positive SM were considered high-risk factors (HRF). Patients were stratified into risk groups based upon the number and type of risk factors: 0-1 IRFs, 2 IRFs, $\geq$3 IRFs, and any HRF. Patients were considered to have ER if they had biopsy confirmed recurrence, or if the imaging or exam was sufficiently suspicious, after discussion with the head and neck team, to warrant treatment to definitive doses of RT (70 Gy). **Results:** Our cohort included 391 patients with SCC of the OCC who were treated with postoperative radiotherapy. 61% of patients were male, 35% had pT3-4 disease, 36% had pN2a-3 disease, 53% had PNI, 20% had LVI, 30% had ENE, and 14% had positive SM. The most common sites were oral tongue (46%), alveolar ridge (18%), and buccal mucosa (13%). 237 (61%) patients underwent postoperative PET/CT planning, and 165 patients (41%) were planned with CT only. Patients screened with post-operative PET/CT were more likely to be diagnosed with ER (46/237, 19.4%) than those simulated with CT only (6/154, 3.9%, $p <$ 0.0001). Among patients simulated with PET/CT, 7%, 9%, 14%, and 35% of patients were diagnosed with ER for patients with 0-1 IRFs, 2 IRFs, $\geq$3 IRFs, and any HRF, respectively. Median follow-up was 4.1 years (95% CI 3.6 – 4.5). Among 52 patients with ER, 24 (49.0%) had local, 41 (83.7%) had regional, and 5 (10.2%) had distant recurrence. 17 (33%) of ER were biopsy proven. For patients with ER, 3-year freedom from locoregional recurrence, distant-metastasis free survival, and overall survival were 45.2% (95% CI 32% - 64%), 55% (95% CI 42% – 72%), and 43% (95% CI 30% - 61%), respectively. For patients without ER, use of postoperative PET/CT was associated with improved disease-free survival (HR 0.68, 95% CI 0.46 – 0.98, p = 0.041) and overall survival (HR 0.59, 95% CI 0.38 – 0.91, p = 0.019). **Conclusions:** Postoperative PET/CT may increase detection ER compared to CT simulation alone and improve risk stratification. Patients with ER are at high risk of locoregional failure, distant metastases, and mortality, despite salvage therapy. A prospective trial is underway at our institution to systemically study the role of PET/CT for detection of ER. Research Sponsor: U.S. National Institutes of Health.

Impact of COVID19 pandemic on treatment outcome of locally-advanced head and neck squamous cell carcinoma (LA-HNSCC): IMPACCT study. *First Author: Pau Guillen Sentis, Institut Catala d'Oncologia, Barcelona, Spain*

Background: Treatment (ttm) of cancer patients (pts) was compromised during the first wave of COVID19 pandemic due to collapse of healthcare systems. Standard of care (SOC) for LA-HNSCC pts had to be adapted as operating rooms were temporarily unavailable, and to reduce risk of COVID19 exposure. The IMPACCT study evaluated the outcome of LA-HNSCC pts treated at the Catalan Institute of Oncology during the first semester of 2020 and compared it to a control cohort previously treated in the same institution. **Methods:** Retrospective single institution analysis of two consecutively-treated cohorts of newly-diagnosed HNSCC pts: from January to June of 2020 (CT20) and same period of 2018 and 2019 (CT18-19). Pt demographics and disease characteristics were obtained from our in-site prospective database. Ttm modifications from SOC as per COVID19-contingency protocol in CT20 for LA-HNSCC were collected. Chi-squared was used to compare variables and ttm response between cohorts. One-year recurrence-free survival (1yRFS) and overall survival (1yOS) of LA-HNSCC pts were estimated by Kaplan-Meier method and compared by Log-rank test. **Results:** A total of 306 pts were included: CT20=99; CT18-19=207. Baseline characteristics were balanced between cohorts (Table1). In pts treated with conservative ttm (non-surgical approach), persistence disease was higher in CT20 vs CT18-19 (26 vs. 10% p=0.02). Median follow-up of CT20 and CT18-19 was 6.8 months (IQR 5.1-7.9) and 12.3 (6.7-18.4), respectively. A trend towards lower 1yRFS and 1yOS was observed in CT20 vs CT18-19 (72 vs 83% p=0.06; 80 vs 84% p=0.07), respectively. Within CT20, 37 pts (37%) had one or more ttm modifications: switch from surgery to conservative ttm (n=13); altered radiotherapy fractionation (n=14); reduced cisplatin cumulative dose to 200mg/m2 (n=19); no adjuvant ttm (n=1). Pts who received modified ttm had no differences in 1yRFS vs those who did not (80 vs 66% p=0.31), but higher 1yOS was observed (97 vs 67% p$<$0.01). When stratified by stage, 1yOS difference remained significant in stage III/IVA (100 vs 61% p$<$0.01) but not in I/II (100 vs 77% p=0.28) or IVB (67 vs 50% p=0.54). **Conclusions:** COVID19 pandemic had a negative impact on ttm outcomes and survival in LA-HNSCC pts when compared to our historical cohort. Ttm modifications based on COVID19-contingency protocol did not compromise ttm efficacy in terms of RFS and was associated with better OS in Stage III/IVA. Research Sponsor: None.

Quality of life analysis of HPV-positive oropharyngeal cancer patients in a randomized trial of reduced-dose (rdCRT) versus standard (sdCRT) chemoradiotherapy: Five-year follow-up. *First Author: Mai Takahashi, Harvard University T H Chan School of Public Health, Boston, MA*

Background: Human papillomavirus-positive oropharyngeal cancer (HPV OPC) portends a more favorable prognosis compared to HPV-negative cases. To prevent overtreatment, long-term morbidity and deterioration in functionality and quality of life (QoL), multiple studies have focused on de-intensification techniques for HPV OPC treatment. To this end, we prospectively assessed differences in patient reported QoL in locally advanced HPV OPC patients receiving rdCRTversus sdCRT)in a randomized trial using a sequential therapy plan. **Methods:** Patients were enrolled between December 2012 and February 2016; received 3 cycles of induction docetaxel, cisplatin, and 5-FU; and were randomized to sdCRT (70 Gy) or rdCRT (56 Gy) with weekly carboplatin. Patients were followed for Progression Free Survival (PFS), Overall Survival (OS), and changes in QoL as assessed by the MD Anderson Dysphagia Inventory (MDADI), MD Anderson Symptom Inventory (MDASI Head and Neck), Xerostomia Questionnaire (XQ), and the European Organization for Research and Treatment of Cancer Questionnaire (EORTC QLQ-C30) with the head and neck module (EORTC HN). A mixed model ANOVA was used to estimate changes from baseline QoL to that at each follow-up timepoint and to compare the difference in QoL changes between the treatment arms. **Results:** We randomized 20 HPV+ locally advanced (LA) patients (median age: 56.5 yrs) to rdCRT (12 subjects) or sdCRT (8 subjects). 70% had high risk features. At a median follow-up of 81.5 mos, PFS and OS were 87.5% and 83.3% for sdCRT and rdCRT, respectively with a median OS of 76 mos in both arms. One patient in the sdCRT arm developed an HPV negative retromolar trigone squamous cell cancer in the radiation field 7 yrs after therapy. Baseline QoL was identical in the 15 patients who completed the QoL modules. Patients receiving rdCRT hadsignificantly lower declines in QoL scores at 3-6 month follow-up. At 5 yrs, differences in QoL changes all favored the rdCRT arm (Table) and two QoL scales reached statistical significance (P$<$0.05). **Conclusions:** In HPV OPC patients, rdCRT resulted in comparable long-term survival and greater improvement in specific domains of QoL when compared to sdCRT. Our results support the need for a larger, long-term Phase 3 study in LA HPVOPC to assess these two treatments with respect to survival, QoL, and safety. Clinical trial information: NCT02945631. Research Sponsor: None.

Evaluating a clinically validated circulating tumor HPV DNA assay in saliva as a proximal biomarker in HPV+ oropharyngeal squamous cell carcinoma. *First Author: Sophie P. Gerndt, Washington University School of Medicine, St. Louis, MO*

Background: HPV genomic DNA in plasma and saliva has been widely studied, however more recently, circulating tumor human papillomavirus DNA (ctHPVDNA) has emerged as a reliable biomarker for surveillance in HPV+ oropharyngeal squamous cell carcinoma (OPSCC). A commercial assay for this biomarker distinguishes tumor-derived viral DNA (tumor-tissue modified viral DNA or TTMV) from other non-cancer associated sources of HPV DNA. The use of this technology has been previously described in plasma, but its utility in saliva is currently unknown. **Methods:** A prospectively collected and banked biospecimen repository was used to identify 46 patients with HPV+ OPSCC with paired pre treatment plasma and saliva samples. All samples were assessed for DNA integrity and TTMV using a clinically validated ddPCR-based assay (NavDx™; Naveris Inc, Natick, MA) to measure TTMV for HPV-16, -18, -31, -33 and -35 from frozen plasma and saliva samples. Retrospective chart review was performed to collect clinical and pathological data. Graphpad was used for statistical analysis. Spearman's r was used to correlate TTMV copies in saliva and plasma. Wilcoxon test was used to compare between sample types. Mann-Whitney test was used for categorical variables. **Results:** TTMV DNA was detectable in 43 of 46 plasma samples and in 44 of 46 saliva samples. One plasma sample failed quality control measures, one of each sample type had undetectable TTMV, and one of each type was indeterminate. Of 41 evaluable patients with paired samples, there were 38 (93%) males, 36 (88%) were stage I-II, 5 (12%) were stage III-IV (AJCC 8th, clinical staging), and 25 (61%) had a history of smoking with a median of 37.5 pack years. TTMV was significantly enriched in saliva compared to plasma ($p<0.0001$), with median copy number 14,139 copies/ml (IQR=193,339.5) and 774.7 copies/ml (IQR=4,826.1), respectively. There was a significant positive correlation between plasma and saliva TTMV levels (r=0.344, p=0.028). There was no difference in overall stage for either specimen type. There was a trend in both sample types toward higher TTMV in patients with a history of smoking. Pack-year history was available for 38 (93%) patients in the final cohort. When grouping by pack-years, plasma TTMV approached significance (p=0.058) while high saliva TTMV was significantly associated with >10 pack-year history (p=0.011). **Conclusions:** This is the first study to demonstrate successful quantification of tumor-tissue modified HPV DNA in saliva. Compared to plasma, pre treatment saliva samples demonstrated significantly higher levels of TTMV. TTMV distinguishes ctHPVDNA from other sources of HPV. These data highlight the potential use of TTMV detection in saliva for early detection of HPV+ OPSCC as well as its potential role in local surveillance after treatment. More research is needed to elucidate the effects of smoking on TTMV levels. Research Sponsor: Naveris Inc.

Quantitative immunofluorescence and mRNA analysis of immune-related biomarker groups in matched paired tumor samples from OPHELIA window study in head and neck squamous cell carcinoma (HNSCC). *First Author: Amanda Psyrri, National Kapodistrian University of Athens, Attikon Hospital, Athens, Greece*

Background: Preclinical models suggest that PARP inhibitor-induced DNA damage can promote immune priming through a range of mechanisms including STING pathway activation. PARP inhibition also leads to adaptive upregulation of PD-L1 expression in preclinical models. To understand the distinct effects that different forms of DDR defects may have on tumor immunogenicity we decided to integrate genomic profiling with gene expression profiling and immunohistochemistry (IHC)/fluorescent assessments of PD-L1 expression, CD8 T-cell infiltration, and broad immune infiltrate, in order to define the overlap between DDR and immune-related biomarker groups and to build a deeper understanding of how DNA damage interfaces with antitumor immunity. **Methods:** 39 patients were enrolled in OPHELIA phase II trial in which pts were randomized 3:3:3:1 to Cisplatin (C) 60 mg/m2 on d1 followed by Olaparib (O) 75mg d 1-5 (Arm A), O 300 mg bid for 21-28 days (Arm B), no treatment (ARM C) or D 1500 mg on d1 followed by O 600 mg daily for 21-28 days (Arm D). PD-L1, STING, Ki67 and γ-H2AX were assessed using quantitative immunofluorescence (QIF). The GeneXpert (GX) closed system real-time quantitative reverse transcription polymerase chain reaction (RT-qPCR) was used for quantitative assessment of CD274 (PD-L1), PDCD1LG2 (PD-L2), CD8A, and IRF1 multiplex mRNA panel in pre- and post-treatment samples. **Results:** Ki67 was decreased in 23 out of 29 (79.3%) available samples when assessed by QIF; 13 / 23 had a decrease of at least 25%. $\Delta\gamma$-H2AX did not differ among treatment groups. A significant increase was observed in PD-L1 and PD-L2 mRNA levels after treatment with D-O ($p = 0.023$ and $p = 0.016$, respectively). An increase trend in posttreatment CD8A mRNA was observed in 23 out of 29 cases in the three treatment arms ($p = 0.21$, ARM A; $p = 0.082$, ARM B; $p = 0.16$, ARM D). IRF1 mRNA and STING protein levels were not upregulated after olaparib- based treatment in the available paired treatment samples. **Conclusions:** This window study demonstrated a significant upregulation of PD-L1 mRNA, corresponding to our previous data of increased Combined Positive Score (CPS) in the D-O arm post-treatment. Our findings suggest that addition of D to O leads to PD-L1 upregulation. Dual blockade of PARP and PD-1 can boost immune response and antitumor activity in HNSCC. Clinical trial information: NCT02882308. Research Sponsor: Astrazeneca.

Cisplatin and capecitabine induction chemotherapy in nasopharyngeal carcinoma. *First Author: Zhiyuan Xu, Department of Clinical Oncology,The University of Hong Kong-Shenzhen Hospital,Shenzhen,China, Shenzhen, China*

Background: Induction chemotherapy (IC) followed by concurrent chemoradiotherapy (CCRT) is now one of the standard treatment for locally advanced nasopharyngeal carcinoma (LANPC). Cisplatin/fluorouracil is one of the recommended IC regimens. Capecitabine is an oral fluoropyrimidine prodrug with higher concentrations of fluorouracil attained in the tumor cells after enzymatic conversions. We conducted this study to evaluate the feasibility, efficacy and safety of cisplatin and capecitabine (PX) IC followed by CCRT in LANPC. **Methods:** Newly diagnosed patients with LANPC (stage III-IVB according to 7th edition of AJCC/UICC system [TNM-7] and stage III-IVA according to 8th edition [TNM-8) were prospectively recruited from January 2015 to October 2019. They received induction PX (cisplatin: 80mg/m2 on day 1 + capecitabine: 1000mg/m2 twice daily from day 1 to 14 every 3 weeks for 3 cycles) followed by CCRT (cisplatin: 100mg/m2 every 3 weeks for a total of 2-3 cycles concurrent with intensity-modulated radiation therapy [IMRT]). IMRT with doses of 70Gy, 63Gy and 56Gy were delivered to 3 levels of planning target volumes (PTV) (high, intermediate and low risk) respectively and simultaneously in 35 fractions/7 weeks. Tumor response by MRI and CT was evaluated after completion of IC and 16 weeks after completion of CCRT according to RECIST v1.1. All adverse events were graded with NCI CTCAE v4.03. **Results:** One hundred and forty-five patients were recruited. The stage distributions according to TNM-8 were 82(56.6%) and 63(43.3%) for stage III and IVA, respectively. One hundred and thirty-seven patients completed 3 cycles of induction PX and 122 patients completed IMRT with 2 to 3 cycles of concurrent cisplatin. The median (interquartile range, IQR) tumor regression rates after 2-3 cycles of PX at the nasopharynx (NP) and the neck region (NK) were 51.2% (37.3%-66.5%) and 71.8% (56.7%-81.1%), respectively. At 16 weeks after CCRT, only one patient had residual disease. After a median follow-up of 33 months, 20 treatment failures and 8 deaths were observed. The estimated 2-year progression-free survival (PFS) and overall survival (OS) were 89.8% and 97.2%. The rates of grade 3/4 leukopenia, neutropenia, anemia, nausea/vomiting and electrolyte disturbance during IC were 6.2%, 15.9%, 6.9%, 4.1% and 9.0%, respectively. The corresponding rates were 45.1%, 24.6%, 27.5%, 2.8% and 11.3% during CCRT. Only 1 (0.7%) grade 3/4 hand-foot syndrome and 3 (2.1%) grade 3/4 diarrhea during IC were observed. The rates of grade 3/4 mucositis and dermatitis were 31.0% and 12.7%, respectively. There were no treatment-related deaths. **Conclusions:** Induction PX followed by CCRT was effective and well tolerated in patients with LANPC. Clinical trial information: NCT03427359. Research Sponsor: Shenzhen Key Medical Discipline Construction Fund (No. SZXK014) and Shenzhen Science and Technology program (Grant No: KQTD20180411185028798).

6066 **Poster Session**

The SINTART 1 study: A phase II trial of induction chemotherapy (IC), surgery, photon-, proton-and carbon ion-based radiotherapy (RT) integration in locally advanced operable sinonasal epithelial tumors patients (pts). *First Author: Carlo Resteghini, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Sinonasal epithelial tumors are rare diseases with several histotypes and poor prognosis. Multimodal approach including surgery is widely used, although no standard therapy has been established in prospective trials. This study assessed activity and safety of an innovative integration of multimodality treatment - IC, surgery and RT - modulated by histology, molecular profile and response to IC. **Methods:** Pts with untreated, operable squamous cell carcinoma (SCC), p53 wild type intestinal type adenocarcinoma (ITAC), sinonasal undifferentiated and neuroendocrine carcinoma (SNUC, SNEC) were enrolled in a single-arm, phase II, multicenter clinical trial from 2014 to 2018. Pts was treated with up to 5 IC cycles, whose regimen was selected according to histotype, followed either by curative radio-chemotherapy (CRT) (pts with ≥80% reduction of initial tumor volume (TV)) or surgery and adjuvant (C)RT. Photon and/or proton/carbon ion-based RT was employed according to disease site and stage. Primary endpoint was 5 years PFS, secondary endpoints were OS, IC ORR per RECIST 1.1 and safety. **Results:** Out of 39 enrolled pts, 35 pts were evaluable for primary endpoint. Two pts were only considered for safety analyses because definitive diagnosis on surgical specimen did not meet the study entry criteria; other two pts were screening failure due to inoperable disease. Five-year PFS was 38% (95% CI, 21 – 69), with a median PFS of 26 months. Five-year OS was 46% (95% CI, 28 – 75), with a median OS of 36 months. Responses to IC are reported in table. Globally, 15 pts avoided surgery. Overall treatment safety was in line with multimodality intensive head and neck cancer treatments (5% of pts with G3-4 adverse event during IC). One sudden cardiac death was recorded. At a median follow up of 27 months, 5 G3-4 RT related late adverse events have been recorded (1 G3 neurotoxicity, 2 G3 hearing impairment, 2 G3 xerostomia). Three-year PFS - OS for pts achieving PR/CR vs SD/PD to IC were 49.8% - 56.7% vs 43.2% - 53%, respectively. **Conclusions:** Treatment of advanced SNC with histology-driven IC followed by locoregional therapy tailored to response to IC was safe and showed survival rate similar to surgery containing case series. In the first prospective study, a surgery sparing multimodal approach proved feasible and effective in IC responsive pts. Clinical trial information: NCT02099175. Research Sponsor: Supported by Fondazione Regionale per la Ricerca Biomedica.

Comparative assessment of the eighth and seventh AJCC staging edition prognostic performance of patients with p16 positive oropharynx cancer. *First Author: Felippe Lazar Neto, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The American Joint Committee on Cancer (AJCC) TNM staging system defines the anatomical extent of disease and serves as a guide for treatment and prognosis. The favorable prognosis of p16+ oropharyngeal squamous cell carcinoma (OPSCC) compared to p16 negative counterpart led to major updates in the AJCC 8th edition. Its prognostic performance, however, warrants further validation. **Methods:** We included patients diagnosed with p16+ OPSCC enrolled in a prospective registry (*Stiefel*) at The University of Texas MD Anderson Cancer Center between March 2015 and December 2018. Patients' stage at diagnosis was classified according to the AJCC 7th (AJCC-7) and 8th (AJCC-8) editions. Overall survival (OS) and progression-free survival (PFS) was defined as time from diagnosis to death or to progression or death, respectively. The Kaplan-Meier method was used to calculate 1- and 3-year survival probabilities. Differences between groups were compared using the log-rank test. Prognostic discriminative performance of each staging system was evaluated using Harrel's C-statistic. Survival differences between heavy ($>$ 10 pack-years [PY]) vs. light/never smokers ($\leq$ 10 PY) by AJCC-8 staging groups was assessed with the log-rank test. **Results:** Of 463 patients, the median follow-up was 34.7 months (2.3-169.74). Nearly 90% (N=413) of patients were down-staged from AJCC-7 to AJCC-8 with 69% of patients with IVA disease based on AJCC-7 (N=319) re-staged as stage I (N=196 [42%]), II (N=79 [17%]) or III (44 [10%]) according to AJCC-8. Over 60% (N=279) of patients were staged as I with AJCC-8. Compared to AJCC-7, AJCC-8 had improved prognostic ability (C-statistic, 0.58 for AJCC-7 vs. 0.63 for AJCC-8) and provided better discriminative survival probabilities at 1 and 3-year follow-up (Table). Similar results were observed for PFS. Smoking status did not impact OS when stratified by AJCC-8 staging groups: I, p=0.347; II, p=0.310; and III, p=0.532 for $>$ 10 vs. $\leq$ 10 PY. **Conclusions:** Our cohort validates that the AJCC-8 provides better prognostic discriminative performance when compared to AJCC-7, however, a disproportionate number of patients were classified as stage I. Smoking was not associated with survival within each staging group. Research Sponsor: Stiefel Oropharyngeal Research Fund.

Survival probabilities at 1- and 3-years follow-up according to the AJCC 7th and 8th edition staging systems.

AJCC	Staging	No. Total	No. Events	1-Year (95%CI)	3-Year (95% CI)	Log-rank

Pathologic and radiographic responses in a window of opportunity for durvalumab plus metformin trial for squamous cell carcinoma of the head and neck (HNSCC). *First Author: Joseph M. Curry, Department of Otolaryngology, Thomas Jefferson University, Philadelphia, PA*

Background: Durvalumab is a human monoclonal IgG1 antibody directed against programmed death-ligand 1 (PD-L1). PD-1/PD-L1 immune checkpoint inhibition (ICI) shows promise in HNSCC, but durable responses have been seen in only a fraction of patients. Metformin, a biguanide oral anti-hyperglycemic, has shown promise in altering immunity within the tumor microenvironment (TME) towards a stronger anti-tumor distribution of immune cells. We aimed to investigate the combined effect of metformin and durvalumab in patients with HNSCC. **Methods**: This was a single-center prospective phase 1, window of opportunity clinical trial in which previously untreated patients with any stage resectable HNSCC were randomized 3:1 to durvalumab + metformin (Arm A) or durvalumab alone (Arm B) during a four-week period between diagnosis and surgical resection. Six patients were included in a safety lead-in of durvalumab and metformin and an additional 32 patients were randomized. The primary endpoint was immune cell polarization. Here we report pathologic and radiographic effect. Pathologic effect was graded independently by two pathologists. Radiographic effect was evaluated using the immune-related Response Criteria (irRC). **Results**: Thirty-eight patients were enrolled (29 Arm A, 9 Arm B). Three patients withdrew consent prior to intervention (2 Arm A, 1 Arm B) and were excluded from analysis. AJCC 8th edition staging was as follows: Stage I (n = 21), Stage II (n = 2), Stage III (n = 3), Stage IVa (n = 6), Stage IVb (n = 3). Primary tumor sites included the oropharynx (n = 20, all p16+), oral cavity (n = 11), larynx (n = 2), maxillary sinus (n = 1), and unknown (n = 1). Pathologic effect was observed in 55% (18/33) of evaluable patients: 60% in Arm A vs 37.5% in Arm B (p = 0.418). 40% of patients with involved lymph nodes had discordance of pathologic effect at the primary site versus lymph node. Radiographic response based on irRC among 30 evaluable patients included 1 CR, 1 PR, 24 SD, and 4 PD. There was a significant correlation between pathologic effect and radiographic disease control, defined as CR, PR, and SD (p = 0.021), but no correlation when looking only at radiographic responders (p = 0.925). No patients experienced Grade 3–4 treatment or immune-related adverse events or a delay in surgery due to trial participation. All patients remained resectable. **Conclusions**: Our data demonstrate that the study intervention was well-tolerated in HNSCC patients. There was a trend towards an increased proportion of pathologic responders in the group receiving metformin. Additional studies targeting the TME are needed to further elucidate whether synergistic effects between metformin and durvalumab were seen in this patient cohort. Clinical trial information: NCT03618654. Research Sponsor: Astra Zeneca.

The efficacy and safety of anlotinib in neoadjuvant treatment in locally advanced thyroid cancer: A single-arm phase II clinical trial. *First Author: Naisi Huang, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Surgery is the primary treatment for locally advanced thyroid cancer (TC). For some locally advanced TC, R0/R1 resection could not be achieved at initial diagnosis and neoadjuvant treatment would be an option. However, there is still little evidence regarding neoadjuvant treatment in locally advanced TC. **Methods:** This single-arm, phase 2 study investigated the efficacy and safety of Anlotinib (12mg orally daily, for two weeks on/on week off) for 2-6 cycles in patients with locally advanced TC in the neoadjuvant setting. Operable patients received surgery after neoadjuvant treatment. The primary endpoint was objective response rate (ORR). **Results:** A total of 13 patients were included and received an average of 3.5 cycles (range: 3-6 cycles) of Anlotinib treatment. 12 cases were papillary thyroid cancer, and 1 was follicular thyroid cancer. The ORR of Anlotinib was 76.9% with 10 partial response (PR), 2 stable disease (SD), and 1 progressive disease (PD). 8 PR and 1 SD patients received surgery after neoadjuvant treatment, of whom 8 had R0/1 resections and 1 had R2 resection. 2 PR patients refused to have surgery and the rest 2 patients were not operable. The R0/1 resection rate for intent to treat population was 61.5% and for per-protocol population was 72.7%. The maximum reduction in sum of tumor diameter was an average of 34.8% (range: 30.9%-45.5%) for PR patients. Most adverse events were grade 1 or 2. Common adverse events of all grade were hypertension (76.9%), hypertriglyceridemia (69.2%), proteinuria (53.8%), TSH increase (53.8%), cholesterol elevation (53.8%) and hand-foot syndrome (38.5%). The majority of adverse events discontinued after the neoadjuvant treatment stopped. **Conclusions:** Anlotinib demonstrated antitumor activity in the neoadjuvant treatment in locally advanced TC and the majority of patients achieved R0/1 resection. Adverse events were consistent with the known Anlotinib adverse event profile. These results suggest that Anlotinib neoadjuvant treatment represents a new option for locally advanced TC. Clinical trial information: NCT04309136. Research Sponsor: CHIA TAI TIANQING PHARMACEUTICAL GROUP CO., LTD.

Planned drug holiday in a cohort study exploring the effect of lenvatinib on differentiated thyroid cancer. *First Author: Makoto Tahara, Department of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Lenvatinib is now available for unresectable radioactive iodine (RAI)-refractory differentiated thyroid cancer (DTC). However, toxicities are considerable and require frequent dose interruption and modification. Recently, planned drug holidays, which are dose interruptions in accordance with the timing of severe or intolerable adverse events, have been proposed to avoid severe adverse events due to lenvatinib (Tahara M.ESMO Open 2018). Our retrospective study demonstrated that progression-free survival (PFS) and overall survival (OS) were significantly longer in patients who used planned drug holidays than those who did not (Matsuyama C et.al, 2020 Annual Meeting of the Japan Association of Endocrine Surgeons). **Methods:** In this prospective observational study, patients with curatively unresectable and progressive RAI-refractory DTC were treated with lenvatinib in a real-world clinical setting. Lenvatinib was administered orally at a dose of 24 mg daily. Dose modification for toxicities were permitted. Primary endpoint was OS, and secondary endpoints were time to treatment failure (TTF), time to failure of strategy (TFS), PFS with clinical progressive disease, response rate, quality of life, safety, and patient reports. This study was registered with UMIN Clinical Trials Registry (UMIN000022243). **Results:** 262 patients were accrued. Of 255 evaluable, 153 were female; median age was 70 (range 27.0-88.0); histology was papillary thyroid carcinoma/follicular thyroid carcinoma/poorly DTC in 204/45/4; previous therapy was surgery/RAI/molecular targeted drug in 246/164/14; reason for initiation of lenvatinib was disease progression/unsuitable for RAI in 241/4. 1-year OS was 85.6% (95%CI: 80.6-89.4%); 1-year TTF rate was 74.9% (95%CI: 69.1-79.8%); 1-year TFS rate was 80.8% (95%CI: 75.4-85.2%); and 1-year PFS rate was 84.4% (95%CI: 79.3-88.4%). Overall response by RECIST was 3 (1.2%) in CR and 151 (61.9%) in PR. Most common grade 3 or 4 toxicities were hypertension (61.4%), hand foot syndrome (10.2%), fatigue (9.1%), anorexia (8.3%) and diarrhea (4.7%). Grade 5 toxicities occurred in 4 patients (fistula, hypoxia, respiratory failure, trachea stenosis). Of 253 patients evaluable for efficacy, 73 used planned drug holidays. TTF, TFS and PFS were significantly longer in patients who used planned drug holiday than those who did not (Table). **Conclusions:** Planned drug holiday for lenvatinib demonstrated significantly better clinical outcomes, including TTF, TFS and PFS, than daily oral administration. These data further support use of a planned drug holiday in RAI-refractory DTC patients receiving lenvatinib. Clinical trial information: 000022243. Research Sponsor: Eisai Co., Ltd.

Planned drug holiday	1-year TTF (95%CI)	1-year TFS (95%CI)	1-year PFS (95%CI)
yes (n = 73)	87.6% (77.6-93.4)	84.9% (74.4-91.3)	94.5% (86.1-97.9)
no (n = 180)	69.8% (62.4-75.9)	65.0% (57.5-71.5)	83.5% (77.2-88.3)

6071 **Poster Session**

Predictive and prognostic biomarker identification in a large cohort of androgen receptor-positive salivary duct carcinoma patients scheduled for combined androgen blockade. *First Author: Gerben Lassche, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Patients suffering from recurrent or metastatic (R/M) salivary duct carcinoma (SDC) are often treated with combined androgen blockade (CAB). This treatment however frequently fails (response rates: 18-53%), resulting in a worse prognosis. Therefore, biomarkers that have prognostic value and can predict treatment response are urgently needed. **Methods:** mRNA from 77 R/M androgen receptor (AR) positive SDC patients treated with leuprorelin acetate combined with bicalutamide was extracted from pre-treatment tumor specimens. AR, Notch, Mitogen-Activated Protein Kinase (MAPK), Transforming Growth Factor beta (TGFβ), Estrogen Receptor (ER), Hedgehog (HH) and the Phosphoinositide 3-Kinase (PI3K) signaling pathway activities were calculated based on expression levels of relevant target genes. Besides this, 5-alpha reductase type 1 (*SRD5A1*) expression and Human Epidermal growth factor Receptor 2 (HER2) status were determined. Clinical benefit was defined as complete or partial response or stable disease $\geq$6 months. **Results:** Of the 7 signaling pathways, AR pathway activity was the best predictor of clinical benefit (AUC 0.67, 95%-CI 0.54-0.80). At a threshold of 47.8, 21% of the patients tested negative, with a negative predictive value of 93%. *SRD5A1* expression outperformed the signaling pathways regarding predictive value (AUC 0.78, 95%-CI 0.67-0.88). Fitting of a multivariable model led to the identification of *SRD5A1*, Notch and TGFβ as most predictive combination (AUC 0.82, 95%-CI 0.72-0.91). AR, Notch, HH and *SRD5A1* were also of prognostic importance regarding progression free survival and *SRD5A1* expression levels also for overall survival (median of 175.0 weeks for high versus 96.7 weeks for low expression). **Conclusions:** Our study revealed predictive and/or prognostic value of AR, HH, Notch and TGFβ signaling activities and *SRD5A1* expression in SDC patients treated with CAB. AR pathway activity can be used for identifying non-responders. Further clinical validation is required before implementation of these biomarkers in clinical practice. The observed role of *SRD5A1* expression in CAB response forms a rational basis for including SRD5A1-inhibitors in the treatment of SDC patients. Research Sponsor: None.

Pathway (mean [range])	Clinical benefit[1]	No clinical benefit[1]	Difference
AR	57.5 [31.7-71.9]	52.2 [29.6-71.9]	p = 0.013

Clinical disease course and survival outcomes following disease recurrence in adenoid cystic carcinoma (ACC) with NOTCH signaling pathway activation. *First Author: Brindley Sonal Hapuarachi, Weston Park Hospital, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*

Background: ACC is a rare salivary cancer for which effective drug therapies remain lacking. The highest rates of disease recurrence are in patients with NOTCH pathway activation, which is reported in 10-20% of ACC tumors. Novel drugs targeting NOTCH signaling are under investigation in the recurrent and metastatic setting. To understand their clinical utility, there is an urgent need to better characterize the disease course and outcomes following current standard of care treatment from diagnosis and following recurrence. **Methods:** 120 patients with ACC underwent clinical review at a single UK Cancer Centre from 2017-19. Patients were retrospectively assessed for tumor NOTCH pathway activation using next generation sequencing (NGS) targeting *NOTCH1/2/3* genes (n = 98) and/or by immunohistochemistry (IHC) for the NOTCH1 intra-cellular domain (NICD1) (n = 87). To understand the disease course with NOTCH pathway activation, treatment data including surgery, radiotherapy and systemic therapies were extracted and presented as swimmer plots. Kaplan-Meier survival analysis was performed and a difference in survival with/without NOTCH activation was calculated with log rank test. Overall survival (OS) was calculated both from diagnosis and from first confirmed disease recurrence or metastasis, and recurrence free survival (RFS) calculated from diagnosis. **Results:** Of 120 patients, median age was 46 years (22-74 years). 114/120 patients (95%) had confirmed disease recurrence at clinical review. The primary site was major salivary gland in 58/120 (48%), the others were minor salivary. NOTCH1/3 activating somatic mutations were identified in 11% by NGS (11/98) and NICD1 diffuse nuclear staining was seen in 6% by IHC (5/87) for overall NOTCH activation in 11% (13/120). In NOTCH activated ACC, primary site was major salivary gland in 7/13 (54%), and non-pulmonary visceral/bone metastases were present in 6/13 (46%). Consistent with other reports, patients with NOTCH activation (n = 13) had shorter RFS (0.9 vs 3.6 years, p = 0.11) and significantly reduced OS from diagnosis (4.0 vs 16.3 years, $p < 0.0001$). Critically, as therapies targeting NOTCH signaling are being evaluated in recurrent/metastatic ACC, there was significantly reduced OS from time of first confirmed disease recurrence or metastasis (1.5 vs 9.6 years, $p < 0.0001$). This reduction in OS for NOTCH activation following recurrence was seen consistently whether patients were classified using NGS (1.9 vs 9.6 years, p = 0.0009) or NICD1 IHC (0.8 vs 8.5 years, $p < 0.0001$). **Conclusions:** This is the first study to report clinical outcomes for patients with NOTCH pathway activated ACC following disease recurrence. Although ACC is frequently considered an indolent disease, the short survival in this sub-group of ACC patients demonstrates the urgent need to develop effective drug therapies in this setting. Research Sponsor: The Ella Project (The Christie Charity), The Infrastructure Industry Foundation and Syncona Foundation, Pharmaceutical/Biotech Company.

Selpercatinib efficacy and safety in patients with *RET*-altered thyroid cancer: A clinical trial update. *First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Selpercatinib, is a first-in-class, highly selective, CNS active and potent RET inhibitor approved in multiple countries for treatment of *RET*-fusion positive lung or thyroid cancers. Reported is an update of efficacy and safety results in *RET*-altered thyroid cancer, with a longer follow up (30 Mar 2020 data cutoff vs 16 Dec 2019) and additional enrolment. **Methods:** Patients (pts) with *RET*-mutant medullary thyroid cancer (MTC) and *RET*-fusion positive thyroid cancer (TC) were enrolled in the global (16 countries, 89 sites) Phase 1/2 LIBRETTO-001 trial (NCT03157128). The primary endpoint was objective response rate (ORR) per RECIST 1.1 by independent review committee (IRC). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), clinical benefit rate (CBR; CR+PR+SD $\geq$16 weeks), and safety. The integrated analysis set (IAS, n = 143) includes efficacy evaluable MTC pts previously treated with cabozantinib and/or vandetanib (cabo/vande). The primary analysis set (PAS), a subset of IAS, is the first 55 enrolled pts. Cabo/vande naïve MTC pts (N = 112) and TC pts with prior systemic treatment (N = 22) were also analyzed. Safety population includes all pts who received $\geq$1 dose of selpercatinib (MTC N = 315; TC N = 42) by data cutoff. **Results:** For MTC patients, the ORR for IAS was 69.2%, in the PAS it was 69.1%, and 71.4% for cabo/vande naïve MTC pts. The ORR for TC pts (n = 22) was 77.3% (see table). Most treatment-emergent adverse events (TEAEs) were low grade; the most common ($\geq$25% of MTC and/or TC pts treated with selpercatinib) were dry mouth, diarrhea, hypertension, fatigue and constipation for both MTC and TC pts, increased ALT/AST, peripheral edema and headache in MTC pts and nausea in TC pts. 4.8% of MTC and TC pts discontinued selpercatinib due to TEAEs but only 1.9% with MTC and none with TC discontinued due to treatment-related adverse events. **Conclusions:** In this updated analysis, selpercatinib continued to show marked and durable antitumor activity in pts with *RET*-altered thyroid cancers. Selpercatinib was well tolerated and no new safety concerns were identified. A global, randomized, phase 3 trial (LIBRETTO-531) evaluating selpercatinib compared to cabo/vande in kinase inhibitor naïve MTC pts is ongoing. Clinical trial information: NCT03157128. Research Sponsor: Eli Lilly and Company.

	PAS (n = 55)	IAS (n = 143)	Cabo/Vande naive (n = 112)	RET-Fusion TC (n = 22)
ORR % (95% CI)	69.1 (55.2, 80.9)	69.2 (61.0, 76.7)	71.4 (62.1, 79.6)	77.3 (54.6, 92.2)
CBR % (95% CI)	92.7 (82.4, 98.0)	90.9 (85.0, 95.1)	93.8 (87.5, 97.5)	100.0 (84.6, 100.0)

Efficacy of selpercatinib after prior systemic therapy in patients with *RET* mutant medullary thyroid cancer. *First Author: Lori J. Wirth, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Selpercatinib is a first-in-class, CNS active, highly selective, and potent RET kinase inhibitor which has demonstrated durable antitumor activity in patients (pts) with *RET* altered thyroid cancer and is approved in multiple countries for the treatment of *RET* fusion+ lung or thyroid cancers. As response rates to cancer therapy usually decline on subsequent lines of therapy, the efficacy of selpercatinib was examined in the context of the last prior therapy received before trial enrollment. **Methods:** Pts with *RET* mutant medullary thyroid cancer (MTC) previously treated with multikinase inhibitors (cabozantinib and/or vandetanib) were enrolled in the global LIBRETTO-001 trial (NCT03157128). This post-hoc exploratory intrapatient analysis, based on March 30, 2020 data cutoff date, was performed to compare the retrospective physician-reported objective response rate (ORR) from the last systemic therapy prior to enrollment, as reported in pts case reports, to ORR by independent review committee per RECIST 1.1 with selpercatinib treatment, with each patient serving as his/her own control. **Results:** Efficacy-evaluable pts, 64% male, 90% white with a median age of 58 years, received prior therapy for MTC (n = 143). Pts had a median of 2 (range 1-8) prior systemic regimens. The ORR on selpercatinib (69%) was markedly higher than for the last prior therapy (10%) received before enrollment. ORR improvements with selpercatinib were observed regardless of prior therapy: cabozantinib (66% vs 14%) or vandetanib (71% vs 12%). Fewer pts had progressive disease as their best overall response with selpercatinib (2/143; 1.4%) compared to last prior therapy (33/143; 23.1%). Notably selpercatinib achieved 62% ORR in pts that did not respond to their previous line of therapy prior to enrolment. This shift from non-responder to responder on selpercatinib therapy was consistent regardless of prior cabozantinib or vandetanib treatment, where pts achieved 57% and 61% ORR respectively when subsequently treated with selpercatinib. In contrast, only 3% of patients did not respond to selpercatinib after a previous response to the immediate prior therapy. Similarly, 5% and 2% of patients were non-responders on selpercatinib after a prior response with cabozantinib and vandetanib therapy respectively. **Conclusions:** Prior to selpercatinib, response with previous multikinase therapy was rare. By contrast, selpercatinib demonstrated robust efficacy regardless of response to or specific prior therapy in pts with *RET* mutant MTC. Clinical trial information: NCT03157128. Research Sponsor: Eli Lilly and Company.

6075 **Poster Session**

Phase Ib, international, dose-escalation study to evaluate the safety, pharmacokinetics (PK) and efficacy of ST-617 for the attenuation of oral mucositis (OM) in patients receiving chemoradiation (CRT) for head and neck (H&N) cancer. *First Author: Daniel Osei-Fofie, Oncology Dept, Kimberley Hospital, Kimberley, South Africa*

Background: OM is a common, painful, and costly toxicity associated with cytotoxic regimens used to treat H&N cancers, which may result in radiotherapy treatment interruptions to negatively impact tumor control. There are currently no approved interventions to successfully prevent or delay OM onset among patients being treated with radiation therapy, with or without concomitant chemotherapy (CRT). Oxidative stress is a critical event in OM's pathogenesis. Through its effect on Nrf2, ST-617 has marked anti-oxidative activity/properties. Supportive Therapeutics is developing ST-617, a dithioethione, for the attenuation of OM onset, duration and severity. The objective of this trial was to assess the safety, tolerability, PK, PD and efficacy of ST-617 in patients at high risk of severe OM (SOM). **Methods:** A dose escalation trial in which ST-617 administered as an oral suspension, 1-2 hours before the administration of daily RT fractions was performed at 9 study sites in South Africa and Australia. Eighteen patients with diagnoses of oral or oropharyngeal CA were enrolled (up to 6 pts/dose). Patients received concomitant cisplatin either weekly or tri-weekly. ST-617 was administered 3 days prior to CRT, and then continuing daily until the end of treatment. Safety outcomes, using CTCAE criteria (v 4.03) were used. Dose escalation occurred in the absence of toxicity. OM occurrence and severity were assessed by trained and validated evaluators using WHO, NCI-CTC and RTOG criteria; scores were centrally assigned. The primary efficacy endpoints included the incidence and duration of SOM (WHO grades 3 or 4) vs historical controls. PD tracking measured total ROS/RNS, GSH/GSSG, regulation in plasma and buccal epithelial cells. **Results:** 17 pts completed the 50, 100 and 150mg/day with no safety issues. No early dose limiting toxicity (DLT) or serious Adverse Event linked to ST-617 were observed. AEs observed were mainly nausea which is usually associated with CRT as expected. The 100 mg/day dose has been well tolerated with no grade 4 OM. No CRT dose interruptions or delays due to OM has been observed. Total ROS/RNS levels in plasma and buccal samples show significant decrease with increased ST-617 dosing from 50 to 100 mg/day. **Conclusions:** ST-617 administration was safe at all doses tested. The course and severity of patients treated with ST-617 compared favorably with historical controls. Mechanistic correlation between ROS/RNS levels was seen. A randomized, controlled, double blind trial is planned with the recommended dose of 100mg/day. Clinical trial information: 20180138. Research Sponsor: None.

Randomized phase II study of sorafenib with or without everolimus in patients with radioactive iodine refractory Hürthle cell thyroid cancer (HCC) (Alliance A091302/ ITOG 1706). *First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: HCC is a rare subtype of follicular cell thyroid cancer that has been poorly studied in the past. Recent genomic studies have shown the PI3K/Akt/mTOR pathway is frequently altered in HCC. In addition, a phase II study of sorafenib (S) and everolimus (E) showed promising data in HCC. A study to evaluate this was initiated through Alliance and the International Thyroid Oncology Group. **Methods:** Patients (pts) were randomized to either sorafenib and everolimus (SE) vs. sorafenib alone (S). Inclusion criteria included; (1) diagnosis of HCC (confirmed through central review), no prior S or E, refractory to radioactive iodine, progressive disease by RECIST over prior 14 months. Primary endpoint was a comparison of progression-free survival (PFS) between SE and S using a stratified 1-sided log-rank test with 0.20 significance level and a power of 80%. 28 events were needed at final analysis. Secondary endpoints consisted of overall survival (OS), confirmed response rate (RR), and adverse events. **Results:** 35 pts were randomized from 10/2014 to 9/2019, 34 of which were evaluable for analysis (17-SE; 17-S) because 1 patient cancelled prior to receiving treatment. Median age was 66.5 years and 74% were male. ECOG performance status (PS) was 0 (47%) and PS 1 (53%). 41% had prior systemic treatment for HCC. No significant differences in baseline characteristics were observed between treatment arms. Median follow-up in 22 alive patients was 39.2 months (range: 15.1-64.9). Seven (21%) patients remain on treatment. PFS was significantly improved in the SE arm as compared to the S arm (HR=0.65 (95% CI: 0.26, 1.57); median PFS: SE=24.7 months (95% CI: 6.1-no upper), S=10.9 months (95% CI: 5.5-no upper); stratified 1-sided p=0.1662). OS was similar between the arms (2-sided p=0.4138). Confirmed response rate was similar between arms as well (SE: 18% (3 partial response (PR) vs. S: 24% (3 PR, 1 complete response)); Fisher's exact p=1.00). Grade 3 adverse event (AE) rates (regardless of attribution) were similar between arms (SE: 77% vs. S: 77%; p=1.00). Each arm had 1 patient with at least one grade 4 AE (SE patient: cardiac arrest, tracheal obstruction, encephalopathy; S patient: mucositis oral) and no grade 5 AEs. **Conclusions:** PFS was improved with the addition of E to S in this small randomized multi-institutional phase II study done. Accrual was difficult, but these promising results suggest that this combination should be further studied. Support: U10CA180821, U10CA180882, U24CA196171; https://acknowledgments.alliancefound.org; Novartis/GSK; ClinicalTrials.gov Identifier: NCT02143726. Clinical trial information: NCT02143726. Radiomics-based prediction of response to multikinase inhibitors in radioiodine-refractory differentiated thyroid cancer patients. *First Author: Valentina Corino, Department of Electronics, Information and Bioengineering (DEIB), Politecnico di Milano, Milan, Italy*

Background: Antiangiogenic tyrosine kinase inhibitors (TKIs) represent the first-line treatment for radioiodine-refractory differentiated thyroid cancer (RR-DTC). Currently, no predictive factors for the activity of these drugs are available. We investigated whether radiomics may have a predictive role in this setting. **Methods**: We retrospectively identified patients (pts) affected by metastatic RR-DTC, treated with TKIs between July 2008 and January 2020 at our Institution, with availability of computed tomography (CT) scans at baseline and after at least 2 courses of TKI. Response to TKIs was evaluated according to RECIST v1.1. Pts with complete or partial response at the first radiological evaluation were considered responders (R), pts with stable or progressive disease non-responders (NR). A dedicated radiologist segmented the target lesions as regions of interest (ROIs). Radiomic features related to multiple categories (shape and size, first order statistics, textural features) were extracted from each ROI and computed using the PyRadiomics library v. 3.0. A semi-supervised form of principal component analysis estimated principal components that were then used for response classification through a k nearest neighbors (kNN) classifier. The quality of the model was assessed through train-validation-test split (55% of the data used as training set, 25% as validation set, 20% as test set), repeated 100 times. Performance of the predictive models was quantified with the mean Area Under the ROC Curve (AUC) obtained in the test set. **Results**: A total of 51 pts with metastatic RR-DTC who had received lenvatinib (n=37), sorafenib (n=4), axitinib (n=3), or vandetanib (n=7) were analyzed. Median age was 64.6 years, with a male prevalence (72.5%). Metastatic sites were lung (84.3%), bone (35.3%), brain (9.9%). Median time from TKI treatment start to the first radiological evaluation was 2.77 months, 24 pts (47%) were R (all partial responses) and 27 (52.9%) NR. In the radiomic analysis, 851 features were computed and 4-19 principal components were selected. Models' performance of prediction of early response to TKIs is presented in Table. For each value of AUC, the corresponding 95% confidence interval is reported in brackets. **Conclusions**: Radiomics predicted the response to TKIs of RR-DTC pts with an accuracy of 71%. Radiomics technique has the potential to enable clinicians to anticipate the probability of response to TKIs at baseline, directing toward the most suitable patient-tailored therapeutic path. Prospective studies may further validate these preliminary findings. Research Sponsor: None.

Early response	Accuracy	TPR	TNR	AUC
Validation set	0.85 ± 0.07	0.83 ± 0.11	0.86 ± 0.09	0.85 (0.83 – 0.86)
Test set	0.71 ± 0.18	0.68 ± 0.26	0.73 ± 0.25	0.71 (0.67 – 0.74)

Legend: TPR = true positive rate; TNR = true negative rate; AUC = area under the curve.

A pooled analysis of response to selective RET inhibitors among patients with medullary thyroid cancer with M918T versus non-M918T RET mutations. *First Author: Janice Kim, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Medullary thyroid cancer (MTC) accounts for 1 to 2% of thyroid cancers in the United States; *RET* alterations occur in >95% of hereditary and 50% of sporadic forms. Up to 80% of patients with sporadic MTC have somatic M918T RET mutations, which is associated with poor prognosis (1). The tyrosine kinase inhibitors (TKIs) cabozantinib and vandetanib are approved to treat patients with MTC regardless of *RET* status; however, retrospective analyses have suggested that there may be greater benefit in patients with M918T mutations (1,2). Newly approved therapies selpercatinib and pralsetinib, developed for patients with *RET* mutations, have demonstrated higher response rates than previous first line therapies. In this analysis, we examine the differences in overall response rate (ORR) between patients with MTC with *RET* M918T non-*RET* M918T mutations. **Methods:** An analysis of ORR in patients with MTC with RET M918T mutations with non-M918T mutations was conducted using the efficacy populations used to support the approvals of pralsetinib and selpercatinib using the following groups: Patients who received prior cabozantinib or vandetanib (referred to as "previously treated"). Patients with no prior cabozantinib or vandetanib ("TKI naïve"). All patients regardless of prior therapy. **Results:** Exploratory analysis of ORR of pooled population of Selpercatinib and Pralsetinib in patients with MTC with RET M918T mutations and non-M918T mutations. [1] Prior vandetanib or cabozantinib. [2] No prior vandetanib or cabozantinib. Two groups of patients were analyzed (*RET* M918T mutation and *RET* non-M918T mutation), with subgroups with respect to prior treatment. Among all patients regardless of prior therapy, the ORR was similar between M918T non-M918T groups. Among previously treated patients, the ORR was lower in the M918T group vs. the non-M918T group, while in the TKI naïve group the ORR was higher in the M918T groups vs the non-M918T group although the 95% CIs overlap in both comparisons. **Conclusions:** There were no major differences in ORR among mutational subtypes in patients with MTC treated with *RET* inhibitors, regardless of prior therapy. ORR was similar between patients with M918T and non-M918T mutations. Additional experience in ongoing clinical studies may provide additional data regarding responses across specific mutation types. Trastuzumab deruxtecan (T-DXd) in patients with human epidermal growth factor receptor 2 (HER2)-expressing salivary duct carcinoma: Subgroup analysis of two phase 1 studies. *First Author: Hideaki Bando, Aichi Cancer Center Hospital, Aichi, Japan*

Background: T-DXd is an antibody-drug conjugate composed of an anti-HER2 antibody, cleavable tetrapeptide-based linker, and membrane-permeable topoisomerase I inhibitor payload. T-DXd has been approved for use in the US and Japan for both breast cancer and gastric cancer and has demonstrated safety and efficacy for additional solid tumors indications in the first-in-human (FIH) (J101; NCT02564900) and drug-drug interaction (DDI) (A104; NCT03383692) phase 1 studies. Here we present the combined subgroup analysis for salivary duct carcinoma. **Methods:** Patients (pts) with HER2-expressing salivary duct carcinoma after standard treatment or without any available standard treatment in both the FIH study and DDI study were included in this analysis. HER2 expression at enrollment was defined by IHC and/or amplification by ISH or NGS via local testing. A retrospective analysis of HER2 IHC and ISH of archived samples was conducted after enrollment by central laboratory per ASCO CAP guidelines. Pts with salivary duct carcinoma received T-DXd at 6.4 mg/kg and 5.4 mg/kg IV every 3 weeks in the FIH study and DDI study, respectively. RECIST version 1.1 was used for efficacy assessments by investigators. **Results:** Of 329 pts enrolled in both the FIH (289 pts) and DDI (40 pts) studies, a total of 17 pts with salivary duct carcinoma were pooled in this analysis: 8 pts with T-DXd at 6.4 mg/kg from FIH study and 9 pts with T-DXd at 5.4 mg/kg from DDI study. The sites of primary disease were parotid gland for 6 pts, submandibular gland for 4 pts, sublingual gland for 1 pt, and unknown for 6 pts. As for HER2 status by the central laboratory, 11 pts were IHC3+, 1 pt was IHC2+/ISH- and 5 pts had no available samples. Fourteen pts received HER2 targeted agents as a prior cancer therapy including trastuzumab. At data cutoff (FIH study: 1 Aug 2019; DDI study: 26 Sep 2018), the confirmed overall response rate was 47% (8/17) and the best overall response was PR in 8 pts and SD in 9 pts. Median duration of response and progression-free survival were 12.9 months and 14.1 months, respectively. Treatment-emergent adverse events (TEAEs) occurred in all 17 pts (grade ≥3, 64.7%); most common grade ≥ 3 TEAEs were decreased neutrophil count (8/17, 47.1%), decreased white blood cell count (6/17, 35.3%), anemia (2/17, 11.8%) and decreased platelet count (2/17, 11.8%). Three pts (3/17, 17.6%) had adjudicated drug related interstitial lung disease (Grade 1 for 2 pts and Grade 3 for 1 pt). Of these 17 pts, 7 pts (41.2%) experienced dose interruption and 3 pts (17.6%) experienced dose reduction due to TEAEs. Four pts (23.5%) discontinued treatment due to TEAEs. **Conclusions:** T-DXd showed promising antitumor activity in HER2-expressing salivary duct carcinoma with durable response. The safety profile was generally consistent with previous results in the other solid tumors. Clinical trial information: NCT02564900 and NCT03383692. Research Sponsor: Daiichi Sankyo Co., Ltd., Japan .

Patient-reported outcomes (PROs) from a phase II trial of pembrolizumab for HPV-associated papilloma patients with laryngeal, tracheal and/or pulmonary involvement. *First Author: Sara I. Pai, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Recurrent respiratory papillomatosis (RRP) is caused by human papillomavirus (HPV) types 6 & 11. RRP proliferates in the respiratory tract impacting breathing, swallowing, and voice and carries a 1-4% risk of malignant transformation.There is no curative therapy for RRP. Given the tolerized host immune response against HPV, the safety and efficacy of pembrolizumab (pembro) as an alternative treatment for this patient population was evaluated in a phase II clinical trial. Patient reported outcomes (PROs) were assessed during the trial to capture the patient perspective of pembro as an alternative to surgery or in office procedures, both standard of care (SOC). **Methods:** RRP patients who had previously undergone >3 procedures in any year, or with known tracheal or pulmonary involvement prior to study entry were treated with pembro 200mg every 3 weeks. The primary endpoint of the trial was best 'overall response rate' (ORR) measured by an endoscopic-based disease burden score (lower score reflects better 'response') and/or RECIST 1.1, secondary endpoint included PROs. Twenty-one patients were required to assess the primary endpoint. Most of the QoL surveys used Likert scale to assess PROs ('never, sometimes, often, most of the time, always'). The percentage reporting 'never' having an issue with symptom or activity at baseline, 6 months, and at time of ORR (nadir disease burden score) is reported here. **Results:** Twenty-one patients were accrued. Median age (range) was 45 (19-68), 57% (12/21) were male and 67% (14/21) were white. Questionnaire completion rates were 100% at baseline, 90% at 6 months, and 85% at ORR. Improvement in: social interactions (less difficulty with: physical intimacy [38%,56%,65% reporting 'never' at baseline, 6 months, and at ORR respectively]), discussing disease diagnosis [19%,21%,39%]); personal feelings (less depression [14%,32%,33%], less anxiety [5%,16%,22%], less embarrassment [19%,37%,50%]), and work-related absences (less frequently fabricating reasons for work absence due to disease-related treatment [57%,78%,56%] and less utilization of family vacation or FMLA for disease treatment [29%,53%,56%]) were reported. At ORR, 72% (13/18) patients reported that IV infusion was not emotionally burdensome and 78% (14/18) reported it as the preferred treatment relative to their perceived experience with SOC surgery or in office procedures. **Conclusions:** PRO results show consistent benefit in key aspects of the patient experience with pembro over procedure based SOC further supporting its overall clinical benefit in patients with HPV-associated RRP. Clinical trial information: NCT02632344. Research Sponsor: MERCK, Other Government Agency.

Molecular profiling and targeted agents in recurrent, metastatic salivary gland tumor (R/M SGT) patients (pts) treated at two academic centers. *First Author: Alberto Hernando-Calvo, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada*

Background: Treatment selection based on actionable alterations (AAs) is an appealing strategy for pts with R/M SGT. The GEMS-001 study (NCT02069730) at Princess Margaret Cancer Centre (PM) and the Vall DHebron Institute of Oncology (VHIO) pre-screening program facilitate the identification of AAs for R/M SGT pts and treatment selection. **Methods:** We analyzed R/M SGT treated at PM and VHIO from 2015 to 2020. Clinicopathological features, molecular alterations and treatment modalities were correlated with outcomes. The primary endpoint was overall response rate (ORR) by RECIST 1.1. Clinical benefit rate (CBR) was defined by pts with partial response or stable disease ≥4 months. Clinical actionability of multigene panel testing (NGS) and immunohistochemistry (IHC) were assessed as per institutional molecular tumor boards or investigators. Pts were opportunistically matched to available therapies from each center. **Results:** In total 206 pts were enrolled. On IHC, HER2 overexpression was present in 9%, Androgen Receptor (AR) 33%, Estrogen/Progesterone Receptor (ER/PR) 11% and ALK overexpression 0%. On NGS, PIK3CA mutation (mut) was in 9%, NTRK fusion 6%, NOTCH1-3 mut 5%, HRAS mut 6%, ERBB2/3 alterations (alt) 4% and FGFR1-4 alt 3%. Up to 92 pts (45%) displayed at least 1 AA and 36 pts (18%) had ≥2 AAs. A total of 60 pts (29%) were matched to AAs. Of those matched, median age was 60 years (range 33-84), M:F 21:39, 95% ECOG≤1 with a median number of prior treatment lines 0 (range 0-3), and their AAs included 26 AR, 9 HER2 or ERBB2 overexpression, 9 PIK3CA mut, 3 NTRK fusion, 3 FGFR1-3 alt and 10 other AAs (2 ER/PR overexpression, 2 EGFR mut, 1 c-kit mut, 1 BAP1 mut, 1 Non-V600 BRAF mut, 1 CDKN2A mut, 1 CHEK2 mut and 1 PTCH1 mut). Overall, ORR was 27% for the matched population. See table for outcomes. **Conclusions:** In our cohort, almost one third of the population received therapies matched to AAs. Our results suggest that targeted therapies have promising activity in pts with R/M SGT supporting comprehensive molecular and IHC profiling in treatment determination. Research Sponsor: None.

AA	ORR	CBR
NTRK	100%	100%
HER2	77%	56%
AR	23%	35%
PIK3CA	0%	67%
FGFR	0%	100%
NOTCH	0%	50%
Other	0%	44%

Benefits of pembrolizumab in progressive radioactive iodine refractory thyroid cancer: Results of the AcSé Pembrolizumab Study from Unicancer. *First Author: Sophie Leboulleux, Institut Gustave Roussy, Villejuif, France*

Background: AcSé Pembrolizumab is a Phase II, non-randomized parallel arm, open-label, multicentric study from Unicancer investigating the efficacy and safety of pembrolizumab monotherapy in different cohorts of patients with rare cancers (NCT03012620). Here we report the first results of pembrolizumab in the radioactive iodine refractory thyroid cancer cohort. **Methods:** Main inclusion criteria were progressive radioactive iodine refractory (RAIR) thyroid cancer (TC) resistant to standard treatment, age > 18, ECOG PS≤1. Patients received pembrolizumab 200 mg IV as a 30-minute infusion on Day 1 of every 21-day cycle for a maximum of 2 years. The primary endpoint was the confirmed objective response (OR) rate according to RECIST v1.1 by investigator. Secondary endpoints included duration of response, progression-free survival (PFS), overall survival (OS), and safety. **Results:** 43 patients (21 female, mean age 64.8 years; range 40-86) with TC (27 patients with differentiated TC (DTC) [papillary: 7; follicular: 14: oncocytic: 5 poorly differentiated: 1] and 16 patients with anaplastic TC (ATC)) were included from September 2017 to December 2020. The median number of previous systemic treatment lines was 2 (range, 0-7) in DTC and 2.5 (range, 1-4) in ATC. The median number of pembrolizumab cycles was 4 (range, 1-35). The median follow-up was 5.9 months (range: 22 days-22.9 months) for DTC and 2.7 months (range: 3 days-24.4 months) for anaplastic TC. For DTC the best tumor response was partial response (PR) in 3 (11.1%) patients and stable disease (SD) in 5 (18.5%). Median duration of response was 2.5 months (range: 5 days-7.2 months). The median PFS was 2.6 months, the 6-month PFS was 16.9 %. The median OS was 12.7 months with a 6-month OS of 73.3%. For ATC the best tumor response was PR in 3 cases (18.8 %) and SD in 1 case (6.2 %). Median duration of response was 1.6 months (range: 2 days-7.2 months). The median PFS was 2.3 months, the 6-month PFS was 33.8 %. The median OS was 3.6 months with a 6-month OS of 32.9%. Treatment emergent adverse event included 9 Grade 1-2, 20 Grade 3 (3 being considered as related and 17 as not related) and 1 Grade 4 (sepsis, unrelated). Overall, the toxicity profile was similar to that observed in other cancers. **Conclusions:** The response rates observed under pembrolizumab is low in DTC and not negligible in ATC, but with a short duration of response. Clinical trial information: NCT03012620. Research Sponsor: La Ligue Nationale contre le Cancer, Other Government Agency, Pharmaceutical/Biotech Company.

***NTRK, RET, BRAF,* and *ALK* fusions in thyroid fine-needle aspirates (FNAs).** *First Author: Lori J. Wirth, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Receptor tyrosine kinase (RTK) fusions may be targeted by small molecule inhibitors to treat various advanced tumors, including thyroid cancer. Clinical trials have studied selective inhibitors of *ALK, BRAF, NTRK* and *RET*, leading to several FDA-approved therapies. The Afirma Genomic Sequencing Classifier (GSC) classifies cytologically indeterminate thyroid nodules as molecularly benign or suspicious. The Xpression Atlas reports 905 genomic variants and 235 fusion pairs on GSC Suspicious, Suspicious for Malignancy (SFM), and Malignant FNA samples at the time of diagnosis. Here we report the prevalence of these fusion genes in real-world clinical practice. **Methods:** We analyzed anonymized data from 50,644 consecutive Bethesda III-VI nodule FNA samples submitted to the Veracyte CLIA laboratory for molecular testing using whole transcriptome RNA sequencing (RNA-Seq). Gene pairs are listed alphabetically. **Results:** 32,080 Bethesda III/IV nodules were classified as GSC Benign and 278 were Parathyroid Classifier positive. No *ALK, BRAF, NTRK1/3,* or *RET* fusions were identified among these samples. Among 16,594 Bethesda III/IV GSC Suspicious FNAs, 3% (n = 529) were positive for *ALK, BRAF, NTRK1/3 or RET* fusions. Among the 1,692 Bethesda V/VI FNAs, the proportion of positive nodules was 8% (n = 135). Among these combined cohorts of Bethesda III/IV GSC Suspicious and Bethesda V/VI, the most common gene fusions observed for each of the 5 studied RTK genes was: *ETV6/NTRK3* (n = 164, 72% of *NTRK3* fusions), *CCDC6/RET* (n = 104, 55% of *RET*), *BRAF/SND1* (n = 32, 20% of *BRAF*), *ALK/STRN* (n = 20, 37% of *ALK*), and *NTRK1/TPM3* (n = 14, 50% of *NTRK1*). *BRAF* showed the highest diversity of fusions, with 80 gene partners. Different gene partners with *RET, ALK, NTRK1,* and *NTRK3* numbered 25, 11, 9, and 5, respectively. **Conclusions:** Whole-transcriptome RNA-seq on small sample thyroid FNA specimens can identify clinically relevant *ALK, BRAF, NTRK,* and *RET* fusions across Bethesda categories. The prevalence ranges from 3% in Bethesda III/IV Afirma GSC Suspicious specimens to 8% among Bethesda V/VI specimens. Future studies need to determine if detection of precision medicine candidates by pre-operative FNA can optimize initial treatment, predict response to treatment, and prioritize selective targeted therapy should systemic treatment be needed. Research Sponsor: Veracyte.

Treatment patterns and systemic therapy outcomes for patients with salivary duct carcinoma and adenocarcinoma NOS. *First Author: Luana Guimarães Sousa, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Salivary duct carcinoma (SDC) and adenocarcinoma, not otherwise specified (Adeno-NOS) are rare and aggressive subtypes of salivary gland cancers. Biomarker studies revealed targetable alterations such as androgen receptor (AR) and HER2 overexpression; nevertheless, chemotherapy (CT) remains the cornerstone treatment of patients (pts) with locally advanced or metastatic disease based on limited efficacy data. We sought to describe the treatment patterns and outcomes of SDC and Adeno-NOS pts. **Methods:** We retrospectively collected clinicopathological, treatment, and outcomes data of SDC or Adeno-NOS pts that were seen at MD Anderson from 1990-2020. AR positivity was defined by IHC staining in ≥ 10% of tumor cells, and HER2 by IHC 2+ or 3+ scores. Overall response rate (ORR) was assessed by an independent radiologist per RECIST v1.1. Recurrence-free survival (RFS) and overall survival (OS) from diagnosis were estimated using log-rank test. A multivariable cox regression model was performed to estimate the hazard-ratio (HR) of risk factors on pts outcomes. **Results:** 200 pts were included, 110 had SDC and 90 Adeno-NOS. Most pts (61%) presented with locoregional disease (stage III-IVB), while 13% had distant metastasis (IVC). AR was positive in 77% of cases, and HER2 in 47%. In the curative setting (N=174), 98% pts underwent surgery and 90% radiotherapy (RT); 15 pts with stage IVA-B disease had aggressive trimodality therapy including surgery, RT, and systemic therapy. Overall, 55% pts recurred. The mRFS and 5-y RFS rate were 24 mos (95%CI, 16-43) and 34.5%, respectively. For pts with IV-A-B stage, trimodality therapy was associated with an improved OS in comparison to surgery and/or RT (39 mos vs NA, p=0.04). In the metastatic setting, 82 pts received ≥1 line of systemic therapy; the preferred 1st line regimen was platinum/taxane with or without trastuzumab (50%). Table summarizes the ORR and mPFS to each therapy line. ORR and PFS was higher for HER2-targeted therapy (1st line: 47% and 11 mos; 2nd line 29% and 6 mos; respectively); only 10 pts received androgen blockage. At a median follow-up of 7.5 y, the mOS was 5 ys and the 5-y OS rate was 50%. In multivariate analysis, higher T and N stages (HR 2.1 and 3.8, p<0.05), and positive margins (HR 2.0, p=0.003) were associated with worse RFS; older age (HR 1.03, p=0.003), and higher TNM stage (HR 1.78, p=0.006) were associated with worse OS. HER2 expression was not prognostic. **Conclusions:** This study validates prognostic factors in SDC and adeno-NOS and is the largest series to report outcomes to palliative systemic therapy per treatment line, providing a benchmark for future studies in these diseases. Aggressive trimodality therapy may improve outcomes of pts with stage IVA-B disease. Research Sponsor: Research funds from Klaus pharma.

Encorafenib and binimetinib with or without nivolumab in treating patients with metastatic radioiodine refractory BRAF V600 mutant thyroid cancer. *First Author: Matthew H. Taylor, Earle A. Chiles Research Institute, Portland, OR*

Background: Differentiated thyroid cancer is the most common endocrine malignancy and has a high frequency of actionable molecular aberrations including BRAF V600E mutations (45%), RET fusions (10%), and NTRK fusions (< 2%). FDA approved systemic therapies for metastatic radioiodine refractory differentiated thyroid cancer (RR-DTC) include multikinase inhibitors (Lenvatinib and sorafenib), NTRK inhibitors (larotrectinib and entrectinib for NTRK fusion+ cancers), and RET inhibitors (selpercatinib and pralsetinib for RET fusion+ cancers). Previous phase II clinical trials showed clinical efficacy with first and second generation BRAF inhibitors in patients with BRAF mutant RR-DTC. BRAF inhibitors have not yet been FDA approved for treatment of BRAF mutant RR-DTC. Effective therapeutic options for patients with BRAF mutant RR-DTC remains an important unmet clinical need. BRAF mutant thyroid cancers often show elevated expression of PD-L1. Additionally, BRAF inhibition results in increased expression of PD-L1 in thyroid cancer. This clinical trial seeks to evaluate the safety and efficacy of encorafenib plus binimetinib with or without nivolumab in patients with BRAF mutant metastatic RR-DTC. Encorafenib and binimetinib are highly selective and potent oral inhibitors of BRAF and MEK, respectively. Nivolumab is a potent inhibitor of the immune co-inhibitory receptor programmed cell death protein 1 (PD-1). **Methods**: This is a phase II, single institution, open-label, randomized clinical trial evaluating the combinations of (Arm 1) encorafenib 450 mg/day + binimetinib 45 mg twice daily and (Arm 2) encorafenib 450 mg/day + binimetinib 45 mg twice daily + nivolumab 480 mg I.V. every 4 weeks in patients with metastatic BRAF mutant RR-DTC. The trial will enroll 20 patients in each arm and treatment will be given in 28 day cycles for up to 2 years. Eligible patients must have metastatic/unresectable BRAF mutant RR-DTC, an ECOG performance status of 0-1 and adequate bone marrow, liver and kidney function. Patients with CNS metastases are included if the metastases have been treated and remained stable or are asymptomatic and ≤10 mm in diameter. Patients may be systemic therapy naïve or have previously been treated with multikinase inhibitors. Prior therapy with BRAF, MEK or immune checkpoint inhibitors is exclusionary. The primary endpoint is confirmed objective response rate (ORR) determined by RECIST v1.1 with restaging imaging every 12 weeks. Secondary endpoints include progression free survival, overall survival, and safety/tolerability (CTCAE v5.0). Arms 1 and 2 will be evaluated independently and are not powered for direct comparison. The trial design includes continuous toxicity monitoring with a Pocock-type stopping boundary. This clinical trial is in progress and 3 patients have been enrolled. Clinical trial information: NCT04061980. Research Sponsor: Bristol Myers Squibb and Pfizer.

TPS6086 **Poster Session**

Phase II multicenter randomized trial to assess the efficacy and safety of first line nivolumab in combination with paclitaxel in subjects with R/M HNSCC unable for cisplatin-based chemotherapy (NIVOTAX): A TTCC study. *First Author: Lara Iglesias, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: Nivolumab is the standard of care for patients (pts) with R/M HNSCC in the platinum-refractory setting. Up to 20% of R/M HNSCC pts are ineligible for cisplatin-based CT due to poor performance status and/or comorbidities. ERBITAX (weekly cetuximab + paclitaxel) is a recommended regimen for this patient population according to the Spanish Society of Medical Oncology guidelines. Preclinical data suggests a role for paclitaxel as immuno-modulator, mainly by increasing tumor infiltrating CD8+ (Galluzzi L., et al 2015). NIVOTAX trial aims to evaluate efficacy and safety of nivolumab + paclitaxel vs ERBITAX as first-line treatment for R/M HNSCC pts with platinum-refractory disease or ineligible for platinum-based chemotherapy. **Methods:** NIVOTAX (NCT04282109) is a randomized, open-label, multicenter, phase II trial sponsored by the Spanish Group of Head and Neck Cancer Treatment (TTCC) including R/M HNSCC pts not amenable for curative-intent therapy, previously untreated for R/M disease and not candidates for cisplatin-based chemotherapy. Population is distributed in 3 Groups: 1= Platinum-refractory; 2=Platinum-sensitive but unable to receive cisplatin due to: Karnofsky performance status (KPS) 70% and/or major comorbidities (renal/heart failure, grade ≥2 hearing loss) and/or previous allergic reactions to platinum compounds; 3= Platinum-sensitive but cumulative cisplatin dose received ≥225 mg/m^2 for locally-advanced disease. Pt are stratified according to: KPS (70% vs 80-100%); PD-L1 by Combined Positive Score (CPS ≥1 vs < 1); and HPV positivity (HPV+ oropharynx vs HPV-/non-oropharyngeal). 141 Pt are being randomized 2:1 to NIVOTAX (nivolumab 240 mg q2 weeks + weekly paclitaxel at 80 mg/m^2 up to 12 weeks followed by maintenance nivolumab 480 mg/ q4 weeks) or ERBITAX (weekly 250 mg/m^2 plus paclitaxel 80 mg/m^2 up to 12 weeks followed by maintenance cetuximab 250 mg/m^2 weekly). Both arms will be continued up to a maximum of 24 months. Primary end-point is to evaluate treatment efficacy in terms of 2-year overall survival (2-y OS). It is assumed that 2-y OS in the NIVOTAX arm will be at least 26% (10% gain when compared to the expected 16% 2-y OS rate in this pt population). Secondary objectives include progression free survival (PFS), overall response rate, disease control rate, duration of response, 6m PFS, 5y-OS and safety profile. Response endpoints will be assessed using RECIST 1.1 criteria. As of February 12, 2021, 64 pts have been randomized. Planned safety data review for the first 10 pts treated with NIVOTAX regimen did not show any unexpected AE. Clinical trial information: NCT04282109. Research Sponsor: Bristol-Myers Squibb.

TPS6087 **Poster Session**

The AIM-HN Study: A pivotal study evaluating the efficacy of tipifarnib in patients with recurrent or metastatic head and neck squamous cell carcinoma with *HRAS* mutations. *First Author: Robert I. Haddad, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Head and neck squamous cell carcinoma (HNSCC) accounts for more than 830,000 new cancer cases each year worldwide. The prognosis for recurrent and/or metastatic (R/M) HNSCC patients remains poor with an estimated median overall survival (mOS) of 7-15 months in the first line setting and 5-8 months in the second line setting and beyond. Approximately 4-8% of HNSCC tumors are driven by gain-of-function mutations in the *HRAS* (m*HRAS*) proto-oncogene. Tipifarnib is a potent and selective farnesyltransferase inhibitor that disrupts HRAS function by blocking required protein membrane localization, and subsequent cellular growth and survival. Data from a prior phase 2 study (RUN-HN; NCT02383927) of tipifarnib in R/M m*HRAS* HNSCC patients in the second line plus setting demonstrated encouraging efficacy, with an objective response rate (ORR) of 55% and mOS of 15.4 months for patients with mHRAS variant allele frequency (VAF) $\geq$ 20%, providing support for pursuing a pivotal trial in this patient population. **Methods:** AIM-HN (NCT03719690) is a global, open-label single-arm pivotal study evaluating the efficacy and tolerability of tipifarnib in second line plus R/M m*HRAS* HNSCC patients. The primary objective is to determine the ORR in patients with a m*HRAS* VAF $\geq$ 20% (High VAF population), as assessed using RECIST v1.1 by Independent Review Facility. Key secondary objectives include the ORR for patients of all VAF levels, and the duration of responses for both VAF$\geq$ 20% and all VAF levels. Key inclusion criteria include: histologically confirmed head and neck cancer of squamous histology not amenable to local therapy with curative intent; known tumor missense *HRAS* mutation (with VAF determined and available) detected by Next Generation Sequencing; ECOG performance status of 0-1; measurable disease by RECIST v1.1; and adequate organ function. Key exclusion criteria include: salivary gland, thyroid, (primary) cutaneous squamous or non-squamous histologies; intolerable Grade 2 or $\geq$ Grade 3 neuropathy or unstable neurological symptoms within 4 weeks of Cycle 1 Day 1; or active, uncontrolled infections requiring systemic therapy. Tipifarnib is administered at a dose of 600 mg, orally with a meal twice a day for 7 days in alternating weeks (Days 1-7 and 15-21) of 28-day cycles until discontinuation criteria are met. All patients are being followed for safety through the End of Treatment visit, roughly 30 days after treatment discontinuation or immediately before the administration of another anticancer treatment, whichever occurs first. Upon therapy discontinuation, all patients are being followed approximately every 12 weeks for survival status, and the use of subsequent therapy. The IDMB last reviewed data in October 2020 and recommended the trial continue as planned. AIM-HN is continuing to enroll patients globally. Ho et al, *JCO*, accepted. Clinical trial information: NCT03719690. Research Sponsor: Kura Oncology.

TPS6089 **Poster Session**

CMP-001-007: Open-label, phase 2 study of intratumoral CMP-001 + pembrolizumab in patients with recurrent or metastatic head and neck squamous cell carcinoma. *First Author: Deborah J.L. Wong, University of California Los Angeles, Los Angeles, CA*

Background: PD-1 blockade ± chemotherapy has recently become a primary systemic therapy recommended by NCCN guidelines for patients (pts) with recurrent or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). However, most pts still do not respond to treatment, indicating a large unmet need for pts with unresectable disease. CMP-001 is a toll-like receptor 9 (TLR9) agonist comprising a CpG-A oligodeoxynucleotide packaged in a virus-like particle that can induce type I interferon secretion from tumor-associated plasmacytoid dendritic cells, promoting a Th1-like chemokine milieu in the tumor microenvironment and inducing an antitumor CD8+ T-cell response. In a phase (ph) 1b study in pts with metastatic melanoma, intratumoral (IT) injection of CMP-001 + intravenous (IV) pembrolizumab (pembro) reversed PD-1 blockade resistance, induced responses in injected and noninjected lesions, and had an acceptable safety profile (Milhem et al, SITC 2020). This combination is therefore being tested in pts with HNSCC. **Methods:** CMP-001-007 (NCT04633278) is an open-label, multicenter, ph 2 study designed to investigate the efficacy and safety of CMP-001 + IV pembro in adult pts with histologically or cytologically confirmed R/M HNSCC considered incurable by local therapies. Eligible pts have undergone a pretreatment tumor biopsy, received no prior systemic therapy in the R/M setting, and have primary tumor locations of oropharynx, oral cavity, hypopharynx, or larynx. In addition, pts must have PD-L1-positive tumors (combined positive score $\geq$1), known tumor human papillomavirus (HPV) status (for oropharyngeal cancer), and measurable disease per RECIST v1.1 with $\geq$1 lesion amenable to IT injection. Pts with primary tumors in the nasopharynx are excluded. Enrolled pts will receive CMP-001 10 mg once weekly for 7 doses and every 3 weeks (Q3W) thereafter. The first dose may be administered subcutaneously or via IT injection, with all subsequent doses administered IT. All pts will also receive pembro 200 mg IV Q3W after the CMP-001 injection. Treatment continues until unacceptable toxicity or disease progression. The primary endpoint is investigator-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints include safety, duration of response (DOR), progression-free survival (PFS), overall survival, and effects of HPV infection and PD-L1 expression on ORR, DOR, and PFS. Exploratory endpoints include analyses of baseline and changes from baseline in tumor or serum biomarkers related to TLR9, immune checkpoints, and potential predictors of response, as well as serum concentrations of CXCL10 and CMP-001. Refer to clinicaltrials.gov/ct2/show/NCT04633278 for the most current information on enrolling sites. Clinical trial information: NCT04633278. Research Sponsor: Checkmate Pharmaceuticals.

TPS6090 **Poster Session**

The BURAN study of buparlisib (AN2025) in combination with paclitaxel compared to paclitaxel alone, in patients with recurrent or metastatic head and neck squamous cell carcinoma. *First Author: Denis Soulieres, Centre Hospitalier de l'Université de Montréal, Montréal, QC, Canada*

Background: Buparlisib (AN2025) is a 2,6-dimorpholino pyrimidine derivative oral pan-class I PI3K inhibitor. The PI3K signaling pathway is one of the most frequently altered pathways in HNSCC. A previous randomized, double-blind, placebo-controlled phase II study (BERIL-1)assessed patients with recurrent/metastatic HNSCC after PD on or after platinum-based chemotherapy in the metastatic setting. Patients assigned 1:1 to receive second-line oral buparlisib or placebo, plus intravenous weekly paclitaxel in 28-day cycles. Median PFS 4.6 months buparlisib arm, 3.5 months placebo arm (hazard ratio 0.65 [95% CI: 0.45–0.95], nominal one-sided p=0.011). Median OS 10.4 months buparlisib arm, 6.5 months placebo arm (hazard ratio 0.72 [95% CI: 0.49-1.04], nominal one-sided p=0.041). Best ORR buparlisib arm 39%, placebo arm 14%. Safety in buparlisib arm was manageable and comparable to placebo arm. (Soulieres, Lancet Oncology). Results suggest that buparlisib in combination with paclitaxel could be effective treatment following failure of platinum-based chemotherapy. **Methods:** The treatment algorithm for HNSCC was recently modified with inclusion of anti-PD-1/PD-L1 agents that provide a survival advantage, defining an unmet need after their use. The BURAN study is initiated as a confirmatory study to define activity in this setting. Methods: A multicenter, randomized, open-label phase III trial evaluating efficacy and safety of daily buparlisib (100 mg) in combination with weekly paclitaxel (80 mg/m^2), compared to weekly paclitaxel alone, in patients with refractory, recurrent, or metastatic HNSCC, progressing after prior anti PD-1/anti PDL-1 therapy either as monotherapy or with a platinum-based regimen (in combination or sequence), and no more than two prior lines of treatment. 483 patients will be randomized 2:1, to receive either buparlisib in combination with paclitaxel or paclitaxel alone, stratified according to historical HPV status. Primary Objective: OS of buparlisib in combination with paclitaxel compared to paclitaxel alone. Secondary Objectives: Comparative PFS, ORR, and DoR, by Investigator and Independent Radiological Review Committee. Efficacy in subgroups of patients by randomization strata. Effect on symptoms and health related QOL. Efficacy related to biomarkers, microbiome analysis. Pharmacokinetics (PK) of buparlisib in combination with paclitaxel. Safety Objective: Comparative safety and tolerability. Primary analysis is OS in the ITT population, once 383 events have occurred, to demonstrate a 20% reduction in risk of death. Survival follow-up is to a maximum of five years. Trial opened December 12, 2020; X patients currently enrolled. Clinical Trial registry number: NCT04338399. Clinical trial information: NCT04338399. Research Sponsor: Adlai Nortye USA Inc.

TPS6091 **Poster Session**

TrilynX: A phase 3 trial of xevinapant and concurrent chemoradiation for locally advanced head and neck cancer. *First Author: Jean Bourhis, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland*

Background: Concurrent chemoradiotherapy (CRT) is the standard of care for previously untreated patients with locoregionally advanced squamous cell carcinomas of the head and neck (LA-SCCHN). Xevinapant (Debio 1143) is an orally available antagonist of inhibitor of apoptosis proteins with the potential to enhance the antitumor activity of platinum-based chemotherapy and radiotherapy. The radiosensitizing effect of xevinapant is mediated through caspase activation and TNF, IFNγ, CD8 T cell-dependent pathways. Three-year follow-up results from a randomized Phase 2 study showed significant improvements of xevinapant versus placebo in addition to standard chemoradiation (CRT) for locoregional control (LRC) rate at 18 months, PFS and OS. The addition of xevinapant was well tolerated, manageable and did not jeopardize backbone therapy [1, 2]. **Methods:** TrilynX is a multinational, Phase 3, double-blind, placebo-controlled, randomized clinical study assessing the efficacy of xevinapant in combination with concurrent CRT compared with placebo in combination with CRT for LA-HNSCC. Adult patients with newly diagnosed, pathologically proven, treatment-naive LA-SCCHN will be enrolled. Study population will include hypopharynx, larynx and p16-negative oropharyngeal. Other eligibility criteria: ECOG PS 0 or 1, AST and ALT $\leq$ 3.0 x ULN, total bilirubin $\leq$ 1.5 $\times$ ULN, and eligible for definitive CRT. Approximately 700 eligible patients will be randomly assigned to receive oral xevinapant at 200 mg per day on days 1 to 14 of 3-week cycles or placebo for three cycles in combination with cisplatin (100 mg/m^2, q3w) for three cycles, and concomitant standard fractionation intensity-modulated radiotherapy (70 Gy/7 weeks). The concurrent CRT period will be followed by a monotherapy period consisting of further three cycles of xevinapant or placebo. The primary endpoint is Event Free Survival (EFS) assessed by a Blinded Independent Radiological Committee (BIRC). An interim analysis will occur when 279 EFS events as assessed by the BIRC are observed. The primary analysis will occur once 429 EFS events are observed. TrilynX has ~90% power to detect the expected hazard ratio benefit of 0.73. Secondary end-points include OS, PFS, LRC, ORR, HRQL, and safety. Data driven design, patients will be followed up for a minimum of 60-months. PK sparse sampling is performed to assess exposure-response relationships with efficacy and safety. Biomarkers of response and resistance will be explored. TrilynX started in August 2020 and it is ongoing. References: [1] X. Sun et. al, Lancet Oncol; 21(9): 1173-1187, 2020. [2] J. Bourhis et al., Ann Oncol; 31 (suppl 4): LBA39, 2020. Clinical trial information: NCT04459715. Research Sponsor: Debiopharm Internation SA.

TPS6092 **Poster Session**

First-in-human phase I/II trial of PRGN-2009 vaccine as monotherapy or with bintrafusp alfa in patients with recurrent/metastatic (R/M) human papillomavirus (HPV)-associated cancers (HPVC) and as neoadjuvant/induction therapy in locoregionally advanced (LA) HPV oropharyngeal (OP) and sinonasal (SN) squamous cell cancer (SCC). *First Author: Charalampos S. Floudas, Genitourinary Malignancies Branch, NCI, NIH, Bethesda, MD*

Background: R/M HPVC (cervical, anal, oropharyngeal, etc.) are incurable by current therapies. For newly diagnosed LA HPV-OPSCC standard-of-care (SOC) is radiotherapy ± chemotherapy (C/RT) or surgery ± adjuvant C/RT, with considerable risk of relapse. Newly diagnosed LA SNSCC treatment follows the OPSCC paradigm, and detection of HPV appears to confer improved prognosis. Neoadjuvant PD-1 immune checkpoint blockade (ICB) before surgery may improve RFS and is being evaluated in a multicenter phase III clinical trial (Keynote-689). PRGN-2009 (P) is a novel gorilla adenovirus vaccine containing 35 non-HLA-restricted epitopes of HPV 16 and 18 shown to induce HPV specific responses (preclinical models). Bintrafusp alfa (BA) is a bifunctional fusion protein targeting TGF-β and PD-L1 with promising activity in HPVC. This trial will evaluate the safety and activity of P/ P + BA in patients with previously treated R/M HPVC and as neoadjuvant/induction therapy before SOC surgery or C/RT in newly diagnosed LA HPV-OPSCC and HPV-SNSCC. **Methods:** This is a first-in-human, investigator-initiated, single-center phase I/II trial. Pts with previously treated (incl. ICB) R/M HPVC are eligible for Phase I: P dose escalation arm (3+3 design, 6-12 patients) testing 2 dose levels ($1x10^{11}$, $5x10^{11}$ viral particle units, SC Q2W three times, then Q4W), and combination arm (10 patients) testing P (recommended phase 2 dose (RP2D), same schedule) + BA (1200 mg IV Q2W). Treatment (both arms) will continue until disease progression, unacceptable toxicity, decision to withdraw. Primary endpoint is safety. Secondary endpoints include ORR (RECIST 1.1), PFS, and OS. For Phase II, patients with newly diagnosed stage II/III (AJCC Cancer Staging Manual, 8th ed.) HPV-OPSCC and stage II/III/IVA/IVB HPV-SNSCC planned for SOC C/RT or surgery will be eligible for two treatment arms of 20+2 patients each (sequential): P arm and P + BA, to evaluate the treatment activity. All patients will have pre-treatment biopsy, receive two cycles of the study treatment at the NCI Clinical Center two weeks apart, followed by post-treatment biopsy and SOC treatment (at the referring institution) 4 weeks after the first study treatment. Primary endpoint is post-treatment $\geq$2-fold increase in tumor-infiltrating CD3+ cells. Secondary endpoints include RFS, OS. Exploratory endpoints for both arms include analyses of immune subsets, soluble factors, and HPV-specific immune responses in peripheral blood and tissue where available, and in Phase II sequencing (exome, scRNA), immune spatial profiling with multiplex immunofluorescence, and salivary HPV DNA. Clinical trial registry: NCT04432597. Clinical trial information: NCT04432597. Research Sponsor: U.S. National Institutes of Health.

TPS6093 **Poster Session**

NRG Oncology HN006: Randomized phase II/III trial of sentinel lymph node biopsy versus elective neck dissection for early-stage oral cavity cancer. *First Author: Stephen Yenzen Lai, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Since patients with early-stage oral cavity cancer (OCC; T1-2N0M0; AJCC 8^{th} ed) have a 20-30% rate of occult nodal metastases despite clinical and radiographic assessment, standard of care treatment includes elective neck dissection (END). Many patients have comprehensive surgical management of the regional cervical nodal basin even though the majority of those necks (70-80%) will not contain disease. Assessment of draining first echelon lymph nodes by sentinel lymph node (SLN) biopsy (Bx), a less invasive surgical procedure, may provide an alternative to END, while potentially reducing morbidity and cost. A decisive clinical trial comparing SLN Bx versus END can focus the HNC clinical and research community and resources on establishing the standard of care for management of the neck in early-stage OCC. **Methods:** In order to address the efficacy of SLN Bx in this population, we recently activated an international multi-institutional phase II/III prospective trial randomizing patients to two surgical arms: SLN Bx and END. PET/CT is an integral imaging biomarker in this trial. A node-negative PET/CT study with central read is required before randomization. Patients with a positive PET/CT central result will remain in a registry to compare imaging findings with final neck pathology. Given the current evidence available regarding morbidity for SLN Bx versus END, the phase II will determine if patient-reported neck and shoulder function and related QOL at 6 months after surgery using the Neck Dissection Impairment Index (NDII) shows a signal of superiority of SLN Bx compared to END. A total of 228 randomized patients with negative PET/CT for potential evaluation of shoulder-related morbidity with difference in 6-month NDII scores (minimum important difference ^{3}7.5; one-sided a = 0.10; 90% power) will serve as the "Go/No-Go" decision to move forward into phase III. The phase III portion is a non-inferiority (NI) trial with disease-free survival (DFS) as the primary endpoint (NI margin hazard ratio 1.34 based on a 5% absolute difference in 2-year DFS; one-sided alpha 0.05; 80% power, and an interim look for efficacy at 67% of the events based on an O'Brien-Fleming boundary). The NDII at 6 months after surgery is a hierarchical co-primary endpoint for the phase III. Target accrual of phase III is 618 PET/CT negative patients, including those randomized in phase II (297 DFS events required for the final analysis). In addition to radiotherapy and imaging credentialing, quality assurance will include central pathology review of all negative SLN Bx cases and surgeon credentialing through an education course and SLN Bx and END case review by the surgical co-chairs. A surgical quality assurance working group will review all trial SLN Bx and END outcomes. As of 02/15/21, 7 patients have been screened and 6 of the planned 228 randomized patients in phase II have been enrolled. Clinical trial information: NCT04333537. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS6094 **Poster Session**

Trial in progress: A phase I/II trial of novel MDM2 inhibitor alrizomadlin (APG-115), with or without platinum chemotherapy, in patients with p53 wild-type salivary gland carcinoma. *First Author: Paul Swiecicki, University of Michigan Medical School, Department of Internal Medicine, Division of Hematology/Oncology, Ann Arbor, MI*

Background: Salivary gland carcinoma is a rare tumor that accounts for 6% of all head and neck cancers. This histologically and anatomically heterogeneous malignant tumor type is largely resistant to platinum and other chemotherapies but commonly has wild-type *TP53* based on next-generation sequencing analysis. Alrizomadlin is a novel, orally active, small molecular agent that binds to MDM2, restoring p53 tumor suppressor function and inducing apoptosis in tumor cells retaining wild-type p53. Preliminary clinical evidence suggests promising antitumor activity and a favorable safety profile for alrizomadlin in the treatment of solid tumors (Rasco 2019). **Methods:** This US multicenter open-label trial is evaluating alrizomadlin with or without platinum chemotherapy in adults with histologically documented wild-type *TP53* salivary gland carcinoma, including primary or metastatic lesions, an ECOG performance status 0-1, and a life expectancy of at least 12 weeks. In addition, subjects need to have measurable disease by computed tomography according to RECIST v1.1, with radiographic disease progression within the prior 12 months, high-grade status with or without metastases, and/or not amenable to curative treatment. An initial randomized phase (Part 1) will be followed by a single-arm phase (Part 2). Treatment arms include a cycle length of 21 days, and the study is using a time-to-event continual reassessment method. In Part 1 (42 patient target), patients are randomly allocated (in a 1:2 ratio) to one of two arms: single-agent alrizomadlin at a starting dose of 150 mg (Arm A) or at a starting dose of 150 mg with concomitant IV carboplatin administered at starting AUC = 4.5 (Arm B). Based on overall response rate (ORR; complete or partial response after Cycle 2) and safety profile, the most promising treatment arm will be advanced to Part 2, which has a target enrollment of 20 patients. Study endpoints are (1) dose-limiting toxicity (DLT), which is defined by the rate of drug-related grade $\geq$ 3 adverse events (by NCI CTCAE v5.0) over the first 2 cycles (6 weeks) of study treatment; (2) maximum tolerated dose based on these DLTs; and (3) ORR by RECIST v1.1 observed at up to 12 months. As of January 27, 2021, 11 of 42 patients had been enrolled in Part 1. Internal study identifier APG-115SG101. Clinical trial registration: NCT03781986. Clinical trial information: NCT03781986. Research Sponsor: Ascentage Pharma Group Corp Limited (Hong Kong); University of Michigan NCI Cancer Center Support Grant (P30CA046592), Ann Arbor, MI.

6500 **Oral Abstract Session**

Racial and ethnic disparities among patients with breast cancer and COVID-19. *First Author: Gayathri Nagaraj, Loma Linda University Medical Center, Loma Linda, CA*

Background: Racial/ethnic minorities have disproportionately increased risk of contracting COVID-19 and experiencing severe illness; they also have worse breast cancer (BC) outcomes. COVID-19 outcomes among racial/ethnic minorities with BC are currently unknown. We sought to compare clinicopathologic characteristics and COVID-19 outcomes stratified by race/ethnicity. **Methods:** The COVID-19 and Cancer Consortium registry (NCT04354701) was used to identify patients with invasive BC and laboratory-confirmed SARS-CoV-2 diagnosed in the U.S. between 2020-03-06 and 2021-02-04. The primary analysis was restricted to women who self-identified as non-Hispanic White (NHW), non-Hispanic Black (NHB), or Hispanic (H). Demographic, cancer characteristics, and COVID-19 outcomes were evaluated. COVID-19 outcomes included: hospital admission, intensive care unit (ICU) admission, mechanical ventilation, death within 30 days of COVID-19 diagnosis and death from any cause during follow-up. Descriptive statistics were used to compare clinicopathologic characteristics and Fisher exact tests were used to compare COVID-19 outcomes across the 3 racial/ethnic groups. **Results:** A total of 1133 patients were identified of which 1111 (98%) were women; of which 575 (52%) NHW, 243 (22%) NHB, 183 (16%) H, and 110 (10%) other/unknown. Baseline characteristics differed among racial/ethnic groups. H were younger (median age: NHW 63y; NHB 62y; H 54y) and more likely to be never smokers (NHW 62%; NHB 62%; H 78%). NHB had higher rates of obesity (NHW 40%; NHB 54%; H 46%), diabetes (NHW 16 %; NHB 32%; H 20%) and combined moderate and severe baseline COVID-19 at presentation (NHW 28%; NHB 42%; H 28%). Cancer characteristics are as shown (Table). Significant differences were observed in outcomes across racial/ethnic groups including higher rates of hospital admission (NHW 34%; NHB 49%; H 34%; P <0.001), mechanical ventilation (NHW 3%; NHB 9%; H 5%; P=0.002), 30-day mortality (NHW 6%; NHB 9%; H 4%; P=0.043) and total mortality (NHW 8%; NHB 12%; H 5%; P=0.05) among NHB compared to NHW and H. **Conclusions:** This is the largest study to show significant differences in COVID-19 outcomes by racial/ethnic groups of women with BC. The adverse outcomes in NHB could be due to higher moderate to severe COVID-19 at presentation and preexisting co-morbidities. H did not have worse outcomes despite having more active disease and recent anti-cancer therapy, including with cytotoxic chemotherapy – potentially due to younger age and nonsmoking status. Research Sponsor: U.S. National Institutes of Health.

Total	NHW n = 575	NHB n = 243	H n = 183

The impact of the COVID-19 pandemic on stage at diagnosis of breast and colorectal cancers. *First Author: Jade Zhou, UC San Diego Health, San Diego, CA*

Background: Effective cancer screening leads to a substantial increase in the detection of earlier stages of cancer, while decreasing the incidence of later stage cancer diagnoses. Timely screening programs are critical in reducing cancer-related mortality in both breast and colorectal cancer by detecting tumors at an early, curable stage. The COVID-19 pandemic resulted in the postponement or cancellation of many screening procedures, due to both patient fears of exposures within the healthcare system as well as the cancellation of some elective procedures. We sought to identify how the COVID-19 pandemic has impacted the incidence of early and late stage breast and colorectal cancer diagnoses at our institution. **Methods:** We examined staging for all patients presenting to UCSD at first presentation for a new diagnosis of malignancy or second opinion in 2019 and 2020. Treating clinicians determined the stage at presentation for all patients using an AJCC staging module (8^{th} edition) in the electronic medical record (Epic). We compared stage distribution at presentation in 2019 vs 2020, both for cancers overall and for colorectal and breast cancer, because these cancers are frequently detected by screening. **Results:** Total numbers of new patient visits for malignancy were similar in 2019 and 2020 (1894 vs 1915 pts), and stage distribution for all cancer patients was similar (stage I 32% in 2019 vs 29% in 2020; stage IV 26% in both 2019 and 2020). For patients with breast cancer, we saw a lower number of patients presenting with stage I disease (64% in 2019 vs 51% in 2020) and a higher number presenting with stage IV (2% vs 6%). Similar findings were seen in colorectal cancer (stage I: 22% vs 16%; stage IV: 6% vs 18%). **Conclusions:** Since the COVID-19 pandemic, there has been an increase in incidence of late stage presentation of colorectal and breast cancer, corresponding with a decrease in early stage presentation of these cancers at our institution. Cancer screening is integral to cancer prevention and control, specifically in colorectal and breast cancers which are often detected by screening, and the disruption of screening services has had a significant impact on our patients. We plan to continue following these numbers closely, and will present data from the first half of 2021 as it becomes available. Research Sponsor: None.

6502 **Oral Abstract Session**

Medicaid patients more likely to die at home without hospice during the pandemic versus before, exacerbating disparities with commercially insured patients. *First Author: Laura Elizabeth Panattoni, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The COVID-19 pandemic dramatically reduced family access to hospitals and created new barriers to home hospice care, raising concerns about how the pandemic has impacted cancer patients' place of death and end of life home hospice support. Hypothesizing that Medicaid-enrolled cancer patients may be at greater risk of disruptions in end-of-life care compared to commercially insured patients, we examined changes in place of death and home hospice support for Medicaid and Commercial enrollees following the pandemic. **Methods:** We linked WA State cancer registry records with claims from Medicaid and approximately 75% of commercially insured cancer patients in the state. Patients ages 18-64 with solid-tumor malignancies who died March-June 2020 (COVID) were compared to those who died March-June 2017-2019 (Pre-COVID). Place of death was categorized as hospital, home with hospice, and home without hospice; nursing home deaths were excluded. Given our sample size, we examined differences in the likelihood of place of death with Fisher's exact tests and multinomial logistic regressions stratified by payer and by COVID period, controlling for age, gender, race, stage, cancer type, and census tract-level neighborhood deprivation. We report marginal effects. **Results:** In Fisher's exact analyses, Medicaid but not commercial patients were significantly less like to die in hospital and more likely to die at home without hospice during COVID (Table). In pre-post adjusted analysis of Medicaid patients, the probability of dying in the hospital was 12.3% (p=0.03) percentage points lower during the pandemic versus before, while the probability of dying at home without hospice was 11.1% (p=0.04) greater. Place of death did not change significantly pre-post for commercial patients. In addition, Pre-COVID, the probability of dying in the hospital was 10.7% (p=0.03) greater for Medicaid than commercial patients. During COVID, the probability of dying at home without hospice was 15.8% (p=0.04) greater for Medicaid versus commercial patients but lower for women (ME=20.2%; p=0.01) and colorectal versus breast cancer patients (ME=39.2%; p=0.01). **Conclusions:** Following COVID, Medicaid patients place of death shifted from hospital to homes, but without an increase in the use of home hospice services. In contrast, place of death and hospice use among commercial patients did not significantly change. This widening disparity in home deaths without hospice services raises concerns that the pandemic disproportionately worsened end of life experience for low income patients with cancer. Research Sponsor: Fred Hutchinson Cancer Research Center.

	Commercial			Medicaid		
Place of Death	Pre-COVID (N=162)	COVID (N=47)	p-value*	Pre-COVID (N=322)	COVID (N=90)	p-value*
Hospital	36.2%	29.8%		46.5%	35.2%	
Home Hospice	41.7%	51.1%	0.56	31.4%	31.9%	0.03

Association between perceptions of prognosis and end-of-life outcomes for patients with advanced lung and gastrointestinal cancer. *First Author: Carlisle E. W. Topping, Massachusetts General Hospital, Boston, MA*

Background: Many patients with advanced cancer maintain misperceptions of their prognosis and are thus unprepared to make difficult decisions regarding their end-of-life (EOL) care. However, studies examining the associations between patients' perceptions of their prognosis and their EOL outcomes are limited. **Methods:** We conducted a secondary analysis using longitudinal data from a randomized controlled trial of a palliative care intervention for patients with newly diagnosed incurable lung and non-colorectal gastrointestinal cancer. We administered the Prognosis and Treatment Perceptions Questionnaire to assess patients' perceptions of their prognosis at baseline, week-12, and week-24, using the final assessment closest to death. We used multivariate logistic and linear regression models, adjusting for age, gender, marital status, cancer type, and randomization to the palliative care intervention, to examine the associations among patients' perceptions of their prognosis with the following EOL care outcomes abstracted from the electronic health record: 1) hospice utilization and length-of-stay (LOS); 2) hospitalizations in the last 30 days of life; 3) receipt of chemotherapy in the last 30 days of life; and 4) location of death. **Results:** We enrolled 350 patients in the parent trial, of which 80.5% (281/350) died during the study period and were included in this analysis. Overall, 59.4% (164/276) of patients reported that they were terminally ill, and 66.1% (154/233) reported that their cancer was likely curable at the assessment closest to death. In multivariate analyses, patients who reported that their cancer was likely curable were less likely to utilize hospice (OR = 0.25, 95%CI 0.10-0.61, P = 0.002) or die at home (OR = 0.56, 95%CI 0.32-0.98, P = 0.043), and more likely to be hospitalized in the last 30 days of life (OR = 2.28, 95%CI 1.20-4.32, P = 0.011). In contrast, patients' report that they were terminally ill was only associated with lower likelihood of hospitalizations in the last 30 days of life (OR = 0.52, 95%CI 0.29-0.92, P = 0.025). Patients' perceptions of their prognosis were not associated with hospice LOS or chemotherapy administration in the last 30 days of life. **Conclusions:** Patients' perceptions of their prognosis are associated with important EOL outcomes including hospice utilization, hospitalizations at the EOL, and death at home. Interventions are needed to enhance patients' perceptions of their prognosis in order to optimize their EOL care. Research Sponsor: Leukemia & Lymphoma Society, U.S. National Institutes of Health.

6504 **Oral Abstract Session**

Cancer diagnosis and adverse financial events: Evidence from credit reports. *First Author: Veena Shankaran, Hutchinson Institute for Cancer Outcomes Research (HICOR), Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Increasing evidence shows that cancer patients (pts) experience financial hardships after diagnosis. Few studies, however, have used objective financial data to estimate the relative risk of adverse financial events (AFEs) in cancer pts versus individuals without cancer. Using a retrospective case-control design, we investigated whether cancer pts are at increased risk of new AFEs, as measured by their credit reports. **Methods:** Western Washington Surveillance Epidemiology and End Results (SEER) cancer registry (cases) and voter registry (controls) records from 2013 to 2018 were linked to quarterly credit records from TransUnion (2012-2020), one of the 3 largest national credit agencies. Controls were age and sex matched to cases and assigned an index date corresponding to the diagnosis (dx) date of the matched case. Individuals with evidence of any AFE in the credit report closest to index/dx date or did not survive to 24 months were excluded. Cases and controls experiencing any of the following AFEs within 24 months were compared, using two-sample z tests: severe (3rd party collections, charge-offs), more severe (tax liens, delinquent mortgage payments), and most severe (foreclosures, repossessions). Multivariate logistic regression models were used to evaluate the association between cancer dx and AFE, adjusting for age, sex, dx year, and available credit 6 months before the index/dx date. **Results:** A total of 332,825 individuals (84,185 cases and 248,640 controls, mean age 66 (SD 13), 52.7% female) were included. The mean available line of credit in the year before index/dx date was $12,303. AFEs were more common in cases versus controls (Table). After adjusting for age, sex, available credit above or below $12,303, and dx year, cancer dx was significantly associated with any AFE (OR 1.77, 95% CI 1.7-1.85, p<0.0001), severe AFEs (OR 1.94, 95% CI 1.85-2.03, p<0.0001), more severe AFEs (OR 1.23, 95% CI 1.12-1.36, p<0.0001), and most severe AFEs (OR 1.46, 95% CI 1.16-1.86, p=0.0016). Age >65 and higher available baseline credit were associated with decreased risk of any and each category of AFE. **Conclusions**: Within 24 months from dx, significantly higher proportions of cancer pts experienced AFEs relative to controls. Such events on credit reports have serious and long-lasting consequences on financial status. Studies that link clinical and financial data to investigate the impacts of these events on treatment decisions, quality of life, and clinical outcomes are needed. Temporal trends in oncology drug revenue among the world's major pharmaceutical companies: A 2010-2019 cohort study. *First Author: Daniel E. Meyers, University of Calgary, Calgary, AB, Canada*

Background: In the past decade there has been a 70% increase in the number of clinical trials for cancer drugs. During this time, there has also been a substantial increase in the price of cancer drugs. It is unclear how these trends have changed the revenue landscape of major pharmaceutical companies. In this study we characterize temporal trends in cancer drug revenue relative to non-cancer drugs. **Methods:** This retrospective cohort study used publicly available global sales data from the 10 pharmaceutical companies with the highest annual revenue in 2019; Abbvie (AB), AstraZeneca (AZ), Bristol Myers Squibb (BMS), GlaxoSmithKline (GSK), Johnson & Johnson (JJ), Merck (M), Novartis (N), Pfizer (P), Roche (R) and Sanofi (S). We quantified the contribution of cancer drugs to net revenue for each company from 2010 – 2019 using consolidated annual financial reports (i.e. 10-K or 20-F forms). Cancer drugs were defined as those with an FDA-approved indication for anti-cancer effect or supportive care. All sales data were converted to USD and adjusted for global inflation. Trends in the percentage of company revenues accounted for by cancer drugs were assessed with the Kendall-Mann test. P-values were adjusted for multiple hypothesis testing using the Benjamini-Hochberg method. **Results:** During 2010-2019, cumulative annual revenue generated from cancer drugs in our cohort of companies (n = 10) increased by 96%, from $52.8 billion to $103.5 billion. The cumulative revenue from non-oncology drugs decreased by 19%, from $342.5 billion to $276.9 billion. The proportion of total revenue generated from cancer drugs grew over time; from 13% in 2010 to 27% in 2019 (p < 0.001). During 2015-2019, annual revenue for the study cohort grew by 12%: from $339.7 billion to $380.4 billion. During this period non-oncology revenues remained stagnant (mean $278.9 billion, range 276.9 – 281.9), while oncology revenues grew by 66%; from $61.4 billion to $103.5 billion. Six companies (AB, AZ, BMS, JJ, N, and P) saw substantial increases in the proportion of revenue attributable to cancer drugs. R had both the highest net revenue ($23.9 billion), and highest proportion of revenue (57%) from cancer drugs in 2010 among the cohort, similar to 2019 ($27.7 billion, 57%; p = 0.37). While not reaching significance over the total study period, M saw increases in oncology revenue from $1.5 billion in 2015 to $12.3 billion in 2019 (4% to 30% of total revenue); driven almost exclusively by sales of Pembrolizumab. **Conclusions:** Amongst the world's largest pharmaceutical companies, sales revenue from cancer drugs have increased by 96% over the past decade, while revenues from non-cancer drugs have decreased by 19%. Revenues from cancer drugs accounted for 27% of company revenues in 2019. Further work is needed to understand if this massive increase in sales revenues has translated into proportional improvements in patient and population outcomes. Research Sponsor: None.

6506 **Oral Abstract Session**

The association of sexual orientation with cancer screening and diagnosis. *First Author: Michael Joseph Herriges, SUNY Upstate Medical University, Syracuse, NY*

Background: Data on heterogeneity in cancer screening and diagnosis rates among sexual minorities (SMs) is lacking. Recent studies have shown SMs are more likely to engage in risky health behavior and have decreased healthcare utilization compared to heterosexual counterparts. However, few studies have examined how sexual orientation (SO) impacts cancer screening and prevalence. We therefore investigated whether SO affects prevalent gender-specific cancer screening and prevalence, including prostate (PCa), breast (BC), and cervical cancer (CC). **Methods:** This was a cross-sectional survey-based US study, including men and women aged 18+ from the Health Information National Trends Survey (HINTS) database (part of the National Cancer Institute's division of cancer control and population sciences) between 2017-2019. The primary endpoint was individual-reported PCa, BC, and CC screening and prevalence rates among heterosexual and SM men and women. Multivariable logistic regression analyses assessed association of various covariates with undergoing screening and diagnosis of these cancers. **Results:** Overall, 4,441 (95.18%) men and 6,333 (96.75%) women reported a SO of heterosexual whereas 167 (3.6%) and 58 (1.2%) men and 105 (1.6%) and 108 (1.6%) women reported a SO of gay and bisexual, respectively. Mean age was higher in the heterosexual group compared to the gay and bisexual groups in both men (57.7 [±16.0] vs. 52.4 [±14.5] and 51.9 [±18.0] years, p = < 0.001) and women (56.2 [±16.7] vs. 49.0 [±17.1] and 40.0 [±14.8] years, p = < 0.001). Homosexuals and bisexuals were less likely to be screened for PCa (30.53% and 27.58% vs 41.27%, p = < 0.001), BC (63.81% and 45.37% vs 80.74%, p = < 0.001), and CC (90.48% and 86.11% vs 95.36%, p = < 0.001) than their heterosexual counterparts. While rates of PCa and BC diagnoses were similar across SO, more homosexual and bisexual women were diagnosed with CC compared to their heterosexual counterparts (4.76% and 3.70% vs 1.85%, p = 0.039). Multivariable logistic regression models showed that SMs were less likely to be screened for cancer with ORs of 0.61 (95% CI 0.39-0.95, p = 0.030) for PCa, 0.52 (95% CI 0.30-0.92, p = 0.025) for BC, and 0.21 (95% CI 0.09-0.46, p = < 0.001) for CC. Although multivariable models did not show that SMs were more likely to be diagnosed with PC, BC, or CC, SMs were more likely to be diagnosed with any cancer with ORs of 1.64 (95% CI 1.06-2.54, p = 0.026) in women only and 1.50 (95% CI 1.11-2.03, p = 0.009) in men and women combined. **Conclusions:** These data suggest that in addition to other established and known specific socio-economic risk factors, SMs may be less likely to undergo screening of prevalent malignancies such as PCa, BC, and CC. This provides more evidence of ongoing healthcare inequality, urging our healthcare system to invest more in cancer screening of this vulnerable population. Research Sponsor: None

Mobile low-dose computerized tomography (LDCT): Three-year follow up of solution for early diagnosis of lung cancer in under-served populations. *First Author: Derek Raghavan, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Randomized trials have proven that screening high-risk patients with LDCT of chest reduces lung cancer mortality compared to screening with chest x-ray. Under-served patients lack access to this test due to geographic and socio-economic factors. We hypothesized that a mobile screening unit would improve access and increase survival in this group, which is most at risk of lung cancer deaths. **Methods:** We installed a BodyTom portable 32 slice low-dose CT scanner (Samsung Inc) into a 35 foot coach (Frazier Inc), reinforced to avoid equipment damage during road travel. It includes waiting area, high speed wireless internet connection for rapid image transfer, and electronic tablets to deliver smoking cessation and health education programs and shared decision-making video aids. We used LUNG RADS approach to lesion classification, yielding high sensitivity and specificity in assessment. All films were reviewed by a central panel. This is certified as a lung cancer screening Center of Excellence by the Lung Cancer Alliance. Protocol was approved by Advarra IRB. Medicare pts excluded as insurance covered them for LDCT, although this reduced potential number of cases diagnosed as this is highest risk population. **Results:** We screened 1200 uninsured or under-insured subjects, mean age 61 years (range 55-64), with average pack year history of 47.8 (30-150); 61% male; 18% Black, 3% Hispanic/Latino; 78% rural. We found 97 pts with LUNG RADS 4 lesions, 30 lung cancers (2.5%), including 15 at stage I-II treated with curative intent; 5 incidental non-lung cancers (renal CA 2, head & neck CA 1, pancreas CA 2); more than 50% with cardiovascular disease or COPD seen on LDCT. Of eligible first-screen subjects (J. Clin. Oncol., 2019, 37, 383S), 440 attended Year 1 repeat LDCT and 161 attended Year 2 LDCT. Only one pt with surgically resected CA lung has relapsed to date. **Conclusions:** Mobile LDCT yields higher screening rate for under-served pts than prior international studies, with strong protocol adherence and paucity of early cancer deaths in high-risk population with traditionally poor compliance. 6508 **Oral Abstract Session**

Reducing racial disparities in time to breast cancer diagnosis: Impact of immediate screening mammogram reads during the COVID pandemic. *First Author: Janeiro Achibiri, Massachusetts General Hospital, Boston, MA*

Background: During the COVID-19 pandemic, barriers to access screening mammography along with goals to reduce visits supported immediate reading of screening mammograms. Typically, screening mammograms are reported after patients have left the facility. If imaging is abnormal, then an additional visit is needed for diagnostic imaging, introducing delays and potential disparities.Thus, we implemented an immediate-read screening mammography program and measured its impact on racial/ethnic disparities in time to diagnostic imaging after an abnormal screening mammogram. **Methods:** Responding to the COVID-19 pandemic, we implemented an immediate read screening program in late May 2020. Patients were provided imaging results before discharge and if the exam was abnormal, efforts were made to perform diagnostic imaging during that visit. We identified consecutive screening mammograms performed weekdays 8:00am-4:30pm and Saturdays 9:00am-4:00pm pre-implementation (6/1/19-10/31/19) and post-implementation (6/1/2020-10/31/2020). Exams left unread while awaiting comparison studies, due to technical factors, or for more than 10 days were excluded. Patient demographics and time from screening exam completion to report finalized were obtained from the electronic medical record. Cancer detection rate (CDR), abnormal interpretation rate (AIR), and positive predictive value (PPV) were calculated. Multivariable linear and logistic regression models were used to compare time from screening exam to report, same-day diagnostic imaging, and screening performance metrics pre- and post-implementation overall and by patient subgroups. **Results:** After 963 exams met exclusion criteria, a total of 8,222 pre- and 7,235 post-implementation exams were included. Median time to report finalization decreased from 61minutes (interquartile range [IQR]:24, 152) to 4 minutes (IQR:2, 7) for pre- and post-implementation periods ($p < 0.001$). During the pre-implementation period, non-white patients had lower odds of having same-day diagnostic imaging after an abnormal screening exam (age-adjusted odds ratio: 0.28; 95% CI: 0.10, 0.78 p = 0.015). There was no evidence of this disparity post-implementation. AIR was higher in the pre- versus post-implementation period (6.3% versus 5.0%; $p < 0.001$). There was no evidence of a difference in CDR (5.8 versus 4.2 cancers/1,000 exams) and PPV (9.2% versus 8.4%) for pre- versus post-implementation periods. **Conclusions:** An immediate read screening mammography program reduces racial/ethnic disparities in time to diagnostic imaging after an abnormal screening mammogram, thus promoting equity in access to care. Research Sponsor: None.

	Pre- implementation	Post- implementation
Age-adjusted OR of a Same-Day Diagnostic Exam, Non-White:White	0.28 (95% CI: 0.10, 0.78, p = 0.015)	0.87 (95% CI: 0.48, 1.56, p = 0.637)

6509 **Poster Discussion Session**

Mortality risk for patients undergoing cancer treatment who acquire SARS-CoV-2: ASCO registry. *First Author: Kathryn Finch Mileham, Levine Cancer Institute/Atrium Health, Charlotte, NC*

Background: The ASCO Registry was created to analyze the impact of COVID-19 (COVID) on treatment (Tx) and outcomes of patients (pts) with cancer. **Methods:** The Registry includes pts with 1) a confirmed COVID diagnosis (Dx) and 2) clinically evident cancer receiving Tx/supportive care or resected cancer on adjuvant Tx <12 mos since surgery. Practices report data on cancer Dx and Tx at COVID Dx, COVID symptoms, comorbidities, cancer/COVID Tx, and survival. Kaplan-Meier estimation provided 30- and 90-day mortality rate estimates for pts with COVID Dx before or since 6/1/20 within pt subgroups with 95% confidence intervals (CI). Data submission cutoff for all practices was 10/24/20, except one that was 11/16/20. **Results:** This analysis reports on 453 pts with COVID Dx 3/5/20 to 10/22/20 who were on anticancer drug Tx for regional (9%) or metastatic (53%) solid tumors or hematologic cancers (38%) at COVID Dx. 38 practices entered data: health system-owned 51% of pts, privately-owned 25%, academic 24%. 53% of pts have ≥30 days follow-up or died ≤30 days from COVID Dx. Median age is 64 years; 53% of pts are female; 28% of pts are asymptomatic at COVID Dx. Multiple myeloma was most frequent cancer (17%). All-cause mortality rates (30 and 90 days) increased with pts' age at COVID Dx [Table]. No mortality difference was seen based on sex, race, or comorbidities (hypertension, diabetes, pulmonary disease). Pts with COVID Dx before June 1 had worse survival than pts diagnosed on/after June 1. Pts with B-cell malignancies had higher mortality rates than pts with solid tumors. **Conclusions:** Severity of COVID illness and mortality were greater for patients with COVID Dx pre-June 1 than on/after June 1. Differences on/after June 1 may be attributed to improvements in COVID management, higher COVID testing rates, and more asymptomatic pts diagnosed. Variations in COVID-19 pt populations over time due to these changes should be considered when analyzing and interpreting pandemic data. Cancer pts with advanced age and B-cell cancers are at greatest risk of death but mortality rates for all groups (except those admitted to ICU) improved after 6/1/2020. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Real-world patient-reported and clinical outcomes of BNT162b2 mRNA COVID-19 vaccine in patients with cancer. *First Author: Ishwaria Mohan Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Most COVID-19 (C19) vaccine trials excluded patients with active cancer. Here, we report our real-world patient-reported and clinical outcomes of BNT162b2 mRNA C19 vaccine in patients with cancer. **Methods:** Our institutional Data-Driven Determinants for COVID-19 Oncology Discovery Effort (D3CODE) follows a longitudinal observational cohort of pts w cancer getting C19 vaccine. Pts complete a validated PRO tool, MD Anderson Symptom Inventory (MDASI, 13 core, 6 interference plus 17 items of symptoms from prior vaccine trials) pre-dose 1, then daily x 6d, then weekly, then on day of dose 2, then daily x 6d, then weekly x 3w. Demographics, cancer variables, prior immune checkpoint inhibitors (ICI), C19 status pre- & post-vaccine are aggregated via Syntropy platform: Palantir Foundry. Primary outcome is incidence of PRO symptoms bw dose 1 & 2 across AYA 15-39y, mid-age 40-64y & senior 65y+ cohorts. Secondary outcomes include PRO symptom incidence post-dose 2, post-vaccine change in cancer symptoms, post-vaccine symptom severity based on prior ICI, and confirmed C19 > 7 days post-dose 2. First planned 8-wk interim analysis is reported here. **Results:** 6388 pts w cancer (4973 w mets) received a BNT162b2 vaccine dose (4811 both doses, 1577 received one & await dose 2). Overall, median age 64y (range 16-95y); 382 AYAs, 2927 mid-age, 3079 seniors (65-70y n = 1158, 70-79y n = 1521, 80-89y n = 378, 90y+ n = 22). 4099 (64%) are White, 823 (13%) AA, 791 (12%) Hispanic, 441 (7%) Asians. Primary cancers: breast (1397), GU (821), heme (775), thoracic/HN (745), and CRC (385). Prior to dose 1, 1862 had no prior systemic tx while 4526 pts did including 3243 who had only non-IO tx (chemo, targeted tx), 1,283 had immunotherapy including 857 who had ICIs prior to dose 1. *Patient-reported symptoms after C19 Vaccine:* Of 6388 pts, 4714 (74% response rate, median age 67y, range 16-95y) completed 16485 PRO surveys. After 2 doses, seniors reported lower mean scores vs mid-age or AYAs on 22 of 36 symptoms including injection site pain, palpitations, itch, rash, malaise, fevers/chills, arthralgia, myalgia, headache, pain, fatigue, nausea, disturbed sleep, distress ($p < 0.05$). Pts w prior ICIs had higher severity of itch, rash ($p < 0.05$) from baseline after both dose 1 & 2 vs pts without systemic tx. Post dose 1, pts with prior ICI had higher increase in fatigue, malaise, itch, rash, myalgia, anorexia from their baseline vs pts without systemic tx ($p < 0.05$). *C19 Outcomes:* Of 6388 pts, 616 had a C19 test at any time post-dose 1: 23 (0.36%) tested positive of whom 20 (0.3%) were between dose 1 & 2; two (0.031%) were within 7 days post-dose 2, and one patient (0.016%) tested positive 16 days after dose 2, requiring admission. **Conclusions:** This real-world observational cohort demonstrates post-vaccine symptom burden and outcomes in patients with cancer. Second interim analysis is planned at 16 weeks. Epidemiology and clinical course of SARS-CoV-2 infection in cancer patients in the Veneto Oncology Network during the first and second pandemic waves. *First Author: Valentina Guarneri, Department of Surgery, Oncology and Gastroenterology, University of Padua, and Division of Medical Oncology 2, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: Since the beginning of the COVID-19 outbreak, the Veneto Oncology Network ROV licensed dedicated guidelines for cancer patients care during the pandemic, and developed a regional registry (ROVID) aimed at describing epidemiology and clinical course of SARS-CoV-2 infection in cancer patients. Preliminary data on 170 patients mainly diagnosed during the first pandemic wave have been published (Guarneri V, Eur J Cancer 2021). Here we report the data of additional 270 patients, comparing clinical data and outcomes between first (W1) and second (W2) pandemic waves. **Methods:** All patients with cancer diagnosis and documented SARS-CoV-2 infection are eligible. Data on diagnosis, comorbidities, anticancer treatments, details on SARS-CoV-infection including source of contagion, clinical presentation, hospitalization, treatments and fate of the infection are recorded. **Results:** 440 patients have been enrolled, 196 diagnosed during W1 (until September 2020) and 244 during W2. The most common cancer type was breast cancer (n = 116). Significant differences in clinical characteristics between W1 and W2 were the followings: ECOG PS 0 (34% vs 58%), presence of cardiac comorbidities (30% vs 13%), presence of any co-morbidities (81% vs 62%), smoking habits (23% vs 13%). Patients diagnosed in W1 were less likely on active anticancer therapy (54% vs 73%) at the time of SARS-CoV-2 infection. Distribution per stage, presence of lung metastases, disease setting (curative vs palliative), active treatment discontinuation due to infection were similar between W1 and W2. Patients diagnosed in W1 were more likely symptomatic for SARS-CoV-2 infection (80% vs 67%), and reported more frequently an in-hospital contact as potential source of infection (44% vs 9%). Significantly more patients diagnosed in W1 were hospitalized (76% vs 25%). All-cause mortality rates were 30.6% for patients diagnosed in W1 vs 12% for patients diagnosed in W2 ($p < 0.001$). However, deaths due to SARS-CoV-2 infection were more frequent in patients diagnosed in W2 (86% vs 54%, odds ratio 3.22; 95% CI 1.97-5.279). **Conclusions**: Differences in clinical characteristics between W1 and W2 reflect different pattern of virus circulation. The dramatic reduction of in-hospital contact as a source of infection reflects the efforts put in place to protect this vulnerable population from in-hospital exposure. The lower all-cause mortality rate observed in W2 is in line with the observed less frail population. However, the higher relative risk of death due to SARS-CoV-2 infection observed in W2 reinforces the need to adopt protective measures including vaccination in cancer patients, irrespectively of age, stage, and comorbidities. Association of state Medicaid income eligibility limits and long-term survival after cancer diagnosis in the United States. *First Author: Jingxuan Zhao, American Cancer Society, Atlanta, GA*

Background: Income eligibility limits for Medicaid, the health insurance programs for low-income populations in the United States, vary substantially by state for the non-elderly population. This study examined associations between state Medicaid income eligibility limits and long-term survival among newly diagnosed cancer patients. **Methods:** 1,426,657 adults aged 18-64 years newly diagnosed with 17 common cancers between 2010 to 2013 were identified from the National Cancer Database. States' Medicaid income eligibility limits were categorized as < = 50%, 51%-137%, and > = 138% of Federal Poverty Level (FPL). Survival time was measured from diagnosis date through December 31, 2017, for up to 8 years of follow-up. Multivariable Cox proportional hazard models with age as time scale were used to assess associations of eligibility limits and stage-specific survival, controlling for age group, sex, race/ethnicity, metropolitan statistical area, number of health conditions other than cancer, year of diagnosis, facility type, and the random effect of state of residence. **Results:** Among newly diagnosed cancer patients aged 18-64 years, 22.0%, 43.5%, and 34.5% resided in states with Medicaid income eligibility limits ≤50%, 51%-137%, and ≥138% FPL, respectively. Compared to patients living in states with Medicaid income eligibility limits ≥138% FPL, patients living in states with Medicaid income eligibility limits ≤50% and 51-137% FPL were more likely to have worse survival for most cancers in both early and late stage. The highest hazard ratios (HRs) were observed among patients living in states eligibility limits ≤50% FPL (p trend < 0.05). For example, for early stage female breast cancer patients, the HRs were 1.31 (95% confidence interval [95% CI]: 1.18 – 1.46) and 1.17 (95% CI: 1.06 – 1.30) for patients living in states with Medicaid income eligibility limits ≤50% and 51%-137% compared to those living in states with Medicaid income eligibility limits ≥138% FPL. **Conclusions:** Lower Medicaid income eligibility limits were associated with worse long-term survival within stage, with variation below the Medicaid eligibility threshold as part of the Affordable Care Act. States that have not expanded Medicaid income eligibility limits should expand them to help improve survival among cancer patients. Research Sponsor: None.

Impact of clinical trial enrollment on episode costs in the Oncology Care Model (OCM). *First Author: Garrett Young, OneOncology, Nashville, TN*

Background: Clinical trials are critical for improving outcomes for patients with cancer. However, there is some concern from health insurers that clinical trial participation can increase total cost of care for cancer patients. We investigated the impact of clinical trial participation on total costs paid by Medicare during the OCM program in a large community-based practice. **Methods:** Tennessee Oncology (TO) is a community oncology practice comprising over 90 oncologists across 30 sites of care. We linked TO trial data and electronic medical record data with OCM data for episodes of care from 2016-2018. To assess the impact of trial participation on total cost relative to routine care, we created matched comparator groups for each OCM episode based on cancer type, metastatic status, number of comorbidities, performance status, and age. Patients with breast cancer receiving hormone therapy only were excluded. Absolute and percent cost differences between groups were calculated for episodes that had a comparator group size of five or greater. Differences in total cost for trial episodes were compared to non-trial episodes, and significance was assessed using the Mann–Whitney U test. We also studied the impact of trial participation on receipt of active treatment in the last 14 days of life (TxEOL), hospice use, and hospitalizations. **Results:** During the study period, 8,026 completed OCM episodes met study criteria. Patients were enrolled in a clinical trial for 459 of these episodes. On average, episodes during which patients were on trial cost $5,973 less than matched non-trial episodes (Table), independent of early versus late-phase trial. Most savings resulted from decreased drug costs. There were no differences in rates of TxEOL (15% vs. 14% p=1.0), rates of hospitalizations (31% vs. 30% p=0.54), or hospice use (52% vs. 62% p=0.08) between trial and non-trial episodes. Median difference from comparator group average cost was significantly lower for clinical trial episodes (-18% vs. -6%, p<0.01). **Conclusions**: In the community setting, total costs paid by Medicare for patients participating in clinical trials during OCM episodes were lower than costs for similar patients receiving routine care. Clinical trial participation did not adversely impact end-of-life care or likelihood of hospitalization. These findings suggest that patient participation in clinical trials does not increase total cost of care nor enhance financial risk to payers. Research Sponsor: None.

A successful model of biosimilar adoption in a community oncology practice. *First Author: Lalan S. Wilfong, Texas Oncology/The US Oncology Network, Dallas, TX*

Background: The emergence of biosimilars creates an opportunity for more cost-effective treatment. Utilization of biologics in cancer care has increased and accounts for 70% of oncologic drug spending growth from 2010 to 2015. Biosimilars can play a vital role in controlling this rapid rise in cost. Practices focused on Value Based Care arrangements, such as the Oncology Care Model, can reduce total cost of care by increasing utilization of biosimilars. The process of interchange is complicated by the designation of each biosimilar which prevents simple interchange. Communication with physicians and the healthcare team along with patient education and consent must be performed. We describe a successful model for therapeutic interchange of brand drugs to biosimilars. **Methods:** Texas Oncology elected to increase utilization of biosimilars in 2020. We collaborated with McKesson Specialty Health to create educational materials for patients and clinical staff. Communication was sent to all personnel about the therapeutic interchange process. A central pharmacy team reviewed all new orders and substituted a biosimilar for brand, unless a payer insisted on origin drug or a biosimilar not in the practice formulary. Additionally, a report was generated weekly of all existing patients who would benefit from switching. The pharmacists, upon consultation with the physician, then substituted a biosimilar for brand drug. Patients were then educated and re-consented. We started with rituximab in 07/2020 followed by bevacizumab in 09/2020 then trastuzumab in 10/2020. **Results:** The table below shows our conversion rate for all administrations. We were able to increase utilization of biosimilars from January of 2020 to December of 2020 from 5% to 80% for Rituximab, 9% to 88% for bevacizumab and 8% to 74% for trastuzumab. Based on average ASP for a 70 kg patient, the potential savings per administration is $550 for bevacizumab, $850 for trastuzumab, and $1400 for rituximab. In one month alone, this project dramatically reduced cost by $4 million or 21% by conversion to these three biosimilars. Additional savings can be realized with the use of biosimilar multi-dose vials vs single dose vials. **Conclusions:** Our comprehensive team approach successfully deploys therapeutic interchange of biosimilars for brand drugs in a community oncology practice which leads to substantial cost savings. This has real implications in controlling the total cost of care. Research Sponsor: None.

Represents all administrations administered during each time period.

Biosimilar Uptake by Month, 2020	Bevacizumab biosimilars	Rituximab biosimilars*	Trastuzumab biosimilars*

Health outcomes and resource utilization associated with postsurgical opioid use among cancer patients undergoing curative-intent surgery. *First Author: Na Lin, The Center for Health Informatics, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada*

Background: To date, it remains unclear whether new persistent post-surgical opioid use is associated with subsequent opioid overdose, higher mortality and greater consumption of healthcare resources among cancer patients. To fill this gap, a population-based cohort study by applying real-world data has been performed to compare the long-term outcomes and healthcare resource use between new persistent and non-persistent opioid users among cancer patients after curative-intent surgery. **Methods:** This retrospective cohort study included all adult cancer patients with solid tumours who received curative-intent surgery in Alberta between 2011 and 2015, with a follow-up period until December 31, 2019. Patients who had multiple tumors, or had a follow-up < 6 months, or > 30 days of hospitalization were excluded. A new persistent post-surgical opioid user was defined as a patient who was opioid-naïve before surgery (no opioid prescription filled prior to the surgery) and subsequently filled at least one opioid prescription between 60 and 180 days after surgery. The outcomes (opioid overdose and mortality within 3 years) and health resource use (emergency department visits and hospitalization within the first year) after surgery were evaluated by applying multivariable logistic and Cox regressions. **Results:** A total of 19,219 patients received curative-intent surgery with a median follow-up of 47 months, of which 1,530 (8.0%) were identified as postoperative new persistent opioid users. Compared with the non-persistent group, a higher rate of opioid overdose (OR = 1.81, 95% CI: 1.49-2.2) within 3 years of surgery has been observed for new persistent opioid users, who were also associated with a greater likelihood of being hospitalized (OR = 2.52, 95% CI: 2.21-2.87) and visiting an emergency room (OR = 2.0, 95% CI: 1.78-2.24) within the first year after surgery. A higher overall (HR = 1.37, 95% CI: 1.2-1.57) and non-cancer caused mortality (HR = 1.39, 95% CI: 1.18-1.65) has also been detected for new persistent opioid users during the study follow-up period. **Conclusions:** For cancer patients undergoing curative-intent surgery, reducing new persistent opioid use is imperative to improve subsequent outcomes and health resource utilization. Disparities in surveillance imaging after breast conserving surgery for primary DCIS. *First Author: Danalyn Byng, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Due to the elevated risk of ipsilateral invasive breast cancer (iIBC) after diagnosis with primary ductal carcinoma in situ (DCIS), professional guidelines recommend surveillance screening within 6-12 months (mo) after completion of initial local treatment and annually thereafter. To characterize adherence to these guidelines, we explored longitudinal patterns of utilization and factors associated with the use of surveillance imaging (mammography, MRI, ultrasound) for women with primary DCIS treated with breast conserving surgery (BCS) ± radiotherapy (RT) within 6 mo of diagnosis. **Methods:** A treatment-stratified random sample of patients diagnosed with screen-detected and biopsy-confirmed DCIS in 2008-15 was selected from 1,330 Commission on Cancer-accredited facilities (up to 20/site) in the US. All imaging exams coded as asymptomatic were collected from 6 mo up to 10 years (yr) post-diagnosis. Time was defined according to 12-mo long surveillance periods. To be included in a given surveillance period, women had to be alive and free of a new breast cancer diagnosis through the end of the period. Women were classified as "consistent" screeners if they had at least one surveillance screen during each period, for the first 5 yr post-treatment or until censoring, whichever occurred first. Repeated measures multivariable logistic regression with generalized estimating equations was used to model receipt of surveillance breast imaging over time. The model included clinical and socioeconomic features. **Results:** The final analytic cohort contained 12,559 women; 8,989 (71.6%) received RT after BCS. Median age was 60 yr (interquartile range: 52-69) and median follow-up was 5.6 yr (95% confidence interval [CI] 5.6-5.7). Among women who received BCS (instead of BCS+RT), 62.5% (79.7%) underwent surveillance imaging within 6-18 mo after diagnosis. 38.7% (54.0%) were categorized as "consistent" screeners. Compared to white women, Black women were less likely to receive surveillance screening after treatment for primary DCIS (odds ratio [OR] 0.85, 95% CI 0.77-0.94). Hispanic ethnicity had a similar association (OR 0.86, 95% CI 0.74-0.99) compared to non-Hispanic ethnicity. Women with private insurance, compared to government insurance, were more likely to receive screening (OR 1.20, 95% CI 1.11-1.30). Prognostic tumor features indicative of a higher risk of subsequent iIBC, including higher grade, presence of comedonecrosis, and hormone receptor-negative DCIS, were not associated with screening uptake. **Conclusions:** Despite guidelines recommending annual surveillance imaging, many women with primary DCIS do not undergo regular imaging after BCS. The findings from this US-based study suggest that disparities in screening uptake are associated with race/ethnicity and insurance status rather than prognostic tumor features. Should we routinely screen for frailty prior to gynecologic oncology surgery? Frailty as a potential predictor of adverse postoperative outcomes in elderly patients. *First Author: Sarah J. Mah, McMaster University, Hamilton, ON, Canada*

Background: Frailty is increasingly recognized as an adverse prognostic factor of postoperative morbidity and survival in several surgical disciplines. There is no consensus on routine frailty screening in Gynecologic Oncology. Our goal was to evaluate the predictive role of the National Surgical Quality Improvement Program(NSQIP) comorbidity-based modified Frailty Index-5(mFI-5) in Gynecologic Oncology patients over the age of 70. **Methods:** Elective laparotomies between 01/2016-09/2020 at the Juravinski Hospital in Hamilton, ON were reviewed using prospectively-collected NSQIP data and chart review. Complication severity was assessed by Clavidien-Dindo classification. The primary outcome was rate of 30-day grade III-V complications. Secondary outcomes were: grade II-V complications, myocardial injury, length of stay(LOS), non-home discharge, and non-initiation/non-completion of adjuvant chemotherapy. Logistic regression analysis was performed. Survival analysis and receiver-operator characteristic curves are underway. **Results:** In this cohort of 259 patients, frail patients(mFI-5$\geq$2) were at significantly greater risk of grade III-V complications (OR23.77, 95%CI 9.69-66.26, $p < 0.0001$), grade II-V complications (OR3.8, 95%CI 1.96-7.85, $p = 0.0002$), myocardial injury (OR3.44, 95%CI 1.66-7.05, $p = 0.0009$), LOS$\geq$5-days (OR2.96, 95%CI 1.61-5.52, $p = 0.0006$), non-home discharge (OR7.37, 95%CI 2.81-20.46, $p < 0.0001$), and non-initiation/non-completion of chemotherapy (OR7.34, 95%CI 2.43-23.06, $p = 0.0006$), than non-frail patients on univariate analysis(UVA). On multivariable analysis, frailty remained independently associated with grade II-V complications and grade III-V complications (OR4.64, 95%CI 2.31-9.94, $p < 0.0001$, controlling for stage, operative duration and intraoperative complication, and OR24.49, 95%CI 9.72-70.67, $p < 0.0001$, adjusting for BMI, stage and operative duration, respectively). On UVA, age, surgical complexity score, and smoking were not predictive of complications. Frailty also independently predicted non-home discharge (OR7.37, 95%CI 2.81-20.46, $p < 0.0001$) when adjusting for age. **Conclusions:** Frailty as assessed with mFI-5, independent of age, strongly predicted morbidity and non-home discharge after Gynecologic Oncology surgery. Strategies for perioperative optimization could help address these disparities. mFI-5 is a concise tool that can be used for routine frailty screening and risk stratification. National Cancer Institute (NCI) implementation of the American Society of Clinical Oncology (ASCO) and Friends of Cancer Research (Friends) broadening clinical trials eligibility criteria. *First Author: Andrea M. Denicoff, National Cancer Institute, Rockville, MD*

Background: The 2017 ASCO/Friends eligibility criteria guidelines recommend inclusiveness to promote generalizable trial results and clear rationale for necessary exclusion. These guidelines focused on brain metastases, minimum age for enrollment, HIV infection, and organ dysfunction and prior and concurrent malignancies. In September 2018, the NCI Cancer Therapy Evaluation Program (CTEP) implemented modernized protocol template language to operationalize these criteria. We evaluated utilization of the new language among CTEP-sponsored treatment trials. **Methods:** We evaluated protocols first approved by CTEP between 11/01/2018 and 4/30/2020. The most recent approved protocol version was evaluated for consistency with the new template language for brain metastases, HIV infection, prior or concurrent malignancies, minimum age, and cardiac, liver and kidney function. If a particular criterion was not relevant for a trial, it was not included in the analysis. We did not score age in pediatric or adult-specific trials (e.g. prostate). **Results:** 122 trials (71% early and 29% late phase) were identified and included in the analysis. Compliance with the new criteria language ranged from a high of 87.7% for liver function to a low of 11.5% for "new or progressive brain metastases" (table). Modernized criteria language was lacking in nearly 46% of trials in the use of concurrent or prior malignancy criteria and 31% of trials for the cardiac criteria. Of the 87 trials for non-localized disease or non-brain tumor trials, 64.4% did not address brain metastases, leaving it to investigator discretion. Thus, 75.9% of trials could theoretically enroll patients with brain metastases. Only 6 trials were considered relevant for patients < 18 years old; 50% were consistent with the age criterion (not shown in table). **Conclusions:** Implementing ASCO/Friends eligibility criteria requires focused reviews during protocol development to ensure compliance. CTEP is using these findings to continue to improve its protocol review processes to broaden eligibility in clinical trials. Maximizing opportunities for diverse populations to participate in trials is a priority for the National Cancer Institute and CTEP will continue efforts to achieve this goal. Research Sponsor: U.S. National Institutes of Health.

Broadened Eligibility Criteria Category	No. of Analyzable Trials	Modernized Criteria Implemented	Modernized Criteria Not Implemented	Criteria Not Addressed in Eligibility
Liver function	122	87.7% (107)	6.6% (8)	5.7% (7)
Kidney function	122	86.1% (105)	9.0% (11)	4.9% (6)
Cardiac function	122	58.2% (71)	31.1% (38)	10.7% (13)
HIV	122	76.2% (93)	6.6% (8)	17.2% (21)
Prior / Concurrent Cancer	122	34.4% (42)	45.9% (56)	19.7% (24)
Treated/ Stable Brain Metastases	87	50.6% (44)	17.2% (15)	32.2% (28)
New/ Progressive Brain Metastases	87	11.5% (10)	24.1% (21)	64.4% (56)

Racial and ethnic representation trends in United States oncology training programs. *First Author: Conner Lombardi, University of Toledo College of Medicine, Toledo, OH*

Background: Utilizing race and ethnicity data from the Accreditation Council for Graduate Medical Education (ACGME), this study aims to assess representation trends across American Society of Clinical Oncology (ASCO) participant specialties from the past five academic years in order to characterize current needs and effectively address these needs moving forward. **Methods:** Self-reported ethnicity/race data from the ACGME database books were collected from academic years 2015-16 to 2019-2020 for the following oncologic training programs: hematology and medical oncology, medical oncology, gynecologic oncology, pediatric hematology and oncology, radiation oncology, complex general surgical oncology. Summary statistics and chi-square analysis were conducted to compare underrepresented minority (URM) trends across programs. URM groups were cross-referenced with definitions provided by the AAMC and included those who identify as Hispanic, Latino or of Spanish origin, Black or African American, and Native American or Alaskan. **Results:** Over the study period, only 1,250 (9.0%) of 13,853 oncology trainees identified as URM. Chi-square analysis demonstrated no significant change in URM representation in all oncology specialties combined between 2015-16 and 2019-20 (8.9% [95% CI, 7.8%-10.0%] vs. 9.7% [95% CI, 8.7%-10.8%]; P=.31). Between 2015-16 and 2019-20, Hematology and oncology (+1.3%), pediatric hematology and oncology (+0.3%) all demonstrated insignificant increasing trends in representation while radiation oncology (-0.3%), complex general surgical oncology (-4.0%) had statistically insignificant decreasing trends in representation. Gynecologic oncology (+6.0%) demonstrated a significant increasing trend in representation. **Conclusions:** This is the first study to characterize the vast disparities in representation in oncologic training programs in the United States. There is a demonstrated lack of representation across all oncology training programs and a lack of significant improvement over the study period. A multiprong approach is needed to improve diversity and representation across the spectrum of the oncology workforce in the United States. Research Sponsor: None.

Individual and institutional predictors of sexual orientation and gender identity data collection in oncology practice: An ASCO survey.

First Author: Charles Stewart Kamen, University of Rochester Medical Center, Rochester, NY

Background: Most oncology practices do not collect patients' sexual orientation (SO) or gender identity (GI) (SOGI), prohibiting assessment of sexual and gender minority (SGM) patients' cancer disparities and identification of such patients in cancer care or research. Studies report that 90% of SGM patients would disclose their SOGI, while 78% of clinicians believe that patients would not. Preliminary evidence indicates that SOGI disclosure improves health outcomes. Organizations, including ASCO and NIH, have called for routine SOGI data collection, but institutional barriers, e.g. lack of SOGI fields in EMRs, hinder progress. This study aimed to delineate institutional and individual-level factors related to SOGI data collection in oncology. **Methods:** From Oct to Nov 2020, an anonymous 54 item online survey was distributed to ASCO members via direct outreach, listservs and social media. The survey assessed whether respondents' institutions collect SOGI data, factors related to SOGI data collection, respondents' attitudes about SOGI data and SGM patients, and demographics. Simple and multiple logistic regression modeling determined factors associated with respondents' reports of SOGI data collection at their institutions. **Results:** Nearly half of 257 respondents reported their institutions collect SO and GI data (42%, 48%, respectively); over a third reported their institutions did not collect SO or GI data (36%, 34%, respectively); and a fifth were unsure (22%, 18%, respectively). Collection of both SO and GI was associated in unadjusted models with leadership support and having resources for SOGI data collection. SO collection was also associated with type of institution, having an SGM family member, and belief that knowing SO is important for providing quality care. GI collection was associated with the respondent's role, SO, political leaning, past SGM training, and belief that knowing GI is important for providing care. Odds ratios (OR) from adjusted models with 95% confidence intervals (CI) comparing respondents who reported SO or GI collection as "Yes" vs. "No" are reported (comparisons to "Unsure" not presented). Most respondents (79%) felt it was important to know both SO and GI to provide quality care, while 14% felt neither was important. **Conclusions:** Whether or not institutions collect SOGI data is related to many factors. Despite limited statistical power, the same three factors emerged as drivers of data collection: leadership support, resources and individuals' attitudes. These are critical and possibly self-reinforcing elements for collecting SOGI data. Research Sponsor: None.

Results from adjusted logistic regression models for SOGI collection.

Predictor	OR (SO)	95% CI (SO)	OR (GI)	95% CI (GI)
Leadership support	8.01	2.45-26.2	6.02	2.32-15.6
Institutional resources	10.6	4.05-27.7	18.7	5.34-65.3
Importance of knowing patient SO or GI	4.28	1.50-12.2	2.76	1.01-7.51

Socioeconomic status variables contribute to the disparities in female triple negative breast cancer outcome in the United States, 2011-2015: A population study based on NCI Surveillance, Epidemiology and End Results (SEER) database.

First Author: Zikun Wang, Indiana University Bloomington School of Public Health, Bloomington, IN

Background: Cancer disparities pertinent to socioeconomic status (SES) still exist in the American healthcare system. How SES variables impact the outcome of triple negative breast cancer (TNBC) needs identification. **Methods:** We enrolled 22,434 women diagnosed with invasive TNBC in 2011 – 2015 from the SEER 18 program. The primary outcome was to identify SES risk factors for TNBC cause specific survival (TNBCCSS)and overall survival (OS) via the Cox Proportional Hazard Regression Model. SES information was collected: race, insurance status, marital status, and percentage of families with incomes below the poverty level and adults with less than high school graduate (<HSG) in a county of the patient's residency; all analyses were also adjusted for clinicopathological characteristics. We categorized rates of poverty and <HSG as quartiles. **Results:** 18,578 (82.8%) women were insured or insured/ no specifics (NS), and 3,360 (15.0%) received Medicaid upon TNBC diagnosis; only 496 (2.2%) patients were uninsured. The TNBCCSS rates of insured, insured/ NS, Medicaid, and uninsured cohorts were 86.6%, 83.6%, 77.4% and 73.2%, respectively. In multivariable adjusted analyses, the TNBC cause specific mortality risk of patients who were uninsured or receiving Medicaid was significantly higher than that of women who were insured (Hazard ratio [HR] = 1.60, 95% confidence interval [CI]: 1.34-1.92 and HR = 1.29, 95% CI: 1.18-1.41, respectively). Women residing in a county with a high poverty rate (the 3rd quartile [rate of 11.1 – <14.3%]) had significantly worse TNBC cause specific mortality risk as compared to women with residency of the lowest poverty rate (HR = 1.25, 95% CI: 1.10-1.41). Single and widowed cohorts had better HR of TNBCCSS compared with the married population (HR = 0.86, 95% CI: 0.79-0.95 and HR = 0.82, 95% CI: 0.73-0.93, respectively). Notably, we observed a synergistic effect among race, insurance status and TNBC OS: black women receiving Medicaid had significantly lower HR compared with their non-Hispanic white counterparts (HR = 0.86, 95% CI: 0.74-0.98). Rate of <HSG was marginally correlated with the TNBCCSS. **Conclusions:** SES variables contribute to the disparities in TNBC survival. TNBC cause specific mortality risk of patients without insurance or with Medicaid at the time of TNBC diagnosis is 60% and 29% higher compared with insured women (Table). Race and insurance status act synergistically upon TNBC OS. Research Sponsor: None.

Results of Multivariable Cox Regression Analysis associating insurance status and TNBC survival.

Investigating tumor molecular profiling as a possible contributor to racial/ethnic disparities in pancreatic cancer.

First Author: Evan Justin Walker, University of California San Francisco, San Francisco, CA

Background: A variety of biologic, socioeconomic, and treatment-related factors may contribute to the racial/ethnic disparities observed in pancreatic ductal adenocarcinoma (PDAC) outcomes. As tumor molecular profiling (TMP) is now recommended for patients (pts) with advanced PDAC to inform treatment selection, we hypothesized that rates of TMP, detection of actionable alterations (AA), and use of molecularly-targeted treatments differ across different racial/ethnic groups and may contribute to disparate outcomes. **Methods:** This retrospective analysis included all Non-Hispanic White (NWH), Asian, Hispanic/Latinx (H/L), and Black/African American (B/AfrAm) pts with PDAC who underwent TMP at UCSF over a 4-yr period. Medical records were reviewed for demographic and disease-specific data. Alterations classified as 'pathogenic' or 'likely pathogenic' in TMP clinical reports were included, and were categorized as 'actionable' if there was clinical or preclinical evidence of benefit from targeted therapy in any cancer. Associations between NHW and other groups were tested with Fishers exact test. **Results:** Between 1/2016-1/2020, 159/727 (22%) pts underwent PDAC TMP. 60 AA were detected in 54 pts. Rates of TMP or AA detection were not associated with racial/ethnic group (Table). Most AA (33/60, 55%) were associated with the Homologous Recombination DNA Damage Repair (HR-DDR) pathway (*ARID1A* n = 15, *ATM* n = 7, and *BRCA1* n = 5). Other common AA included *PIK3CA* alterations (n = 6), *CDK4/6* amplifications (n = 5), *AKT2* amplifications (n = 4) and *KRAS* G12C mutation (n = 4). Molecular targets differed between groups (HR-DDR genes comprised 55% AA in NHW vs 100% in H/L, p = 0.03). Regarding treatment, rates of platinum chemotherapy for HR-DDR gene-altered PDAC differed significantly between groups. Three NHW pts with HR-DDR alterations received a PARP-inhibitor +/- ATR inhibitor. **Conclusions:** To our knowledge, this is the first study to report PDAC TMP rates and therapeutic implications across racial/ethnic groups. Acknowledging the limitations of sample size and what defines AA, we observed no significant differences in rates of testing nor AA detection. Further study is needed to evaluate whether rates of molecularly-informed treatment selection contribute to racial/ethnic disparities in clinical outcomes. As therapeutic advances increase the likelihood of identifying AA, equitable access to both TMP and targeted treatments must be ensured for all pts with PDAC. Research Sponsor: None.

Racial and ethnic enrollment disparities in acute myeloid leukemia clinical trials.

First Author: Andrew Hantel, Dana-Farber Cancer Institute, Boston, MA

Background: Racial and ethnic disparities in clinical trial enrollment compound inequities in drug development and the delivery of patient-centered care. Despite significant survival disparities in acute myeloid leukemia (AML), enrollment disparities data are limited. **Methods:** We performed a structured search and abstraction of demographic data for all United States (US) AML clinical trials from 2002-2017 listed on clinicaltrials.gov and compared the results to the incidence and demographic distribution of AML using the Surveillance, Epidemiology, and End Results program and 2010 US Census. We calculated enrollment fractions (the number of enrollees divided by the number of incident cases) for the five mutually exclusive race/ethnicity groups of non-Hispanic White (NH-White), Black (NH-Black), Asian/Pacific Islander (NH-Asian/PI), American Indian/Native Alaskan (NH-AI/AN), and Hispanic patients. We compared these using X^2 testing, with NH-White as the comparator, and reported odds ratios with 95% confidence intervals (CI). To assess trends over time, we adjusted enrollment from 2005-2008 for changes in AML incidence and NH-White enrollment for a later period (2011-2014), comparing this expected enrollment fraction to the actual enrollment fraction during that later period. **Results:** Of 223 eligible studies (patient N=17372) on clinicaltrials.gov, 99 (44.4%) reported racial demographics (N=8417; 48.5%) and 68 (30.5%) reported race and ethnicity (N=6554; 37.7%). Enrollment and incidence proportions by race are shown in the table. Among trials reporting race and ethnicity, all groups had lower odds of enrollment compared to NH-White patients (Table). For the 99 trials reporting race data, Black and AI/AN patient enrollment odds were lower (OR 0.60 [95% CI: 0.55, 0.65]; 0.50 [95% CI: 0.33, 0.76]), but Asian/PI enrollment was not (OR 0.91 [95% CI: 0.82, 1.01]). The relative enrollment of NH-Black, NH-Asian/PI, and Hispanic patients declined later in the study period (Table). **Conclusions:** In AML clinical trials performed in the US from 2002-2017, NH-White patients were enrolled at higher rates compared to other racial and ethnic groups; enrollment diversity declined over time. An important first step to reducing enrollment disparities will be to improve the reporting of demographic enrollment data. Research Sponsor: U.S. National Institutes of Health.

Association of electronic-health record (EHR)-derived race with BRCA testing in patients (pts) with breast cancer (BC) with similar genetic ancestry (GA) in a clinicogenomic database (CGDB). *First Author: Yanling Jin, F. Hoffmann-La Roche Ltd., Mississauga, ON, Canada*

Background: Disparities in health outcomes can be affected by biological factors associated with GA and social determinants of health. These factors can be teased apart using GA data from comprehensive genomic profiling (CGP) in pts with cancer. CGDBs that link EHR data with CGP enable the selection of pts with similar GA. Holding GA constant provides an opportunity to directly study the effects of reported race in health disparities. This study evaluated a published racial disparity (BRCA testing rates in African American [AA] vs White pts with BC) in a population with fixed, similar GA. **Methods:** The nationwide (US-based) deidentified Flatiron Health and Foundation Medicine (FMI) BC CGDB (Q3 2020) was used. For each pt, GA fractions from 5 geographic ancestry groups (African [AFR]; Admixed American; East Asian; European [EUR]; South Asian) were derived by FMI using an admixture analysis workflow using genes captured in the CGP assay. To focus on BRCA testing in AA vs White pts and find a sufficient population with similar GA but AA or White race, pts with admixture of both EUR and AFR ancestry were selected. The chosen fractions were: Cohort 1=35%-65% AFR and EUR each; Cohort 2=25%-60% AFR and EUR each; Cohort 3=30%-60% AFR. Cohorts overlap but were chosen to increase sample size. In each cohort, documented BRCA testing prevalence, time from diagnosis to BRCA test date, age at BRCA test and overall survival (OS) were compared between races. Other race (OR) and missing race (MR) were also reported. **Results:** Most pts (4130/6903) in the BC CGDB had ≥75% EUR ancestry; 129 pts had AFR ancestry fractions ≥25% with EUR ancestry >0%. AA pts had the lowest BRCA testing rates (39%, 43%, 44% for Cohorts 1-3, respectively), which were 18%, 10% and 17% lower compared with White pts, respectively (Table). In Cohorts 1-3, AA pts experienced a longer median time between diagnosis and testing (399, 668, 900 days) compared with White pts (93, 667, 106 days). The median age at BRCA test was 16, 9 and 8 years younger in AA pts (49, 47 and 50 years) compared with White pts. Although pts with MR data had the lowest OS compared with the other races within each cohort, the sample size of each arm for all cohorts was too small to make conclusions. **Conclusions:** This study demonstrated that when holding GA constant, racial disparities persist in BRCA testing patterns and outcome in pts with BC from a CGDB. With increasing availability of linked clinical and genomic data, further exploration of disparities in genetically similar cohorts can provide deeper insight for cancer outcomes and health disparities research. Research Sponsor: Genentech, Inc.

Impact of Medicaid expansion on two-year mortality among stage IV breast cancer (BC) patients according to race. *First Author: Catalina Malinowski, MD Anderson Cancer Center, Houston, TX*

Background: Inadequate access to healthcare services is associated with worse outcomes. Disparities in access to cancer care are more frequently seen among racial/ethnic minorities, uninsured patients, and those with low socioeconomic status. A provision in the Affordable Care Act called for expansion of Medicaid eligibility in order to cover more low-income Americans. In this study, we evaluate the impact of Medicaid expansion in 2-year mortality among metastatic BC patients according to race. **Methods:** Women (aged 40-64) diagnosed with metastatic BC (stage IV *de novo*) between 01/01/2010 and 12/31/2015 and residing in states that underwent Medicaid expansion in 01/2014 were identified in the National Cancer Database. For comparison purposes, 2010-2013 was considered the pre-expansion period and 2014-2015 the post-expansion period. We calculated 2-year mortality difference-in-difference (DID) estimates between White and non-White patients using multivariable linear regression models. Results are presented as adjusted differences (in % points) between groups in the pre- and post-expansion periods and as adjusted DID with 95%CI. Covariates included age, comorbidity, BC subtype, insurance type, transfer of care, distance to hospital, region, residence area, education, income quartile, facility type and facility volume. In addition, overall survival (OS) was evaluated in pre- and post-expansion periods via Kaplan-Meier method and Cox proportional hazards models; results are presented as 2-year OS estimates, hazard ratios (HRs), and 95% CIs. **Results:** Among 7,675 patients included, 4,942 were diagnosed in the pre- and 2,733 in the post-expansion period. We observed a reduction in 2-year mortality rates in both groups according to Medicaid expansion. Among Whites 2-year mortality decreased from 42.5% to 38.7% and among non-Whites from 45.4% to 36.4%, resulting in an adjusted DID of -5.2% (95%CI -9.8 to -0.6, p = 0.027). A greater reduction in 2-year mortality was observed among non-Whites in a sub-analysis of patients who resided in the poorest quartile (n = 1372), with an adjusted DID of -14.6% (95%CI -24.8 to -4.4, p = 0.005). In the multivariable Cox model, during the pre-expansion period there was an increased risk of death for non-Whites compared to Whites (HR 1.14, 95% CI 1.03 to 1.26, P = 0.04), however no differences were seen in the post-expansion period between the two groups (HR 0.93, 95% CI 0.80 to 1.07, P = 0.31). **Conclusions:** Medicaid expansion reduced racial disparities by decreasing the 2-year mortality of non-White patients with metastatic breast cancer and reducing the gap when compared to Whites. These results highlight the positive impact of policies aimed at improving equity and increasing access to health care. Financial toxicity, symptom burden, illness perceptions, and communication confidence in cancer clinical trial participants. *First Author: Subha Perni, Harvard Radiation Oncology Program, Massachusetts General Hospital and Brigham and Women's Hospital/Dana-Farber Cancer Institute, Boston, MA*

Background: Cancer clinical trial (CCT) participants are at high risk for experiencing adverse effects from financial toxicity, yet this remains understudied in the CCT population. We sought to describe associations among patient-reported financial toxicity (financial burden [FB] and trial cost concerns), physical and psychological symptoms, illness perceptions, and communication confidence in CCT participants. **Methods:** From 7/2015-7/2017, we prospectively enrolled CCT participants who expressed interest in financial assistance and a group of patients matched by age, sex, cancer type, specific trial, and trial phase. We assessed FB (burdened by costs of cancer care), trial cost concerns (worried about affording medical costs of a CCT), physical (Edmonton Symptom Assessment Scale [ESAS]) and psychological (Patient Health Questionnaire-4 [PHQ-4]) symptoms, illness perceptions (Brief Illness Perception Questionnaire [BIPQ]), and communication confidence (Perceived Efficacy in Patient-Physician Interactions [PEPPI]). We used regression models to explore sociodemographic associations with FB and trial cost concerns, and to examine associations of FB and trial cost concerns with patients' symptom burden, illness perceptions, and communication confidence, adjusting for age, sex, race, performance status, marital status, and metastatic status. **Results:** Of 198 patients enrolled, 112 (56.6%) reported FB and 82 (41.4%) had trial cost concerns. Patients with FB were younger (OR 0.96, 95% CI 0.94-0.98) and had lower incomes (< $100,000, OR 4.61, 95% CI 2.35-9.01). Patients reporting trial cost concerns also had lower incomes (< $100,000, OR 2.78, 95% CI 1.45-5.29). On adjusted analyses, patients with FB had higher ESAS total (OR 1.03, 95% CI 1.02-1.05), ESAS physical (OR 1.04, 95% CI 1.02-1.07), PHQ-4 depression (OR 1.54, 95% CI 1.22-1.94), and PHQ-4 anxiety (OR 1.30, 95% CI 1.08-1.55) scores, as well as more negative illness perceptions (OR 1.04, 95% CI 1.01-1.07), but no significant difference in communication confidence (OR 0.98, 95% CI 0.93-1.05). Patients reporting trial cost concerns had higher ESAS total (OR 1.03, 95% CI 1.01-1.05), ESAS physical (OR 1.04, 95% CI 1.01-1.06), PHQ-4 depression (OR 1.35, 95% CI 1.10-1.65), and PHQ-4 anxiety (OR 1.27, 95% CI 1.07-1.51) scores, as well as more negative illness perceptions (OR 1.06, 95% CI 1.03-1.10), and lower communication confidence (OR 0.93, 95% CI 0.87-0.99). **Conclusions:** In this study of CCT participants, younger patients with lower incomes were most vulnerable to financial toxicity. Financial toxicity was associated with greater symptom burden, more negative illness perceptions, and lower communication confidence, which underscores the importance of addressing these issues when seeking to alleviate the adverse effects of financial toxicity in CCT participants. Social determinants of health, genetic ancestry, and mortality in ECOG-ACRIN E5103. *First Author: Samilia Obeng-Gyasi, The Ohio State University, Columbus, OH*

Background: Social determinants of health (SDH) and genetic ancestry have been independently implicated in breast cancer presentation, treatment and mortality. However, little is known about the relationship between SDH and genetic ancestry on clinical trial outcomes. The objective of this study is to assess the association between SDH, genetic ancestry and clinical outcomes in patients enrolled in an adjuvant breast cancer clinical trial. **Methods:** ECOG-ACRIN (EA) 5103 randomized patients to receive AC + taxane + bevacizumab or placebo. SDH were operationalized as insurance status at trial registration (individual SES) and neighborhood socioeconomic status (nSES). Insurance categories included: (1) Private, 2) Medicare including private/Medicare, military, 3) Medicaid including Medicaid/Medicare, uninsured, 4) self-pay). The nSES index was calculated using zip codes linked to county level data on occupation, income, poverty, wealth, education and crowding. Genome-wide single-nucleotide polymorphism arrays were used to define African ancestry (AA), European ancestry (EA) and other (OA). Multivariable regression and Cox-Proportional Hazard models (odds ratios (OR) and hazard ratios (HR) with corresponding 95% confidence intervals (CI)) were used to assess associations with chemotherapy completion and overall mortality. Estimates were adjusted for the following clinical covariates: age, tumor size, nodal status, hormone receptor status, and primary surgery at randomization. **Results:** The study cohort included 2453 EA (79.2%), 381 AA (12.2%) and 265 OA (8.6%). Medicaid patients (OR 0.76(0.59-0.99); ref private) and those with AA (OR 0.62(0.49-0.78); ref EA) were less likely to complete chemotherapy. Regarding overall mortality, Medicaid insurance (HR 1.42(1.05-1.92) was associated with a higher mortality than private insurance. Conversely, there was no significant difference in mortality by ancestry (AA HR 1.27 (0.97-1.66); OA HR 0.90 (0.63-1.29): ref EA). Neighborhood socioeconomic status did not appear to be associated with chemotherapy completion or mortality. **Conclusions:** SDH reflective of individual SES, such as insurance, appear to be stronger drivers of trial completion and mortality compared to nSES among patients enrolled in E5103. Moreover, study results suggest an interplay between ancestry and individual proxies for SDH in trial completion. Nevertheless, the relationship between ancestry and lower rates of chemotherapy completion do not appear to translate into higher mortality rates among patients of AA. Differences by race in patient-reported symptoms during chemotherapy among women with early-stage, hormone receptor-positive breast cancer.

First Author: Xin Hu, Emory University, Rollins School of Public Health, Department of Health Policy and Management, Atlanta, GA

Background: Symptom burden may contribute to racial differences in cancer treatment adherence and survival. Evidence on changes in symptom burden during chemotherapy and whether these differ by race is scarce. We used patient reported outcomes data collected before and after breast cancer chemotherapy initiation to compare symptom burden by race. **Methods:** Using electronic medical records of a large cancer center in the southern region of the US, we identified Black and White women diagnosed with stage I-III, hormone-receptor positive breast cancer from January 2007 to December 2015. A tablet-based platform [ConcertAI] was used to collect patient reported symptoms at the point of care. We included patients with at least one completed symptom report before and during chemotherapy. We focused on two standardized composite scores – physical symptoms and treatment side-effect (mean of 50 and standard deviation of 10), and calculated changes in symptoms using the closest report before chemotherapy and the most severe score reported during chemotherapy. Patients with a 10-point increase were classified as having a clinically meaningful increase in symptom burden. We used Oaxaca-Blinder decomposition to quantify racial differences in symptom burden change explained by baseline characteristics. These included baseline symptom scores, sociodemographic characteristics (age, regional level household income and education, state) and clinical characteristics (cancer stage and primary chemo regimen). **Results:** Among 1,167 included patients, Black women (30%) were younger (52 vs. 55 years old, $p< .001$), more likely to live in areas with lower median household income and less education, and reported most severe scores about 2 weeks later than White women ($p< .05$). They were also more likely to report a 10-point increase in symptom burden for physical (68.5% vs. 61.2%, $p= .017$) and side-effects symptoms score (49.0% vs. 41.4%, $p= .015$). This was driven by larger increases in selected individual symptoms among Black women, such as sweating, itching, and numbness (under physical symptom score), and hair loss and taste change (under side-effect score). Decomposition analyses showed that baseline characteristics (especially primary chemo regimen) explained 79.2% ($p= .002$) and 35.2% ($p= .131$) of the increased probability of Black women reporting a 10-point increase in physical symptom and side-effects scores respectively. **Conclusions:** Black women with early-stage breast cancer were more likely to report a clinically meaningful increase in treatment side-effects and physical symptoms during chemotherapy compared to White women. Differences by race in physical symptoms scores were mostly explained by baseline characteristics. Future studies should examine whether racial differences in symptom burden translate into differences in treatment adherence and mortality. Research Sponsor: U.S. National Institutes of Health.

Uptake of immunotherapy in patients with advanced cancer: A population-based study using health administrative data from Ontario, Canada.

First Author: Jacques Raphael, London Regional Cancer Program, Western University, London, ON, Canada

Background: The introduction of immunotherapy (IO) in the treatment of patients with cancer has significantly improved clinical outcomes. Herein we report on IO uptake in Ontario, Canada, a publicly funded healthcare system. **Methods:** We conducted a retrospective cohort study using provincial health administrative data to: 1) assess IO uptake in adult patients with advanced melanoma, bladder, lung, head and neck (HN) and kidney cancers; and 2) identify predictors of IO usage between 2011 (pre-IO funding) and 2019. The datasets were linked using unique encoded identifiers and analyzed at ICES. IO uptake was captured between cancer diagnosis and last follow up and reported as a proportion of the entire cohort and by tumor site and drug type. A competing risk Fine and Gray regression model with death as competing risk was used to identify factors associated with IO use. **Results:** Among 59,510 patients with one of the five advanced cancers of interest, 7,660 (12.9%) received IO. Details of IO uptake are summarized in Table. IO uptake increased yearly from 2011 (2.7%) to 2019 (34.0%). Uptake was highest in melanoma (48.2%) and lowest in HN cancer (5.8%). The most commonly used drugs used were pembrolizumab (41.1%) and nivolumab (40.5%). In adjusted analysis, predictors of lower IO uptake included older age (hazard ratio (HR) 0.953, 95%CI 0.934-0.972 with every additional 10 years), female sex (HR 0.859, 95%CI 0.819-0.9), lower income quintile (HR 0.893, 95%CI 0.83-0.96), history of hospital admission (HR 0.768, 95%CI 0.734-0.805), female oncologist (HR 0.942, 95%CI 0.892-0.995), and *de novo* stage 4 cancer (HR 0.918, 95%CI 0.873-0.966). Predictors of higher IO uptake were low Charlson score (HR 1.118, 95%CI 1.01-1.236) and previous radiation therapy (HR 1.438, 95%CI 1.367-1.512). IO uptake was heterogeneous across cancer centres levels (1 to 4) and regions. **Conclusions:** While the use of IO for advanced cancer has steadily increased over time, uptake is associated with patient and physician characteristics, as well as system level factors. This variation suggests potential inequity in access to these potentially life-prolonging drugs and should be further investigated and addressed. Research Sponsor: Medical Oncology Research Fund (MORF) (University of Western Ontario), type: seed grant for the division of medical oncology.

Process redesign and daily management to improve cancer care access at the public healthcare system in Sao Jose dos Campos, Brazil.

First Author: Carlos Frederico Pinto, Instituto de Oncologia do Vale, Sao Jose Dos Campos, Brazil

Background: Cancer is the second leading cause of death in Sao Jose dos Campos (SJC, a mid-sized city with 720,000 hab. in Sao Paulo state, Brazil) and the most relevant budget in tertiary care. The City Healthcare Authority created in October 2018 a team to manage and provide more effective and efficient cancer care and access to the public healthcare system by using process redesign and daily management tools (Previna Project). The aim was to guarantee access to cancer specialist and care up to 60 days form diagnosis, understanding that this can impact in cancer morbidity, mortality, and cost. **Methods:** The Previna was grounded in 4 major actions: (1) process redesign (2) escalated daily management system, (3) improve communication channels to all providers connecting primary care to specialized care, (4) and emergency access. (1) Process Redesign involved connecting and linking access to several providers and eliminating unnecessary steps or repeated orders in the system, it also involved alerts into the system for specific conditions like elevated PSA or CEA; positive fecal occult blood test; BIRADS 4-5 mammogram; abnormal PAP smears; and new screening protocols for prostate and colorectal cancer. (2) Daily Management involved internal daily discussions about capacity and review of system alerts or demands. Weekly discussions on specialized procedures including imaging, biopsies, chemo, radiation or surgery flows; and biweekly meetings with all providers (3 hospitals and 4 specialized practices). (3) Communication channels improvements involved a hotline to access flow managers for primary and secondary care units, specialist's consultancy by phone, and (4) emergency access provided for units with special needs or urgent care requirements. All actions were connected by flow managers using alert systems, visual boards, kanban and similar tools to manage daily progress. **Results:** The access to cancer care and treatment up to 60 days improved from 2017 to 2020 almost two-fold with the Previna (Table). Cancer diagnosis also increased substantially, and it is expected to be related to previous periods underdiagnosed patients. Flow redesign also reduced median time to process Her2, ER and PR for breast cancer from 38 days in 2018 to 9 days in 2019 and 4 days in 2020, positively impacting treatment decisions. The hotline access reviewed and answered 2,389 demands from care providers between 2018 and 2020. Access to Cancer Care for ICD C00 – C97 (excl. C44 and C73) in SJC. **Conclusions**: The combined use of daily management, lean tools and flow redesign in the Previna was able to improve access and anticipate cancer diagnosis in a public healthcare system using simple and low-cost initiatives. Disparities in cancer prevalence in African Americans: A United States population study 2021.

First Author: Ahmad Nader Kassem, Metrohealth Medical Center Case Western Reserve University, Cleveland, OH

Background: African-Americans (AA) have the highest incidence and death rates from cancer and the shortest survival of all racial groups in the USA, as reiterated by the American Cancer Society's Cancer Facts and Figures for AA from 2019. We studied cancer prevalence in AA compared to Caucasians, focusing on patients with above-normal Body Mass Index (BMI). **Methods:** Data was collected from Explorys, IBM, a national database including over 73 million patients. Patients were divided based on age (18-64 and $\geq$ 65 years; for female cancers 18-49 and $\geq$ 50 years), race (Caucasians and AA), and BMI (18.5 - $<$ 25 and $\geq$ 25.0 kg/m^2). The odds ratio (OR) and 95% confidence interval (CI) for multiple cancer rates in AA compared to Caucasians were calculated with P values $<$0.001 considered significant. **Results:** N: Normal BMI EW: Excess weight (Females) C: Caucasian S: Significant NS: Non-significant. **Conclusions**: Our results show a significantly lower than expected prevalence of screenable cancers in AA compared to Caucasians, diverging widely from established incidence rates. The difference was more remarkable in pre-Medicare age ($<$ 65 years) and excess weight patients. These disparities are concerning for a compromised healthcare access contributing to underdiagnosis of cancer or shorter survival among AA in the US. Research Sponsor: None.

Association of the Affordable Care Act with survival among adolescents and young adults with lymphomas in California. *First Author: Renata Abrahão, University of California, Davis, Sacramento, CA*

Background: Our recent study showed that the implementation of the Affordable Care Act (ACA) was associated with increased health insurance coverage among adolescents and young adults (AYAs, 15–39 years) diagnosed with lymphomas in California and decreased likelihood of late stage at diagnosis. However, AYAs of Black or Hispanic race/ethnicity (vs Whites) and those living in lower socioeconomic (SES) neighborhoods were at higher risk of presenting with advanced stage. We aimed to determine whether the increased insurance coverage under the ACA was associated with improved survival, and to identify the main predictors of survival among AYAs with lymphomas. **Methods:** We used data from the California Cancer Registry linked to Medicaid enrollment files on AYAs diagnosed with a primary non-Hodgkin (NHL) or Hodgkin (HL) lymphoma during March 2005–September 2010 (pre-ACA), October 2010–December 2013 (early ACA) or 2014–2017 (full ACA). Patients were followed from lymphoma diagnosis until death, loss to follow-up or end of the study (12/31/2018). Health insurance was categorized as continuous Medicaid, discontinuous Medicaid, Medicaid enrollment at diagnosis/uninsured, other public or private. We used multivariable Cox proportional regression to examine the associations between all-cause survival and era of diagnosis, adjusting for sex, age and stage at diagnosis, health insurance, race/ethnicity, neighborhood SES, treatment facility, comorbidities, and marital status. **Results:** Of 11,221 AYAs, 5,878 were diagnosed with NHL and 5,343 with HL. Most patients were male (56%), White (45%), presented with earlier stage (I/II, 56%), and had private insurance (57%). The proportion of AYAs who received initial care at National Cancer Institute-Designated Cancer Centers (NCI-CCs) increased from 24% pre-ACA to 31% after full ACA implementation ($p < 0.001$). AYAs diagnosed in the early (aHR = 0.76, 95% CI 0.67–0.88) and full ACA (aHR = 0.55, 95%CI 0.47–0.64) eras had better survival than those diagnosed pre-ACA. Compared to those with private insurance, survival was worse among patients with no insurance (HR = 2.13, 95% CI 1.83–2.49), discontinuous Medicaid (HR = 2.17, 95% CI 1.83–2.56) and continuous Medicaid (HR = 1.93, 95% CI 1.63–2.29) at diagnosis. Regardless of their insurance, older AYAs, males, unmarried, those with later stage (II–IV), residents in lower SES neighborhoods, and those of Black, Hispanic, Asian/Pacific Islander, and American Indian/Alaskan Native race/ethnicity experienced worse survival. **Conclusions:** Following the ACA implementation in California, AYAs diagnosed with lymphomas experienced increased access to care at NCI-CCs and improved survival. Yet, racial/ethnic and socioeconomic survival disparities persisted. Moving forward, policy actions are required to mitigate structural and social determinants of health disparities in this population. Measuring disparities in quality of oncology care across oncology practices. *First Author: Nancy Lynn Keating, Harvard Medical School, Boston, MA*

Background: Equity is now recognized as an essential aspect of health care quality. Racial inequities in clinical performance diminish overall system performance. We assessed the feasibility and reliability of practice-level measures of racial disparities in chemotherapy-associated emergency department (ED) visits and hospitalizations. **Methods:** Using fee-for-service Medicare data, we identified 1,196,970 Black or White fee-for-service Medicare beneficiaries with cancer receiving chemotherapy in 2016-2019, who were attributed to 5511 oncology practices that treated at least 1 Black and 1 White beneficiary (96.4% of all beneficiaries). We studied two CMS quality measures: chemotherapy associated ED visits and chemotherapy associated hospitalizations. For each outcome, we estimated multi-level models with separate practice-level random intercepts for Black and White patients to quantify practice-level Black-White disparities in adjusted rates of these measures and assess the associations of these rates with the proportion of Black patients in the practice. **Results:** Overall, 108,177 Black and 966,381 White beneficiaries with cancer were treated at 1321 practices with reliable estimates (reliability ≥70%) of Black-White differences in rates of chemotherapy-associated ED visits; 101,411 Black and 915,895 White beneficiaries were treated at 1,012 practices with reliable estimates of chemotherapy-associated hospitalizations. These practices treated 80% or more of all Black and White beneficiaries; 10% of these practices treated 75% of Black beneficiaries. The median adjusted Black-White rate difference across practices was +8.9% [interquartile interval (IQI) +5.0%, +12.8%; 5th, 95th percentile -1.8 to +19.2%] for chemotherapy associated ED visits and +4.4% [IQI +1.3%, +7.7%; 5th, 95th percentile -3.5% to +13.5%] for chemotherapy associated hospitalizations. Chemotherapy-associated ED visit rates were 3.2 percentage points higher for Black vs White patients ($P < .001$) at the practice with the mean % of Black patients, but the difference was smaller in practices with more Black patients (0.4 percentage points less for each 10% increase in Black share, $P < .001$). Chemotherapy-associated hospitalization rates were 0.6 percentage points lower for Black vs White patients ($P = .01$) but did not vary by practice racial composition. **Conclusions:** Using data from more than 1000 practices over 4 years, we calculated reliable estimates of practice-level racial disparities in chemotherapy-associated ED visits and hospitalizations. Practice-level performance for these quality measures was generally lower for Black versus White beneficiaries. Measuring and providing feedback on practice-level Black-White disparities in oncology performance measures may be one effective tool for advancing racial equity in care quality for cancer patients receiving chemotherapy. What accounts for the racial disparity in survival from estrogen receptor-positive, axillary node-negative breast cancer in the United States? An analysis of the SEER-Oncotype database. *First Author: Kent Hoskins, University of Illinois at Chicago College of Medicine, Division of Medical Oncology, Chicago, IL*

Background: In a previous analysis of the SEER-Oncotype database (Hoskins, et al. JAMA Oncol, 2021), we reported that among women with estrogen receptor (ER)-positive, axillary node-negative breast cancer (BC), Black women were more likely than non-Hispanic White (White) women to have a high risk Oncotype Recurrence Score (RS), and the adjusted hazard for BC-specific death was 1.5-2.5 times higher for Black than for White women within each RS risk category. In this study we examined the role of health insurance, census tract socioeconomic status and tumor biology in the racial disparity in ER-positive BC mortality among US women. **Methods:** We obtained BC-specific survival data from the SEER-Oncotype database for women diagnosed with first primary, stages I-II, ER-positive, node-negative BC between 1/1/2004 -12/31/2015 who had an Oncotype Recurrence Score (RS) through Genomic Health Laboratory. The racial (Black:White) BC mortality disparity was estimated as a disparity hazard ratio (HR) from a series of Cox proportional hazards models of time to BC death. The baseline model adjusted for SEER registry and age at diagnosis (included in all models). We estimated the disparity HR after controlling for variable domains one at a time, as well as cumulatively in this order: neighborhood SES index (a composite measure including census tract education, income and poverty) and insurance (none, public, private); tumor biology (RS, PR status, tumor grade); tumor size; and treatment (surgery type, initiation of radiation and chemotherapy). **Results:** The analysis included 57,428 White and 6,003 Black women with node-negative, ER-positive BC (median follow-up = 54 months). The total disparity HR for BC death was 1.67 (95% CI: 1.37, 2.02). Tract SES and insurance together accounted for 21% of the disparity HR (adjusted HR 1.52, 95% CI: 1.22, 1.88); most of this was due to differences in insurance status, with tract SES accounting for 7% of the disparity when considered in isolation. Tumor biology (RS, PR status and grade) accounted for 30% of the disparity (adjusted HR = 1.41, 95% CI:1.14, 1.75); together, the domains of social determinants and tumor biology accounted for 50% of the disparity HR (adjusted HR = 1.30, 95% CI: 1.04, 1.62). Tumor size and treatment initiation each explained roughly 10% of the disparity HR when considered in isolation but did not account for any of the disparity once other factors were accounted for. Results obtained from additional methods for mediation analyses, including a method of rescaled coefficients and structural equation modeling (SEM) applied to discrete-time survival analysis will also be presented. **Conclusions:** In this study of node-negative, ER-positive BC, much of the BC survival disparity among US women could be explained by racial differences in measured tumor biology and social determinants of health. Accessibility of Telehealth services for cancer care at cancer hospital in the United States. *First Author: Victoria A. Marks, Yale School of Medicine, New Haven, CT*

Background: The COVID-19 pandemic has dramatically accelerated the availability of telehealth services for patients with cancer. However, little national cross-sectional data is available to inform potential gaps in access. We aimed to characterize overall access to and trends in telehealth availability for new cancer care patients at hospitals across the United States. **Methods:** We performed a cross sectional secret-shopper study to evaluate the availability of telehealth services for new patients for three major cancer types—colorectal, breast, and skin cancer—at Commission on Cancer accredited hospitals during the period of April to November 2020. American Hospital Association and Center for Medicare and Medicaid Service databases were queried to determine hospital characteristics. We described hospital variation in access to telehealth services using descriptive statistics. Univariable and multivariable logistic regression were used to identify factors associated with telehealth availability. **Results:** Of 334 successfully contacted facilities, 248 (74%) offered new patient telehealth services for at least one cancer type. However, access differed by cancer site: telehealth availability for new patients with skin, colorectal, and breast cancer was 47%, 42%, and 38%, respectively. Of the facilities sampled, 47% offered telehealth for one cancer type, 40% for two cancer types, and 14% for all three cancer types. Rates of any telehealth access among the cancer types ranged from 61% at Community Cancer Programs to 100% at NCI Designated Programs. In multivariable logistic regression, facility type was significantly associated with telehealth access while factors such as bed size, ownership, and volume were not significantly associated. **Conclusions:** Although access to telehealth services for patients with cancer has increased, overall gaps in access remain. Within facility differences in telehealth access imply opportunities to better align services within institutions, though further investigation is warranted as these offerings mature. Research Sponsor: None.

Significant decline in cancer diagnostic testing in U.S. CMS population during the COVID-19 pandemic. *First Author: Dave Smart, Diaceutics, Belfast, United Kingdom*

Background: The COVID-19 pandemic has caused >400,000 infection related deaths in the US to January 2021. Actions taken to limit COVID-19 infection and mortality could potentially lead to unintended consequences, precipitating excess mortality due to other causes. One such cause is delayed cancer diagnosis. Significant decreases in presentation for cancer diagnosis at the primary care level have been noted in the UK. This study aimed to look for evidence of a similar effect in the US. **Methods:** CMS claims data from JAN18-JUN20 associated with primary diagnosis across 11 cancers (bladder, breast, cervical, colorectal, endometrial, lung, ovarian, pancreatic, prostate, sarcoma and thyroid) were analyzed for use of surgical pathology (SP), a procedure associated with initial diagnosis, and immunohistochemistry (IHC). Test volumes varied widely by test and cancer so were normalized to enable comparison across indications. This was done by dividing the month-on-month difference for the period JAN19-JUN19 vs JAN20-JUN20 by the median monthly test volume for the period JAN18-DEC19 ("pre-COVID period"). Extent and duration of declines in test rates and number of missing patients as the sum of these declines were then determined. The ratio of IHC to SP testing was taken to determine any decline in likely post-initial diagnosis testing. **Results:** There were significant (>10%) declines in test volumes for SP for all 11 cancers at some time in Q1-Q2 2020. Table. Extent, duration and return to pre-COVID levels for SP testing across 11 cancers Median extent and duration of the decline was 56% (range 41.1%-80.4%) and 2 months (range 1- >4). This equates to 32,192 missing diagnoses across all cancers. SP test volumes for all cancers except lung and breast had returned to around pre-COVID levels by JUN20. There was no significant (>10%) increase in normalized SP test volume after the COVID dip for any cancer. While SP showed decreased test volumes across all cancers at some point during the first half of 2020, test volume ratios of IHC to SP showed increases for most cancers in the same time period. **Conclusions:** These data highlight that the decline in patients presenting to their primary care physicians with suspicion of cancer for diagnostic investigation was linked to COVID-19 prevention strategies. No evidence for increased, "catch up" testing to address presentational/diagnostic backlog was observed. Thus, it is predicted that these patients may subsequently present with a more advanced cancer. Potential excess morbidity, mortality and cost associated with absent or delayed diagnosis should be factored into cancer control programs going forward. Research Sponsor: Diaceutics Inc.

Racial differences in geriatric assessment (GA) impairments, health-related quality of life (HRQOL), and body composition in older adults with gastrointestinal (GI) malignancies: Results from the Cancer and Aging Resilience Evaluation (CARE) registry. *First Author: Grant Richard Williams, Institute for Cancer Outcomes and Survivorship, University of Alabama at Birmingham, Birmingham, AL*

Background: Despite recent cancer advances, racial disparities in outcomes persist. Our objective was to examine racial differences in GA impairments, HRQOL, and body composition metrics as a novel way to understand outcome disparities in older adults with GI malignancies. **Methods:** The CARE registry at the University of Alabama at Birmingham (UAB) is an ongoing prospective cohort study that consecutively enrolls older adults (≥60y) with GI malignancies. The CARE registry utilizes a patient-reported GA that measures a broad range of aging-related health issues. HRQOL is measured using PROMIS Global-10. Computed-Tomography (CT) images are procured to measure skeletal muscle index (SMI) and skeletal muscle density (SMD) from the L3 cross-section. For this study, we examined the adjusted odds ratio (aOR) for racial differences in GA impairments, HRQOL, sarcopenia (defined as men BMI < 25, SMI ≤43 cm^2/m^2; men BMI ≥25, SMI < 53 cm^2/m^2; women SMI < 41 cm^2/m^2), and myosteatosis (defined as BMI < 25, < 41 Hounsfield Units [HU]; BMI ≥25, < 33 HU), adjusting for age, sex, education, cancer type, cancer stage, and comorbidity. **Results:** We included 448 patients with GI malignancies, with self-reported race as White or Black, a completed GA and available CT imaging +/- 60 days of GA completion. Mean age at enrollment was 70±7.2y, 58% were male and 25% were Black. Primary cancer diagnoses included colorectal cancer (33%), pancreatic cancer (25%), and other GI malignancies (52%). Black participants had lower education (high school or < 54% vs. 38%, $p< 0.01$) and were less likely to be married (55% vs 71%, $p< 0.01$). Black participants reported more limitations in activities of daily living (aOR = 2.0 (95% confidence level [CI] 1.01-3.9, $p= 0.03$) and frailty (aOR = 1.9, 95% CI 1.1-3.3, $p= 0.02$). Similarly, Black participants reported lower HRQOL (physical: β coefficient, -2.7; $p= 0.03$; mental: β coefficient, -2.4; $p= 0.03$). Conversely, Black participants were less likely to have sarcopenia (aOR = 0.5, 95% CI 0.3-0.9, $p= 0.02$) and myosteatosis (aOR = 0.12, 95% CI 0.02-0.8, $p= 0.02$). **Conclusions:** Differences in frailty, HRQOL, and body composition between Black and White participants present the first step towards understanding disparities in cancer outcomes amongst older adults. Research Sponsor: U.S. National Institutes of Health.

One size does not fit all: Evaluating disparities in lung cancer screening eligibility amongst Hispanic/LatinX and African Americans. *First Author: Coral Olazagasti, Northwell Health, New Hyde Park, NY*

Background: Lung cancer (LC) is the leading cause of cancer death among Hispanic men. African Americans (AA) have the highest LC mortality rate in the United States (US). We sought to identify the tendencies for screening eligibility amongst Hispanic/LatinX (H/L) and AA prior to their LC diagnosis according to the National Comprehensive Cancer Network (NCCN) and The United States Preventive Service Task Force (USPSTF) guidelines. **Methods:** We conducted an observational study in patients diagnosed with LC from 2016 to 2019. Current and former smokers were included in the analysis. Charts were reviewed for demographics, smoking history, family history, personal history of other malignancy, and prior exposures to assess screening their eligibility prior to LC. The chi-square test was used to examine the association between race and ethnicity with each screening criteria. **Results:** A total of 530 subjects were reviewed, of which 428 were included in the analysis. One hundred and fifty three and 245 subjects were ineligible for NCCN and USPSTF screening criteria prior to their LC diagnosis. Twenty-eight of the subjects failing to meet NCCN criteria identified as AA and 12 as H/L. Forty and 20 of the USPSTF ineligible subjects identified as AA and H/L. There was a significant association between ethnicity and individual screening eligibility, where 52% of H/L met NCCN eligibility compared to 20% of H/L who met USPSTF eligibility (p = 0.0010). There was a significant association between ethnicity and USPSTF criteria (p = 0.0166), as 80% of H/L subjects were screening ineligible under USPSTF criteria compared to 56% of non-Hispanic or other [Table]. **Conclusions:** In our study, H/L had significant lower tendencies of meeting the USPSTF LC screening eligibility criteria than non-H/L or other. Notably, there was a profound association between ethnicity and eligibility of screening criteria, where a proportionally higher number of H/L who were ineligible under USPSTF criteria met NCCN criteria. These findings suggest that leniency in the screening criteria can possibly lead to earlier detection of lung cancer in high-risk individuals. Our study is in line with developing data that minority individuals at high-risk for lung cancer can be missed, mainly if current USPSTF criteria was to be applied. Recently, USPSTF has modify their criteria which may benefit more of these individuals. To improve rates of screening and overall mortality of minorities, organizations should continue to re-evaluate and liberalize their screening guidelines. Research Sponsor: None.

Screening criteria eligibility per race and ethnicity.

Insurance status and survival in diffuse large B-cell lymphoma: A National Cancer Database study before and after the Affordable Care Act. *First Author: Antoine N Saliba, Mayo Clinic, Division of Hematology, Rochester, MN*

Background: The impact of insurance status on survival in diffuse large B-cell lymphoma (DLBCL), the most common aggressive lymphoma, has not been evaluated after the implementation of the Affordable Care Act (ACA). The aim of this study is to compare overall survival (OS) in patients across insurance status groups and in the periods before and after the ACA. **Methods:** Adult patients with newly diagnosed DLBCL were identified from the National Cancer Database. The analysis was restricted to patients 64 years of age or younger as most patients 65 years or older are eligible for Medicare under the ACA. The 2004-2017 period was chosen to represent the immunochemotherapy era preceding and following the ACA. Logistic regression was used to explore associations between abstracted variables and insurance status groups. The Kaplan-Meier method and Cox proportional hazards model were used for survival analysis. **Results:** 93,692 adults (age < 64 years) with newly diagnosed DLBCL and known insurance status were identified (41.3% female, median age 54 years [range: 18 – 64], 81.8% White and 12.1% Black). 7,211 (7.7%) patients were uninsured, 64,744 (69.1%) had private insurance, 11,936 (12.7%) had Medicaid, and 9,801 (10.5%) had Medicare. When compared to insured patients (private insurance, Medicaid or Medicare), uninsured patients were more likely to have a median household outcome of < $38,000 [OR 1.93 (95% CI 1.79-2.07)], less likely to receive chemotherapy [OR 0.69 (0.64-0.77)], more likely to be male [OR 1.14 (1.07-1.21)], more likely to be non-White [OR 1.30 (1.20-1.40), and more likely to present with stage III or IV disease [OR 1.24 (1.16-1.32)]. Uninsured patients had an inferior OS [HR 1.21 (95% CI 1.15-1.27)] when compared to insured patients after adjustment for baseline comorbidity (Charlson-Deyo score ≥2), advanced stage, treatment with chemotherapy, and sociodemographic factors including sex, age, race, household income, facility type (academic/community), and location (urban/rural). With a median follow-up time of 14.8 years (95% CI 14.6-not reached), median OS was lower in uninsured patients [13.4 years (12.3-not reached) vs 14.8 years (14.7-not reached); p < 0.0001]. Despite the lack of major changes in DLBCL therapies, a diagnosis after the implementation of the ACA (in 2010 or later) was associated with a superior OS when compared with the outcomes of patients diagnosed in 2010 or earlier [HR 0.93 (95% CI 0.90-0.95)]. Similarly, five-year OS was superior in the insured group [HR 0.93 (95% CI 0.89-0.96)]. **Conclusions:** Uninsured patients with DLBCL and < 64 years old had inferior OS when compared with insured patients, and uninsured status emerged as an independent risk factor for inferior OS. Our data highlight the independent effect of insurance disparities - a potential indicator of variations in access to health care - on survival in DLBCL. Research Sponsor: None.

High incidence of concurrent disease states detected during mobile lung cancer screening in an underserved population. *First Author: Daniel R. Carrizosa, Atrium Health Levine Cancer Institute, Charlotte, NC*

Background: Studies such as the National Lung Screening Trial (NLST; N Engl J Med 2011;365:395-409) have shown a survival benefit to low-dose Lung CT screening in high-risk smokers. Levine Cancer Institute (LCI) initiated the first mobile low dose computerized tomographic (LDCT) lung screening program for underserved populations in 2017. In addition to being able to intervene early in the natural history of lung cancer, the project has also shown a previously unreported high incidence of incidental diseases in this population. We characterize these findings in 1198 patients. **Methods:** From May 2017, subjects with criteria eligible for NLST screening were identified and underwent LDCT for lung cancer detection. Patients screened in the program were all uninsured or underinsured, mean age 60.8 years, 18% were African American, 3% Latin-x and 78% were rural with an overall 47.1 mean pack-year smoking history. These patients were screened using a novel mobile LDCT (J Clin Oncol 37, 2019 suppl; abstr 6567) created for this program. By December 2020, 1198 patients completed their first screening. All CT scans were reviewed by two separate radiologists and were reviewed for quality assurance by a separate expert multidisciplinary team. **Results:** Of the 1198 subjects, 84% (1006 subjects) were found by LDCT to have a least one incidental disease. More than half of the subjects (645, 53.8%) had coronary atherosclerosis. Of those, 25% (183) were described to have at least moderate disease with 8% (96) described as severe. Overall, 42% (504) were found to have emphysema and 25% (299) had vascular atherosclerotic disease; 1.8% (22) of those screened had a detected aortic aneurysm. In total, thirty separate disease findings were found (listed from fourth to tenth most common finding: degenerative spine changes [205], cholelithiasis [59], hiatal hernia [52], pericardial effusions [38], fatty liver [32], kidney stone [3]), and cardiomegaly [30]). 3.5% (42) were found to have an undiscovered breast, adrenal, liver or kidney mass that required further workup. **Conclusions:** The number of incidental findings in our mainly rural underserved subject group was very high (84%). 35.5% of patients in the National Lung Screening Trial died from heart disease or respiratory disease. These numbers have not been overtly discussed and our study confirms the number of concerning incidental diseases that can lead to morbidity or mortality. In this high-risk, underserved population of heavy smokers, the opportunity for positive impact on other disease states can be increased by a mobile lung cancer screening program by increasing access to care. Racial disparities in second-line (2L) treatment and overall survival among patients (pts) with hormone receptor positive HER2 negative (HR+HER2-) metastatic breast cancer (mBC) treated in routine practice. *First Author: Xiaoliang Wang, Flatiron Health, New York, NY*

Background: In the US, African American (AA) women have similar incidence of breast cancer (BC) as White women, but have 40% higher BC mortality. This disparity results from differences in biological and social determinants of cancer treatment. Previous studies have focused primarily on first-line(1L) treatment, but little is known about racial differences in treatment beyond 1L and the impact these differences may have on outcomes. **Methods:** This analysis utilized data from the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database and included pts with mBC initiating 2L treatment between 2/3/2015-2/29/2020. 2L treatment was caterogized broadly as CDK 4/6 inhibitors (CDKi), endocrine monotherapy, everolimus combination therapy, and chemotherapy and other systemic therapies. Real-world overall survival (rwOS) was defined as time from 2L initiation to death (censored at last EHR activity). Multinomial logistic regression was used to assess the likelihood of 2L treatment between AA and White (reference) pts, adjusted for demographics and clinical factors, including ECOG performance score, 1L treatment and 1L progression. Median rwOS was estimated using the Kaplan-Meier method and adjusted hazard ratios (aHR) were estimated using multivariable Cox proportional hazards models additionally adjusted for 2L treatment. Stratified analysis was conducted by 1L and 2L treatment. **Results:** A total of 389 AA and 2776 White pts were included. Compared to White pts, AA pts were younger (median age: 61 vs 65) and more likely to be under-insured (8% vs 3%), and present with de novo metastatic disease (30% vs 26%). AA pts were also less likely to receive CDKi in 2L (29% vs 35% in White), but this difference was not statistically significant after adjustment (OR = 0.83; 95% CI: 0.62-1.11). Compared to White pts who had a median rwOS of 25.6 months (95% CI: 24.5-27.4), AA pts had a median rwOS of 20.4 months (95% CI: 17.3-24.0). Poorer rwOS among AA pts was observed across all 2L treatment groups. After adjusting for covariates and 2L treatment, the observed rwOS difference was no longer statistically significant. However, in stratified analysis among pts who did not receive 1L CDKi, AA pts had 48% higher hazard of death if they received 2L CDKi (aHR = 1.48; 95% CI: 1.08-2.00), and 49% higher hazard of death if received 2L endocrine monotherapy (aHR = 1.49; 95% CI: 1.15-1.94). In contrast, adjusted rwOS was similar between AA and White pts among those who received 1L CDKi. **Conclusions:** These exploratory findings suggest that AA pts were less likely, partially associated with other factors, to receive CDKi at 2L. In addition, AA pts had worse rwOS than White pts even after receiving 2L CDKi among those who did not receive 1L CDKi. This disparity was not observed among patients who received 1L CDKi. Prostate cancer treatment disparities during the COVID-19 pandemic, lessons from a multi-institutional collaborative. *First Author: Adrien Bernstein, Fox Chase Cancer Center, Philadelphia, PA*

Background: Minority communities have been disproportionately affected by COVID-19, however the impact of the pandemic on prostate cancer (PCa) treatment is unknown. To that end, we sought to determine the racial impact on PCa surgery during the first wave of the COVID-19 pandemic. **Methods:** After receiving institutional review board approval, the Pennsylvania Urologic Regional Collaborative (PURC) database was queried to evaluate practice patterns for Black and White patients with untreated non-metastatic PCa during the initial lockdown of the COVID-19 pandemic (March-May 2020) compared to prior (March-May 2019). PURC is a prospective collaborative, which includes private practice and academic institutions within both urban and rural settings including regional safety-net hospitals. As data entry was likely impacted by the pandemic, we limited our search to only practices that had data entered through June 1, 2020 (5 practice sites). We compared patient and disease characteristics by race using Fisher's exact and Pearson's chi-square to compare categorical variables and Wilcoxon rank sum to evaluate continuous covariates. Patients were stratified by risk factors for severe COVID-19 infection as described by the CDC. We determined the covariate-adjusted impact of year and race on surgery, using logistic regression models with a race*year interaction term. **Results:** 647 men with untreated non-metastatic PCa were identified, 269 during the pandemic and 378 from the year prior. During the pandemic, Black men were significantly less likely to undergo prostatectomy compared to White patients (1.3% v 25.9%;$p < 0.001$), despite similar COVID-19 risk-factors, biopsy Gleason grade group, and comparable surgery rates prior (17.7% vs. 19.1%;$p = 0.75$). White men had lower pre-biopsy PSA (7.2 vs. 8.8 vs. $p = 0.04$) and were older (24.4% vs. 38.2% < 60yr;$p = 0.09$). The regression model demonstrated an 94% decline in odds of surgery(OR = 0.06 95%CI 0.007-0.43;$p = 0.006$) for Black patients and increase odds of surgery for White patients (OR = 1.41 95%CI 0.89-2.21;$p = 0.142$), after adjusting for covariates. Changes in surgical volume varied by site (33% increase to complete shutdown), with sites that experienced the largest reduction in cancer surgery, caring for a greater proportion of Black patients. **Conclusions:** In a large multi-institutional regional collaborative, odds of PCa surgery declined only among Black patients during the initial wave of the COVID-19 pandemic. While localized prostate cancer does not require immediate treatment, the lessons from this study illuminate systemic inequities within healthcare, likely applicable across oncology. Public health efforts are needed to fully recognize the unintended consequence of diversion of cancer resources to the pandemic in order to develop balanced mitigation strategies as viral rates continue to fluctuate. Research Sponsor: PURC is funded by the Health Care Improvement Foundation through practice participation.

COVID-19 and exacerbation of screening mammography inequities. *First Author: Gary X. Wang, Massachusetts General Hospital, Boston, MA*

Background: After state-mandated cessation of screening mammography (SM) in Spring 2020 due to COVID-19, centers were urged to resume screening, particularly of patients at increased risk. As our tertiary-care medical center's screening program provides SM at four sites across our metropolitan area, we examined whether sites that historically served more patients from more disadvantaged areas returned slower to pre-COVID volumes. **Methods:** Patient records were linked by ZIP code of residence to ZIP Code Tabulation Area (ZCTA)-level area-based social metrics (ABSMs) from the 2014-2018 American Community Survey. We compared baseline pre-COVID (May-October, 2015-2019) SM population ABSMs between our four imaging sites for: % persons below poverty (≥ vs < 10%), % persons of color (POC) (quintiles: top 2 vs bottom 3), index of racialized economic segregation (quintiles: bottom 2 [more POC low-income households] vs top 3 [more white non-Hispanic (WNH) high-income households]); and race/ethnicity (% WNH vs POC). We modeled weekly SM volumes per screening day by site using Poisson regression and tested for weekly differences at each site, COVID-era (May-October 2020) vs pre-COVID; and tested for monthly differences in SM population composition by logistic regression modeling. **Results:** There were 89,082 pre-COVID and 16,220 COVID-era SM exams. At pre-COVID baselines the four sites differed in population composition by ABSMs and race/ethnicity (all chi-square P values < .001) (Table). The two sites that served more disadvantaged populations (A, B) returned slower to pre-COVID volumes (site-specific weekly screening volume no longer different [$P > .05$] vs pre-COVID) (Table). As a result, compositions of the aggregate SM population across all sites showed a smaller proportion of patients from the most disadvantaged ZCTAs by ABSMs (all P values < .001) before returning to pre-COVID compositions three months after SM resumption. **Conclusions:** SM was slower to return to pre-COVID volumes at imaging sites that historically served lower-income communities of color. As a result, our COVID-era SM population skewed away from patients in disadvantaged ZCTAs. Our findings highlight the need to monitor for emergent disparities in the pandemic era. Future work will focus on understanding causes of inequitable SM engagement across our imaging sites to mitigate care disparities for our most vulnerable patients. Research Sponsor: None.

Composition of patients screened by imaging site, 2015-2019, and time needed to return to pre-COVID screening volumes in the COVID era at each site.

	Zip code tabulation area-level area-based social metrics		Persons of color (POC) in screening population		Time to return to pre-COVID volume
	Poverty rate ≥ 10%		POC, top 2 quintiles (more POC)		Segregation, bottom 2 quintiles (more POC low-income households)
Site A	68.8%	63.5%	46.2%	42.3%	14 weeks
Site B	41.6%	21.8%	15.6%	21.9%	12 weeks
Site C	13.5%	4.3%	3.5%	12.3%	5 weeks
Site D	25.9%	8.5%	7.4%	5.9%	3 weeks

Association of parental cancer and school absenteeism, medical financial hardship, healthcare use, and psychological distress among minor children. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: A cancer diagnosis can affect the entire family, including minor children. However, little is known about the association of parental cancer on minor children's school absenteeism, family's financial ability to afford healthcare for children, as well as healthcare use, psychological distress, and behavioral problems. **Methods:** The 2015 to 2018 National Health Interview Survey was used to identify minor children (ages 5-17 years) whose parent(s) reported a cancer history (n = 695, representing 1.2 million children) and children whose parent did not report a cancer history (n = 19,122, representing 35.7 million children). Separate multivariable logistic regressions were used to compare school absenteeism, financial hardship, healthcare use, and psychological distress among children with and without parental cancer history. All analyses adjusted for children's age group (5-11 years, 12-14 years, and 15-17 years), sex, family income as a percentage of the federal poverty line, marital status of their parents, survey year, and region. **Results:** Children of cancer survivors were more likely to receive annual well-child checkups, experience school absenteeism, take prescription medications for more than 3 months, visit hospital emergency rooms, suffer psychological distress, and have behavioral problems than children of parents without a cancer history (Table). **Conclusions:** Parental cancer history is associated with disruption in their minor children's life. The associated psychological distress and physical and emotional health among these children may develop into more severe health issues in adulthood. Special attention to minor children of parents with a cancer history may be required to help prevent development of longer-term physical and mental health problems. Research Sponsor: None.

Barriers to web-based symptom management systems (web-SyMS). *First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA*

Background: Web-SyMS can reduce the burdens of cancer and its treatment. While patients frequently express willingness to use these systems, only a subset actively engages with them. Some patients may lack the tools and confidence needed to benefit from web-SyMS. We sought to characterize these barriers among community-based cancer patients receiving care across six diverse healthcare systems. **Methods:** We surveyed patients receiving chemotherapy at three healthcare systems (Baptist, TN; Maine Medical, ME; Dana-Farber, MA) and patients recovering from cancer-directed surgery at three healthcare systems (West Virginia University, WV; Dartmouth-Hitchcock, NH; Lifespan, RI). Surveys were conducted as part of a pre-implementation analysis of eSyM – an EHR-embedded web-SyMS that collects, tracks, and manages patient reported outcomes during cancer therapy. **Results:** Among 563 respondents, access to tech devices (i.e., tablet, computer, or smartphone) was high: 78% reported access to ≥2 devices and only 5% reported access to no devices. However, confidence using tech devices to accomplish online tasks varied: 45% very confident, 38% somewhat confident, 11% little-no confidence. Compared to medical oncology patients, surgery patients were more likely to report being very confident (57% vs. 31%). There were significant differences based on patients' self-reported tech confidence (Chi-square $P<.05$ for all values in the table). **Conclusions:** Low self-reported tech confidence may identify patients who are at high risk for experiencing the burdens of cancer but may be less likely to benefit from web-SyMS. Addressing this barrier is critical to improving outcomes and addressing disparities. Clinical trial information: NCT03850912. Research Sponsor: U.S. National Institutes of Health.

Disparity in telehealth and emergency department use among Medicaid and commercially insured patients receiving systemic therapy for cancer in Washington State following the COVID-19 Pandemic. *First Author: Scott David Ramsey, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Washington was the first US state to experience the COVID-19 pandemic. Transmission risks and patient fears of visiting oncology practices during its onset resulted in rapid adoption of telehealth services. We hypothesized that the pandemic would widen disparities in oncology practice visits between Medicaid and commercially insured patients, resulting higher rates of emergency department (ED) visits during initial treatment. **Methods:** Linking Washington State SEER records with Medicaid and commercial insurance enrollment and claims records, we compared adults age <65 with new solid tumor malignancies who received systemic treatment at academic and community oncology practices. Persons starting therapy March – June 2020 (COVID) were compared with those starting therapy March-June 2017-2019 (Pre-COVID). Poisson regressions were used to evaluate differences in oncology practice office visits and telehealth visits. Logistic regressions were used to evaluate the likelihood of at least one ED admission among patients starting systemic therapy pre- and post-COVID. **Results:** Among patients who met inclusion criteria (652 Commercial, 349 Medicaid), Medicaid enrollees had more advanced disease and more comorbidity versus commercial enrollees. In unadjusted analysis of E&M and telehealth service visit codes, office-based visits fell for both insurance groups (Table) while telehealth service visits (negligible pre-COVID) were higher for commercial versus Medicaid enrollees post-COVID. The proportion of persons with ≥ 1 ED visit during therapy fell for both insurance groups. In Poisson models, Medicaid enrollees had significantly fewer total visits (P=0.001) and fewer telehealth visits ($p<0.001$) compared commercial enrollees during the COVID period. In the logit models, ED visits trended lower for both groups after COVID (OR 0.53 95% CI 0.279 to 1.008). Among Medicaid enrollees, persons ages 40-49 and breast cancer patients were more likely to visit the ED. Among the commercially insured, persons with 2 or more comorbidities were more likely to visit the ED. The pre-post COVID change in likelihood of an ED visit was not significantly different between insurance groups (p=0.355). **Conclusions**: In Washington State, the COVID-19 pandemic created a substantial disparity in access to office-based and telehealth care for low-income patients receiving systemic therapy for new cancers. Reduced oncology practice visits among Medicaid patients did not widen existing disparities in utilization of emergency care. Research Sponsor: U.S. National Institutes of Health.

Average visit days per patient, March- June.

Disruptions to U.S. medical oncology care during the COVID-19 Pandemic: CancerLinQ Discovery (CLQD) analysis. *First Author: Abdul-Rahman Jazieh, Cincinnati Cancer Advisors, Cincinnati, OH*

Background: The COVID-19 pandemic disrupted all facets of healthcare delivery including cancer care. This study evaluates the disruptions to US medical oncology practice during the pandemic in terms of number and type of patients (pts) encounters to determine the impact on continuity of patient care. **Methods:** We conducted a retrospective cohort analysis using the CLQD electronic health record database, containing data from 2+ million pts from all 50 states. We assessed changes in the monthly proportions of visit encounter types (in-person outpatient [IPOP] and telehealth [TE]) for new and established patients (NP and EP) with an invasive malignancy, benign or in situ neoplasm, or benign hematology diagnosis having an encounter between 1/1/2018 and 9/30/2020. **Results:** 781,945 pts were studied. Median age on 1/1/2018 was 64 years (IQR: 53-73), 38% were female, and 58% had an invasive malignancy. From 12/2019 to 9/2020, total monthly encounters dropped from 157,964 to 90,662. Monthly IPOP visits for NP dropped from 11.2% to 7.9%, an absolute drop of 3.3% and a relative drop of 30%; TE for NP increased by 1.1% (Table). Monthly IPOP visits for EP, as a percentage of all visits, dropped from 94.4% to 86.6% from 12/2019 to 6/2020 but rebounded to 90.4% by 9/2020. Fraction of TE increased substantially during the pandemic period reaching a peak in 6/2020 (13.8% for EP and 1.6% for NP) and decreased in 9/2020 to 9.6% and 1.1% for EP and NP, respectively. Compared to non-Hispanic patients, Hispanic patients had a larger reduction in IPOP and more TE during the study period. Percentage of monthly encounters, by type, from baseline*. **Conclusions:** We observed a reduction in the absolute number and monthly percentage of IPOP encounters during the COVID-19 pandemic. For EP, increases in TE does not fully compensate for reductions in IPOP. The reduction in IPOP NP encounters is particularly concerning since it was not accompanied by a compensatory increase in TE. The reduction in NP is consistent with reported pandemic-associated reductions in cancer screening and suggest a notable delay in cancer diagnoses during the pandemic. Reduction in Hispanic IPOP encounters warrants further evaluation. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Access to cancer care for Medicaid patients at cancer hospitals in the United States. *First Author: Victoria A. Marks, Yale School of Medicine, New Haven, CT*

Background: As the result of expansions associated with the Affordable Care Act (ACA), one in five Americans are now insured through Medicaid. Despite overall increases, access to care for Medicaid-insured patients with cancer may be limited by facilities due to lower reimbursement and administrative burden. We aimed to directly assess facility-level acceptance of Medicaid patients with a new diagnosis of cancer. **Methods:** We performed a cross-sectional secret shopper study to evaluate access to cancer care for colorectal, breast, urologic, and skin cancer at Commission on Cancer (CoC) accredited hospitals. We studied the relationship between Medicaid access and facility-level characteristics assessed through American Hospital Association and Center for Medicare and Medicaid Service data using univariable statistics and multivariable logistic regression. **Results:** Among 334 CoC facilities contacted, the overall rate of Medicaid acceptance for at least one investigated cancer type was 99% (n = 331). However, we identified hospital-level variation in Medicaid acceptance across cancer types, where Medicaid acceptance for colorectal, breast, urologic, and skin cancer was 90%, 96%, 87%, and 80%, respectively. Of the hospitals that accepted Medicaid, 2% accepted Medicaid for one cancer type, 8% for two, 21% for three, and 68% for all four cancer types. In multivariable logistic regression, odds of Medicaid acceptance were lowest in comprehensive community cancer centers ($p < 0.05$ for colorectal and urologic cancer) and for-profit designated facilities ($p < 0.05$ for urologic and skin cancer) (Table). Hospitals in states with Medicaid expansion were also more likely to accept Medicaid for urologic (OR: 2.5, 95% CI: 1.2-5.2) and breast (OR: 12.8, 95% CI: 2.7-60.2) cancer care. **Conclusions:** Access disparities persist for patients with Medicaid, with acceptance rates differing substantially within and between facilities. Facility-level differences in Medicaid access among CoC facilities are notable given the use of hospital registry data to estimate ACA-related effects. Research Sponsor: None.

Disparities in reporting and representation of women, older adults and racial minorities in immune checkpoint inhibitor (ICI) clinical trials. *First Author: Irbaz Bin Riaz, Mayo Clinic, Rochester, MN*

Background: Representation and outcomes of women, older adults, and racial minorities in ICI trials has not been previously described. **Methods:** MEDLINE and Embase were searched to identify ICI RCTs. Data for trial characteristics, proportion of trials reporting race, age and sex as well as the proportion of patients by race, age and sex enrolled in ICI trials was collected. Descriptive statistics were reported for trials reporting minority representation and proportion of included patients by race, age and sex. Disparities in representation were calculated using enrollment incidence disparity (EID) and enrollment incidence ratios (EIR) by comparing trial enrollment against U.S. population-based estimates acquired from the SEER 18 incidence database. The relationship of EID to key trial characteristics were compared using standard parametric and non-parametric statistical tests. Trends in EIR were analyzed using the Joinpoint Regression Analysis software. **Results:** 108 ICI trials from 2009 to 2020 with 48,360 patients were included in this analysis. All RCTs reported sex (101/101). 78 trials reported race (72%), of which only 41 trials (38%) reported data on all 5 U.S. racial categories (Black, White, Asian, Pacific Islander and Native American). Participation of Black patients was reported in 66 trials (61%), White participants in 78 trials (72%), Asians in 69 trials (64%), Native Americans and Pacific Islanders in 41 trials (38%), and Hispanics in 24 trials (22%). Age categories were inconsistently defined, and 80 trials (74%) reported the proportion of patient by age categories. Subgroup analyses of clinical outcomes by race, age and sex were reported in 17 (22%), 62 (79%) and 57 (73%) trials respectively. Women (trial proportion [TP]: 32%; EIR: 0.77), patients aged $\geq$ 65 years (TP: 42%; EIR: 0.74), Black participants (TP: 1.8%; EIR: 0.17) and Hispanic participants (TP: 5.9%; EIR: 0.67) were largely underrepresented, and Asians were overrepresented (TP: 15.9%; EIR: 2.64). Black patients were underrepresented across all cancer types. Similarly, women, older adults ($>$ 65 years of age) and Hispanic patients were consistently underrepresented across cancer types with few exceptions. Representation of older adults increased significantly from 2010-2020 (APC: 2.72), while representation of Black patients decreased significantly from 2009-2020 (APC: -23.37). Black patients were found to be significantly underrepresented in phase III trials ($p = 0.0005$), trials with OS as the primary endpoint ($p = 0.004$), and PD1 inhibitor trials ($p = 0.002$). Hispanics were significantly underrepresented in PD1 inhibitor trials ($p = 0.003$). **Conclusions:** There is both suboptimal reporting about participation and underrepresentation of women, racial minorities (particularly Black patients) and older adults in ICI trials as compared to their cancer incidence. Research Sponsor: None.

Racial disparity in uterine cancer treatment and survival: A matter of Black women's lives. *First Author: Alexandrina Balanean, Cardinal Health, Dublin, OH*

Background: Despite similar incidence rates of uterine cancer (UC) in Black and White women, the former have worse prognosis and survival. Absence of denominator correction for UC hysterectomy (prevalence varies within the United States [US] by race/region) may underestimate incidence. The objective of this study is to compare treatment and survival of patients with UC by race in a large, contemporary, population-based study with at least 5 years of follow-up. **Methods:** With the latest available data from the Surveillance, Epidemiology, and End Results database, comparisons between Black and White patients were made using chi-square and Mann-Whitney tests. Cox proportional hazards regression estimated the adjusted risk of mortality by including age at diagnosis, race, US region, tumor histology/stage/grade, and receipt of hysterectomy as covariates. **Results:** A total of 105,036 women (11,028 Black and 94,008 White) newly diagnosed with UC in 2000-2013 and followed through 2018 were identified. Median age at diagnosis was 62 years, and more patients in the South were Black (41% vs 17%, $P<.0001$). Higher rates of type 2 (15% vs 6%), late-stage (44% vs 28%), and high-grade (48% vs 25%) tumors at diagnosis were also found in Black women (all $Ps<.0001$; Table). Compared with White women, Black women had lower 5-year survival rate (18% vs 37%, $P<.0001$), shorter survival (median 49 vs 78 months, $P<.0001$), and higher adjusted mortality risk (hazard ratio [HR]: 1.3, 95% CI: [1.3, 1.4], $P<.0001$). Lack or unknown status of hysterectomy was also associated with higher death risk (HR: 3.6, 95% CI: [3.4, 3.9], $P<.0001$). **Conclusions:** Correcting for hysterectomy attenuates racial disparity in incidence; however, black women have inferior outcomes primarily due to increased aggressive histology, late-stage, and high-grade tumors as well as decreased use of hysterectomy. Underestimation of at-risk populations may be misdirecting cancer control efforts, highlighting the importance of accurate reporting to inform potential treatment adaptations. Next steps are to assess cancer-specific mortality with Fine-Gray competing risk models. Research Sponsor: Cardinal Health.

Comparison of patient-reported impact of COVID19 on cancer care delivery: A prospective, cross-sectional study. *First Author: Emily Hsu, University of Connecticut Health Center, Farmington, CT*

Background: Impact of COVID19 on cancer care delivery and outcomes remains unknown. Few trials have investigated patients' perceived risks and benefits, and cancer care delivery (CCD) alterations related to COVID19. We sought to identify differences on behaviors and social determinants of health in Hispanics and other underrepresented populations (H/UP) compared to the general population (GP). **Methods:** An IRB-approved validated 27-item questionnaire was offered in English and Spanish to all pts. receiving cancer care at participating cancer centers over a 4 month period. Examined variables included demographic information, social risk and behavioral factors, preferred sources of health information, and overall satisfaction with CCD during the pandemic. **Results:** A total of 180 pts were enrolled in the study. Compared to GP, H/UP's perceived risk of COVID19 was higher with 93% vs 87% more likely to cancel or avoid social gatherings and 54% vs 46% more likely to change daily routine. H/UP appeared more concerned with personal and financial safety; if unable to find work/get paid for 2 weeks, 26% H/UP vs 10% GP would struggle to keep up with expenses. 40% H/UP vs 10% GP have concerns on perceived ability to secure food on short term and consider COVID19 a major threat to their health (70% vs 46%) and financial situation (63% vs 35%). H/UP's perceived benefits of protective measures is higher with 81% vs 60% routinely practicing social distancing (SD) and 79% vs 66% in agreement with punitive actions for not following SD. Analysis demonstrated no significant difference by age, gender, level of education, marital status, however Hispanic ethnicity and Spanish as primary language was a statistically significant variable ($p = 0.025$) in perceived risks and satisfaction with CCD. No major differences were noted on sources of health information although more H/UP relied on social media (33% vs 24%). H/UP appeared to be more skeptical about availability and safety of targeted vaccines (40% vs 15%). Satisfaction regarding CCD was comparable (84% vs 86%), although more H/UP perceived CCD alterations (15% vs 10%). Going forward, H/UP would prefer to incorporate virtual visits (VV) when possible (36% vs 25%). **Conclusions:** COVID19-related societal, financial, health and personal fears are increased in H/UP which likely negatively affects quality of life of these at-risk populations. H/UP's trust in SD recommendations is heightened although linguistically and culturally appropriate information may be deficient. H/UP's belief in vaccine availability and safety is comparable to GP, although recent reports suggest deeper fear and emphasize their fear of experimentation. Interventions aimed to decrease these differences could incorporate standard communications with special attention to social media. H/UP would prefer to incorporate VV into their care, although most do not possess appropriate technology to do so. Research Sponsor: None.

Effect of income on patient decision-making in localized prostate cancer. *First Author: Xinglei Shen, University of Kansas Cancer Center, Westwood, KS*

Background: Socioeconomic status affects goals of care and treatment choices. We investigated the impact of low household income on diagnosis, goals of care, and treatment choice in patients with localized prostate cancer. **Methods:** The North Carolina Prostate Cancer Comparative Effectiveness & Survivorship Study (NC ProCESS) is a population-based cohort of prostate cancer patients identified at the time of diagnosis, enrolled from 2011-2013, and followed prospectively. Sociodemographic information and decision making factors including goals of care were collected by patient report. Patients were asked to rate the importance of quality of life, cure, burden to friends and family, cost, and effect on daily activity as well as which of these goals was the most important in their treatment decision making. Annual household income was stratified in to 3 levels: < 40K (low), 40-90K (middle),>90K (high). **Results:** Of 1382 patients, 539 (39%), 553 (40%), and 290 (21%) reported low, medium, and high household income. Lower income patients were less college educated, more frequently unemployed, and had higher rates of either no insurance or government sponsored insurances. Low income patients had higher PSA and worse clinical stage at diagnosis. In goals of care, low income patients more frequently rated high importance on burden (78.8% vs 76.0% vs 65.2% p<0.01) and cost of cancer (61.2% vs 38.5% vs 14.5% p<0.01), and factors other than cure as the most important treatment decision factor. While overall treatment rate at 1 year was similar by income group, the type of treatment differed. On multivariate analyses, adjusting for age, race, clinical risk group, employment, insurance, and treatment goal, high income was associated with increased odds of having surgery (OR 1.81, CI 1.16 – 2.81), and reduced odds of having radiation (0.60, CI 0.36-0.99). **Conclusions:** Poor patients with low household income have worse prostate cancer at diagnosis. These patients have different goals of care which impact their choice of treatment. These findings provide novel insight into disparities in diagnosis and outcome in prostate cancer. Research Sponsor: PCORI.

Stage, goals of care and treatment of newly diagnosed prostate cancer patient by income.

Racial disparities in access to prostate cancer clinical trials: A county-level analysis. *First Author: Aasthaa Bansal, University of Washington, Seattle, WA*

Background: African American men (AAs) have a higher burden of prostate cancer compared to other populations. We sought to determine if they experience disparities in access to prostate cancer clinical trials. **Methods:** We created a county-level database of all U.S. counties by linking together prostate cancer clinical trial data from the Aggregate Analysis of ClincalTrials.gov (AACT) database with county-level socioeconomic, demographic and healthcare facility data derived from several external data sources. Using this data linkage, we examined two specific potential access barriers. First, we investigated the relationship between %AAs in the county and access to NCI designated cancer facilities, adjusting for county population size and other characteristics. Then, among counties with cancer facilities, we investigated the relationship between the %AAs in the county and number of available prostate cancer treatment trials per capita per year. We used logistic and negative binomial regression models, respectively, to address these questions. **Results:** Between 2008 and 2015, 613 prostate cancer trial sites were found among 3,145 U.S. counties. Counties with higher %AAs were less likely to have cancer facilities (adjusted odds ratio = 0.85, 95% CI (0.78, 0.92)). Among counties with cancer facilities, those with higher %AAs had significantly fewer prostate cancer trials per capita per year (rate ratio per 10% increase in %AAs: 0.90, 95% CI (0.83,0.96)), after adjusting for county-level sociodemographic and healthcare system factors. **Conclusions:** Counties with higher proportions of AAs appear to be less likely to have access to NCI designated cancer facilities. Among counties with cancer facilities, those with higher proportions of AAs appear to have fewer available prostate cancer treatment trials per capita per year. Clinical trials in prostate cancer therapy should ensure adequate availability of enrollment sites in regions with high concentrations of AAs. Research Sponsor: U.S. National Institutes of Health.

Mediators of racial disparity in the use of prostate MRI. *First Author: Michael S. Leapman, Department of Urology, Yale School of Medicine, New Haven, CT*

Background: Evidence of racial disparity in the use of prostate MRI presents new obstacles to closing recognized gaps in treatment and outcome for black men with prostate cancer. To anticipate strategies for improving equity in cancer care, we examined mediators of racial disparity in the use of prostate MRI surrounding the diagnosis of prostate cancer. **Methods:** We conducted a multiple mediation analysis among patients with localized prostate cancer in the Surveillance, Epidemiology, and End Results (SEER)-Medicare database between January 2008 and December 2015. We assessed claims for prostate MRI within the six-month period preceding or following diagnosis. We first identified candidate clinical and sociodemographic meditators based on their association with both race and prostate MRI, including the Index of Concentrations at the Extremes (ICE), a measure of racialized residential segregation calculated at the zip code or census tract level. We used non-linear Multiple Additive Regression Trees (MART) models to estimate the direct and indirect relative effects of mediators. **Results:** We identified 71,597 eligible patients. Black patients with prostate cancer were less likely (5.3%) to receive a prostate MRI when compared with white patients (7.0%; unadjusted odds ratio 0.75, 95% CI 0.67-0.84, p < 0.001). 33.1% (95% CI 20.6-44.9) of the racial disparity in prostate MRI use was attributable to variation in SEER region, 22.5% (95% CI 13.0-30.2) to residence in a high poverty area, 17.2% to residential segregation (ICE group 17.2%, 95% CI 8.1-27.9%), and 13.2% to dual eligibility for Medicaid (95% CI 8.6-20.2%). Clinical and pathologic factors were not significant mediators. After accounting for the mediators, the direct effects of race accounted for 6.2% of the observed disparity in prostate MRI use. **Conclusions:** Sociodemographic factors including geographic region, and area-level measures of income and residential segregation explain the majority of the observed racial disparity in the use of prostate MRI among older Americans with prostate cancer. The findings underscore that measurable structural factors can be readily identified that underlie racial disparity in access to emerging diagnostic tools for patients with cancer. Research Sponsor: U.S. National Institutes of Health.

Examining racial disparities in male breast cancer. *First Author: Elizabeth Shurell Linehan, Division of Breast Surgical Oncology, Kaiser Permanente, San Francisco, CA*

Background: Male breast cancer (MBC) accounts for approximately 1% of all breast cancers. Racial disparities have not been examined in MBC. **Methods:** Within a large, integrated health delivery system, all adult female and male patients who were diagnosed with breast cancer from 01-01-2010 to 12-31-2018 were examined. Bivariate analysis was performed to examine clinical and demographic factors associated with breast cancer-related mortality. We conducted more detailed chart review in the MBC-only group (data period 01-01-2010 to 12-31-2019) to assess the mean time to treatment (from diagnosis to surgery, surgery to chemotherapy, and surgery to radiation) stratified by race using bivariate (t-test, one way ANOVA) analyses. **Results:** 32,848 female breast cancer and 226 MBC patients were evaluated; MBC patients represented 0.63% of all breast cancer patients. Between males and females, there was no statistically significant difference in race, with an overall distribution of 62% White, 19% Asian, 8% Black, and 11% Hispanic. To our knowledge, this is the largest and most racially diverse sample of MBC patients to date. MBC patients at diagnosis were significantly older (p < .0001), more obese (p < 0.0018), and sicker according to the Charlson Comorbidity Index (CCI) (p < 0.0001) compared to female breast cancer patients. Males were more likely to be diagnosed at an advanced stage (19.2%) compared to females (12.5%) (p = 0.0037). With a mean follow up of 5 years, overall mortality was statistically significantly worse in MBC (23.0%) compared to female breast cancer patients (12.0%) (p < 0.0001). Furthermore, breast cancer-related mortality was significantly higher in males (8.1%) than in females (4.5%) (p = 0.0124). In the MBC-only analysis, stage at diagnosis was not influenced by patient race. Asian and White MBC patients had the shortest mean time from diagnosis to surgery (27 and 29 days, respectively), with Hispanic MBC patients experiencing the longest time to surgery (46 days). Black MBC patients experienced the shortest mean time to chemotherapy after surgery (39 days), whereas Asian MBC patients experienced the longest time to chemotherapy (50 days). In survivorship, Black and Asian patients were least likely to undergo screening mammography (33.3%, and 43.3%, respectively), compared to 52% of White and 50% of Hispanic MBC patients. Ultimately, 13% of Asian and 11% of Hispanic MBC patients died of breast cancer, compared to 6.7% of Black and 6.2% of White MBC patients. **Conclusions:** While we found no statistically significant differences in mortality by race among MBC patients, our findings indicate that non-white patients had longer time to treatments, less survivorship screening, and worse disease related mortality than their white counterparts. Future study can elucidate these racial inequalities, enabling more equitable breast cancer treatment among patient subgroups. Research Sponsor: Kaiser Permanente Community Benefit Grant.

In-hospital outcomes of CAR T-cell therapy in United States in 2018: A nationwide analysis. *First Author: Manoj P. Rai, Asante Rogue Regional Medical Center, Medford, OR*

Background: CAR T-cell therapy is a type of adoptive cell transfer (ACT). In 2017 CAR T-cell therapy was approved by the Food and Drug Administration (FDA) for management of diffuse large B-cell lymphoma refractory to at least two prior lines of therapy (DLBCL) including primary mediastinal large B-cell lymphoma (PMBCL), and B cell precursor acute lymphoblastic leukemia (ALL) up to 25 years of age that is refractory or in second or later relapse. Since its inception, several patients underwent CAR T-cell therapy but data on real world outcome is limited. In this study we aim to evaluate the in-hospital outcomes of CAR T-cell therapy in the United States in 2018. **Methods:** This is a cross-sectional study using National Inpatient Sample 2018 database. Discharges with the ICD-10-PCS code for CAR T-cell therapy and ICD-10-CM code of ALL, DLBCL or PMBCL were included in the study. We analyzed their in-hospital outcomes (Total discharges, length of stay in days, hospitalization cost, and mortality - number of deaths). We applied the cost to charge ratio to hospitalization charges to estimate the mean hospitalization cost. The weighted sample represents national estimates. **Results:** We identified 785 discharges with CAR T cell therapy and diagnosis of ALL, DLBCL or PMBCL. 155 (19.75 %) were ALL, 620 (78.98%) DLBCL, and 10 (1.27%) PMBCL. Mean length of stay for the study cohort was 23.26 days. Specifically, for ALL mean LOS was 33.67 days, DLBCL 20.76 days, and PMBCL 17 days. Mean hospitalization cost for the study cohort was $285,989, specifically for ALL it was $342,228, DLBCL $274,102, PMBCL $179,431. There were a total of 60 (7.6%) deaths in the study cohort. Diagnosis specific mortality was 20 (12.9%) in ALL, 40 (6.4%) in DLBCL and none in PMBCL. **Conclusions:** Majority of discharges who underwent CAR T-cell therapy were DLBCL followed by ALL and PMBCL. CAR-T Cell hospitalizations have high costs and long length of stays. Mean length of stay was highest in ALL discharges, least in PMBCL. Mean hospitalization cost was higher in DLBCL discharges compared to ALL and was least in PMBCL discharges. The in-hospital mortality with the CAR-T cell therapy appears to be higher than reported in clinical trials, especially for ALL. Research Sponsor: None.

	CAR T-cell therapy (Overall)	CAR T-cell therapy for ALL	CAR T-cell therapy for DLBCL	CAR T-cell therapy for PMBCL
Total number of hospitalizations	785	155 (19.75 %)	620 (78.98%)	10 (1.27%)
Mean length of stay (days)	23.26 (20.15 - 26.37)	33.68 (24.6 - 42.70)	20.76613 (17.62 - 23.91)	17 (14.22 - 19.78)
Mean hospitalization Cost ($)	285,989 (246,781.9 – 325,197)	342,228.3 (241,621.5 - 442,835)	274,101.9 (232,857 – 315,347)	179,431.2 (19,658 – 339,205)
Mortality (n)	60 (7.6%)	20 (12.9%)	40 (6.4%)	0 (0%)

Total number of hospitalizations, mean length of stay, mean hospitalization cost and mortality in discharges with CAR T-cell therapy (overall vs. ALL vs. DLBCL vs. PMBCL).

Characteristics of patients hospitalized through the emergency department with an oncology drug-related side effect. *First Author: Elisea Avalos-Reyes, CVS Health, Irving, TX*

Background: Recent advances in oncology treatment present an expanding spectrum of cancer-treatment-related emergencies.Many aspects of healthcare utilization, specifically emergency department (ED) visits, are not well studied in this population. The purpose of this study is to determine (1) what proportion of cancer patients visit the ED with an oncology drug-related side effect and are admitted and (2) what factors impact the probability of inpatient admission among these patients. **Methods:** This study evaluated ED visits by adult patients undergoing active drug treatment for cancer insured by a large commercial and Medicare health plan in the United States between January 1, 2018, and September 30, 2019. Among cancer-related ED visits, logistic regression was used to determine the marginal effect of demographic and clinical characteristics of patients on acute inpatient admission. **Results:** There were 39,921 total ED visits among patients undergoing drug treatment for cancer; of these, 76% presented with an oncology drug-related side-effect. 36% of all ED visits resulted in admission, 5% resulted in an observation stay. After adjusting, age was not a significant predictor of inpatient admission. Being male ($p < 0.01$) and living in urban ($p < 0.01$) or suburban ($p < 0.01$) zip codes significantly increased the likelihood of admission. Patients with colorectal ($p = 0.019$), gastrointestinal ($p < 0.01$), blood ($p < 0.01$), lung ($p < 0.01$), metastatic ($p < 0.01$) cancers, or Hodgkin's lymphoma ($p < 0.01$) had significantly increased risk of admission. Patients with prostate ($p < 0.01$) cancer had a significantly reduced risk of admission. The primary complaint upon presentation to the ED was the most important predictor of inpatient admission; sepsis, pneumonia, medical complications, white cell disorders, metastatic cancer, and fractures were all associated with a significantly higher (all $p < 0.001$) risk of admission. Patients with comorbid heart failure ($p < 0.001$), those taking ulcer medications ($p < 0.01$), or inflammatory bowel disease ($p = 0.03$) had a significantly increased risk of admission. Results were consistent regardless of payer (Medicare or commercial health plan). **Conclusions:** This study identified cancer patients for whom acute inpatient admission from an ED presentation is more likely. Future studies identifying cancer patients who may be at risk of making an ED presentation based on demographic, clinical and disease-related characteristics are needed and may help inform targeted follow up of patients to mitigate potentially avoidable ED presentation and subsequent inpatient admission. Research Sponsor: None.

Supportive oncology care at home intervention for patients with pancreatic cancer. *First Author: Ryan David Nipp, Department of Medicine, Division of Hematology & Oncology, Massachusetts General Hospital & Harvard Medical School, Boston, MA*

Background: Patients with pancreatic cancer receiving chemotherapy often experience substantial symptoms and high healthcare utilization. We sought to determine the feasibility of delivering a Supportive Oncology Care at Home intervention designed to address the needs of patients receiving treatment for pancreatic cancer. **Methods:** We prospectively enrolled patients with pancreatic cancer who were participating in a parent trial of neoadjuvant FOLFIRINOX and residing in-state, within 50 miles of our hospital. Patients received the Supportive Oncology Care at Home intervention during neoadjuvant treatment (i.e., up to 4 months). The intervention entailed: 1) remote monitoring of daily patient-reported symptoms, daily vital signs, and weekly body weight; 2) a hospital in the home care model for symptom assessment and management; and 3) structured communication with the oncology team. We defined the intervention as feasible if ≥60% of patients enrolled in the study and ≥60% completed the daily assessments within the first two weeks of enrollment. We tracked numbers of phone calls, emails, and home visits generated by the intervention. We conducted exit interviews with patients, caregivers, and oncology clinicians to assess the acceptability of the intervention. In addition, we compared rates of treatment delays, urgent clinic visits, emergency room (ER) visits, and hospitalizations among those who did (n = 20) and did not (n = 24) receive Supportive Oncology Care at Home from the parent trial. **Results:** From 1/2019-9/2020, we enrolled 80.8% (21/26) of potentially eligible patients. One patient became ineligible following consent due to moving out-of-state, resulting in 20 participants (median age = 67 years [range 55-77]; 60.0% female). Within the first two weeks of enrollment, 65.0% completed all the daily assessments, with participants reporting 96.1% of daily symptoms, 96.1% of daily vital signs, and 92.5% of weekly body weights. Each participant generated an average of 2.22 phone calls (range 0.62-3.77), 2.96 emails (range 1.50-5.88), and 0.15 home visits (range 0-0.69) per week. During exit interviews, > 80% of patients, caregivers, and clinicians found the intervention to be helpful and convenient, and they reported high satisfaction with the communication among patients, clinicians, and the hospital in the home team. Patients receiving the intervention had lower rates of treatment delays (55.0% v 75.0%), urgent clinic visits (10.0% v 25.0%), ER visits or hospitalizations (45.0% v 62.5%), as well as a lower proportion of days spent in urgent clinic, ER, or hospital (2.7% v 7.8%), compared with those not receiving the intervention who were in the same parent trial. **Conclusions**: These findings demonstrate the feasibility and acceptability of a Supportive Oncology Care at Home intervention. Future work will investigate the efficacy of this intervention for decreasing healthcare use and improving patient outcomes. Clinical trial information: NCT03798769. The impact of HIV infection on overall survival among women with stage IV breast cancer in South Africa. *First Author: Yoanna S Pumpalova, Columbia University Irving Medical Center, New York, NY*

Background: Advanced stage at breast cancer (BC) diagnosis is common in sub-Saharan Africa. In public hospitals across South Africa (SA), 10-15% of women present with metastatic BC, compared to <5% in the U.S., and 20% of new BCs are diagnosed in women living with HIV (WLWH). We evaluated the impact of HIV on overall survival (OS) among women with stage IV BC, which is associated with a poor prognosis in SA. **Methods:** We conducted a prospective cohort study of women diagnosed with stage IV BC between February 2, 2015 and September 18, 2019 at six public hospitals in SA. Baseline characteristics were compared by HIV status and multivariate Cox regression models were used to estimate the effect of HIV on OS. **Results:** Among 550 eligible women, 147 (26.7%) were WLWH. Compared to HIV-negative BC patients, WLWH were younger (median age 45 vs. 60 years, p<0.001), predominantly black (95.9% vs. 77.9%, p<0.001), and more likely to have hormone receptor-negative BC (32.7% vs. 22.6%, p=0.016). HER2 tumor status did not differ by HIV status (25.3% HER2 positive overall), and Ki67 index was not increased among WLWH (57.1% Ki67 > 20 overall). Receipt of systemic anti-cancer therapy did not differ by HIV status (80.9% treated overall) and most women were treated with anthracycline (55.5%). HIV status was not associated with OS (Hazard Ratio (HR)=1.13, 95% confidence interval (CI)=0.89-1.44) (Table). In an exploratory subgroup analysis, WLWH and hormone receptor-negative BC had shorter OS compared to HIV-negative women (1-year OS: 27.1% vs. 48.8%, p=0.003; HR=1.94, 95% CI=1.27-2.94), which was not observed for hormone receptor-positive BC. Results were unchanged when analysis was restricted to black women only. **Conclusions:** HIV status was not associated with worse OS in women with stage IV BC in SA and cannot account for the poor survival in our cohort. Subgroup analysis revealed that WLWH with hormone receptor-negative BC had worse OS; this differential effect of HIV on BC survival by hormone receptor status is a novel finding that warrants further investigation. Research Sponsor: U.S. National Institutes of Health.

Multivariate Cox proportional hazard ratio model of risk factors for mortality in women with stage IV breast cancer in South Africa (2015-2019), stratified by self-identified ethnicity.

	All Women*		Black Women*	
	HR (95% CI)	P-value	HR (95% CI)	P-value
HIV Positive	1.13 (0.89-1.44)	0.32	1.08 (0.84-1.40)	0.55
Age ≥50	1.16 (0.93- 1.46)	0.20	1.20 (0.94-1.53)	0.15
T-stage (T4)	1.60 (1.27-2.02)	**<0.001**	1.56 (1.20-2.01)	**0.001**
Hormone Receptor Negative	1.39 (1.10-1.76)	**0.006**	1.46 (1.13-1.87)	**0.003**
HER2 Positive	1.07 (0.85-1.35)	0.56	1.07 (0.83-1.37)	0.60
Ki67 proliferation index >20%	1.47 (1.18-1.83)	**0.001**	1.51 (1.19-1.93)	**0.001**
Visceral Metastases	1.31 (1.06-1.61)	**0.01**	1.34 (1.07-1.69)	**0.01**
Had surgery	0.50 (0.35-0.72)	**<0.001**	0.44 (0.29-0.67)	**<0.001**
Had chemotherapy	0.12 (0.09-0.16)	**<0.001**	0.12 (0.09-0.17)	**<0.001**

Changes in patient-reported outcomes (PROs) and tumor markers (TMs) to predict treatment response and survival outcomes in patients with metastatic gastrointestinal (GI) cancer. *First Author: Joy X. Jarnagin, Massachusetts General Hospital, Boston, MA*

Background: PROs assessing quality of life (QOL) and symptoms at a single timepoint frequently correlate with clinical outcomes in patients with cancer, yet efforts to understand how longitudinal changes in PROs can predict for treatment outcomes are lacking. In practice, oncologists often use changes in serum TMs (CEA and CA19-9) to monitor patients with GI cancer, and thus we sought to examine associations of 1-month changes in PROs and TMs with treatment response and survival outcomes among patients with advanced GI cancer. **Methods:** We prospectively enrolled patients with metastatic GI cancer prior to initiating chemotherapy at Massachusetts General Hospital from 5/2019-12/2020. At baseline (start of treatment) and 1-month later, we collected PROs (QOL [Functional Assessment of Cancer Therapy General {FACT-G}], physical symptoms [Edmonton Symptom Assessment System {ESAS}], and psychological symptoms [Patient Health Questionnaire-4 {PHQ-4}]) and TMs. We used regression models to examine associations of 1-month changes in PROs and TMs with treatment response (clinical benefit [defined as decreased or stable tumor burden] or progressive disease at the time of first scan) and survival outcomes (progression-free survival [PFS] and overall survival [OS]), adjusted for baseline values of each respective variable. **Results:** We enrolled 159 of 191 patients approached (83.2% enrollment); 134 had 1-month follow-up data (median age = 64 years [range: 28 to 84 years], 64.2% male, 46.3% pancreaticobiliary cancer). For treatment response, 63.4% had clinical benefit and 36.6% had progressive disease at the time of first scan (mean time to first scan = 2.01 months). Changes in PROs (ESAS-Total: OR = 0.97, p = 0.022; ESAS-Physical: OR = 0.96, p = 0.027; PHQ-4 depression: OR = 0.67, p = 0.014; FACT-G: OR = 1.07, p = 0.001), but not TMs (CEA: OR = 1.00, p = 0.836 and CA19-9: OR = 1.00, p = 0.796), were associated with clinical benefit at the time of first scan. Changes in ESAS-Total (HR = 1.03, p = 0.004), ESAS-Physical (HR = 1.03, p = 0.021), PHQ-4 depression (HR = 1.22, p = 0.042), FACT-G (HR = 0.97, p = 0.003), and CEA (HR = 1.00, p = 0.001) were predictors of PFS. Changes in ESAS-Total (HR = 1.03, p = 0.006) and ESAS-Physical (HR = 1.04, p = 0.015) were predictors of OS, but 1-month changes in TMs (CEA: HR = 1.00, p = 0.377 and CA19-9: HR = 1.00, p = 0.367) did not significantly predict for OS. **Conclusions:** We found that 1-month changes in PROs can predict for treatment response and survival outcomes in patients with advanced GI cancers. Notably, 1-month changes in CEA only correlated with PFS, while changes in CA19-9 did not significantly predict treatment response or survival outcomes. These findings highlight the potential for early changes in PROs to predict treatment outcomes while underscoring the need to monitor and address PROs in patients with advanced cancer. Concomitant infections in patients with cancer and COVID-19: A COVID-19 and Cancer Consortium (CCC19) study. *First Author: Kyle T. Enriquez, Vanderbilt University Medical Center, Nashville, TN*

Background: COVID-19 has been associated with immune modulation that may predispose infected patients to bacterial, viral, or fungal co-infections. Due to critical illness, $>$ 70% of patients with severe COVID-19 receive empiric antibacterial or antifungal therapy, along with standard anti-COVID-19 treatments. However, the frequency of proven or probable secondary infections is $<$ 10%. To our knowledge, there are no studies evaluating co-infections in patients with cancer and COVID-19, a vulnerable group with multiple risk factors for co-infections. We aim to describe the prevalence of bacterial, viral, and fungal co-infections, identify risk factors for coinfection, and investigate the potential impact of co-infections on mortality, in patients with a history of cancer and COVID-19. **Methods:** The CCC19 registry (NCT04354701) includes patients with active or prior hematologic or invasive solid malignancies reported across academic and community sites. We captured bacterial, fungal, or viral co-infections diagnosed within ±2 weeks from diagnosis of COVID-19, identified factors associated with an increased risk of having a co-infection, and evaluated the association of co-infections with 30-day all-cause mortality. **Results:** We examined 6732 patients with a history of cancer and a laboratory-confirmed diagnosis of SARS-CoV-2 reported to CCC19 by 82 sites between March 17, 2020 and February 3, 2021, with complete data on coinfection status. Median age was 65 (interquartile range: 55-75) years with 48% male, 52% non-Hispanic white, 19% non-Hispanic black, and 16% Hispanic. 5448 (81%) had solid tumors and 1466 (22%) had hematologic malignancies. Bacterial infections were reported in 823 patients (12%), including 296 Gram+ and 245 Gram- bacterial events. Documented viral (176 patients, 3%) and fungal (59 patients, 0.9%) co-infections were rare. The risk for co-infections increased with age, and they were more frequent among men, older patients, and those with diabetes, pulmonary or renal comorbid conditions, active progressive cancer, or hematologic malignancies (unadjusted $P<$ 0.01). The frequency of reported co-infections decreased over the study period (divided into quartiles, Mantel-Haenszel $P<$ 0.01). All-cause mortality rates were higher among those with bacterial (24% vs. 10%), viral (22% vs. 12%), and fungal (37% vs. 12%) coinfections compared to those without (unadjusted $P<$ 0.01). **Conclusions:** The frequency of bacterial infections in patients with cancer and COVID-19 is relatively low. Viral and fungal co-infections are uncommon. Co-infections are associated with higher mortality rates. Several patient and tumor factors can be used for risk stratification and guide early empiric antimicrobial agent selection, which may improve clinical outcomes. These data could inform antimicrobial stewardship interventions in this tenuous patient population. Research Sponsor: U.S. National Institutes of Health.

Impact of disruptions in breast cancer control due to the COVID-19 pandemic on breast cancer mortality in the United States: Estimates from collaborative simulation modeling. *First Author: Oguzhan Alagoz, University of Wisconsin-Madison, Madison, WI*

Background: The COVID-19 pandemic has disrupted breast cancer control through short-term declines in screening, delays in diagnosis and reduced/delayed treatments. We projected the impact of COVID-19 on future breast cancer mortality. **Methods:** Three established Cancer Intervention and Surveillance Modeling Network (CISNET) models projected the impact of pandemic-related care disruptions on breast cancer mortality between 2020 and 2030 vs. pre-pandemic care patterns. Based on Breast Cancer Surveillance Consortium data, we modeled reductions in mammography screening utilization, delays in symptomatic cancer diagnosis, and reduced use of chemotherapy for women with early-stage disease for the first six months of the pandemic with return to pre-pandemic patterns after that time. Sensitivity analyses were performed to determine the effect of key model parameters, including the duration of the pandemic impact. **Results:** By 2030, the models project 1,297 (model range: 1,054-1,900) cumulative excess deaths related to reduced screening; 1,325 (range: 266-2,628) deaths from delayed diagnosis of symptomatic women, and 207 (range: 146-301) deaths from reduced chemotherapy use for early-stage cancer. Overall, the models predict 2,487 (range 1,713-4,875) excess deaths, representing a 0.56% (range: 0.36%-0.99%) cumulative increase over deaths that would be expected by 2030 in the absence of the pandemic's disruptions. Sensitivity analyses indicated that the impact on mortality would approximately double if the disruptions lasted for a 12-month period. **Conclusions:** The impact of the initial pandemic-related disruptions in breast cancer care will have a small long-term cumulative impact on breast cancer mortality. The impact of the initial pandemic-related disruptions on breast cancer mortality will largely be mitigated by the rapid return to usual care. As the pandemic continues it will be important to monitor trends in care and reassess the mortality impact. Research Sponsor: U.S. National Institutes of Health.

Scenario	Cumulative number of deaths by 2030 Median (range across models)	
No COVID-19 impact	473,903 (444,352-493,595)	
	Excess number of deaths Median (range)	% increase Median (range)
2: Reduced screening (50% of women missed their scheduled screening exams)	1,297 (860-1900)	0.27% (0.19-0.38)
3: Delayed diagnosis (25% of women delayed evaluation of breast cancer symptoms for 6 months)	1,325 (266-2629)	0.30% (0.06-0.53)
4: Reduced chemotherapy (50% of women older than 70 and 25% of women younger than 70 who are diagnosed with ER+/HER2- tumors in Stages I and IIA during the pandemic period would not receive clinically indicated adjuvant chemotherapy)	207 (146-301)	0.04% (0.03-0.06)
5: Disruptions in screening & diagnosis (Scenarios 2 & 3)	2,365 (1576-4580)	0.53% (0.33-0.93)
6: Disruptions in screening & diagnosis & chemotherapy (Scenarios 4 & 5)	2,487 (1713-4875)	0.56% (0.36-0.99)

Lower respiratory tract disease (LRTD) in patients with cancer and COVID-19: A COVID-19 and Cancer Consortium (CCC19) study. *First Author: Dimpy P. Shah, University of Texas Health Science Center San Antonio, San Antonio, TX*

Background: Immunodeficiency in patients (pts) with cancer can lead to the progression of common respiratory viral infections to lower respiratory tract disease (LRTD) with potentially high mortality. Understanding risk factors of SARS-CoV-2 related LRTD in pts with cancer is imperative for the development of preventive measures. **Methods:** We examined all patients aged 18 years or older with cancer and laboratory-confirmed SARS-CoV-2 infection reported between March 16, 2020 and February 6, 2021 in the international CCC19 registry. We examined frequency of LRTD (pneumonia, pneumonitis, acute respiratory distress syndrome, or respiratory failure), demographic and clinicopathologic factors associated with LRTD, and 30-day and overall mortality in pts with and without LRTD. **Results:** Of 7,289 pts with a median follow-up time of 42 (21-90) days, 2187 (30%) developed LRTD. Pts of older age (65 yrs or older), male sex, pre-existing comorbidities, baseline immunosuppressants, baseline corticosteroids, and ECOG performance status of 2 or more had substantially higher rates of LRTD compared to those without these risk factors (Table). We did not observe differences in LRTD rates between pts of different racial/ethnic groups, smoking history, hypertension, obesity, cancer status, timing or type of anti-cancer therapy. LRTD was more likely in pts with thoracic malignancy (39%), hematological malignancy (39%) compared to those with other solid tumors (27%). The majority of pts (86%) had symptomatic presentation; however, 8% of pts with asymptomatic presentation developed LRTD. 30-day and overall mortality rates were significantly higher in pts with LRTD than those without LRTD (31% vs. 4% and 38% vs. 6%, P $<$ 0.05). **Conclusions:** COVID-19 related LRTD rate is high and associated with worse mortality rates in pts with cancer. The majority of risk factors associated with LRTD demonstrate underlying immunodeficiency or lung structural damage as a driving force in this population. Identifying pts at high-risk for developing LRTD can help guide clinical management, improve pt outcomes, increase the cost-effectiveness of antiviral therapy, and direct future clinical trial designs for vaccine or antiviral agents. Research Sponsor: American Cancer Society and Hope Foundation for Cancer Research for Cancer, U.S. National Institutes of Health.

Baseline risk factors for COVID-19 related LRTD.

Risk Factor	LRTD rate in presence of a risk factor	LRTD rate in absence of a risk factor
Older age (65 years or older)	1423/3827 (37%)	759/3462 (22%)
Male sex	1223/3449 (35%)	958/3784 (25%)
Cardiovascular comorbidity	858/2117 (41%)	1304/5097 (26%)
Pulmonary comorbidity	567/1455 (39%)	1595/5759 (28%)
Renal comorbidity	473/1062 (45%)	1689/6152 (27%)
Diabetes mellitus	766/1935 (40%)	1396/5279 (26%)
Baseline immunosuppressants	175/402 (44%)	1942/6643 (29%)
Baseline corticosteroids	132/289 (46%)	1909/6546 (29%)
ECOG PS (2+)	416/1016 (41%)	1077/4201 (26%)

Predictors of surgery preference and quality of life in DCIS after breast MRI: A trial of the ECOG-ACRIN Cancer Research Group (E4112). *First Author: Soudabeh Fazeli, University of California San Diego Medical Center, San Diego, CA*

Background: Management of ductal carcinoma in situ (DCIS) remains variable, requiring an understanding of patient preferences and concerns to enhance the treatment decision-making process. Pre-operative MRI and surgeon recommendation can further inform surgery choice. Quality of life (QoL) is also an important consideration in treatment decision-making. The aims of this study were to assess patients' treatment preferences before and after MRI and surgeon consultation, concordance between treatment preference and surgery received, and trends in health-related QoL (HRQL) among a prospective cohort of women newly diagnosed with DCIS. **Methods:** A prospective nonrandomized clinical trial by the ECOG-ACRIN Cancer Research Group (E4112) enrolled women diagnosed with unilateral DCIS from 75 institutions between March 2015 and April 2016. Participants underwent either wide local excision (WLE) or mastectomy. Surveys queried patient-reported outcomes (PRO) including treatment preference and concerns, and HRQL before and after surgery. Logistic regression models were used to associate surgery preference and actual surgery received with demographic, clinical and PRO data. Change from baseline in HRQL was assessed using linear regression. **Results:** At study entry, age (OR 0.39, per 5-year increment, 95%CI, 0.21-0.75; p = 0.005) and treatment goals related to the importance of keeping one's breast (OR 0.51, 95%CI 0.34-0.76; p = 0.001) and removal of the breast for peace of mind (OR 1.46, 95%CI 1.09-1.95; p = 0.01) drove surgery preference for mastectomy vs. WLE. After receipt of MRI and surgeon consultation, surgery preference was primarily mediated by MRI upstaging (OR 11.18, 95%CI 3.19-39.16; p < 0.001). Only 4% of women received a type of surgery that did not match their final treatment preference. The strongest predictors of actual surgery received were MRI upstaging (OR 15.80, 95%CI 4.85-51.46) and surgeon recommendation of mastectomy (OR 4.60, 95%CI 1.52-13.94). Receipt of a single surgery was associated with significantly improved mental health from baseline to one year after definitive surgery (p = 0.02 for mastectomy; p = 0.003 for single WLE). Self-reported Black race was an independent predictor of worsened mental (p = 0.001) and physical (p = 0.04) health at one year after definitive surgery, despite no significant racial differences in baseline HRQL. **Conclusions:** Our findings highlight the importance of communication between providers and patients regarding treatment preferences and goals, the clinical significance of MRI findings, and the benefits/risks of available treatment options. Future research to identify modifiable factors associated with declining mental and physical health is needed to inform targeted interventions to mitigate racial disparities and enhance HRQL in patients with DCIS. Research Sponsor: U.S. National Institutes of Health.

6565 **Poster Session**

Initial reporting from the prospective National Cancer Institute (NCI) COVID-19 in Cancer Patients Study (NCCAPS). *First Author: Larissa A. Korde, Clinical Investigations Branch, National Cancer Institute, Bethesda, MD*

Background: Patients (pts) with cancer are at increased risk of SARS-CoV-2 infection and severe COVID-19 disease. Longitudinal follow-up is needed to characterize the severity, sequelae and outcomes in pts with cancer who develop COVID-19. **Methods:** NCCAPS is a prospective, longitudinal study (NCT04387656) aiming to accrue 2,000 pts with cancer undergoing active treatment or prior stem cell transplant for hematologic or solid tumor malignancy. Adult patients are eligible to enroll within 14 days of their first positive SARS-CoV-2 test; pediatric patients may also enroll retrospectively. Clinical data, patient-reported outcomes, blood specimens, and imaging are collected for up to 2 years. This abstract provides initial baseline and 2-month follow-up data. **Results:** As of Jan 22, 2021, 585 pts (552 adults and 33 pediatric pts) had complete baseline data and of these pts, 215 adults had 2 months of complete follow-up data. 23.4% of adults and 42.4% of pediatric pts were of non-White race and/or Hispanic/Latinx ethnicity. The most common cancer diagnoses were breast (19.6%), lung (9.9%) and multiple myeloma (8.9%) in adults and acute leukemia (AML/ALL; 63.6%) in children. The most recent treatment was chemotherapy in 38.2%, immunotherapy in 9.6%, and radiation in 5.4%. Median time from positive SARS-CoV-2 test to study enrollment was 10.5 days in adults and 18 days in pediatric pts. Preliminary analysis of plasma cytokines will be presented. At enrollment, 84.6% of adults had COVID-19 symptoms. 55.9% reported symptoms 2 weeks after their positive SARS-CoV-2 test; this fell to 39.0% at 1 month and 28.8% at 2 months (see Table). Of the 215 adults with complete data at 2 months, sequelae included pulmonary (n=22, 10%), cardiovascular (n=12, 6%) thromboembolic (n=9, 4%), bleeding (n=9, 4%) and gastrointestinal (n=11, 5%). 144 (67%) reported at least one cancer treatment disruption in the first 2 months, most commonly delayed therapy (n=98; 46%).Of the 348 adults with baseline data and SARS-CoV-2 test date prior to Nov 23, 2020, 6.3% had died (median time from SARS-CoV-2 test to death: 27 days), and 22.1% reported at least one hospitalization for COVID-19. No deaths were reported in the pediatric population. **Conclusion**: Cancer pts with COVID-19 report ongoing symptoms after acute infection and a substantial number develop sequelae. Cancer treatment disruptions are common in the initial months following SARS-CoV-2 infection. Longer follow-up will inform whether these treatment disruptions are associated with adverse outcomes. Clinical trial information: NCT04387656. Research Sponsor: U.S. National Institutes of Health.

Symptom, % reporting	Baseline N=542	2 weeks N=249	1 month N=293	2 months N=159
Fatigue/malaise	55.7	34.5	25.9	11.9

Initial report on hospitalized cancer patients with COVID-19 from the National Cancer Institute (NCI) COVID-19 in Cancer Patients Study (NCCAPS). *First Author: Nicholas M. Mark, Swedish Medical Center, Seattle, WA*

Background: Hospitalized cancer patients (pts) with COVID-19 have a severe disease course and high mortality. Pts with lung cancer, hematologic malignancies and metastatic disease may be at higher risk. Detailed prospective inpatient data may help to identify those at greatest risk for poor outcomes. **Methods:** NCCAPS is a longitudinal study aiming to accrue 2,000 cancer pts undergoing treatment for hematologic malignancy or solid tumor with COVID-19. For pts' first COVID-19 hospitalization, clinical data, research blood specimens and imaging are collected, and additional clinical data are collected during subsequent hospitalizations. **Results:** As of Jan. 22, 2021, among 757 enrolled adult patients from 204 sites, 124 (16.3%) reported at least one hospitalization for COVID-19, and discharge data was available for 98 hospitalizations in 88 patients. The median age was 67 (range 21-93, 1Q:56, 3Q:72), 35/88 (40%) were female. The most common malignancies in hospitalized adult pts were lymphoma (18.2%), lung cancer (15.9%) and multiple myeloma (10.2%). The most common presenting symptoms were shortness of breath (65%), fatigue/malaise (64%), and fever (49%). 8/88 (9%) pts were neutropenic (ANC < 1000) at presentation; 17/88 (19%) were thrombocytopenic. Median length of stay was 6.5 days (range 1-41, 1Q:4, 3Q:12). Among those hospitalized, 20/88 (22.7%) received care in the ICU or high dependency unit, with a median ICU stay of 7 days (range 1-22, 1Q:2.5, 3Q:9.5); of those admitted to the ICU, 25% (5/20) received invasive mechanical ventilation. Of those in whom inpatient medications were recorded (n = 63), 63% received corticosteroids, 46% received remdesivir, and 14% received convalescent plasma. One pt received bamlanivimab and 2 patients received tocilizumab. Most (46/63; 73%) received anticoagulation, primarily prophylactic low molecular weight heparin; 11/63 (17%) received therapeutic dose anticoagulation. Inpatient D-dimer values were recorded in 43 inpatients, 26 of whom had multiple measurements. 16/98 hospitalizations ended with death (16%). **Conclusions:** Preliminary analysis of NCCAPS data reveals that inpatient hospital admission is common among oncology patients with COVID-19 and mortality rates appear high within this cohort. Hematologic malignancies and lung cancer are the most common underlying diagnoses in patients requiring hospitalization. Corticosteroids and anti-coagulation were the most commonly used therapies. Despite high rates of ICU admission, invasive mechanical ventilation may be instituted less often in an oncology cohort. These observations may inform decisions about vaccine policy and decisions to limit life sustaining treatment. Clinical trial information: NCT04387656. Research Sponsor: U.S. National Institutes of Health.

Quality-adjusted time without symptoms of disease progression or toxicity (Q-TWiST) of nivolumab plus cabozantinib (N+C) versus sunitinib (SUN) in treatment-naïve, advanced/metastatic renal cell carcinoma (aRCC): A post-hoc analysis of CheckMate 9ER (CM 9ER) data. *First Author: David Cella, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL*

Background: In CM 9ER (ClinicalTrial.gov identifier NCT03141177), N+C demonstrated significant progression-free survival gains (median: 17.0 vs. 8.3 months [mos]; hazard ratio [HR]: 0.52; $P < .0001$) and overall survival (OS) benefits (median: not reached vs. 29.5 mos; HR: 0.66; $P < .001$) vs. SUN as a first-line treatment for aRCC (Motzer et al. ASCO-GU 2021). To more fully understand the clinical benefits and risks associated with N+C vs. SUN from a patient perspective, we applied the Q-TWiST method to CM 9ER data to assess the quality-adjusted survival of these two treatment options, after a minimum follow-up of 16 mos (Sept DBL 2020). **Methods:** OS was partitioned into 3 states: time with any grade 3 or 4 adverse events (TOX), time without symptoms of disease or toxicity (TWiST), and time after progression (REL). The Q-TWiST is a metric that combines the quantity and quality (i.e., "utility") of time spent in each of the 3 states TWiST, TOX, and REL. Sensitivity analyses estimated Q-TWiST across varying values of TOX and REL utilities. Subgroup analyses were conducted based on geographic region, programmed cell death-ligand 1 status, and International Metastatic RCC Database Consortium risk score. Based on minimal important difference norms (Revicki et al, Qual Life Res, 2006), a relative gain in Q-TWiST (i.e., Q-TWiST gains divided by OS in SUN) of ≥ 10% and ≥ 15% were qualified as "clinically important" and "clearly clinically important" gains, respectively. Non-parametric bootstrapping was used to generate 95% confidence intervals (CI). **Results:** In the intent-to-treat (ITT) population (N = 651), the Q-TWiST gain in the N+C arm was 4.0 mos (95% CI: 2.4, 5.7) vs. SUN arm, resulting in a relative gain of 16.9%. N+C patients had significantly longer TWiST (4.7 mos [95% CI: 2.9, 6.7]) and TOX (0.5 mos [95% CI: 0.1, 0.9]), but significantly shorter REL (-2.0 mos [95% CI: -4.1, -0.1]) than did SUN patients. Sensitivity analyses were consistent with the main analysis—the Q-TWiST benefit was robust across different ranges of U(TOX) and U(REL), with minimum and maximum Q-TWiST gains of 2.7 mos (11.7% relative gain) and 5.2 mos (22.2% relative gain), respectively. Subgroup analyses were consistent with the ITT population, with all results demonstrating ≥10% ("clinically important") gains favoring N+C. **Conclusions:** In CM 9ER, N+C resulted in a statistically significant and "clearly clinically important" (i.e., ≥ 15%) longer quality-adjusted survival vs SUN. Most gains were driven by added time in relatively good health (i.e., TWiST). These Q-TWiST results may help inform both aRCC patients and their clinicians to assess more comprehensively the clinical benefits and risks of N+C and SUN in making critical treatment decisions. Clinical trial information: NCT03141177. Research Sponsor: Bristol Myers Squibb.

6568 **Poster Session**

Long-term trend of quality-adjusted time without symptoms or toxicities (Q-TWiST) of nivolumab+ipilimumab (N+I) versus sunitinib (SUN) for the first-line treatment of advanced renal cell carcinoma (aRCC). *First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: After a minimum follow-up of 48 months (mos), the CheckMate 214 trial (phase 3, NCT02231749) continued to demonstrate a significant overall (OS) and progression-free (PFS) survival benefit for N+I vs. SUN in aRCC patients (pts) with intermediate (I) or poor (P) International Metastatic RCC Database Consortium (IMDC) risk factors (median OS: 48.1 vs. 26.6 mos, HR: 0.65, 95% confidence interval [95% CI]: 0.54, 0.78; 48-mos PFS: 32.7% vs. 12.3%, HR: 0.74, 95% CI: 0.62, 0.88) (Albiges et al. ESMO Open 2020). To further understand the clinical benefits and risks of N+I vs. SUN, we evaluated the Q-TWiST over time using up to 57 mos of follow-up in CheckMate 214. **Methods:** OS was partitioned into 3 states: time with any grade 3 or 4 adverse events (TOX), time without symptoms of disease or toxicity (TWiST), and time after progression (REL). The Q-TWiST is a metric that combines the quantity and quality (i.e., "utility") of time spent in each of the 3 states TWiST, TOX, and REL. Prior research (Revicki et al, Qual Life Res, 2006) has established that relative gains in Q-TWiST (i.e., Q-TWiST gain divided by OS in SUN) of $\geq$ 10% and $\geq$ 15% can be considered as "clinically important" and "clearly clinically important", respectively. Non-parametric bootstrapping was used to generate 95% CIs. To observe changes in quality-adjusted survival gains over time, absolute and relative Q-TWiST were calculated up to 57 mos at intervals of 12-mos. **Results:** With 57-mos follow-up, compared to SUN pts, N+I pts (N = 847) had significantly longer time in TWiST state (+7.1 mos [95% CI: 4.2, 10.4]). The between-group differences in TOX state (0.3 mos [95% CI: -0.2, 0.8]) and REL state (-1.2 mos [95% CI: -4.1, 1.5]) were not statistically significant. The Q-TWiST gain in the N+I vs. SUN arms was 6.6 mos (95% CI: 4.1, 9.4), resulting in a 21.2% relative gain. Q-TWiST gains progressively increased over the follow-up period and exceeded the "clinically important" threshold around 27 mos (Table). These gains were driven by steady increases in TWiST gains from 0.4 mos (after 12 mos) to 7.1 mos (after 57 mos). **Conclusions:** In CheckMate 214, N+I resulted in a statistically significant and "clearly clinically important ($\geq$ 15%)" longer quality-adjusted survival vs. SUN, which increased over the longer follow-up time. Q-TWiST gains were primarily driven by time in "good" health (i.e., TWiST), which largely resulted from the long-term PFS benefits seen for N+I vs. SUN. Clinical trial information: NCT02231749. Research Sponsor: Bristol Myers Squibb.

Follow-up (mos)	N+I	SUN	Q-TWiST Gain	Relative Gain
12	9.0 (8.7, 9.3)	8.6 (8.3, 8.9)	0.4 (-0.0, 0.9)	3.8%
24	15.9 (15.1, 16.6)	14.2 (13.4, 14.9)	1.7 (0.6, 2.8)	9.7%
36	21.5 (20.4, 22.6)	18.2 (17.1, 19.4)	3.3 (1.7, 5.0)	14.2%
48	26.7 (25.1, 28.3)	21.5 (19.9, 23.0)	5.2 (3.1, 7.5)	18.5%
57	30.2 (28.3, 32.2)	23.6 (21.6, 25.4)	6.6 (4.1, 9.4)	21.2%

Post-intervention lung cancer screening compliance among internal medicine resident physicians at a primary care clinic in Hartford, Connecticut. *First Author: Nerea Lopetegui-Lia, University of Connecticut Health Center, Farmington, CT*

Background: Lung cancer (ca) screening has shown to reduce mortality by up to 20%.Despite this, only 4% of eligible patients in the US undergo screening. Our initial analysis revealed that 18.3% of patients who met screening criteria had an appropriately ordered LDCT scan, with an 8.7% completion rate. The aim of this study was to improve lung ca screening compliance following the USPSTF guidelines among residents from the University of Connecticut Internal Medicine (IM) residency program at a Clinic in Hartford, Connecticut. **Methods:** Care provided to patients by an IM resident at the Gengras Clinic were included. After initial data was gathered, we implemented an intervention to improve screening compliance between October 2019 and March 2020, when SARS-CoV-2 pandemic occurred and routine services were interrupted. USPSTF screening guidelines were emailed monthly to residents and attendings; they were reminded of the importance of lung ca screening; updating the pack-year smoking history; as well as instructions on correctly ordering LDCT and documenting shared decision making, which is needed for insurance approval. In-person reminders also occurred at the clinic. **Results:** Post-intervention, 601 charts were reviewed. 168/601 (27%) patients met screening criteria. 433 patients were excluded due to unclear pack-year, did not meet screening criteria, were deceased or last seen at the clinic prior to the intervention. 63/168 (37.5%) met the criteria and had an appropriately ordered LDCT; 51/168 (30.35%) had a completed LDCT in chart. The remaining 12/168 (7.14%) with an appropriately ordered LDCT, had it scheduled at the time of data collection or it had been cancelled for unclear reasons. 20 patients' LDCT was ordered by their pulmonologist. 94 (62.5%) who met screening criteria did not have a LDCT ordered. 11 patients with a smoking history, who did not meet screening criteria had a LDCT ordered because of clinical suspicion for cancer. Lastly, 4/168 (2.4%) had a diagnosis of personal history of lung ca. **Conclusions:** After our educational intervention, patients who qualified had an increase of LDCT being ordered (37.5% from 18.3%) and completed (30.3% from 8.7%). This is, to our knowledge, the first study of its kind. We identified areas of improvement that were key to achieving higher screening rates: educating all residents and attendings on lung ca screening guidelines; educating patients on the importance of undergoing screening tests; creating a best practice advisory in the electronic medical record system that reminds provider to input pack-year smoking history and if the criteria for screening is met, a pop-up prompting the provider to order LDCT; obtaining insurance approval; and lastly, stressing the importance on screening and overall outcomes. The landscape of mortality during or within 30 days after non-palliative radiotherapy across 11 major cancer types. *First Author: Michael Xiang, Department of Radiation Oncology, University of California, Los Angeles, Los Angeles, CA*

Background: The rate of peri-RT mortality (death that occurs during or within 30 days after non-palliative radiotherapy) has not been previously characterized. Risk factors and predictors for peri-RT mortality are unknown. **Methods:** Adult and pediatric patients with non-metastatic cancer who received non-palliative external beam radiation between 2004-2016 were identified in the National Cancer Database for 11 cancer types: breast, prostate, genitourinary (non-prostate), bone/soft tissue, gynecological, head/neck, lymphoma, gastrointestinal, small cell lung, non-small cell lung, and central nervous system (CNS). Multivariable logistic regression was used to identify predictors of peri-RT mortality while controlling for 16 covariates, including patient, tumor, and treatment factors. **Results:** Approximately 1.32 million patients were identified. Peri-RT mortality was 2.8% overall but spanned 2 orders of magnitude depending on cancer type, ranging from 0.1% for breast cancer to 8.6% for CNS malignancies. Other cancers with $>$ 5% peri-RT mortality were non-prostate genitourinary, small cell lung, and non-small cell lung. Peri-RT mortality steadily improved from 3.5% in 2004 to 2.0% in 2016 ($P <$ .0001). Major predictors of peri-RT mortality were cancer stage, older age, baseline comorbidity, and lack of private insurance, while male sex, Black race, and geographical region were associated with modestly increased risk (all $P <$ .0001). Conversely, treatment at an academic center, higher patient volume at the treating facility, concurrent chemotherapy, and intensity-modulated radiotherapy were associated with modestly decreased risk (all $P <$ .0001). Among patients receiving stereotactic radiotherapy, peri-RT mortality was 1.0% (adjusted odds ratio 0.27, 95% confidence interval 0.24-0.30, $P <$ .0001), underscoring the excellent safety record of this treatment approach. **Conclusions:** Peri-RT mortality varied considerably as a function of multiple disease-specific and sociodemographic differences, which highlight potential areas of health disparities. Early recognition of patients at increased risk may facilitate closer monitoring or other prophylactic interventions. Research Sponsor: None.

Overall survival, quality of life and magnitude of clinical benefit of breast cancer drugs over the last 25 years. *First Author: J. Carlos Tapia, Hospital Sant Pau, Barcelona, Spain*

Background: The American Society of Clinical Oncology Cancer Research Committee (ASCO-CRC), the ASCO Value Framework Net Health Benefit score version 2 (ASCO-VF), and the European Society for Medical Oncology-Magnitude of Clinical Benefit Scale version 1.1 (ESMO-MCBS) are validated tools quantifying the clinical benefit for cancer drugs. Here, we assess the overall survival (OS), quality of life (QoL) and magnitude of clinical benefit of trials supporting breast cancer drug approval by the US Food and Drug Administration (FDA) in the last 25 years. **Methods:** We searched Drugs@FDA website for all breast cancer drug approvals from January 1, 1995 to December 30, 2020. Drug labels and reports of registration trials were reviewed. We collected data on trial characteristics, efficacy, toxicity and QoL. When more than one study supported a single indication, we preferred efficacy-oriented endpoints (typically OS) to QoL. We excluded trials supporting accelerated-approval indications if these were converted to regular approval during the study period. We scored clinical benefit using the ASCO-CRC in palliative setting, and ASCO-VF and ESMO-MCBS in both curative and palliative setting. Substantial clinical benefit was defined as: OS gains $\geq$2.5 months and progression-free survival gains $\geq$ 3 months for ASCO-CRC criteria; ASCO-VF scores $\geq$ 45 and grade of A or B for trials of curative intent and 4 or 5 for those of non-curative intent using ESMO-MCBS. Trends over time were assessed using Chi-squared test for trend. **Results:** We identified 51 trials supporting the approval of 32 individual drugs for 51 indications; 12 (24%) were in the curative setting and 39 (76%) in the palliative setting. At the time of approval, 8 (16%) trials reported significant improvement in OS. QoL was reported in 22 trials (43%). Among these, 8 (36%) showed improvement in QoL. For curative intent, we applied ASCO-VF and ESMO-MCBS score to 11 (92%) trials, finding clinical benefit in 10 (91%) and 2 (18%) trials, respectively. In the palliative setting, we used ASCO-CRC, ASCO-VF and ESMO-MCBS scores to rate 32 (82%), 33 (85%) and 38 (97%) trials. Substantial clinical benefit was observed in 20 (63%), 12 (36%) and 7 (19%) trials, respectively. Over time, there has been a decrease in the number of trials supporting approval based on OS (1996-2003 50% vs 2004-12 38% vs 2013-20 13%, P trend = 0.033). There were no statistically significant changes over time in QoL, ASCO-CRC, ASCO-VF and ESMO-MCBS scores. **Conclusions:** For palliative intent, most trials supporting FDA approval of breast cancer drugs do not meet the ASCO-VF or ESMO-MCBS criteria for substantial clinical benefit. There is substantial inter-framework variability in the assessment of clinical benefit in the curative setting. Over time, there has been a substantial shift towards use of surrogate endpoints as the basis for approval without a clear improvement in substantial clinical benefit. Research Sponsor: None.

Should PICCs be avoided in patients with certain solid organ cancers? *First Author: Urvashi Mitbander, Department of Internal Medicine, University of Michigan Health System, Ann Arbor, MI*

Background: Peripherally inserted central catheters (PICCs) are widely utilized in oncology. Previous studies have shown a high risk of catheter-related thrombosis and bloodstream infection in the uniquely susceptible oncologic population; however, most studies are limited by single center, outpatient, retrospective designs. Therefore, we performed a multi-center study to further describe PICC use and complications in the solid tumor population within the inpatient setting. **Methods:** Data was collected on PICC lines inserted across 50 hospitals in Michigan from November 2013 to December 2019. Patients with a solid tumor diagnosis at time of PICC insertion were selected (n = 3,956). Indications for PICC placement, catheter characteristics, and associated complications were compared by metastatic (n = 1,488) and non-metastatic (n = 2,468) disease. Complications were also compared by cancer type. Major complications were defined as central line associated blood stream infection (CLABSI), catheter occlusion, deep vein thrombosis (DVT), and pulmonary embolism (PE). Paired t-test and Pearson Chi-square test were used for analyses. **Results:** PICCs were most commonly placed for antibiotics (n = 1232, 31%) and chemotherapy (n = 907, 23%). The majority of catheters were multi-lumen with 61% (n = 2362) double lumen and 8% (n = 326) triple lumen. Median dwell time was 13 days. Notably, 17% of patients had another central venous catheter (CVC) at time of placement. Metastatic patients were more likely to have a PICC placed for difficult venous access (24.7% vs 17.7%, $p < 0.001$) and total parenteral nutrition (20.2% vs 12.3%, $p < 0.001$) as well as to have a current CVC in place (22% vs 14%, $p < .001$). Non-metastatic patients were more likely to have a PICC placed for chemotherapy (24.1% vs 20.9%, p = 0.02) and have a longer median dwell time (13.0d vs 11.0d, p = 0.04). Of all solid tumor patients, 15.5% (n = 612) experienced a major complication. Catheter occlusion occurred most frequently (n = 402, 10.2%) followed by DVT (n = 138, 3.5%), CLABSI (n = 107, 2.7%), and PE (n = 22, 0.6%). Catheter occlusion was more likely to occur in non-metastatic patients (11% vs 8.8%, p = 0.03). Rates of CLABSI, DVT, and PE did not differ significantly by presence of metastases. Certain cancers had a higher frequency of major complications when compared to the average solid tumor cohort rate of 15.5%; these were malignant brain (17.2%), pancreatic (18.4%), uterine (18.5%), and ovarian tumors (24.2%). **Conclusions:** PICCs are associated with significant complications in 16% of patients with solid organ cancers. Alternate access such as an implanted port should be considered; alternatively, limiting PICC placement in the presence of concurrent CVC or minimizing use of multiple lumen PICCs may limit complications and resultant morbidity. Specifically, these considerations may apply preferentially to patients with certain solid organ cancers with higher rates of PICC associated morbidity. Research Sponsor: Blue Cross/Blue Shield of Michigan and Blue Care Network.

A new option in pain prevention with bliss, a therapeutic virtual reality solution in bone marrow biopsy context: Results of a French open-label multicenter randomized phase II/III study (REVEH Trial). *First Author: Katell LE DU, Centre Jean Bernard-Clinique Victor Hugo, Institut Inter-Régional De Cancérologie, Le Mans, France*

Background: The prevention of care-induced pain is a central concern for all healthcare teams in hematology units. Use of MEOPA (Oxygen + Nitrous Oxide) is today a standard of care for relaxation procedure. Distraction through immersion in virtual reality (VR) has already documented its analgesic effects in several phase II trials but comparison with standard treatments in a large randomized study is needed. **Methods:** We conducted an open-label multicenter randomized phase III trial (ClinicalTrials.gov identifier: NCT03483194). We assessed the safety and efficacy of a new therapeutic virtual reality solution for pain distraction, Bliss, in prevention of pain and anxiety before performing a bone marrow biopsy. Bliss is a VR software with four imaginary interactive environments in three dimensions with binaural sound (head-mounted display). Efficacy was evaluated by pain intensity with visual analog scale (score from 0 to 10) just after the biopsy and anxiety by 2 questionnaires (fear of pain before the biopsy and revised STAI questionnaire before and after the biopsy). The primary end point was patient-assessed pain intensity after the bone marrow procedure. **Results:** A total of 126 patients were enrolled with previously untreated malignant hemopathy between September 6, 2018 and May 18, 2020. They were randomly assigned in a 1:1 ratio to receive pain prevention with MEOPA (n=63) or Bliss (n=63) before and during their bone marrow biopsy. All patients received a local anesthesia with lidocaïne before the biopsy. Median age of the study population was 65.5 years old (range 18 to 87) and 54,2% were men. The average pain intensity was 3.5 (standard deviation 2.6) for the MEOPA group and 3.0 (SD 2.4) for the VR group (p=0,26) without any significant difference according to age, gender or hemopathy. Concerning anxiety, 67.5% of patients were afraid before the biopsy and anxiety scores were moderate to very high in 26.3% of patients before the biopsy (STAI questionnaire) and 9.0% after the biopsy for all patients (17.3% of reduction in anxiety for the MEOPA group and 17.2% for the VR group, p=0.83). Immersion in VR was well tolerated in 100% of patients included in the VR group. Physicans were very satisfied by the relaxation procedure in 64.9% of cases (52.5% in the MEOPA group and 77.6% in the VR group, p=0.01) and recommended re-use of the technique in 54.2% in the MEOPA group and 79,1% in the VR group (p=0.02). **Conclusion:** The intensity of pain did not significantly differ in both arms. Bliss-based relaxation method was well tolerated and the satisfaction of patients and physicians was very high in VR group. This study validates the use of immersion in VR with Bliss as a new digital therapeutics and support the integration of the software in the panel of supportive care. Key words: virtual reality, bone marrow biopsy, pain. Clinical trial information: 03483194. Research Sponsor: Roche, Other Foundation, Elsan group.

Ovarian function suppression in premenopausal patients with concurrent endocrine therapy use. *First Author: Nicole Margo Grogan, University of Michigan Rogel Cancer Center, Ann Arbor, MI*

Background: The addition of ovarian function suppression (OFS) to endocrine therapy (ET) for premenopausal women with high risk, hormone receptor-positive breast cancer improves disease outcomes. However, in the SOFT-EST study, up to 17% of patients receiving gonadotropin-releasing hormone agonists (GnRHa) did not have appropriate ovarian suppression within the first year of treatment. Few studies have explored the long-term effectiveness of OFS to maintain estrogen suppression. Guidelines for estradiol monitoring during OFS therapy are not clearly defined. **Methods:** We performed a retrospective, single institution review of all patients who received concurrent GnRHa injections and ET since 2010. Only estradiol concentrations that were assessed during OFS treatment were abstracted from the medical record and included in the analysis. The primary endpoint was the percentage of patients with a non-suppressed estradiol concentration (defined as standard estradiol or high-sensitivity estradiol $\geq$ 10 pg/ml) identified during OFS cycle 2 ($>$ 35 days after OFS initiation) and/or later cycles. The secondary endpoint, which included only those patients with estradiol assessment within 35 days of OFS initiation, was the percentage of patients with a non-suppressed estradiol level when measured within the first 35 days after OFS initiation. For both cohorts, differences in age, body mass index (BMI), and previous chemotherapy use were summarized via multivariable logistic regression. **Results:** 148 patients received concurrent OFS and ET. Patients were excluded because of lack of estradiol assessment during OFS therapy (n = 13) and non-compliance with GnRHa injections (n = 4). The average age and BMI were 43.1 years and 29.1 kg/m^2, respectively. 35 of 131 patients (26.7%) had at least one non-suppressed estradiol level during OFS cycle 2 and/or later cycles. The median time to detection of non-suppression was 250 days (range: 53 – 2573 days). Patients whose estradiol concentration remained suppressed throughout treatment with OFS and ET were more likely to be older (OR 1.12 [95% CI 1.05-1.22], p = .02), have a lower BMI (OR 0.88 [95% CI 0.82-0.94], $p < .001$), and have received chemotherapy (OR 6.30 [95% CI 2.06-20.8], p = .002). For the secondary endpoint, 20 of 83 patients (24.1%) had a non-suppressed estradiol level within 35 days of OFS initiation. Lower BMI was associated with achieving ovarian suppression by 35 days (OR 0.85 [95% CI 0.77-0.93], $p < .001$); no association was noted for age or chemotherapy. **Conclusions:** More than one-fourth of patients in this "real world" population had at least one non-suppressed estradiol level during treatment, both the month after the initial OFS dose and at later time points. Patients on OFS, especially those on aromatase inhibitor therapy and those at increased risk of non-suppression, may require frequent and long-term estradiol monitoring during treatment. Prevalence of discordant QTc values among cancer patients by the Bazett, Fridericia, and Framingham formulae: Evidence for a standardized approach. *First Author: P. Christopher Parish, UNC Eshelman School of Pharmacy, Chapel Hill, NC*

Background: Many chemotherapies have the potential to prolong the QT interval, requiring monitoring of the corrected QT (QTc) to prevent life-threatening arrhythmias. Most clinical guidelines recommend adjusting/holding chemotherapy with Grade 3 or higher toxicity by CTCAE (QTc$\geq$500). Several formulae are used for QTc monitoring including Bazett, Fridericia, and Framingham. The most commonly used formula, Bazett, is well-documented to result in inappropriately high QTc values although the potential impact of this overcorrection on cancer treatment is unknown. We aimed to describe the prevalence of QTc prolongation among cancer patients and the effects on CTCAE adverse event grading by various QTc formulae to determine the potential impact on clinical management. **Methods:** We performed a single-center retrospective analysis of QT values from electrocardiograms (ECGs) collected January 2010-April 2020 and evaluated associations between QTc values, medications, and patient characteristics. QTc prolonging agents were determined by FDA package insert and cross-referenced with CredibleMeds.org. **Results:** 20,017 ECGs were evaluated. 18.6% (3,730) met ACC/ACCF/HRS criteria for prolonged QTc by $\geq$1 QT correction formula (either Bazett, Fridericia, or Framingham). 7.5% (1,494) were prolonged with all three formulae, and 8.6% (1,635) were prolonged only with Bazett. The CTCAE classification using the Bazett formula differed from both Fridericia and Framingham in 37.9% (7,583) of the ECGs. In contrast, Fridericia and Framingham formulae resulted in the same CTCAE classification in 94.5% (18,912). Of 1,789 ECGs classified as Grade 3 toxicity by Bazett, 72.0% (1,288, 6.4% of all ECGs) were classified as Grade 2 or less by both Fridericia and Framingham. 12.0% (2,340) of all ECGs were taken from patients (n = 421) on 24 different QT-prolonging chemotherapies. In 38.8% (909) of the ECGs, the CTCAE classification using the Bazett formula differed from both Fridericia and Framingham while use of Fridericia and Framingham formulae resulted in the same classification in 93.0% (2,176) of the ECGs. Of 293 ECGs classified as Grade 3 toxicity by Bazett, 65.2% (191) were classified as Grade 2 or less by both Fridericia and Framingham. **Conclusions:** To our knowledge, this is the largest analysis of discrepancies between different QTc formulae in patients receiving chemotherapy. These findings demonstrate an unacceptably high rate of discordance between formulae. Discordant data can lead to inconsistent clinical management and adverse event grading underscoring the urgent need to standardize QTc monitoring and reporting. These findings support the discontinuation of the routine use of the Bazett correction formula among cancer patients as CTCAE Grade 3 reporting from the Bazett formula is unreliable in over 65% of cases. Research Sponsor: None.

A review of evidence supporting NCCN category 2B off-label recommendations for determination of Medicare reimbursement eligibility. *First Author: Molly Erin DiScala, Tempus Labs, Inc, Chicago, IL*

Background: Antineoplastic indications supported by a category 1 or 2A NCCN recommendation are reimbursed by insurance and Medicare, as are FDA-approved indications. While initial reimbursement requests for "off-label" NCCN category 2B indications may be denied, Medicare will reimburse off-label antineoplastic use supported by evidence from a peer-reviewed publication from one of 26 designated journals. Here, we evaluated the published clinical evidence supporting NCCN category 2B indications. **Methods:** Category 2B drug indications for the 10 most common solid tumor types were identified in the NCCN compendium (n=104). The results were then filtered to include drugs with only category 2B indications in a particular tumor type (n=14). Similarly, FDA-approved indications were excluded, resulting in a list of drugs with only a 2B indication that are not FDA approved in the specified cancer type (n=8). Published clinical studies supporting these category 2B indications were assessed for study type and journal name in PubMed, and journal names were cross-referenced with the CMS-supported list. **Results:** Among the 8 non-FDA-approved drug indications with only category 2B recommendations, 7 (87%) had at least one publication of a clinical trial in one of the 26 designated journals. The only 2B indication without supporting literature was single-agent gemcitabine hydrochloride in bladder cancer. For further details, see Table. **Conclusions:** These results suggest that clinicians should consider pursuing the appeals process and provide supporting evidence in cases of claim denial. While coverage is not guaranteed, the evidence supporting 2B indications frequently meets the criteria identified in the Medicare statute. Further studies will evaluate if these findings extrapolate to less common tumor types. Research Sponsor: None.

Comprehensive or specialty-specific cancer care in the United States: A story of continuing underperformance. *First Author: Christopher Thomas Aquina, Division of Surgical Oncology, Department of Surgery, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: "Textbook oncologic outcome" (TOO) is a composite measure representing the "ideal" outcome for patients undergoing cancer surgery and is associated with improved survival. Using TOO as the primary outcome, we asked whether hospitals are high-performing across multiple cancer types. **Methods:** Patients undergoing potentially curative breast, colon, rectal, lung, or pancreatic cancer resection were identified within the National Cancer Database (2010-2016). Organ-specific TOO was defined as: adequate lymph node yield, R0 resection, non-length of stay outlier, no hospital readmission, no 90-day postoperative mortality, and receipt of guideline-concordant chemotherapy and/or radiation. Mixed-effects analyses estimated the risk-adjusted TOO rate for each hospital stratified by cancer type. **Results:** Among 1,094,550 cancer resections (breast = 690,442; colon = 213,918; lung = 121,771; rectum = 40,315; pancreas = 28,104), 434 hospitals performed $\geq$10 resections for each cancer type. Only 11 hospitals (2.5%) ranked in the top quartile for adjusted TOO rate for all five cancer types. Of the 323 hospitals (74.4%) that ranked in the top quartile for one cancer type, 149 hospitals (46.1%) also ranked in the bottom quartile for another cancer type. There was a weak correlation between hospital rankings across cancer types with the strongest correlations between colon and rectal cancer (R^2= 0.148) and lung and pancreatic cancer (R^2= 0.098). **Conclusions:** Most U.S. hospitals do not provide high-quality care across cancer types with respect to TOO. Perhaps this knowledge should be used to guide referral for oncology care. Research Sponsor: None.

Associations between patient knowledge of others' experiences and treatment choice in men with localized prostate cancer. *First Author: Aaron J. Katz, University of Kansas Medical Center, Kansas City, KS*

Background: Men with localized prostate cancer must select from multiple treatment options, without one clear best choice. Consequently, personal factors, such as knowing other prostate cancer patients who have undergone treatment, may influence patient decision-making. However, associations between knowledge about others' experiences and treatment decision-making among localized prostate cancer patients has not been well characterized. We used data from a population-based cohort of localized prostate cancer patients to examine whether patient-reported knowledge of others' experiences is associated with treatment choice. **Methods:** The North Carolina Prostate Cancer Comparative Effectiveness & Survivorship Study (NC ProCESS) is a population-based cohort of localized prostate cancer patients enrolled from 2011-2013 throughout the state of North Carolina in collaboration with the North Carolina Central Cancer Registry. All patients were enrolled prior to treatment and followed prospectively. Patient decision-making factors including knowledge of others' experiences with prostate cancer treatment options were collected through patient report. Patient treatment choice was determined through medical record abstraction and cancer registry data. **Results:** Among 1,202 patients, 17% reported knowing someone who pursued active surveillance (AS) while 28%, 46%, and 59% reported knowing someone who received brachytherapy, external beam radiation (EBRT), or radical prostatectomy (RP), respectively; 26% underwent AS, 9% brachytherapy, 21% EBRT, and 39% RP as their initial treatment. In unadjusted analyses, patients with knowledge of others' experiences with brachytherapy, EBRT or RP had more than twice the odds of receiving that treatment compared to patients who did not. Knowledge of others' experience with AS was not associated with choice to undergo AS. Multivariable analysis adjusting for age, race, risk group, and patient-reported goals of care showed knowledge of others' experiences with brachytherapy (OR 4.60, 95% confidence interval [CI] 2.76 to 7.68), EBRT (OR 2.38, 95% CI 1.69 to 3.34), or RP (OR 4.02, 95% CI 2.84 to 5.70) was significantly associated with odds of receiving that treatment. The odds of receiving a particular treatment option were further increased among patients who reported knowing someone who had a "good" experience with the treatment in question. **Conclusions:** This is the first population-based study to directly demonstrate the impact of a patient's knowledge of others' experiences on treatment choice in prostate cancer. These data provide a new consideration to clinicians in their counseling of patients with newly diagnosed prostate cancer, and also impacts research into the informed decision-making process for this disease. Knowledge about risks, benefits, and curative potential of immunotherapy among patients with advanced lung cancer or melanoma. *First Author: Laura A Petrillo, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Immunotherapy is a novel treatment paradigm that has improved survival for patients with advanced melanoma and lung cancer and poses new risks of immune-related adverse events, which are important for patients to recognize promptly. We aimed to describe patients' knowledge about the risks and benefits of immunotherapy, and their understanding of the goal of treatment with immunotherapy. **Methods:** We conducted a cross-sectional study of patients at a single institution who had initiated therapy with an immune checkpoint inhibitor for advanced melanoma, small cell lung cancer, or non-small cell lung cancer in the past 12 weeks. We assessed patients' knowledge about immunotherapy with a 9-item knowledge questionnaire (score range 0-100; higher score represents greater knowledge). We used the Perception of Treatment and Prognosis Questionnaire to assess patients' understanding of the goal of their treatment. We used the two-sample t-test to compare knowledge scores and chi-square test to compare goals of therapy between patients with melanoma and lung cancer. **Results:** A total of 105 patients (57 with melanoma, 48 with lung cancer) completed the study questionnaire. Participants had a median age of 69 years (range 36-89), and 33% (35/105) were female. Participants' mean knowledge score was 69.0 (SD = 23.3). Overall, 91% (96/105) of patients endorsed that immunotherapy works by turning on the body's immune system to recognize and attack cancer cells and 33% (35/105) correctly identified that immunotherapy does not kill all rapidly dividing cells. With respect to immunotherapy side effects, 68% (71/105) of patients reported that immunotherapy side effects can affect any organ in the body and 65% (68/105) endorsed that side effects from immunotherapy can occur at any time, even after the treatment ends. Overall, 34% (36/105) of participants reported that the primary goal of their treatment is to cure their cancer. Participants with melanoma had higher mean knowledge scores compared to those with lung cancer (74.7 vs. 62.3, P = 0.003). Participants with melanoma were also more likely to report that the goal of their immunotherapy was to cure compared to those with lung cancer (58% [33/57] vs. 6% [3/48], P $<$ 0.001) and that their oncologist had said that immunotherapy would cure their cancer (19% [11/57] vs. 0% [0/48], p = 0.005). **Conclusions:** We observed substantial knowledge deficits about immunotherapy and perceptions that immunotherapy is a cure for advanced cancer, particularly among patients with melanoma. These findings underscore the need for interventions to enhance patients' knowledge about immunotherapy and to help them understand the goal of immunotherapy for patients with advanced cancer. Provision of subspecialized expert oncology (SEO) opinions using Navya Cancer Data Model (NCDM), a technology-based platform: Prospective study to facilitate access to care. *First Author: Tiffany A. Traina, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Outcomes for patients (pts) with cancer may vary widely based on accessibility and quality of care. Subspecialized expert care is associated with improved outcomes yet access to this scarce resource is limited. Providing SEO opinions in legacy ways is time-consuming and difficult to scale. We hypothesized that summarizing comprehensive pt records could enhance efficiency of a remote opinion process. In this prospective pilot, oncologists (MDs) at Memorial Sloan Kettering (MSK) tested the NCDM, a clinically-validated, semi-automated system which abstracts pertinent data elements from medical records into a structured summary to support SEO decision making for remote opinions. **Methods:** From July to December 2020, 12 MSK MDs provided remote opinions to consecutive pts from an international second opinion service who were specifically seeking MSK expertise. NCDM summaries, with relevant DICOM imaging, were provided to MDs via web and mobile app. MDs answered a brief survey about their experience after each opinion. Time spent to read and respond to an NCDM summary was tracked electronically. Pt feedback was collected by prospective phone follow up. **Results:** N = 101 remote opinions. Cancer type (N): breast (24), gastrointestinal (15), heme malignancy (14), prostate (12), renal (8), gynecologic (7), head & neck (11), lung (9) and skin (1). 92% MD response rate. Pt characteristics: median age (60 years, range 17-83); stage of disease (early stage 41%, advanced 59%); 86% of pts had received prior treatment. MDs survey responses: median time to complete record review and render opinion = 4.8 min (IQR 2.7 – 7.9 min); NCDM provided adequate information needed to make a decision in this case = 95.7% (89/93); Decision making was easy in this case with data presented in the NCDM format = 96.8% (90/93). Pt survey responses (71/88): 92% shared recommendation with local MD; 87% received the recommended treatment; 99% stated they would recommend a NCDM enabled remote opinion service to others. **Conclusions:** NCDM summaries enabled subspecialized MSK cancer experts to provide oncology remote opinions with ease. Patients reported high satisfaction with the experience. Technology assisted abstraction and case summary can facilitate access to subspecialized expert opinions at a global scale. Impact of cancer on the risk of unplanned 30-day readmissions. *First Author: Alexander S. Qian, Department of Radiation Medicine and Applied Sciences, University of California San Diego, La Jolla, CA*

Background: Hospital readmission are associated with unfavorable patient outcomes and increased costs to the healthcare system. Devising interventions to reduce risks of readmission requires understanding patients at highest risk. Cancer patients represent a unique population with distinct risk factors. The purpose of this study was to define the impact of a cancer diagnosis on the risks of unplanned 30-day readmissions. **Methods:** We identified non-procedural hospital admissions between January through November 2017 from the National Readmission Database (NRD). We included patients with and without a cancer diagnosis who were admitted for non-procedural causes. We evaluated the impact of cancer on the risk of 30-day unplanned readmissions using multivariable mixed-effects logistic regression models. **Results:** Out of 18,996,625 weighted admissions, 1,685,099 (8.9%) had record of a cancer diagnosis. A cancer diagnosis was associated with an increased risk of readmission compared to non-cancer patients (23.5% vs. 13.6%, $p < 0.001$). However, among readmissions, cancer patients were less likely to have a preventable readmission (6.5% vs. 12.1%, $p < 0.001$). When considering the 10 most common causes of initial hospitalization, cancer was associated with an increased risk of readmission for each of these 10 causes (OR range 1.1-2.7, all $p < 0.05$) compared to non-cancer patients admitted for the same causes. Compared to patients aged 45-64, a younger age was associated with increased risk for cancer patients (OR 1.29, 95%CI [1.24-1.34]) but decreased risk for non-cancer patients (OR 0.65, 95%CI [0.64-0.66]). Among cancer patients, cancer site was the most robust individual predictor for readmission with liver (OR 1.47, 95%CI [1.39-1.55]), pancreas (OR 1.36, 95%CI [1.29-1.44]), and non-Hodgkin's lymphoma (OR 1.35, 95%CI [1.29-1.42]) having the highest risk compared to the reference group of prostate cancer patients. **Conclusions:** Cancer patients have a higher risk of 30-day readmission, with increased risks among younger cancer patients, and with individual risks varying by cancer type. Future risk stratification approaches should consider cancer patients as an independent group with unique risks of readmission. Research Sponsor: U.S. National Institutes of Health.

Bone modifying agents in veterans with castration-resistant prostate cancer. *First Author: Jordan Bauman, University of Michigan, Ann Arbor, MI*

Background: Skeletal related events (SREs) are a known complication for the 80% of men with metastatic prostate cancer who have bone metastases. Previous studies have demonstrated that bone modifying agents (BMAs) such as zoledronic acid and denosumab reduce SREs in men with metastatic castration-resistant prostate cancer who have bone metastases and are now recommended by national guidelines. We sought to investigate factors associated with use of BMAs in Veterans with CRPC across the Veterans Health Administration (VA). **Methods:** Using the VA Corporate Data Warehouse, consisting of aggregated medical record data from 130 facilities, we used an algorithm previously published to identify men with a diagnosis of castration-resistant prostate cancer (CRPC) based on rising prostate specific antigen (PSA) levels while on androgen deprivation therapy and who received systemic treatment for CRPC with one of the commonly used therapies: abiraterone, enzalutamide, docetaxel, ketoconazole between 2010 and 2017. To account for clustering among facilities, we used a multilevel multivariable logistic regression to determine the association of patient and disease-specific variables on the odds of a patient receiving a BMA after they started treatment for CRPC. **Results:** Of 4,998 patients with CRPC in our cohort, 2223 (44%) received either zoledronic acid or denosumab at some point after they were initiated on treatment for CRPC. After adjusting for other variables and accounting for a facility, the odds of receiving a BMA decreased by 3% for every additional year of age (odds ratio [OR] 0.97, 95% confidence interval [CI] 0.96-0.98), and decreased significantly with increasing comorbid conditions (OR 0.94, 95% CI 0.72-0.98 for Charlson Comorbidity Index [CCI] of 1; OR 0.69, 95% CI 0.59-0.81 for CCI 2+). Patients who were Black had 25% lower odds of receiving a BMA than patients who were White (OR 0.75, 95% CI 0.65-0.87). PSA at time of CRPC treatment start had a small but not significant effect on receipt of a BMA (OR 1.04, 95% CI 1.00-1.08) for every unit increase of PSA on the log scale. PSA doubling time was not associated with receipt of a BMA. The presence of a diagnosis code for bone metastases was far lower than expected in this cohort of patients with CRPC (40.7%), and thus was not included in the model. We did not expect the presence of bone metastases to vary significantly among the other independent variables. **Conclusions:** Despite most patients with CRPC historically having bone metastases, less than half of patients with CRPC received a BMA. Patients who are older, had more comorbidities, or were Black were less likely to receive a BMA after starting treatment for CRPC. Understanding factors that lead to different patterns of treatment can guide initiatives toward more guideline-concordant care. Research Sponsor: Megan Caram was funded by a Prostate Cancer Foundation Young Investigator Award.

Identifying gaps in the coverage of survivorship care services. *First Author: Anne Hudson Blaes, University of Minnesota, Minneapolis, MN*

Background: Despite advancements in reimbursement, anecdotal evidence suggests patients are not able to access guideline concordant survivorship care services due to a lack of coverage by payers. We present the results of a mixed methods study aimed to determine the practice-reported rates and sources of delay/denial on evidence-based, guideline concordant survivorship care services. **Methods:** A quantitative survey was developed by ASCO's Cancer Survivorship Committee (CSC) to assess which services are being denied by payers for coverage/reimbursement. Questions were limited to disease sites for which practice guidelines exist. 533 ASCO members who provide survivorship care were surveyed, with a focus on obtaining representation from rural/urban, academic/private practice, pediatric/adult, and geographic location across the U.S. Semi-structured telephone interviews were conducted in October and November 2020 with geographic sub sample representation to further explore the nature of and extent to which coverage barriers are experienced for guideline-concordant care, specific to the provider or clinic's primary disease site or specialty. **Results:** 120 responses from 50 states were included. Respondents were primarily clinicians (88%) with the majority treating patients with Medicare/Medicaid/CHIP (60%), followed by private/employer insurance (38%). There was little issue with coverage of hormone therapies. One-third reported issues some of the time with maintenance chemotherapy (38%) and immunotherapy (35%). Coverage denials for screening for recurrence for breast cancer (MRI, 63.5%), Hodgkin Lymphoma (PET/CT 47%; Breast MRI, 44.4%), and lung cancer (Low-dose CT 37.4%) were common. Half of the survey respondents reported denials for supportive care/symptom management services (Table). Private or employer-based insurance denials were most often the source of barriers (57.7%). Through interviews, denials were found to be the same across sites and not unique to a single payer or region. Most had a process to appeal denials for evidence-based services. **Conclusions:** Denial for survivorship care, particularly supportive care services, is common. There is a need for better advocacy with payers, improved policy, and support for providers/practices to implement protocols to obtain coverage for services, particularly in the face of burnout. Research Sponsor: ASCO.

Clinical trial representativeness and treatment intensity in a real-world sample of women with early-stage breast cancer. *First Author: Nicole E. Caston, University of Alabama at Birmingham, Birmingham, AL*

Background: Early stage breast cancer (EBC) treatment is used in women of all ages, races, and health states. However, as clinical trials often do not represent real-world populations, the extent to which evidence-based treatments are prescribed to populations not well represented in these trials is not known. This study evaluated treatment intensity for patients traditionally well represented, underrepresented, and unrepresented in clinical trials. **Methods:** This retrospective cohort study used the nationwide de-identified electronic health record derived Flatiron Health database for patients diagnosed with EBC between 2011-2020. We categorized treatments as either high- (AC-TH [doxorubicin, cyclophosphamide followed by paclitaxel or docetaxel, trastuzumab]; ACT [paclitaxel or docetaxel, doxorubicin, cyclophosphamide]; TCH [paclitaxel or docetaxel, carboplatin, trastuzumab]; TCHP [paclitaxel or docetaxel, carboplatin, trastuzumab, pertuzumab]) or low-intensity (AC [doxorubicin, cyclophosphamide]; TC [paclitaxel or docetaxel, cyclophosphamide]; TH [paclitaxel or docetaxel, trastuzumab]). Unrepresented patients often have one or more comorbidities and/or prior cancer; underrepresented patients are typically Black, Indigenous, people of color, or of age extremes ($<$ 45, 70+); well represented patients are White and between the ages of 45-69. Odds ratios (OR), predicted proportions, and 95% confidence intervals (CI) from a two-level (patients nested in practice) hierarchical logistic regression model evaluated associations between receipt of high-intensity chemotherapy and patient characteristics of clinical trial representation (age, race/ethnicity, presence of comorbidity). **Results:** Our study included 970 patients with EBC with 13%, 45%, and 41% characterized as unrepresented, underrepresented, and well represented in clinical trials, respectively. In the adjusted model, those aged $\geq$ 70 vs 45-69 had lower odds of receiving a high-intensity treatment (OR 0.40, 95% CI 0.26-0.60), while those aged $<$ 45 vs 45-69 had higher odds of receiving high-intensity treatment (OR 1.82, 95% CI 1.10-3.01). The predicted proportion of patients receiving a high-intensity treatment was 87% (95% CI: 80%-92%) for patients aged $<$ 45, 79% (95% CI: 74%-84%) for patients aged 45-69, and 60% (95% CI: 50%-70%) for patients aged $\geq$ 70. Neither race/ethnicity nor comorbidity status were associated with odds of receiving high-intensity chemotherapy. **Conclusions:** Over half of the EBC population is not well represented in clinical trials. Age was associated with differential treatment intensity, despite a lack of evidence that these differences are appropriate. Widening clinical trial eligibility criteria is one way to better understand survival outcomes, identify potential toxicities, and ultimately make evidence-based treatment decisions using a more diverse sample. Patterns and predictors of rehabilitation therapy among older patients with advanced cancer admitted to nursing homes: A SEER-Medicare analysis. *First Author: Huiwen Xu, University of Rochester Medical Center, Rochester, NY*

Background: Functional impairments affect $>$ 40% of hospitalized patients (pts) with advanced cancer. After hospital discharge, about 20% of pts received rehabilitation (rehab) in nursing homes (NHs) to maintain functional independence. There is evidence from broad pt cohorts that Medicare Prospective Payment (PP) financially incentivizes NHs to provide extra rehab. This study examines rehab utilization among pts with advanced cancer admitted to NHs. **Methods:** The 2011-2016 SEER-Medicare data were linked with NH Minimum Data Set 3.0 data, which includes sociodemographic and clinical characteristics at admission. Study cohort included traditional Medicare pts with stage IV breast, lung, and colorectal cancer who were admitted to NHs after hospital discharge. Outcomes: total weekly rehab minutes of physical therapy, occupational therapy, and speech-language pathology; ultra-high rehab ($\geq$720 min/wk); and rehab within 10 minutes of threshold (720-730 min/wk). Function and cognition were assessed by Activities of Daily Living (ADL) [7 domains; total score ranges 0 to 28 (higher = dependent)] and Cognitive Function Scale (intact, mild, moderate, severe impairment). Charlson Comorbidity Index (CCI) and survival from NH admission were computed. Generalized linear mixed models examined predictors of rehab outcomes adjusting for NH random effects. **Results:** A total of 7,453 pts were included (mean age 78.0, 85.8% White, 74.1% lung/ 16.1% colorectal/ 9.7% breast cancer; 76.1% had surgery, 8.9% had chemotherapy; mean CCI 1.9). The mean ADL score was 18.0, with on average 4.7 impairments; 40.2% reported $\geq$ mild cognitive impairment. Pts received on average 498 (SD = 245) min/wk rehab, but the distribution was trimodal. The number of pts who received 720-730 min/wk rehab was 2.7 times of the secondary peak at 500-510. From 2011-2016, the proportion of pts receiving ultra-high therapy (19.5%-48.4%) and within-threshold rehab (11.0%-32.0%) more than doubled. Only 5.9% of pts were documented on admission as having a life expectancy $<$ 6 months, yet 32.1% and 74.3% died in 30 days and 6 months, respectively. Multivariable regressions indicate that compared to pts with $\geq$6 months' expectancy, those with $<$ 6 months' expectancy received less rehab (β = -117.6), especially ultra-high rehab (odds ratio = 0.31). Pts with cognitive impairments received less rehab. **Conclusions:** Rehab utilization in older NH pts with advanced cancer mirrors patterns found in broader cohorts. Under PP, rehab minutes provided strongly followed payment thresholds. Over 5 years, more pts were provided 720-730 min/wk rehab, and 1/3 of these pts were at the end of life. Poor prognostication might contribute to the use of ultra-high rehab. Future work should evaluate whether the new Patient Driven Payment Model avoids excessive rehab use in patients with limited life expectancies. Patient and treatment characteristics of emergency presentations due to immune-mediated toxicities. *First Author: Sharon Hyo-Eun Nahm, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: The prevalence of immune-mediated toxicities from immune checkpoint inhibitors (ICIs) is well described. However, the characteristics and treatment patterns for patients with emergency presentations due to immune-mediated toxicity are less well known. **Methods:** This study of all emergency presentations in patients treated with ICIs was performed at The Christie NHS Foundation Trust, Manchester, United Kingdom from May 2018-February 2020. The aims were to describe the patient and treatment characteristics of those diagnosed with an immune-mediated toxicity. **Results:** In total, 597 patients receiving ICIs had an emergency presentation and 191/597 (32%) were diagnosed with an immune-mediated toxicity. Of these patients, the median age was 64 years and 127/191 (67%) were male. The most common tumour types were melanoma (53%) and lung (22%) and the most common ICI received was ipilimumab + nivolumab combination immunotherapy (42%), followed by pembrolizumab monotherapy (21%) and nivolumab monotherapy (20%). The median number of cycles received was 3 (range 1-54), and 73/191 (38%) previously had $\geq$ grade 2 immune-mediated toxicity. The most common diagnoses were colitis (38%), hepatitis (15%), and pneumonitis (14%). The majority, 180/191 (94%) received steroids and 52/180 (29%) patients required second-line immunosuppression. The most common second-line immunosuppressants used were mycophenolate mofetil (58%) and infliximab (50%). Eleven patients (22%) required more than one second-line immunosuppressant. **Conclusions:** The majority of patients with emergency presentations due to immune-mediated toxicity were being treated with combination immunotherapy for melanoma. More than a third of patients had previous $\geq$ grade 2 immune-mediated toxicity. Over one quarter of patients treated with steroids required second-line immunosuppression. Identifying these characteristics can help inform which patients receiving ICIs seeking medical review need admission to a center with experience in managing immune-mediated toxicity. Research Sponsor: None.

Disparity in utilization of multiagent therapy for acute promyelocytic leukemia (APL): A large National Cancer Database (NCDB) analysis. *First Author: Prajwal Dhakal, University of Nebraska Medical Center, Dept of Internal Medicine, Omaha, NE*

Background: Clinical trials have demonstrated a high rate of cure in APL with the use of multiagent therapy; however, overall survival in real world practice is significantly lower than that in the trials (Blood 2020; 136 (s 1): 13-14). We performed a large NCDB analysis to determine the appropriateness of treatment as a possible explanation for worse survival outside of the clinical trials. **Methods:** We included a total of 7190 APL cases reported to NCDB between 2004-2015. Multiple logistic regression analysis was used to evaluate the effect of covariates on probability of multiagent therapy use. **Results:** Only 64% of total patients received multiagent therapy; 29% received singe agent therapy and 4% received unknown therapy. 3% (n = 207) did not receive any treatment for reasons including early death (n = 8), patient refusal (n = 15), perceived contraindication (n = 12) and unknown reasons (n = 182). Compared to patients $>$ 60 years, younger patients aged 0-18 years (hazard ratio [HR] 3.2, 95% confidence interval [CI] 1.8-5.5, $p < 0.001$), 19-40 years (HR 1.6, 95% CI 1.03-2.54, $p = 0.03$) and 41-60 years (HR 1.6, 95% CI 1.3-1.9, $p < 0.001$) were more likely to receive multiagent chemotherapy. Patients with Medicaid were more likely to receive multiagent therapy compared to those with private insurance (HR 1.2, 95% CI 1.01-1.42, $p = 0.04$), possibly because patients with Medicaid are younger. The likelihood of receiving multiagent therapy decreased in uninsured patients (HR 0.6, 95% CI 0.5-0.8, $p < 0.001$). Compared to academic cancer centers, patients treated at community cancer center (HR 0.5, 95% CI 0.3-0.7, $p = 0.001$), comprehensive community cancer center (HR 0.7, 95% CI 0.6-0.8, $p < 0.001$)) and integrated network cancer center (HR 0.8, 95% CI 0.6-0-0.9, $p = 0.01$) were less likely to be treated with multiagent therapy. Lower comorbidity index increased the likelihood of receiving multiagent therapy. The likelihood of receiving multiagent therapy was not influenced by sex, race, annual income, distance traveled to treatment facility and high school education. **Conclusions:** To our knowledge, this is the first large scale analysis of utilization of multiagent therapy in APL in real world practice. In our study, 3% of patients did not receive treatment, a much smaller proportion of patients compared to acute myeloid leukemia, where a quarter to a third of patients do not receive any chemotherapy (Blood Adv; 2018 (2): 1277–1282). However, 29% of APL patients received suboptimal treatment with single agent therapy. The use of single agent therapy was higher in older adults and those with greater comorbidity. About half of the patients were treated outside of academic centers, which was associated with a higher probability of receiving single agent therapy. Uninsured patients were more likely to receive single agent therapy. Our findings highlight disparity based on insurance and health system factors. Research Sponsor: None.

Activity of daily living of elderly patients with gastric cancer after surgery. *First Author: Ayako Okuyama, National Cancer Center, Center for Cancer Control and Information Services, Center for Cancer Registries, Chuo-Ku, Japan*

Background: Elderly patients are concerned with the physical burden of cancer treatments. This study aimed at investigating the reduction of the activity of daily living (ADL), length of hospital stay and readmission rate after surgery for gastric cancer. **Methods:** Insurance claim data linked with hospital-based cancer registries in Japan for gastric cancer patients diagnosed in 2015 from 431 hospitals was used. This data is expected to cover 49.0% of new cancer cases in Japan. To compare the effect of the treatment by age group, we analyzed the reduction of ADL between admission and discharge, length of hospital stay and readmission rate after endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR) for patients with cT1N0M0, and open surgery for patients with cM0. Patients who aged 40 years or older with independent ADL at admission for their first-course treatment was included. ADL was assessed using Barthel index (0-100 points). ADL decrease by 10 points or more was identified as ADL reduction. **Results:** Overall, 25,521 patients receiving ESD/EMR and 10,527 patients receiving open surgery were identified. ADL reduction after ESD or EMR under 80 years old was less than 1%, while over 80 years old ADL reduction was more than 2.5%. Length of hospital stay (11 days) and unexpected readmission rate (2 to 3 %) was almost similar. ADL reduction after open surgery under 75 years old was less than 3%. This reduction rates have increased with age, 11.5% for over 85 years old. Length of hospital stay also tended to increase by age (21 days for under 65 years old, 29 days for over 85 years old). Unexpected readmission rate for over or 80 years old (1.4%) was slightly higher under 80 years old (less than 1%). **Conclusions:** The effect of ADL reduction after ESD/EMR was not so significant for patients over 80 years old. While ADL reduction after open surgery tended to increase for aged 80 years and older. Providing these information to elderly patients and their families can be important in deciding treatment options. Research Sponsor: the Grants-in-Aid for Scientific Research (KAKENHI20EA1011) in Japan.

Assessment of vitamin D deficiency and COVID-19 diagnosis in patients with breast or prostate cancer using electronic medical records. *First Author: Aaron Galaznik, Acorn AI By Medidata, a Dassault Systèmes Company, New York, NY*

Background: While patients with cancer are known to be at increased risk of infection in part due to the immunocompromising nature of cancer treatments, recent data indicate a particularly high risk for COVID-19 infection and poor outcomes (Wang et al., 2020). A recent study (Meltzer et al., 2020) demonstrated Vitamin D deficiency may increase risk of COVID-19 infection, and a small randomized controlled trial in Spain reported significant improvement in mortality among hospitalized patients treated with calcifediol. Vitamin D deficiency has been reported in two leading causes of cancer deaths: breast and prostate. In this study, we performed a retrospective cohort analysis on nationally representative electronic medical records (EMR) to assess whether Vitamin D deficiency affects risk of COVID-19 among these patients. **Methods:** Patients with breast (female) or prostate (male) cancer were identified between 3/1/2018 and 3/1/2020 from EMR data provided pro-bono by the COVID-19 Research Database (covid19researchdatabase.org). Patients with an ICD-10 code for Vitamin D deficiency or $<$ 20ng/mL 20(OH)D laboratory result within 12 months prior to 3/1/2020 were classified as Vitamin D deficient. COVID-19 diagnosis was defined using ICD-10 codes and laboratory results for COVID-19 at any time after 3/1/2020. Logistic regressions, adjusting for baseline demographic and clinical characteristics, were conducted to estimate the effect of Vitamin D deficiency on COVID-19 incidence in each cancer cohort. **Results:** A total of 16,287 breast cancer and 14,919 prostate cancer patients were included in the study. The average age was 68.9 years in the breast cancer cohort and 73.6 years in the prostate cancer cohort. The breast cancer cohort consisted of 85% Whites, 13% Black or African Americans, and less than 5% of other races. A similar race distribution was observed in the prostate cancer cohort. Unadjusted analysis showed the risk of COVID-19 was higher among Vitamin D deficient patients compared to non-deficient patients in both cohorts (breast: OR = 1.60 [95% C.I.: 1.15, 2.20]; prostate: OR = 1.59 [95% C.I.: 1.08, 2.33]). Similar findings were observed when assessed in subgroups of patients with newly diagnosed cancer in the dataset, as well as after adjusting for baseline characteristics. **Conclusions:** Our study suggests breast and prostate cancer patients may have an elevated risk of COVID-19 infection if Vitamin D deficient. These results support findings by Meltzer et al., 2020 demonstrating a relationship between Vitamin D deficiency and COVID-19 infection. While a randomized clinical trial is warranted to confirm the role for Vitamin D supplementation in preventing COVID-19, our study underscores the importance of monitoring Vitamin D levels across and within cancer populations, particularly in the midst of the global COVID-19 pandemic. Timing of steroid use and outcomes of immune checkpoint inhibitor: A population based study. *First Author: Nikita Nikita, Thomas Jefferson University, Philadelphia, PA*

Background: Immune checkpoint inhibitors (ICIs) have rapidly become the treatment of choice for multiple cancer types. However, the relationship between the timing of immunosuppressive agents, such as steroids use, preceding ICI initiation and subsequent treatment outcomes remains unknown due to lack of data. This study was undertaken to address this knowledge gap. **Methods:** We used the Surveillance, Epidemiology and End Results (SEER)-Medicare linked data to identify patients with melanoma receiving Ipilimumab, Nivolumab, Pembrolizumab, or Ipilimumab/Nivolumab combination in 2010-2015. Last steroid exposure within 12 months prior to ICI use was categorized (none, 0-1, 1-3, and 3-12 months prior). Cox models were used to generate covariate-adjusted hazard ratios of overall mortality following ICI initiation. Because the hazards were not proportional over time, we allowed the hazard ratios to differ in three periods (<3, 3-6, and more than 6 months post ICIs). **Results:** We identified 3,149 melanoma patients (median age 68 years) using ICIs; among these 1,352 received steroid within 12 months prior. Steroid use within 1 month prior to using ICIs was associated with a 93% and 102% increased risk in overall mortality within 3 months and 3-6 months post ICI initiation. The risk diminished over time (Table). A similar pattern was observed for steroid use 1-3 months prior. Steroid use beyond 4 months prior to ICI was not associated with increased mortality. **Conclusions**: This was the first major study to document that timing of steroid use prior to ICI is associated with the risk of mortality and how the increased risk diminishes over time. Further studies are warranted to confirm the findings and understand potential mechanisms. Research Sponsor: None.

Timing of last steroid use prior to immune check inhibitors (ICIs) and relative risk of all-cause mortality after ICIs.

Timing of last steroid use prior to ICI	<3 months post ICI Hazard Ratios	3-6 months post ICI Hazard Ratios	>6 months post ICI Hazard Ratios
No steroid 12 month prior N= 1,797	Ref	Ref	Ref
Steroid use 0-1 month prior N= 593	1.93 (1.54-2.41)*	2.02 (1.16-2.60)*	1.16 (0.96-1.39)
Steroid use 1-3 month prior N= 305	1.72 (1.28-2.30)*	1.23 (0.84-1.81)	0.89 (0.69-1.15)

Phenotyping of clinical trial eligibility text from cancer studies into computable criteria in electronic health records. *First Author: Yun Mai, Sema4, Stamford, CT*

Background: Clinical trial phenotyping is the process of extracting clinical features and patient characteristics from eligibility criteria. Phenotyping is a crucial step that precedes automated cohort identification from patient electronic health records (EHRs) against trial criteria. We establish a clinical trial phenotyping pipeline to transform clinical trial eligibility criteria into computable criteria and enable high throughput cohort selection in EHRs. **Methods:** Formalized clinical trial criteria attributes were acquired from a natural-language processing (NLP)-assisted approach. We implemented a clinical trial phenotyping pipeline that included three components: First, a rule-based knowledge engineering component was introduced to annotate the trial attributes into a computable and customizable granularity from EHRs. The second component involved normalizing annotated attributes using standard terminologies and pre-defined reference tables. Third, a knowledge base of computable criteria attributes was built to match patients to clinical trials. We evaluated the pipeline performance by independent manual review. The inter-rater agreement of the annotation was measured on a random sample of the knowledge base. The accuracy of the pipeline was evaluated on a subset of randomly selected matched patients for a subset of randomly selected attributes. **Results:** Our pipeline phenotyped 2954 clinical trials from five cancer types including Non-Small Cell Lung Cancer, Small Cell Lung Cancer, Prostate Cancer, Breast Cancer, and Multiple Myeloma. We built a knowledge base of 256 computable attributes that included comorbidities, comorbidity-related treatment, previous lines of therapy, laboratory tests, and performance such as ECOG and Karnofsky score. Among 256 attributes, 132 attributes were encoded using standard terminologies and 124 attributes were normalized to customized concepts. The inter-rater agreement of the annotation measured by Cohen's Kappa coefficient was 0.83. We applied the knowledge base to our EHRs and efficiently identified 33258 potential subjects for cancer clinical trials. Our evaluation on the patient matching indicated the F1 score was 0.94. **Conclusions:** We established a clinical trial phenotyping pipeline and built a knowledge base of computable criteria attributes that enabled efficient screening of EHRs for patients meeting clinical trial eligibility criteria, providing an automated way to efficiently and accurately identify clinical trial cohorts. The application of this knowledge base to patient matching from EHR data across different institutes demonstrates its generalization capability. Taken together, this knowledge base will be particularly valuable in computer-assisted clinical trial subject selection and clinical trial protocol design in cancer studies based on real-world evidence. Efficacy and cost-effectiveness of breast cancer (BC) screening in female survivors of childhood Hodgkin lymphoma (HL). *First Author: Florence Lennie Wong, City of Hope, Duarte, CA*

Background: Female childhood HL survivors treated with ≥10 Gy of chest radiation are at high risk of developing BC. The Children's Oncology Group (COG) guidelines recommend lifetime annual mammography (MAM) and breast Magnetic Resonance Imaging (MRI) starting 8y after chest radiation or age 25, whichever is later, and clinical breast examination (CBE) annually from puberty and semiannually from age 25. Initial model results suggest that CBE adds no survival benefit in this cohort. Digital breast tomosynthesis (DBT) is increasingly replacing digital MAM in clinical practice. Here, we present the efficacy and cost-effectiveness of COG's imaging-based screening recommendations. **Methods:** Life-years (LYs), quality-adjusted LYs (QALYs), BC mortality, and costs (2017 U.S.$) were estimated from simulating the lifetimes of 5-million chest-irradiated 25y old HL survivors who underwent BC screening with each of the following strategies: annual digital MAM, MRI, MAM+MRI, annual DBT or DBT+MRI from age 25 onward. Treatment-related BC risk (in-situ and invasive) and non-BC mortality were estimated from female 5y HL survivors in the Childhood Cancer Survivor Study and from U.S. population rates. Test sensitivity was 70-74% for MAM (based on prior HL studies) and 89% for DBT and MRI (based on women at high risk of *de novo* BC). Costs and quality of life weights were obtained from medical literature. **Results:** For HL survivors with no screening, lifetime BC risk was 42.7% and BC mortality was 18.1%. BC risk and non-BC mortality were, respectively, 7.4- and 5.2-fold higher at age 50 in HL survivors relative to the general population. Screening at ages 25-74 had similar LY gain and BC mortality reduction compared to lifetime screening; hence, we focused on screening for ages 25-74. For all strategies screening provided LY gain of 0.34-0.47 and reduced BC mortality by 6.7-9.8% compared with no screening; incremental cost-effectiveness ratio (ICER), or cost per QALY gained, for MAM alone was $58,726 and for DBT alone was $62,989. ICER of adding MRI to MAM ($385,285) or to DBT ($513,358) indicated lower cost-effectiveness of supplemental MRI (Table). **Conclusions:** Annual screening at ages 25-74y in chest-irradiated HL survivors appears beneficial. Using $100K per QALY gained as cost-effectiveness threshold, annual MAM or DBT are more cost-effective, whereas adding MRI to MAM is less cost-effective. Research Sponsor: American Cancer Society, U.S. National Institutes of Health.

Leveraging the electronic medical record (EMR) to predict patient reported financial hardship in cancer patients. *First Author: Sandeep Sai Voleti, Mayo Clinic Alix School of Medicine, Scottsdale, AZ*

Background: Patient reported financial hardship (FH) in cancer care is a growing challenge for patients, their caregivers and healthcare providers. As treatment costs escalate, it is imperative to develop effective strategies to proactively recognize and mitigate FH within oncology practice. Using automated processes to screen and refer patients to appropriate resources is a potential option. At Mayo Clinic, screening for FH involves using a single financial strain question ' How hard is it for you to pay for the very basics like food, housing, medical care, and heating?' completed by all cancer patients annually as part of the Social Determinants of Health (SDOH) assessment. In this study, we describe the prevalence and predictors for FH (denoted by the answer 'hard and very hard') in our patient population. **Methods:** Patients receiving cancer care at the three Mayo Clinic sites (Minnesota, Arizona, and Florida) who completed the FH screen at least once were included in this study. Demographics (age, gender, race/ ethnicity, insurance, employment status, marital status, and zip code) and disease state data for included patients was extracted from the EMR and Mayo Clinic Cancer Registry. Disease state was categorized by type of cancer (hematological or solid malignancy) and cancer stage. Zip code was used to derive median income, rural/urban residence and distance from the cancer center. Multivariable logistic regression models were utilized to examine factors associated with FH. **Results:** The final study cohort included 31,969 patients with median age 66 years (IQR 57,73), 51% females, and 76% married. Race/ethnicity composition was 93% White, 3% Black, and 4% Hispanic. 52% of patients had Medicare and 43% had commercial insurance. Other notable factors included 48% retired, 41% working/ students, 76% married, and 72% urban residents. Median time from cancer diagnosis was 1.1 year (IQR 0.1, 3.8) and median income was $64,406 (IQR 53,067, 82,038). 31% of patients had hematological malignancies, 20% of the cancers for which staging information was available were metastatic. FH was reported by 4% (n = 1194) of the patients. A significantly higher likelihood of endorsing FH ($p < 0.001$ for all) was noted in Hispanic (OR 1.64), Black (OR 1.84), American Indian/ Alaskan native (OR 2.02), below median income (OR 1.48), rural (OR 1.17), self-pay (OR 2.77), Medicaid (OR 2.29), Medicare (OR 1.43), unemployed/disabled (OR 2.39), single (OR 2.07), or divorced (OR 2.43) patients. Older age, being retired, and living farther from the cancer center were associated with significantly less likelihood of endorsing FH. **Conclusions:** Our study successfully leveraged the EMR to identify key sociodemographic groups more likely to report FH. An electronic trigger to flag such patients at high-risk of FH and proactively address FH is currently being developed. Research Sponsor: Mayo Clinic Internal Research Funding.

6595 **Poster Session**

Comparative study of prevalence and costs of depression and anxiety among elderly cancer patients. *First Author: Stacey DaCosta Byfield, OptumLabs, Minnetonka, MN*

Background: Depression and anxiety are common among cancer patients and can worsen outcomes. We studied the occurrence of depression and anxiety in three common cancers to investigate whether healthcare costs were greater for cancer patients with two mental health disorders (MHD), depression and anxiety, compared to patients without MHD. **Methods:** This retrospective analysis used deidentified medical and pharmacy claims from a large national U.S. health insurer. Patients were Medicare Advantage enrollees ≥65 years diagnosed with breast, colorectal, or prostate cancer and continuously enrolled from 1/2018–12/2019. We determined statistically whether the annual prevalence of the two MHDs varied by cancer types. Total costs and costs exclusive of MHD-related expenses in five sub-categories were compared: inpatient, emergency room, non-inpatient medical, professional, and pharmacy. Costs from 2019 claims were presented as per-patient per-month (PPPM). Direct depression- and anxiety-related costs were from claims with depression/anxiety diagnoses or drugs. The impact of MHDs on 2019 healthcare spending was examined using multiple linear regression, controlling for demographic and clinical characteristics. LASSO was used for variable selection. Mann-Whitney U tests compared differences in costs by service types between patients with and without MHDs. **Results:** Of 19,304 study patients, 8,916 (46%) had coexisting depression or anxiety: (i) 4% depression only; (ii) 27% anxiety only; (iii) 7% depression and anxiety; and (iv) 8% were on antidepressant without MHDs diagnoses. There were significant differences in the rates of MHDs between the three cancer groups, with the highest frequency in breast cancer (*breast vs colorectal*. 56% vs 49%, $p < 0.0005$; *breast vs prostate*. 56% vs 38%, $p < 0.0005$; *colorectal vs prostate*. 49% vs 38%, $p < 0.0005$). After excluding the MHDs-related costs (PPPM mean = $44), the monthly spending was 54% higher for patients with MHDs ($2,184 MHDs vs. $1,406 non-MHDs). After adjusting for covariates, the PPPM costs were 23%–58% higher for the MHD-cohort vs. the non-MHD cohort for each cancer type (*non-MHD vs. with depression only*, CI 13%–34%, $p < 0.0001$; *non-MHD vs. with anxiety only*, CI 40%-52%, $p < 0.0001$; *non-MHD vs. with depression and anxiety*, CI 48%-70%, $p < 0.0001$; *non-MHD vs. with antidepressant only*, CI 28%-45%, $p < 0.0001$). **Conclusions:** We found high prevalence of MHDs in patients diagnosed with cancer. Analyses showed that total spending was significantly higher in individuals with cancer and MHD for all cost categories. Explanations for higher costs are unclear, as costs remain high even after adjusting for MHD-related care costs. Research on specific healthcare services driving higher costs and the risk factors for depression and anxiety is needed to address broader MHDs to improve cancer care. Research Sponsor: None.

Improving patient and caregiver understanding of risks and benefits of immunotherapy for melanoma or lung cancer. *First Author: Laura A Petrillo, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Immune checkpoint inhibitors (ICI) extend survival for patients with advanced cancer, particularly melanoma and lung cancer, though responses are heterogeneous and treatment may be complicated by immune-related adverse events that are important for patients and their caregivers to recognize. The aim of this trial is to evaluate the feasibility and preliminary efficacy of an educational video and question prompt list (QPL) in improving patients' and caregivers' understanding of what to expect from immunotherapy. **Methods:** In this randomized controlled trial of a novel educational intervention to improve immunotherapy knowledge, we will enroll 140 adult patients with advanced melanoma or lung cancer (small cell or non-small cell) who have a plan to initiate therapy with an ICI and their caregivers. Patients assigned to the intervention will receive a link to a video about the risks and benefits of ICI treatment developed by the study team as well as an ICI-focused QPL that includes questions about the goal and likelihood of benefit of ICIs. We will enroll the first ten patients in an open pilot and we will refine the intervention and study procedures based on pilot findings. We will randomize the remaining 130 patients to receive either the intervention or a usual care control. Randomization will be carried out using the permuted block approach with stratification by cancer type, and patient-caregiver dyads will be assigned to the same study arm. Participants on both arms will complete surveys at enrollment (baseline), 72 hours post-enrollment, and 6 weeks post-enrollment. The primary outcome of the study is feasibility of intervention delivery, defined as 70% of approached patients enrolling in the trial and 80% of enrolled patients watching the video, reviewing the QPL and completing the first assessment. We will also evaluate the preliminary efficacy of the intervention in 1) improving patient and caregiver knowledge, measured by a survey of knowledge questions that we developed and previously pilot tested with a sample of 105 patients; 2) enhancing patient-clinician communication, assessed by evaluating the number of questions patients asked in audio-recorded visits with their oncology clinicians after reviewing the QPL; and 3) reducing anxiety, measured by the State and Trait Anxiety Index. We will assess change in knowledge scores and anxiety from baseline to 72 hours post-enrollment and 6-weeks post-enrollment using the analysis of covariance model, adjusting for baseline scores and relevant covariates. The number of questions asked by patients and caregivers will be assessed by coding transcripts of oncology visits and comparing between arms using the negative binomial model. Study accrual to the open pilot phase began in February 2021. Current enrollment: n = 5. Clinical trial information: 04670445. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

The PLATON pilot-study "Platform for analyzing targetable tumor mutations": A PLATON network study. *First Author: Arndt Vogel, Hannover Medical School, Hannover, Germany*

Background: PLATON Network is designed as a platform to improve personalized therapy based on genomic profiles in gastrointestinal cancer patients. PLATON's study-design focuses on patient's molecular profiling and will provide a network web application for interlinking PLATON investigators which integrates information of the participating centers, their patients, the molecular profiles and available clinical trials at PLATON`s study-sites. **Methods:** The PLATON Network is designed as a permanent open, multicenter, prospective, cohort study with biobanking, with a shared platform infrastructure for associated sub-studies. In a first approach the PLATON Network enrolls within its pilot-study 200 patients in Germany of both sexes and ages over 18 at 40 study sites (NCT04484636) with signed informed consent. All patients of the pilot-study are diagnosed with hepatocellular cancer (HCC), intra- and extrahepatic cholangiocellular carcinoma (CCA), gallbladder carcinoma (GBCA), pancreatic cancer (PDCA) or esophagogastric cancer (EC/GC). At the time of enrolment, patients are within their first-line therapy and no local curative therapy is available. Molecular profiling will be performed with the Foundation Medicine Assays FoundationOne CDx and FoundationOne Liquid CDx. Investigators may use the platform for searching clinical trials matching the individual molecular profile of their patients or may identify a patient, who may be eligible for a study or other treatment options available at the corresponding centers of the PLATON network. The interactive network web application will comprise a dashboard and a moderated chat room to interact for example in a virtual Molecular Tumor Board. The first patient was included on the 25th of November 2020. Up to 12th of February 2021, a total of 36 patients HCC (N = 1), CCA (N = 6), PDCA (N = 12), GBCA (N = 0) and EC/GC (N = 16) were enrolled at 11 study-sites and the results of 29 genetic analyses were completed. All cohorts of the pilot-study are open for recruitments up to a maximum of 40 individuals per diagnostic group. Clinical trial information: NCT04484636. Research Sponsor: Roche Pharma AG.

7000 **Oral Abstract Session**

OPTIC primary analysis: A dose-optimization study of 3 starting doses of ponatinib (PON). *First Author: Jorge E. Cortes, Georgia Cancer Center, Augusta, GA*

Background: PON, a third-generation tyrosine kinase inhibitor (TKI), demonstrated deep and long-lasting responses and survival in patients (pts) with chronic-phase chronic myeloid leukemia (CP-CML) resistant/intolerant to second-generation TKI therapy (PACE; NCT01207440); post hoc analysis suggested a relationship between dose and both adverse events and response. Here we present the primary analysis of OPTIC (NCT02467270), an ongoing, randomized, phase 2 trial with a novel response-based dosing regimen of PON in pts with resistant/intolerant CP-CML. **Methods:** Pts with CP-CML resistant/intolerant to ≥2 TKIs or with the *BCR-ABL1* T315I mutation were randomized to PON starting doses of 45 mg (cohort A; 45 mg → 15 mg), 30 mg (B; 30 mg →15 mg), and 15 mg (C) once daily. Doses were reduced to 15 mg with achievement of ≤1% *BCR-ABL1*^{IS} in cohorts A and B. The primary endpoint is ≤1% *BCR-ABL1*^{IS} at 12 mo; secondary endpoints include cytogenetic and molecular responses and safety outcomes. AOEs were adjudicated prospectively by an independent review committee. **Results:** 283 pts were randomized (A/B/C: n=94/95/94) and had the following baseline characteristics: median age 48 y (18–81 y); 98% received ≥2 (55% ≥3) TKIs; 99% had resistant disease; 40% had ≥1 baseline mutations (23% T315I). At the primary analysis with 32 mo median follow-up, 134 pts (47%; n=50/41/43) remained on treatment and 204 pts (72%) had PON exposure ≥12 mo. At 12 mo, 44% (41/93) in A, 29% (27/93) in B, and 23% (21/91) in C achieved ≤1% *BCR-ABL1*^{IS} (Table); primary endpoint was met by cohort A. Dose reductions to 15 mg after achieving response (A/B) were 48/29%. Most common grades ≥3 TEAEs were thrombocytopenia, 27%; neutropenia, 17%; and anemia, 7%. AOEs/serious AOEs were reported in cohorts A (10%/4%), B (5%/4%), and C (3%/3%). Dose reductions or discontinuations for TEAEs (A/B/C) were 46/35/32% and 19/16/14%, respectively. **Conclusions:** The OPTIC primary analysis demonstrates the optimal benefit:risk profile for PON was achieved with a response-based dosing regimen starting with 45 mg/d, followed by dose reduction to 15 mg/d upon achieving ≤*1% BCR-ABL1*^{IS}; 30 mg→15 mg and 15 mg cohorts may provide benefit, especially in pts without T315I mutation (Table). The observed ≤1% *BCR-ABL1*^{IS} responses are supported by robust survival outcomes in pts with CP-CML resistant to second-generation BCR-ABL1 TKI therapy, both with and without *BCR-ABL1* mutations. Clinical trial information: NCT02467270. Research Sponsor: ARIAD Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, with additional funding from Incyte Corporation, Wilmington, DE.

Response[a]	Cohort A 45 mg	Cohort B 30 mg	Cohort C 15 mg
BCR-ABL1^{IS} ≤1% at 12 mo, % (n/N)	44 (41/93)	29 (27/93)	23 (21/91)
BCR-ABL1^{IS} ≤1% by 12 mo by mutation status at baseline, % (n/N)	52 (48/93)	35 (33/93)	25 (23/91)
Response in pts with T315I mutation	60 (15/25)	25 (5/20)	11 (2/19)
Response in pts without T315I mutation	48 (32/66)	38 (28/73)	30 (21/71)
Survival probability at 36 mo, % (95% CI)			
PFS	73 (58, 84)	66 (48, 80)	70 (55, 80)
OS	89 (79, 95)	89 (77, 95)	92 (82, 96)

[a]Includes all pts who are randomized and with measurable *BCR-ABL1*^{IS} at BL.

Combination of ponatinib and blinatumomab in Philadelphia chromosome-positive acute lymphoblastic leukemia: Early results from a phase II study. *First Author: Nicholas James Short, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Achievement of a complete molecular remission (CMR) is associated with superior outcomes in patients with Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL). Ponatinib and blinatumomab both produce high rates of molecular remission in Ph+ ALL. The combination of these two agents may lead to durable responses and reduce the need for allogeneic hematopoietic stem cell transplant (AHSCT). **Methods:** This is a single-arm phase 2 study in adults with newly diagnosed (ND) or relapsed/refractory (R/R) Ph+ ALL. Patients received up to 5 cycles of blinatumomab as a continuous infusion at standard doses. Ponatinib 30mg daily was given during cycle 1. Ponatinib was decreased to 15mg daily once CMR was achieved. After completion of blinatumomab, ponatinib was continued for at least 5 years in responding patients. Twelve doses of prophylactic intrathecal chemotherapy were administered. For patients with ND Ph+ ALL, the primary endpoint was the CMR rate. For patients with R/R Ph+ ALL, the primary endpoint was the overall response rate (defined as the composite of CR/CRi). **Results:** Twenty-eight patients were treated (19 FL and 9 R/R). Median age was 59 years (range, 25-83 years); 62 years (range, 34-83 years) in the ND cohort and 36 years (range, 25-61 years) in the R/R cohort. Transcripts were p190 in 69% of patients the ND cohort and 100% in the R/R cohort. Among R/R patients, 44% were in Salvage 2+. No early death within 4 weeks were observed. Overall, 95% of patients responded; the response rate was 100% in the ND cohort and 88% in the R/R cohort. Among responding patients, 86% achieved CMR: 87% in the ND cohort and 86% in the R/R cohort. Median time to CMR was 1 month (range, 1-13 months). None of the patients in the ND cohort underwent AHSCT; 4 patients (44%) with R/R disease underwent subsequent AHSCT. With a median follow-up of 14 months, the estimated 1-year overall survival (OS) rate was 94% and event-free survival (EFS) rate was 81% for the entire study population. In the ND cohort, no patients have relapsed or died, and the 1-year OS and EFS rates were both 100%. In the R/R cohort, 1-year OS and EFS rates were 88% and 55%, respectively. The treatment was well-tolerated. Most side effects were grade 1-2. No patient discontinued ponatinib due to toxicity. One patient discontinued blinatumomab due to recurrent grade 2 tremor. **Conclusions:** The chemotherapy-free combination of ponatinib and blinatumomab shows encouraging results in Ph+ ALL. The regimen results in high rates of CMR and durable responses, potentially obviating the need for chemotherapy and AHSCT in many patients, particularly when used as frontline therapy. Clinical trial information: NCT03263572. Research Sponsor: Takeda; Amgen.

7002 **Oral Abstract Session**

Phase 2 results of the ZUMA-3 study evaluating KTE-X19, an anti-CD19 chimeric antigen receptor (CAR) T-cell therapy, in adult patients (pts) with relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-ALL). *First Author: Bijal D. Shah, Moffitt Cancer Center, Tampa, FL*

Background: ZUMA-3 is a Phase 1/2 multicenter study evaluating KTE-X19, an autologous anti-CD19 CAR T-cell therapy, in adult pts with R/R B-ALL. Phase 1 efficacy results at the recommended Phase 2 dose (1×10^6 CAR T cells/kg) were encouraging (Shah et al. ASCO 2019 #7006). Here, we present the pivotal Phase 2 results. **Methods:** Eligible adults had R/R B-ALL, > 5% bone marrow (BM) blasts by local evaluation, and ECOG 0–1. Pts received a single infusion of KTE-X19 after conditioning chemotherapy. The primary endpoint was the overall complete remission (CR) rate (CR + CR with incomplete hematologic recovery [CRi]) by central review. Key secondary endpoints were duration of remission (DOR), relapse-free survival (RFS), overall survival (OS), measurable residual disease negativity (MRD–) rate by flow cytometry, and safety. Data are reported in all treated pts. **Results:** As of 9/2020, 55 of 71 enrolled pts received KTE-X19, with a median follow-up of 16.4 mo (range, 10.3–22.1). Adverse events (AEs; n = 8) and ineligibility (n = 4) were the most common reasons enrolled pts did not receive KTE-X19 infusion. Median age was 40 y (range, 19–84), median BM blasts at screening were 65% (range, 5–100), and 47% of pts had ≥3 prior therapies, with 45%, 22%, and 42% having previously received blinatumomab, inotuzumab ozogamicin, or allogeneic stem cell transplant (alloSCT), respectively. The CR/CRi rate was 71% (95% CI, 57–82; 56% CR, 15% CRi); 31% of responders had ongoing responses. Median (95% CI) DOR, RFS, and OS were 12.8 mo (8.7–not estimable [NE]), 11.6 mo (2.7–15.5), and 18.2 mo (15.9–NE), respectively. In responders, median (95% CI) RFS and OS were 14.2 mo (11.6–NE) and not reached (16.2–NE). The MRD– rate was 97% among pts with CR/CRi. Among 25 pts with prior blinatumomab treatment, the CR/CRi rate was 60%. Ten pts (18%) received subsequent alloSCT at a median 98 days post–KTE-X19 infusion. Median DOR remained unchanged when not censoring for alloSCT. Grade ≥3 AEs occurred in 95% of pts, most commonly anemia (49%) and neutropenia (49% [febrile 13%]). Grade ≥3 cytokine release syndrome (CRS; per Lee at al. *Blood* 2014) and neurologic events occurred in 24% and 25% of pts, respectively, and were generally reversible. Two Grade 5 KTE-X19–related events occurred (brain herniation, n = 1; septic shock, n = 1). Median times to onset of CRS and neurologic events were 5 d and 9 d, with median durations of 7.5 d and 7 d, respectively. Median peak CAR T-cell levels (cells/μL) were 40.5 (range, 1.3–1533.4) in pts with CR and 0 in nonresponders. CAR T cells were undetectable by 9 mo in ongoing responders. **Conclusions:** After a median follow-up of 16.4 mo, KTE-X19 demonstrated compelling clinical benefit in heavily pretreated adults with R/R B-ALL, with the median OS not yet reached for responding pts and a manageable safety profile. Clinical trial information: NCT02614066. Research Sponsor: Kite, a Gilead Company.

The results of multicenter phase II, double-blind placebo-controlled trial of maintenance ixazomib after allogeneic hematopoietic cell transplantation (alloHCT) for high-risk multiple myeloma (MM) from the Blood and Marrow Transplant Clinical Trials Network (BMT CTN 1302). *First Author: Taiga Nishihori, Department of Blood & Marrow Transplant and Cellular Immunotherapy, Moffitt Cancer Center, Tampa, FL*

Background: The role of alloHCT and subsequent maintenance for the treatment of high-risk MM has not been fully defined. We evaluated the efficacy of ixazomib maintenance therapy after alloHCT using reduced intensity fludarabine/melphalan/bortezomib (Flu/Mel/Bort)-based conditioning regimen to treat patients with high risk MM. **Methods:** This phase 2 prospective multicenter trial (NCT#02440464) enrolled adults 70 years or younger, with either high-risk MM defined by cytogenetics or plasma cell leukemia (PCL) or relapse within 24 months after autologous HCT. Conditioning regimen consisted of Flu/Mel/Bort. Patients received HLA-matched donor unmanipulated peripheral blood grafts. Graft-versus-host disease (GVHD) prophylaxis was tacrolimus plus methotrexate. Between days +60 and +120 after allogeneic HCT, patients were randomly assigned (1:1, stratified by number of prior progressions) to receive ixazomib at 3 mg orally on days 1, 8, 15 on a 28-day cycle or matching placebo for 12 cycles. The study aimed to enroll 138 patients with 110 patients achieving randomization for a progression-free survival (PFS) comparison ixazomib maintenance vs. placebo. **Results:** Fifty-seven patients from 15 centers were enrolled (2015-18), of whom 52 (91.2%) received allogeneic HCT, and 43 (82.7%) proceeded to randomization (21 assigned to ixazomib and 22 to placebo). Enrollment was delayed by a clinical hold after enrollment of 17 patients due to toxicity concerns related to the conditioning regimen. Remaining patients were enrolled after an amendment reduced bort to a single pre-HCT dose. These and other delays in enrollment led to premature study closure. Median age was 56 (range, 35-65) years, and 33 patients (57.9%) had high-risk MM with 9 patients (15.8%) with primary PCL. At 24 mo post alloHCT, PFS and OS among all alloHCT recipients was 52% and 85% respectively with a corresponding transplant-related mortality (TRM) of 11%. At 21 mo post-randomization, ixazomib vs. placebo groups had similar PFS (55.3% vs. 59.1%) and OS (95% vs. 87%, p = 0.17). Cumulative incidences of grade III-IV acute GVHD at 100 days (9.5% vs. 0%) or chronic GVHD at 12 months (69% vs 64%) were similar. Best response, incidence of progression for ixazomib vs. placebo groups were similar while cumulative incidence of transplant-related mortality (TRM) at 21 months was 0.0% and 4.5% (90%CI: 0.5-16.5%), respectively. **Conclusions:** AlloHCT with reduced intensity fludarabine/melphalan and a single pre-HCT dose of bortezomib is safe and can produce durable disease control in extremely high-risk patients. ixazomib maintenance after alloHCT could not be assessed as intended due to early termination of study, but there was no signal of an impact in outcomes. Clinical trial information: NCT02440464. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

7004 **Oral Abstract Session**

Letermovir prophylaxis and cytomegalovirus reactivation in adult allogeneic hematopoietic cell transplant recipients with graft versus host disease. *First Author: Delaney Wolfe, The Ohio State University, Columbus, OH*

Background: Cytomegalovirus (CMV) is the most common clinically significant infection after allogeneic hematopoietic-cell transplantation (allo-HCT) and is associated with increased mortality. The risk for CMV reactivation increases with HLA mismatch, high dose corticosteroids, and graft versus host disease (GVHD). GVHD contributes to significant morbidity and mortality and is treated with immunosuppressive therapies that further increase CMV infection risk. In a phase III trial, letermovir prophylaxis had a lower incidence of CMV infection post-allo-HCT in patients at high risk of CMV reactivation when compared to placebo when given up to day +100. There is a lack of data concerning the effectiveness of letermovir in patients who develop GVHD and may continue letermovir past day +100. **Methods:** This was a single-center, retrospective study conducted at The Ohio State University. Demographics and transplant details were collected from medical records. The primary outcome was incidence of clinically significant CMV infection (CS-CMVi) within 200 days of allo-HCT. Secondary outcomes included incidence of CMV viremia, duration of letermovir therapy, mortality, and risk factors for CS-CMVi. Early death without CMV was treated as a competing risk for CS-CMVi, while relapse was a competing risk for non-relapse mortality (NRM). Proportional subdistribution or Cox hazards models were used to evaluate the association between use of letermovir and risk of CS-CMVi, NRM, or overall survival (OS) adjusting for potential confounding factors, where use of letermovir and GVHD were treated as time-dependent variables. **Results:** A total of 262 CMV-seropositive patients who received an allo-HCT between June 1, 2016 and June 30, 2020 were included. Of these, 119 patients received letermovir prophylaxis. A total of 111 patients received treatment for CS-CMVi, which included 82 of 143 (57%) who did not receive letermovir compared to 29 of 119 (24%) who received letermovir. Incidence of CMV viremia was significantly reduced with the use of letermovir in all patients (HR 0.21, 95% CI 0.12–0.34, $p < 0.001$) and among patients with acute GVHD grade >2 within 200 days post-allo-HCT (HR 0.12, 95% CI 0.05–0.32, $p < 0.001$), adjusting for age, gender, GVHD prophylaxis and use of ATG or T-cell depleted graft. The median duration of letermovir therapy was 97 days. Nine patients were continued on letermovir indefinitely for recurrent CMV viremia. Patients who received letermovir had decreased NRM (HR 0.41, 95% CI 0.18-0.96, $p = 0.04$) and improved OS (HR 0.46, 95% CI 0.23-0.95, $p = 0.04$). **Conclusions:** Letermovir prophylaxis significantly decreased CS-CMVi and improved NRM and OS in this real-world analysis. In addition, patients with acute GVHD had significantly less CMV viremia, suggesting potential benefit in continuing letermovir prophylaxis in this patient population. Research Sponsor: None.

7005 **Oral Abstract Session**

Prospective longitudinal evaluation of microbiome diversity in patients with hematological malignancy undergoing allogeneic hematopoietic stem cell transplantation (HSCT). *First Author: Emily Walsh, Seres Therapeutics, Cambridge, MA*

Background: Studies suggest that decreased microbial diversity due to chemotherapeutic and antibiotic exposure may be associated with acute graft vs host disease (aGvHD) and mortality in patients undergoing allogeneic HSCT. In addition, disruption of the microbiome by antibiotics may lead to intestinal domination by pro-inflammatory bacteria, resulting in increased risk of aGvHD. This relationship has been described in settings with prophylactic antibiotic use, a standard of care in most transplant centers. Here we assessed how the microbiome and GvHD outcomes differ when prophylactic use of antibiotics is avoided. **Methods:** We collaborated on an observational study (COLLECT) to evaluate changes in microbial diversity over time in subjects undergoing allogeneic HSCT. According to protocol at the University Hospital of Cologne, antibiotics were administered only as empiric treatment for febrile neutropenia or as targeted treatment. Stool was collected weekly from 65 subjects at baseline (pre-HSCT) to day 28 with additional time points taken at day 56, day 90, day 365, and upon diagnosis of intestinal GvHD (GvHD-day 0 and GvHD-day 7). Patients were monitored for incidence of GvHD, including acute GvHD of the liver, intestine, and skin. Microbiome 16SV4 profiles were generated from 381 stool samples. Linear effects models were developed to evaluate the association between Shannon diversity, intestinal domination, and the incidence of intestinal GvHD and mortality. **Results:** Of the 65 subjects, 28 subjects (42%) went on to develop intestinal GvHD, and 16 subjects (25%) did not survive to day 365. A decline in Shannon diversity was observed during the neutropenic period following HSCT. Subjects who went on to develop intestinal GvHD had significantly lower Shannon diversity at the time of stem cell engraftment ($p < 0.0468$). Furthermore, lower diversity was observed throughout the study period in subjects experiencing intestinal GvHD. We developed a linear model evaluating the association between mortality and Shannon diversity and found a significant relationship at days 28 and 90 post HSCT ($p < 0.0001$ and 0.0121, resp). Intestinal domination by Enterobacteriaceae or Enterococcus was significantly associated with the incidence of intestinal GvHD ($p < 0.0082$) or mortality ($p < 0.001$), respectively. **Conclusions:** Data from this observational study (COLLECT) suggests decreases in microbial diversity over time occur in subjects undergoing allogeneic HSCT despite the lack of prophylactic antibiotics. Investigation of whether administration of microbiome therapeutic drugs prior to transplant and/or at the time of engraftment can reduce morbidity and mortality in this high-risk patient population is warranted. Clinical trial information: NCT03148197. Research Sponsor: Seres Therapeutics.

7006 **Oral Abstract Session**

Effect of olutasidenib (FT-2102) on complete remissions in patients with relapsed/refractory (R/R) m*IDH1* acute myeloid leukemia (AML): Results from a planned interim analysis of a phase 2 clinical trial. *First Author: Stéphane De Botton, Institut Gustave Roussy, Villejuif, France*

Background: Olutasidenib, a potent, selective, oral, small molecule inhibitor of mutant IDH1 (m*IDH1*), has exhibited favorable tolerability and clinical activity in high-risk AML patients (pts) in a phase 1 trial (Watts, *Blood* 2019). Here, we present interim analysis results of a phase 2 trial (NCT02719574) in R/R m*IDH1* AML pts receiving olutasidenib monotherapy 150 mg twice daily. **Methods:** The efficacy evaluable (EE) set comprised m$IDH1^{R132X}$ pts whose first dose was ≥180 days before the data cut-off (18-JUN-20). The primary endpoint was CR+CRh (complete remission [CR] or CR with partial hematologic recovery [CRh] according to modified IWG 2003 criteria) rate. CRh was defined as bone marrow blasts <5%, absolute neutrophil count $>0.5\times10^9$/L, *and* platelet count $>50\times10^9$/L. Overall response rate (ORR) comprised CR+CRh+CR with incomplete recovery (CRi) + morphologic leukemia-free state (MLFS) + partial response (PR). Duration of treatment (DOT), duration of response (DOR), and overall survival (OS) were estimated using Kaplan-Meier methodology. **Results:** This clinical trial met its pre-specified early enrollment-stopping criteria for efficacy. A total of 153 pts with R/R AML received olutasidenib; median DOT, 5.5 mo (95% CI: 4.4, 8.7). 43 pts (28%) remain on treatment and 110 (72%) discontinued, most commonly due to: disease progression, 31%; AEs, 14%; death, 10%; and transplant, 8%. For the EE set (123 pts), the median age was 71 y (range: 32–87) with a median number of prior therapies of 2 (1–7). The CR+CRh rate was 33% including 30% of pts in CR (Table). Median duration of CR+CRh was not reached (NR) and 13.8 mo in a sensitivity analysis when HSCT or relapse was deemed end of response. ORR was 46% and median duration of ORR was 11.7 mo. Of responders who were transfusion-dependent at baseline, 56-day platelet transfusion independence (TI) and RBC TI were gained by 100% and 83%, respectively, of pts who achieved CR+CRh, and by 56% and 50% who did not. Median OS was 10.5 mo (EE set). In CR+CRh responders, median OS was NR and the estimated 18-mo OS was 87%. TEAEs in ≥25% of pts were nausea, 38%; constipation, 25%; leukocytosis, 25%. Grade 3/4 all-causality TEAEs in >10% of pts were febrile neutropenia, 20%; anemia, 19%; thrombocytopenia, 16%; neutropenia, 13%. Investigator-assessed IDH1 differentiation syndrome (any grade) was observed in 21 pts (14%); most cases resolved with treatment management; one case was fatal; 19 pts had concomitant leukocytosis. **Conclusions:** Olutasidenib was well tolerated and induced durable CR in a subset of high-risk R/R m*IDH1* AML pts. TI was achieved in all response groups. Clinical benefit, per DOR and OS, extended beyond CR+CRh responders. Clinical trial information: NCT02719574. Research Sponsor: Forma Therapeutics, Inc.

Olutasidenib response rates in R/R m*IDH1* AML: EE population.

Response n (%)	Overall (N = 123)
ORR	57 (46)
CR	37 (30)
CRh	4 (3)
CRi	14 (11)

PR	1 (<1)

7007 **Oral Abstract Session**

Efficacy and safety of aspacytarabine (BST-236) as a single-agent, first-line therapy for patients with acute myeloid leukemia unfit for standard chemotherapy. *First Author: Jessica K. Altman, Lurie Comp Cancer Ctr of Northwestern Univ, Chicago, IL*

Background: Aspacytarabine (BST-236) is a prodrug of cytarabine, the backbone of acute myeloid leukemia (AML) standard of care chemotherapy, associated with toxicity which precludes its administration in older patients and patients with comorbidities. Aspacytarabine is inactive in its intact prodrug form until cytarabine is gradually released at pharmacokinetics which decrease the systemic exposure to peak toxic cytarabine levels, resulting in reduced systemic toxicity and relative sparing of normal tissues, enabling therapy with high cytarabine doses to patients otherwise unfit to receive it. **Methods:** A phase 2b open-label, single-arm study to evaluate the efficacy and safety of aspacytarabine as a first-line single-agent therapy in newly-diagnosed AML patients unfit for standard chemotherapy (NCT03435848). Aspacytarabine is administrated at 4.5 g/m^2/d (containing 3 g/m^2/d cytarabine) in 1-2 induction and 1-3 consolidation courses, each consisting of 6 daily 1-hour infusions. Patients with secondary AML, prior hypomethylating agent (HMA) therapy, and therapy-related AML, are eligible. **Results:** To date, in the ongoing study, 46 newly-diagnosed AML patients unfit for standard chemotherapy (median age 75 years) were treated with aspacytarabine and completed 1-4 courses of 4.5 g/m^2/d aspacytarabine, including 26 patients (63%) with *de novo* AML and 17 (37%) with secondary AML. Six patients (13%) were previously treated with HMA (median 12 courses). The baseline median bone marrow blasts was 52%, and 54% and 29% of patients had adverse or intermediate European LeukemiaNet (ELN) score, respectively. Twenty (43%) patients had ECOG 2. Aspacytarabine is safe and well-tolerated in repeated-course administration. Grade > 2 drug-related adverse events include mainly hematological events and infections. The 30-day mortality rate is 11%. Of 43 patients evaluable for efficacy analysis to date, 15 patients (35%) reached a complete remission (CR) following 1 (13 patients) or 2 (2 patients) induction courses, all with complete hematological recovery (median 27.5 days, range 22-39 days). The CR rates in *de novo* AML patients and patients with adverse ELN score are 46% and 33%, respectively. Of the 11 patients evaluable to date for minimal residual disease (MRD) flow cytometry test, 8 are MRD negative (73%). While aspacytarabine treatment consists of a limited number of courses, median duration of response and median overall survival for responders are not reached at 12 and 24 months, respectively (end of follow up). Updated results will be presented at the meeting. **Conclusions:** The cumulative clinical data suggest that aspacytarabine, a time-limited single-agent treatment, is safe and efficacious as a first-line therapy for patients who are unfit for intensive chemotherapy, which may establish it as a new tolerable AML chemotherapy backbone. Clinical trial information: NCT03435848. Research Sponsor: BioSight Ltd.

7008 **Oral Abstract Session**

Phase 1 first-in-human study of irreversible FLT3 inhibitor FF-10101-01 in relapsed or refractory acute myeloid leukemia. *First Author: Mark J. Levis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: FF-10101-01 is a selective and irreversible FMS-like tyrosine kinase 3 (FLT3) inhibitor with potent *in vitro* activity against *FLT3*-mutated AML. FF-10101-01 is highly active against *FLT3* internal tandem duplication (ITD) mutations associated with high relapse and low survival/remission rates, as well as resistance-conferring D835 and F691 tyrosine kinase domain (TKD) and non-canonical FLT3 activating mutations. Here we report on a Phase 1 dose escalation trial examining the safety, efficacy, pharmacokinetics, and pharmacodynamics of FF-10101-01 in patients (pts) with relapsed/refractory primary or secondary AML. **Methods:** To determine the recommended Phase 2 dose, pts with or without a FLT3 mutation received FF-10101-01 orally once (QD) or twice (BID) daily until unacceptable toxicity was observed or pts had no further clinical benefit (1 cycle = 28 days). Composite complete remission (CRc) and partial remission (PR) rates were assessed. Inhibition of FLT3 phosphorylation was evaluated using a plasma inhibitory activity assay and was correlated with associated FF-10101-01 exposure. **Results:** Fifty-two pts [median age 61 (range, 21-84); 52% female; FLT3: ITD [22 (42%)], TKD [5 (10%)], ITD+TKD [1 (2%)], Wt [24 (46%)] received continuous dosing of FF-10101-01 at 10 - 225 mg QD or 50 - 100 mg BID. Median number of prior therapies was 3 (range, 0-6) and the majority [23/28 (82%)] of pts with known FLT3 mutations had received prior FLT3 inhibitors. The median duration on study was 5.7 (range, 0.1-36) weeks. FF-10101-01 was generally well-tolerated up to total daily doses of 150 mg. The most common treatment related adverse events included nausea [n = 18 (35%)] diarrhea [14 (27%), 2 Grade (Gr) 3/4], elevations in creatine kinase [CK; 14 (27%), 4 Gr 3/4], vomiting [10 (19%)] and increased AST [10 (19%), 2 Gr 3]. Grade 3/4 differentiation syndrome (n = 4, 8%) was observed at 75 - 150 mg/day. Dose-limiting cardiac toxicity (heart failure with reduced ejection fraction; Gr 3 increased troponin/CK) was observed at total daily doses ≥200 mg. The CRc rate was 13% (4/30 pts evaluable for response): 1 CR at 75 mg BID (FLT3-ITD); 1 CRp at 100 mg BID (Wt-FLT3); and 2 CRi's at 50 mg BID, one that previously progressed on gilteritinib. The median time to overall response was ~13.3 weeks. Four pts achieved a PR (≥50% decrease in BM blasts to 5 - 25% abnormal cells) at total daily doses of 50 - 150 mg; 2 had ITD mutations, and all had received prior FLT3 kinase inhibitors. At ≥75 mg BID, trough plasma concentrations were > 90 ng/ml and associated with > 90% p-FLT3 inhibition maintained over the dosing interval. **Conclusions:** The FF-10101-01 FLT3 inhibitor has shown activity in pts with refractory/relapsed AML, including those with activating FLT3-ITD mutations resistant to gilteritinib and other FLT3 kinase inhibitors. Doses of 50-75 mg BID were well tolerated and resulted in sustained FLT3 inhibition. Clinical trial information: NCT03194685. Research Sponsor: FUJIFILM Pharmaceuticals U.S.A, Inc.

7009 **Poster Discussion Session**

Second-line bosutinib (BOS) for patients (pts) with chronic phase (CP) chronic myeloid leukemia (CML): Final 10-year results of a phase 1/2 study. *First Author: Carlo Gambacorti-Passerini, University of Milano-Bicocca, Monza, Italy*

Background: BOS is approved for Philadelphia chromosome (Ph)+ CML resistant/intolerant to prior therapy and newly diagnosed Ph+ CP CML. In a phase 1/2 study, second-line BOS showed durable efficacy and manageable toxicity in pts with imatinib-resistant (IM-R) or -intolerant (IM-I) Ph+ CP CML. **Methods:** This final efficacy and safety analysis of the phase 1/2 study and extension study was based on ≥10 y of follow-up (FU). Ph+ CP CML pts who received BOS starting at 500 mg/d after prior treatment (Tx) with imatinib only were included. **Results:** 19% of pts were on BOS at y 10, and 13% were still on BOS at study completion after ≥10 y; 19% completed ≥10 y of FU. Median duration of Tx and FU were 26 and 54 mo, respectively. Median (range) dose intensity was 436 (87–599) mg/d. The most common primary reasons for permanent Tx discontinuation were lack of efficacy (unsatisfactory response or disease progression; 27%) and adverse events (AEs; 26%). In pts with a valid baseline assessment, cumulative complete cytogenetic response (CCyR), major molecular response (MMR) and MR^4 rates (95% CI), respectively, were 50% (43–56), 42% (35–49) and 37% (30–44) (IM-R: 48% [41–56], 46% [37–55] and 39% [31–48]; IM-I: 53% [41–64], 36% [25–48] and 33% [22–45]). Responses were durable, with estimated probabilities of maintaining CCyR, MMR and MR^4 > 50% after ≥10 y (Table). At 10 y, cumulative incidence of on-Tx progression/death was 24% and Kaplan-Meier (K-M) overall survival 72% (Table); 55 deaths (IM-R: n = 41; IM-I: n = 14) occurred on study, none BOS-related. Any grade Tx-emergent AEs (TEAEs) in ≥40% of pts were diarrhea (86%), nausea (46%) and thrombocytopenia (42%). Pleural effusion, cardiac and vascular TEAEs occurred in 13%, 12% and 11% of pts, respectively. 28% of pts had AEs leading to permanent Tx discontinuation; most common (≥2% of pts) were thrombocytopenia (6%), neutropenia (2%) and alanine aminotransferase increased (2%). **Conclusions:** These 10-y data are consistent with prior results of durable efficacy and manageable toxicity with second-line BOS and support long-term BOS use in CP CML pts after imatinib failure. Clinical trial information: NCT00261846 and NCT01903733. Research Sponsor: Pfizer.

Phase II study of the IDH2-inhibitor enasidenib in patients with high-risk IDH2-mutated myelodysplastic syndromes (MDS). *First Author: Sangeetha Venugopal, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Isocitrate dehydrogenase 2 (*IDH2*) mutations occur in 5% of patients (pts) with MDS. Enasidenib (ENA) is a selective oral inhibitor of the mutant IDH2 enzyme with single-agent activity in relapsed/refractory acute myeloid leukemia (AML). We report the results of the open label phase II study designed to evaluate the efficacy and tolerability of ENA, as monotherapy or in combination with azacitidine (AZA) in pts with higher-risk *IDH2*-mutated MDS (NCT03383575). **Methods:** Pts with higher-risk [Revised International Prognostic Scoring System risk > 3 or high molecular risk (HMR)] MDS/CMML or LB AML naïve to hypomethylating agents (HMA) received ENA100 mg orally daily for 28 d of each 28-d cycle + AZA 75 mg/m2 IV or SC on d 1-7 of each cycle (ENA+AZA), and pts with refractory or progressive MDS to prior HMA therapy received ENA alone (ENA), in 28-d cycles until unacceptable toxicity, relapse, transformation to AML, or progression. The primary endpoint was overall response rate (ORR) [complete remission (CR), marrow CR (mCR), partial remission (PR) and hematologic improvement (HI)]. Other endpoints include safety, and survival outcomes. **Results:** 48 pts received ENA+AZA (n = 26) or ENA (n = 22). The median age was 73 yrs (range, 46-83). Most pts (72%) had HMR: *ASXL1* (39%), and *RUNX1* (17%). Median number Tx cycles was 4 (2–32) in the ENA+AZA, and 7 (1–23) in the ENA arm. Common Tx-related grade 3–4 AEs in the ENA+AZA arm were neutropenia (64%), thrombocytopenia (28%), and anemia (8%); these occurred in 10%, 0%, and 5%, in the ENA arm. Grade 3–4 infections occurred in 32% (ENA+AZA) and 14% (ENA). IDH differentiation syndrome occurred in 3 pts (12%) in the ENA+AZA and 5 pts (24%) in the ENA arm. Two deaths occurred during the initial 60 d, both unrelated to study and due to COVID. In response-evaluable pts (n=46), ORR was 84% (n = 21/25; 24% CR + 8% PR+44% mCR+ 8% HI] in the treatment naïve ENA+AZA and 43% (n = 9/21; 24% CR+5%PR+5% mCR+10% HI) in the HMA failure ENA arm (Table). Most common reason for Tx discontinuation was disease progression (ENA+AZA 20%, ENA 33%).5 pts (20%) received HCT in the ENA+AZA and 1 (5%) in the ENA arm. 7 pts in the ENA+AZA and 5 in the ENA arm were ongoing at data cutoff (Dec 31, 2020). After a median follow up of 12.6 mo, median OS was 32.2 mo in the ENA+AZA and 21.3 mo in the ENA arm. **Conclusions:** ENA is well tolerated and shows promising efficacy in *IDH2*-mutated higher risk MDS. Follow up and accrual is ongoing to better define duration and biomarkers of response. Clinical trial information: NCT03383575. Research Sponsor: brystol meyer squibb.

Venetoclax and azacitidine combination in chemotherapy ineligible untreated patients with therapy-related myeloid neoplasms, antecedent myelodysplastic syndromes, or myelodysplastic/myeloproliferative neoplasms. *First Author: Vinod Pullarkat, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Patients (pts) with therapy-related myeloid neoplasms (tMN), antecedent myelodysplastic syndrome, or antecedent myelodysplastic/myeloproliferative neoplasms (A-MDS/MPN) may have poor outcomes due to age and adverse genetic/karyotypic features. In the VIALE-A study, pts with tMN and A-MDS/MPN unfit for intensive chemotherapy treated with venetoclax (Ven) and azacitidine (Aza) demonstrated superior response rates and overall survival (OS) than Aza alone. Herein, the efficacy and safety of Ven+Aza among pts with tMN and A-MDS/MPN are described. **Methods:** Data were pooled from pts enrolled in VIALE-A (NCT02993523) comparing pts who received Ven+Aza or placebo (Pbo)+Aza and a prior phase 1b study (NCT02203773) where pts received Ven+Aza. Enrolled pts were ≥18 years, treatment-naïve with no prior exposure to hypomethylating agents, and ineligible for intensive chemotherapy. Pts on Ven+Aza received Ven 400 mg orally (days 1–28) and Aza (75 mg/m^2; days 1-7/28-day cycle). Composite complete remission rate (CRc; complete remission [CR] + CR with incomplete hematologic recovery [CRi]), duration of response (DoR), and OS were assessed. Disease assessments were per modified International Working Group response criteria for AML. **Results:** In this pooled analysis, tMN was observed in (Ven+Aza/Pbo+Aza) 31/9 and A-MDS/MPN in 59/26 pts. Poor-risk cytogenetics were observed in 18 (58%)/6 (67%) with tMN (5 or 5q deletion [del]: 4/1 ; 7 or 7q del: 6/1 ; complex [≥ 3 clonal abnormalities]: 10/4), and 19 (32%)/13 (50%) with A-MDS/MPN (5 or 5q del: 10/5; 7 or 7q del: 6/1; complex: 14/9). *TP53* mutation was observed in 5/3 pts with tMN and 8/0 pts with A-MDS/MPN. Pts with tMN received a median (Ven+Aza/Pbo+Aza) of 5/4 cycles of treatment. CRc was achieved by 19 (61%)/1 (11%). The mDoR was not reached (NR) (95% CI: 17.8, NR)/8.5 (NR, NR) months. The mOS was 16.4 (95% CI: 4.1, NR)/11.3 (0.6, 17.5) months. Pts with A-MDS/MPN received a median (Ven+Aza/Pbo+Aza) of 9/5 cycles of treatment. CRc was achieved by 39 (66%)/7 (27%) pts with mDoR of 17.3 (95% CI: 9.6, NR)/5.8 (1.1, NR) mos. The mOS was 15.9 (95% CI: 11.5, NR)/10.1 (4.7, 14.5) mos. Common grade≥3 adverse events (Ven+Aza/Pbo+Aza) were febrile neutropenia (tMN: 39%/11% and A-MDS/MPN: 36%/12%) neutropenia (tMN: 29%/33%; A-MDS/MPN: 39%31%), and thrombocytopenia (tMN: 32%/33%; A-MDS/MPN: 39%/62%). **Conclusions:** Ven+Aza compared to Aza monotherapy resulted in higher CRc rates with longer DoR and median OS among treatment-naïve pts with tMN and A-MDS/MPN ineligible for intensive chemotherapy. The safety profile was similar to overall pts with the Ven+Aza combination. Outcomes by cytogenetic and molecular risk-groups will be presented. Clinical trial information: NCT02993523, NCT02203773. Research Sponsor: AbbVie, Genentech.

A phase Ib/II study of ivosidenib with venetoclax +/- azacitidine in IDH1-mutated myeloid malignancies.

First Author: Curtis Andrew Lachowiez, M.D. Anderson Cancer Center, Houston, TX

Background: Isocitrate dehydrogenase-1 (*IDH1*$^{+}$) mutations are present in 5-15% of myeloid malignancies, promoting leukemogenesis through production of the oncometabolite 2-hydroxyglutarate resulting in arrested myeloid differentiation. *IDH1*$^{+}$ malignancies demonstrate increased reliance on the anti-apoptotic protein BCL-2, enhancing susceptibility to the BCL-2 inhibitor venetoclax (VEN). We report an interim safety and efficacy analysis of the IDH1 inhibitor ivosidenib (IVO; 500 mg PO daily D15-continuous) combined with VEN (D1-14) +/- azacitidine (AZA; 75mg/m^2 D1-7 every 28 days). **Methods:** Eligible patients age ≥18 with *IDH1*$^{+}$ MDS, newly diagnosed AML (ND: treatment naïve [TN] or secondary/treated secondary AML [sAML]), or relapsed/refractory (R/R) AML enrolled into three dose levels (DL): DL1 (IVO+VEN 400 mg), DL2 (IVO+VEN 800 mg), DL3 (IVO+VEN 400 mg+AZA). Primary objectives included safety and tolerability, and IWG defined overall response (ORR: CR+CRi+CRh+PR+MLFS). Prior receipt of IVO or VEN was exclusionary. **Results:** 25 evaluable patients (DL1: 6, DL2: 6, DL3: 13) enrolled with a median follow-up of 16.1 months. Median age was 67 (range: 44-84). 84% (N=21) of patients had AML (ND: N=13 [TN: 8, sAML: 5], R/R: N=8), while 16% (N=4) had MDS. ELN risk was intermediate and adverse in 16% (N=4) and 56% (N=14). Median *IDH1* VAF at enrollment was 22.7% (range: 5.1%-47.8%). Two patients had received a prior IDH1 inhibitor. The ORR was 92% (DL1: 67%, DL2: 100%, DL3: 100%). Composite CR (CRc: CR+CRi+CRh) was 84% (DL1: 67%, DL2: 100%, DL3: 85%) including 92% (TN: 100%, sAML: 80%), 63%, and 100% of patients with ND-AML, R/R-AML, or MDS. Median number of cycles received was 4 (DL1: 8.5, DL2: 6, DL3: 4) with ongoing responses in 62% (DL1: 33%, DL2: 50%, DL3: 82%) at 1-year. 8 patients transitioned to SCT (DL1: 0, DL2: 2, DL3: 6), and 8 patients remain on study (DL1: 2, DL2: 1, DL3: 5). 1-year OS was 68% for the entire study population (DL1: 50%, DL2: 67%, DL3: 78%), 71% in ND-AML (TN: 86%, sAML: 60%), 50% in R/R-AML, and 100% in MDS. Measurable residual disease negative CRc by multiparameter flow cytometry was attained in 60% (ND-AML: 67%, R/R-AML: 60%, MDS: 33%) correlating with improved OS (median OS: NR vs. 8.5 months, p-value: 0.038). Common grade 3/4 adverse events included febrile neutropenia (28%) and pneumonia (24%). Tumor lysis and differentiation syndrome occurred in two and four patients; all cases resolved with medical management. **Conclusions:** IVO+VEN +/- AZA is an effective treatment regimen in patients with *IDH1*$^{+}$myeloid malignancies. The combination therapy is associated with an acceptable and expected toxicity profile with notable efficacy and high rates of MRD-negative CRc in AML. Enrollment into the study continues. Clinical trial information: NCT03471260. Research Sponsor: V foundation Award.

Follow-up of patients with *FLT3*-mutated R/R AML in the phase 3 ADMIRAL trial.

First Author: Alexander E. Perl, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA

Background: The phase 3 ADMIRAL trial demonstrated the superiority of gilteritinib to salvage chemotherapy (SC) in patients (pts) with *FLT3*-mutated (*FLT3*$^{mut+}$) R/R AML. **Aim/Objective:** A follow-up of ADMIRAL assessed long-term survivors, transplant (HSCT) outcomes. and gilteritinib safety beyond 1 year. **Methods:** A data cut was performed on September 20, 2020—2 years after the primary analysis. Patients who were alive without relapse, pts who underwent HSCT, and adverse events of interest (AEIs) in Years 1 (≤12 months) and 2 (> 12 months) of gilteritinib therapy were evaluated. **Results:** As of September 20, 2020, 17% (n = 63/371) of pts in the intention-to-treat (ITT) population were alive (gilteritinib, n = 49; SC, n = 14); 16 pts assigned to gilteritinib remained on treatment. After a median follow-up of 37.1 months, 26 of the 49 pts in the gilteritinib arm who were alive were also without relapse; 18 of these 26 pts underwent HSCT, with 16 receiving post-HSCT gilteritinib maintenance therapy. Nineteen of the 26 pts in the gilteritinib arm without relapse continued gilteritinib beyond 1 year and remained in CR. Of the 371 ITT pts, 83 (22%) underwent HSCT during the study (gilteritinib, n = 64; SC, n = 19). Pre-HSCT CRc rates were similar across arms (gilteritinib: n = 40/64; 63%; SC: n = 11/19; 58%); 10 of 11 pts preselected for low-intensity SC achieved pre-HSCT CRc (gilteritinib, n = 9; SC, n = 1). Forty of 64 (63%) transplanted pts in the gilteritinib arm received post-HSCT gilteritinib maintenance after achieving pre-HSCT CRc; the 24-month relapse rate in pts who resumed gilteritinib after pre-HSCT CRc was 19%. Post-HSCT treatment with chemotherapy or other tyrosine kinase inhibitors was administered in 26 pts who received gilteritinib before transplantation. Cumulative 24-month relapse rates in gilteritinib-treated pts who achieved pre-HSCT CR and CRc were 20% and 45%, respectively. Median post-HSCT overall survival (landmarked to HSCT date), was similar across arms (gilteritinib, 16.1 months; SC, 15.3 months; HR = 1.076; 95% CI: 0.536, 2.160). Overall, 10.2% (n = 25/246) had ≥24 months of gilteritinib exposure. Most common AEIs during Years 1 and 2 of gilteritinib therapy were elevated ALT/AST levels. Incidences of all AEIs declined in Year 2. Cardiac AEIs in Year 2 were nonfatal cardiorespiratory arrest (n = 1) and ventricular tachycardia (n = 1). One case of differentiation syndrome and cutaneous squamous cell carcinoma occurred in Years 1 and 2, respectively. **Conclusions:** A high proportion of gilteritinib-treated R/R *FLT3*$^{mut+}$ AML pts who were alive without relapse had received HSCT followed by gilteritinib maintenance. Among all transplanted pts in ADMIRAL, pre-HSCT remission rates and post-HSCT survival were similar across arms. Post-HSCT gilteritinib maintenance may relate to the low post-HSCT relapse rate in the gilteritinib arm. The safety profile of gilteritinib is stable at 2 years with no new or significant safety signals. Clinical trial information: NCT02421939. Research Sponsor: Astellas Pharma, Inc. .

Prognostic factors of overall (OS) and relapse-free survival (RFS) for patients with acute myeloid leukemia (AML) in remission after intensive chemotherapy (IC): Multivariate analyses from the QUAZAR AML-001 trial of oral azacitidine (Oral-AZA).

First Author: Gail J. Roboz, Weill Cornell Medicine and The New York Presbyterian Hospital, New York, NY

Background: Demographic and disease factors influence outcomes for patients (pts) with AML. In the phase 3 QUAZAR AML-001 trial, Oral-AZA significantly prolonged OS and RFS vs. placebo (PBO) for pts with AML in first remission after IC (Wei, *NEJM*, 2020). Univariate analyses showed OS and RFS benefits with Oral-AZA vs. PBO across pt subgroups defined by baseline (BL) characteristics. MV analyses were performed to identify BL characteristics independently predictive of OS/RFS in QUAZAR AML-001, and to assess Tx effects of Oral-AZA vs. PBO on survival when adjusted for BL factors. **Methods:** Pts were aged ≥55 yrs with AML in complete remission (CR) or CR with incomplete count recovery (CRi) after induction ± consolidation. Within 4 months of CR/CRi, pts were randomized 1:1 to receive Oral-AZA 300 mg or PBO for 14d/28d cycle. Cox proportional hazards models were used to estimate Tx effects of Oral-AZA vs. PBO on OS and RFS, adjusting for BL age, sex, ECOG PS score, cytogenetic risk at diagnosis (Dx), prior MDS, geographic region, CR/CRi after induction (per investigator) and at BL (per sponsor), MRD status, receipt of consolidation, number of consolidation cycles, platelet count, and ANC. In a stepwise procedure, randomized Tx and BL variables were selected incrementally into a Cox model if $P \leq 0.25$. After each addition, the contribution of the covariate adjusted for other covariates in the model was evaluated and retained in the model if $P \leq 0.15$. **Results***:* Oral-AZA Tx remained a significant independent predictor of improved OS (HR 0.70) and RFS (HR 0.57) *vs.* PBO after controlling for BL characteristics (Table). MRD status, cytogenetic risk, and pt age were each also independently predictive of OS and RFS. Response after induction (CR *vs.* CRi) and BL ANC were predictive of OS but not RFS, whereas prior MDS, CR/CRi at BL, and number of consolidation cycles were only predictive of RFS. **Conclusions:** Tx with Oral-AZA reduced the risk of death by 30% and risk of relapse by 43% vs. PBO independent of BL characteristics. Cytogenetic risk at Dx, MRD status, and pt age also independently predicted survival outcomes. Clinical trial information: NCT01757535. Research Sponsor: Bristol Myers Squibb.

Variable	OS HR [95%CI] *P* value	RFS HR [95%CI] *P* value

A mixed methods study exploring the role of perceived side effects on treatment decision-making in older adults with acute myeloid leukemia (AML).

First Author: Dawn Maze, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: AML patients may be treated with intensive chemotherapy (IC), or non-intensive chemotherapy (NIC) or they may receive best supportive care (BSC) or hospice care. Balancing treatment efficacy and toxicities is key in treatment decision-making. IC is efficacious with extensive toxicities, while NIC has lower risk of toxicities but reduced efficacy. This study provides an international, multi-stakeholder perspective on the role of side effects in AML treatment decision-making. **Methods:** We conducted one-on-one, 60-minute interviews with 28 AML patients (>65 years, not receiving IC), 25 of their family members and 10 independent physicians from the US, UK and Canada. Interviews included open-ended questions to explore the treatment decision-making process. Participants also rated the importance of various factors in AML treatment decision-making from 0 (not important) to 3 (very important). **Results:** The sample included patients with varying treatment histories (13 no treatment, 11 on NIC, 3 discontinued NIC, 1 BSC). Side effects were rated as a 'very important' factor in treatment decision-making by a greater proportion of patients not on treatment (n = 9/13; 69.2%) and their relatives (n = 12/13; 92.3%) compared to those with experience of NIC (n = 5/11 who answered, 45.5%), their relatives (n = 3/11; 27.3%), and physicians (n = 4/10; 40.0%). When discussing side effects in detail, there was a disconnect between perceptions of patients not on treatment, and side effects that patients on NIC actually experienced. Many patients with no treatment experience were worried that side effects would be worse than their current symptoms (n = 6/13), referring to constant vomiting, hair loss, organ failure, or death. Fear of side effects was the primary reason for opting not to take treatment (n = 9/13), though it was not clear if these patients were distinguishing between IC and NIC. In contrast, although two patients' experiences of side effects resulted in them discontinuing NIC (n = 2/14), a higher proportion (n = 9/14) reported that the side effects had little impact on their life. Side effects most frequently reported by patients with experience of NIC (n = 11/14) were considered mild and included fatigue, reduced appetite, generally feeling unwell, nausea and injection site irritation (all n = 3). It was most commonly reported that the worst aspect of NIC was the time commitment (n = 4/8 asked). When accounting for different treatments paths no international variation in findings was observed. **Conclusions:** The nature and severity of side effects of AML treatment were perceived to be worse than reality. This incorrect perception may lead to undertreatment of patients and result in worse outcomes. There is a need for more patient education and resources about the lived treatment experience, to enhance understanding and mitigate pre-conceived notions of side effects. Research Sponsor: Pfizer.

7017 **Poster Discussion Session**

A registry-based, observational safety study of inotuzumab ozogamicin (InO) treatment in patients (pts) with B-cell precursor acute lymphoblastic leukemia (ALL) who proceeded to hematopoietic stem cell transplant (HSCT).

First Author: Marcos J.G. De Lima, University Hospitals Cleveland Medical Center, Cleveland, OH

Background: InO is a CD22-directed antibody-drug conjugate indicated for treatment of relapsed/refractory (R/R) ALL. InO has been associated with hepatotoxicity and hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS), particularly post-HSCT. Registry data (Center for International Blood and Marrow Transplant Research [CIBMTR]) was analyzed to assess toxicity in pts with ALL who received InO prior to HSCT. **Methods:** CIBMTR patient data are being collected for a 5-year period after US approval of InO (Aug 2017 – Aug 2022). Data from US pts age ≥18 y treated with InO who proceeded to allogeneic HSCT were included. Using interim data at 3 y, we evaluated post-HSCT outcomes, including clinical status, overall survival, transplant-related (non-relapse) mortality (NRM), relapse, death after relapse (time from HSCT to death after the first 28 d from any cause with prior relapse/progression post-HSCT), and investigator-defined adverse events, including hepatic VOD/SOS. All statistical analyses are descriptive. **Results:** Data accrued from 18 Aug 2017 to 17 Aug 2020 for 131 adult pts (median age 40 y) who proceeded to first allogeneic HSCT: 31% in first complete remission (CR1), 46% in CR2, 13% in ≥CR3, 5% in 1st relapse, 2% in ≥3rd relapse, and 3% in primary induction failure. A majority (70%) had transplants from peripheral blood stem cells, and 47% involved an HLA-identical sibling or other related donor. Nearly half received myeloablative conditioning regimens. Before HSCT, 36% of pts received 1 cycle of InO, 46% had 2 cycles, and 17% had ≥3 cycles. Half (48%) received InO as a single agent. Median time from last dose of InO to HSCT was 2.0 mo (range: 0.4–26.2). At time of data-lock (11 Nov 2020), post-transplant data were available for 131 pts. Outcomes for these pts are shown in the Table. Among a subgroup of adults with active R/R ALL (n = 91) at time of HSCT (median of 4 lines prior therapy), VOD/SOS incidence within 100 d of HSCT was 18%. **Conclusions:** Incidence of VOD/SOS after first HSCT in InO-treated pts with R/R ALL in this study was similar to the 18–19% reported in pooled analyses of 2 clinical trials among InO-treated pts with R/R ALL (Marks et al, *Biol Blood Marrow Transplant* 2019) and in the INOVATE study (Kantarjian et al, *Lancet Haematol* 2017). The NRM at 1 y of 21% (23% R/R ALL) is lower than the NRM at 1 y of 38% reported in the pooled analyses of R/R ALL InO recipients. Research Sponsor: Pfizer.

	Adults (n = 131)
VOD/SOS within 100 d post-HSCT, n (%)	17 (13)
Post-HSCT continued complete remission (CR)*, n (%)	117 (89)
Post-HSCT overall survival, 12 mo, % (95% CI)	55 (45–65)
HSCT-related mortality (NRM), 12 mo, % (95% CI)	21 (14–29)
Post relapse mortality, 12 mo, % (95% CI)	25 (17–33)
Post-HSCT relapse, 12 mo, % (95% CI)	36 (27–45)

*Continued CR is defined as a patient who underwent HSCT during CR, and the CR is sustained post-HSCT.

7018 **Poster Discussion Session**

Measurable residual disease response in acute myeloid leukemia treated with venetoclax and azacitidine.

First Author: Keith Pratz, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA

Background: In the phase 3 VIALE-A trial, rates of composite complete remission (CRc; complete remission [CR] + CR with incomplete hematologic recovery [CRi]) and measurable residual disease response (MRD$<10^{-3}$) were higher in patients (pts) treated with venetoclax (Ven) + azacitidine (Aza) compared to Aza alone (23.4%/7.6%, p<0.001). There is limited evidence of the clinical significance of MRD monitoring in pts receiving low-intensity chemotherapy. Herein, we explored the outcomes of pts treated with Ven+Aza who achieved both CRc and MRD$<10^{-3}$ in the VIALE-A trial (NCT02993523). **Methods:** Enrolled pts were ≥18 years and unfit for intensive chemotherapy. Pts received Ven 400 mg orally; days 1–28 and Aza 75 mg/m^2; days 1-7/28-day cycle. Bone marrow aspirate samples for multiparametric flow cytometry assessments by integrated leukemia-associated immunophenotypes and different than normal procedures were collected for central analysis (Covance Central Laboratory Services) at baseline, end of cycle 1, and every 3 cycles thereafter. Assessments were performed independent of disease responses. MRD response was defined as <1 residual blast /1000 leukocytes (<10^{-3}). CRc, DoR, OS, and EFS were assessed. Disease assessments were per modified International Working Group response criteria for AML. **Results:** 211/286 (74%) pts treated with Ven+Aza with at least one valid post-baseline MRD assessment were considered MRD evaluable; 78/211 (37%) achieved MRD$<10^{-3}$ and 133/211 (63%) had MRD≥10^{-3}. Median age (MRD$<10^{-3}$/ MRD≥10^{-3}) was 76 (range: 49-89)/77 (58-91) yrs. Pts (MRD$<10^{-3}$/ MRD≥10^{-3}) received median of 14.5 (range: 1-28) /7.0 (1-30) cycles of Ven+Aza. At median follow-up of 22.0 (range: 20.1-23.0)/20.8 (19.8-22.3) months (mos), CRc + MRD$<10^{-3}$/ MRD≥10^{-3} was achieved by 67 (86%)/ 97 (73%); 20/67 (30%) achieved CRc + MRD$<10^{-3}$ by end of cycle 1. Median DoR, OS, and EFS were not reached in pts with CRc + MRD$<10^{-3}$ response (Table). The 12-mo estimates for DoR, OS, and EFS for pts with CRc + MRD$<10^{-3}$response were 81.2%, 94.0%, and 83.2%, respectively. Adverse events ≥grade 3 (MRD$<10^{-3}$/ MRD≥10^{-3}) were febrile neutropenia (50%/43%), neutropenia (50%/35%), and thrombocytopenia (44%/44%), similar to the overall population. **Conclusions:** Pts with best response of CRc who achieved MRD$<10^{-3}$ response with Ven+Aza treatment had longer DoR, OS, and EFS than pts who were CRc and MRD positive. Clinical trial information: NCT02993523. Research Sponsor: AbbVie, Genentech.

DoR, OS, and EFS in patients with composite complete response treated with venetoclax and azacitidine.

Predictive phosphoproteomic signatures for midostaurin plus chemotherapy response in FLT3 mutant positive acute myeloid leukaemia.

First Author: Arran David Dokal, Kinomica Limited, Macclesfield, United Kingdom

Background: Midostaurin is approved for FLT3 mutant-positive (FLT3+) acute myeloid leukemia (AML), however efficacy has also been observed in a subpopulation of FLT3 mutant-negative AML, suggesting that FLT3 mutation is not the only determinant in conferring midostaurin sensitivity. We previously described a phosphoproteomic signature significantly elevated in primary AML blasts that responded to midostaurin *ex vivo* (Casado et al Leukaemia 2018). This signature includes phosphorylation sites on protein kinase C delta (a midostaurin off-target) and its substrate GSK3A. In this study, we tested whether these phospho-signatures could group FLT3+ patients based on clinical responses to midostaurin plus chemotherapy. **Methods:** We obtained FLT3+ bone marrow (BM) and peripheral blood (PB) diagnosis specimens (n=56 cases) from the Leukemia Tissue Bank at Princess Margaret Cancer Centre. These patients were treated with standard chemotherapy plus midostaurin. Phospho-signatures quantified using mass spectrometry were analysed with a classification machine learning algorithm to group patients based on response to treatment as a function of phospho-signature status. Other features (e.g. genetic mutations, HSC-transplant) were also analysed. Differential survival analysis was carried out with Kaplan-Meier and Log Rank test methods. Phospho-signatures for BM and PB samples were analysed independently. **Results:** A first ML model was developed based on the signature described in the Casado et al study. Patients positive for this signature exhibited a survival probability of 243 weeks, compared to 126 weeks in signature negative patients (averages by geometric mean, Log Rank p = 9.88e-05). As the patients in the current study received chemotherapy, in addition to midostaurin, we also identified a new signature consisting of 26 phospho-sites (model 2), which partially overlapped with the first model. Patients positive for model 2 signature showed a markedly longer survival time than negative patients (269 vs 76 weeks, Log Rank p = 1.30e-05 for PB and 241 vs 56, Log Rank p = 2.13e-09 for BM specimens, Table). No other features separated survival as clearly as model 2. **Conclusions:** We have identified phospho-signatures with the potential to further stratify FLT3+ AML for midostaurin treatment. The presence of PRKCD signalling components in signatures provides a rationale for midostaurin activity in sensitive cases. Analysis will also be performed on FLT3 mutant-negative cases to validate the signature in this group. Research Sponsor: Innovate UK, UK Research and Innovation, Pharmaceutical/Biotech Company.

	Signature	Cases	Events	Geometric Mean	SE	Median
PB samples	Negative	9	6	76	42	26
	Positive	25	2	269	15	ND*
BM samples	Negative	16	12	56	27	26
	Positive	37	6	241	20	ND*

Disease free survival in weeks as a function of model 2 phospho-signature. * Kaplan-Meier curves did not reach 50% reduction in disease free survival.

High dimensional mapping of temporal evolution within the marrow microenvironment in response to FLT3 inhibitor therapy.

First Author: Matthew Newman, Oregon Health & Science University, Portland, OR

Background: The advent of genomic sequencing technologies has revealed underlying genetic alterations, such as FLT3 mutations, that can be targeted in acute myeloid leukemia (AML). However, development of resistance limits the durability of response. Recent data has implicated that factors from the bone marrow microenvironment mediate initial resistance to FLT3 inhibitors (FLT3i) in AML. We combined high dimensional characterization techniques, time-of-flight mass cytometry (CyTOF) and RNA sequencing, to examine sequential marrow stromal samples from a subset of patients with FLT3 mutated AML treated with the FLT3i gilteritinib. Here, we report on the heterogeneity and evolution of cell surface and secreted factors over time. **Methods:** RNA sequencing of primary FLT3-ITD stromal samples (N = 29) from pre-study and on-treatment patients enabled prioritization of candidate targets for CyTOF. Target-specific purified antibodies were purchased pre-conjugated to metal lanthanides or conjugated in house according to manufacturer protocols (after validation via traditional flow cytometry). Primary stromal cells were cultured ex vivo until confluent and were harvested and stained according to a standardized protocol, and subsequently run on a Helios (Fluidigm) mass cytometer. A computational approach was employed to compensate and visualize data via the CATALYST R package. A total of four pre-treatment and four post-gilteritinib timepoint isolates (N = 8) were analyzed. **Results:** A 36-target mass cytometry panel revealed protein level differences in patients before and after gilteritinib therapy. Dimensional reduction techniques such as MDS and UMAP showed that samples taken from later timepoints clustered together compared to their earlier counterparts with respect to global protein expression. Inflammatory mediators such as IL1-beta and MCP-1 were upregulated in patient stroma soon after gilteritinib treatment and therefore potentially contribute to early resistance. Novel markers previously implicated in early resistance to targeted therapies in AML such as FGF2 and FGFR1 similarly peaked earlier in treatment, mimicking the clinical course of expression observed in marrow stroma of patients treated with another FLT3 inhibitor quizartinib (Traer et al. Cancer Res. 2016). **Conclusions:** Our findings show that primary marrow stroma evolves during gilteritinib treatment, and that stromal proteins previously reported to promote early resistance to FLT3i are also upregulated during gilteritinib resistance. The heterogeneity of stromal cell isolates detected by mass cytometry highlights the utility of high dimensional tracking of disease course in patients, and may enable a better understanding of how the temporal evolution of the marrow microenvironment contributes to development of resistance to targeted therapies such as gilteritinib and other FLT3i over time. Research Sponsor: U.S. National Institutes of Health.

7021 **Poster Session**

Effect of geriatric assessment (GA) and genetic profiling on overall survival (OS) of older adults with acute myeloid leukemia (AML). *First Author: Vijaya Raj Bhatt, Fred and Pamela Buffett Cancer Center, University of Nebraska Medical Center, Omaha, NE*

Background: GA can predict the risk of toxicities of chemotherapy in older adults. Genetic risk categories correlate with OS in AML. We previously reported a reduction in early mortality in a pre-planned interim analysis of a phase II trial with the use of GA and genetic profiling to personalize therapy selection (NCT03226418) (Blood 2019; 134(s1):120). Here, we present the results of a propensity score matched analysis demonstrating an improvement in OS over a historical control. **Methods:** Patients ≥60 years with a new diagnosis of AML underwent GA. Patients were considered fit for intensive chemotherapy if they had robust physical function [normal activities of daily living (ADL) and instrumental ADL, and short physical performance battery score of ≥10 out of 12], normal cognitive function (Montreal Cognitive Assessment score of ≥26 out of 30), and hematopoietic cell transplantation comorbidity index (HCT CI) of 0-2 (except for treatment related AML, where a score of 0-2 in addition to the prior history of malignancy was acceptable). Genetic profiling for therapy selection relied on karyotyping and followed the 2017 ELN criteria. Fit patients with good or intermediate-risk AML received intensive chemotherapy. Patients with high-risk AML received low-intensity chemotherapy, or CPX 351 if they were fit and met the FDA-approved indications. Pragmatic aspects of the trial included broad eligibility criteria (e.g. patients on treatment for other malignancy were enrolled) and co-management of patients with community oncologists. Mortality was compared with a historical control treated during the years 2004-2016 (after approval of HMA) and matched on gender, age, Karnofsky Performance Status (KPS), HCT CI and ELN risk category. **Results:** Treatment group (n = 27) vs. historical controls (n = 32) were matched in terms of age (median age, 70 vs. 68.5 years), ELN risk category (adverse risk 59% vs. 53%), HCT CI (median score of 2), KPS (median 80 vs. 85), and gender (male 44% vs. 50%). In the treatment group, 3 patients received intensive chemotherapy: CPX 351 (n = 2) or 7+3+ gemtuzumab (n = 1). Other patients received HMA alone (n = 16), decitabine and midostaurin (n = 3), or azacitidine and venetoclax after the approval of venetoclax (n = 5). Treatment in the historical control included intensive chemotherapy (n = 20) such as 7+3, or mostly HMA based low intensity chemotherapy (n = 12). OS was significantly higher in the treatment group over historical control with 1-year OS of 66% (95% CI 60-87%) vs. 16% (95% CI 7-35%). **Conclusions:** Our model to personalize AML therapy selection represents an innovative approach to precision medicine that incorporates both GA for patient profiling and genetic profiling of leukemia cells. Our results appear promising with superior OS (an absolute difference of 50% in 1-year OS) compared to a matched historical control. Clinical trial information: NCT03226418. Research Sponsor: U.S. National Institutes of Health.

Adult Philadelphia-like B-cell acute lymphoblastic leukemia: Characteristics, outcomes, and role of allogeneic hematopoietic cell transplantation in comparison to Philadelphia-positive and Philadelphia-negative acute lymphoblastic leukemia. *First Author: Zaid Abdel Rahman, Mayo Clinic, Jacksonville, FL*

Background: Philadelphia-like Acute Lymphoblastic Leukemia (Ph-like ALL) is a high-risk subset of adult ALL. Until recently, there has not been a systematic platform to recognize this entity in clinical practice. Furthermore, data regarding the role of allogeneic hematopoietic cell transplantation (allo-HCT) is lacking. We conducted this study to identify patients with Ph-like ALL and describe their outcomes in comparison to Ph^+ and Ph^- ALL with emphasis on the role of allo-HCT. **Methods:** To identify cases of Ph-like ALL, available diagnostic cytogenetic pellets for patients in the Mayo Clinic ALL cohort (N=365) were tested using a targeted fluorescence *in situ* hybridization (FISH) panel developed by the Mayo Clinic Genomics Laboratory and includes probes to detect Ph-like-specific rearrangements (i.e., *ABL1, ABL2, PDGFRB, JAK2* and *CRLF2*). **Results:** Thirty-three (9%) patients with Ph-like ALL were identified, the remaining patients were classified as Ph^+ (N=132, 36%) or Ph^- ALL (N=200, 55%). Patients with Ph-like ALL were younger (Median: 39 vs. 50 vs. 49 years, *P*=.01), had higher WBC (Median: 27.9 vs. 21.5 vs. 4.5 x10^9/L, *P*<.001), were less likely to achieve CR (91% vs. 99% vs. 96%, *P*=.02), more likely to be MRD+ (64% vs. 34% vs. 36%, *P*=.03), had a higher relapse rate (5-year: 39% vs. 24% vs. 38%, *P*=.01) and lower OS (5-year: 41% vs. 64% vs. 49%, *P*=.02), see Table. Patients who achieved MRD negativity had better OS (MRD+ vs MRD-, *P*=.01). Importantly, no statistically significant difference in OS, relapse or non-relapse mortality were noted between the 3 groups in patients who underwent allo-HCT in CR1. **Conclusions:** Ph-like ALL is a high risk subgroup with increased prevalence in younger adults. Allo-HCT appears to offset the poor prognosis associated with this entity. A targeted FISH panel offers timely recognition of this entity in a clinical setting. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Outcome	N	Ph-like ALL (N=33)	Ph+ ALL (N=132)	Ph- ALL (N=200)	P-value

Updated results from DIAMOND-01 (CLI24-001) trial: A phase I/II study of SEL24/MEN1703, a first-in-class dual PIM/FLT3 kinase inhibitor, in acute myeloid leukemia. *First Author: Scott R. Solomon, Northside Hospital Cancer Institute, Atlanta, GA*

Background: SEL24/MEN1703, a dual PIM/FLT3 kinase inhibitor, in the dose escalation (DE) DIAMOND-01 trial (CLI24-001, NCT03008187), showed an acceptable safety profile up to the recommended dose (RD) of 125 mg along with initial evidence of single agent activity and meaningful target engagement in heavily pre-treated patients (pts) with AML (Solomon et al, EHA 2020; Tomirotti et al, ASH 2020). Here we present updated data including pts enrolled in the Phase II, cohort expansion (CE) of the study. **Methods:** DIAMOND-01 trial enrolled pts unsuitable for chemotherapy having relapsed or refractory (R/R) (DE and CE) or previously untreated (DE) AML. Previous targeted therapies – except PIM inhibitors – were allowed. SEL24/MEN1703 was given orally, QD, 14 days ON / 7 days OFF until progression/unacceptable toxicity. The DE tested MEN1703 escalating doses from 25 to 150 mg, whereas in the CE the RP2D (125 mg) was administered. The key objectives of the CE were the confirmation of the safety profile determined in the DE along with further investigation of single agent activity. Adverse events (AEs) were graded according to NCI-CTCAE v.4.03; responses assessed as per ELN 2017 criteria. **Results:** As of January 21, 2021 (cut-off date), n = 48 pts were treated across DE (n = 25) and CE (n = 23). Median age was 69 (25-84) years. Overall, 20 (43%) and 15 (32%) pts had non de novo AML and primary refractory AML, respectively. Adverse karyotype was reported in 7 (15%) pts. Most frequently reported mutations were FLT3/ITD (23%, n = 11), DNMT3A (15% n = 7), NPM1 (15%, n = 7), IDH1 (13%, n = 6) and IDH2 (4%, n = 2), CEBPA (4%, n = 2), FLT3/TKD (2%, n = 1). Median number of cycles was 2 (1-8). At the RD (n = 30), most frequent serious treatment-emergent AEs (serious TEAEs) were pneumonia (23%), sepsis and febrile neutropenia (13%) and pulmonary mycosis (10%) whereas most frequent G≥3 TEAEs were febrile neutropenia and pneumonia (23%), leukocytosis (20%) and neutrophil count decrease, platelet count decrease, lymphocyte count decrease and sepsis (13%). Responses occurred in 2 pts in the CE, both with IDH1 mutant disease (naïve to IDH inhibitors) who achieved complete remission with incomplete hematologic recovery (CRi). Both responses occurred by Cycle 3, with a duration of 79 (ongoing at cut-off date) and 43 days, respectively. Across DE and CE, 4 CR/CRi occurred, three of which in pts with IDH mutations. A total of 3 out of 6 pts with IDH mutations treated at doses ≥75 mg achieved CR/CRi, including a CR in a patient with IDH2 mutant AML relapsed on Enasidenib. **Conclusions:** SEL24/MEN1703 confirmed a manageable safety profile at RD and showed preliminary single agent efficacy in R/R AML, particularly clustering in pts with IDH mutant disease either naïve or previously exposed to IDH inhibitors. These results warrant further investigation of SEL24/MEN1703 in AML, with potential focus in the IDH mutated subset. Clinical trial information: NCT03008187. Research Sponsor: Menarini Ricerche.

Molecular annotation of extramedullary acute myeloid leukemia to identify prevalence of targetable mutations. *First Author: Somedeb Ball, Division of Hematology and Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Extramedullary (EM) involvement, including myeloid sarcoma (MS) and leukemia cutis (LC), is uncommon in patients with acute myeloid leukemia (AML). Mutational landscape of EM-AML is not well characterized, including concordance of sequencing data from EM vs. non-EM site (blood or bone marrow) and the potential for personalized targeted therapy in this patient cohort. **Methods:** In a multicenter retrospective study, clinical and genomic data were collected on EM-AML patients treated at Moffitt Cancer Center, Memorial Healthcare System, and University of Miami, as well as sequenced cases at a central laboratory. Next generation sequencing (NGS) data come from panels that interrogated 24- 406 genes, with 15 genes covered by all panels, including notably, *IDH1*, *IDH2*, *KIT*, *KRAS*, *NPM1*, *NRAS*, and *TP53*. Survival estimates using Kaplan-Meier statistics and multivariate analysis with Cox-regression were performed in SPSS (v.26). **Results:** Our study included 58 patients with EM-AML. Median age at diagnosis was 62 years; 55% of patients were males. In our cohort, 34 (59%) patients had MS, and 19 (33%) had LC. EM-AML was noted during relapse in 60% of evaluable patients (n=45), and 31% had isolated EM disease. Patients with LC had a significantly worse median overall survival (OS) than those with MS (5.7 months vs. 21.9 months, p= 0.008); Pattern of EM involvement (MS vs. LC) remained an independent prognostic factor for OS (p= 0.04) in a multivariate analysis including disease setting (new diagnosis vs. relapse) and ELN risk category. Results of NGS performed during EM presentation were available in 48 patients, 19 of which had NGS data from EM site. Most commonly mutated genes were *NRAS* on EM site NGS (37%) and *NPM1* on non-EM site NGS (28%). Based on EM NGS, 52% patients had a targetable genomic alteration, with 37% mutations in *IDH*, 21% *NPM1*, 5% *FLT3*, and 11% *MLL-PTD*. Five (two with concurrent M+EM disease) out of nine evaluable patients had significant discordance in targetable mutations between EM and non-EM NGS at EM-AML. Three of four patients who received treatment with *IDH1/2* inhibitors based on EM NGS achieved complete response. **Conclusions:** EM-AML has a distinct molecular architecture with an inferior OS in LC vs. MS patients. We conclude that EM site NGS is critical in patients with EM-AML, as 52% have potentially targetable mutations and could benefit from specific targeted therapies. Research Sponsor: None.

Common EM site Mutations	*NRAS*	37%

Contemporary outcomes for adults with AML requiring ICU admission. *First Author: Danielle Hammond, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients (pts) with AML frequently encounter life-threatening complications requiring transfer to an intensive care unit (ICU). **Methods:** Retrospective analysis of 145 adults with AML requiring ICU admission at our tertiary cancer center 2018-19. Use of life-sustaining therapies (LSTs) and overall survival (OS) were reported using descriptive statistics. Logistic regression was used to identify risk factors for in-hospital death. **Results:** Median age was 64 yrs (range 18-86). 47% of pts had an ECOG status of ≥ 2 with a median of at least 1 comorbidity (Table). 117 pts (81%) had active leukemia at admission. 68 pts (47%) had poor-risk cytogenetics (CG) and 32 (22%) had TP53-mutated disease. 61 (42%), 27 (19%) and 57 pts (39%) were receiving 1st, 2nd and ≥ 3rd line therapy. 33 (23%) and 70 pts (48%) were receiving intensive and lower-intensity chemotherapy, respectively, and 77 pts (53%) were concurrently on venetoclax. Most common indications for admission were sepsis (32%), respiratory failure (24%) and leukocytosis (12%); Table outlines additional ICU admission details. Median OS from the date of ICU admission was 2.0 months (mo) for the entire cohort and 6.9, 1.6 and 1.2 mo in pts with favorable-, intermediate- and poor-risk CG. Median OS of pts receiving frontline vs. ≥ 2nd line therapy was 4.2 vs. 1.4 mo (P<0.001). Median OS in pts requiring 0-1 vs. 2-3 LSTs was 4.1 vs. 0.4 mo (P<0.001). OS was not different by age, co-morbidity burden nor therapy intensity. In a multivariate analysis that included SOFA scores, only adverse CG (OR 0.35, P = 0.028), and need for intubation with mechanical ventilation (IMV; OR 0.19, P = 0.009) were associated with increased odds of in-hospital mortality. **Conclusions:** A substantial portion of pts with AML survive their ICU admission with sufficient functionality to return home and receive subsequent therapy. In contrast to general medical populations, age, co-morbidities, and SOFA scores were not independently predictive of in-hospital mortality. Disease CG risk and the need for IMV were the strongest predictors of ICU survival. This suggests that many pts with AML can benefit from ICU care. Preliminary results of V-FAST, a phase 1b master trial to investigate CPX-351 combined with targeted agents in newly diagnosed AML. *First Author: Vinod Pullarkat, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: CPX-351 (US: Vyxeos; EU: Vyxeos Liposomal), a dual-drug liposomal encapsulation of daunorubicin and cytarabine in a synergistic 1:5 molar drug ratio, is approved by the US FDA and EMA for adults with newly diagnosed t-AML or AML with myelodysplasia-related changes. Preclinical data suggest CPX-351 may exert synergistic activity when combined with agents such as the BCL-2 inhibitor venetoclax (VEN) or FLT3 inhibitor midostaurin (MIDO). **Methods:** V-FAST (Vyxeos – First Phase Assessment With Targeted Agents) is an open-label, multicenter, phase 1b master trial (NCT04075747) to evaluate safety and establish the recommended phase 2 dose (RP2D) of CPX-351 combined with targeted agents in patients (pts) aged 18-75 y with untreated AML who are fit for intensive chemotherapy. The study includes a dose-exploration phase (3+3 design) and subsequent expansion phase. Pts received CPX-351 (dose level 1 for first induction [DL1]: 100 units/m^2 on Days 1, 3, and 5) plus VEN (Arm A; DL1: 400 mg on Days 1-14), MIDO (Arm B; DL1: 50 mg BID on Days 8-21), or the IDH2 inhibitor enasidenib ([ENA] Arm C; DL1: 100 mg on Days 8-28) based on mutation testing. **Results:** Among 21 pts with available data enrolled by 11/06/20 (24 pts enrolled total; data cut-off: 01/19/21), the median age was 54 y (range: 35, 69). In Arm A (n = 17), 11 (65%) pts had *de novo* AML, 5 (29%) had an antecedent hematologic disorder (2 [12%] had myelofibrosis), and 2 (12%) had t-AML; 12 (71%) had adverse-risk AML; and 6 (35%) had mutated *TP53*. In Arms B (n = 3) and C (n = 1), all pts had intermediate-risk *de novo* AML. DL1 was the RP2D in Arms A and B; the RP2D in Arm C is still under investigation. In Arm A, 1/6 pts in the dose-exploration phase had 2 dose-limiting toxicities (DLTs) of grade 4 neutropenia and thrombocytopenia that extended beyond 49 days; no DLTs have occurred for Arms B and C. The combinations exhibited manageable safety profiles (Table). Of pts with available response data, complete remission (CR) or CR with incomplete platelet or neutrophil recovery was achieved by 6/14 (43%) pts in Arm A, including 4 (29%) with CR. All pts in Arms B and C achieved CR. **Conclusions:** These preliminary results suggest CPX-351 can be combined with VEN and MIDO with manageable toxicities in newly diagnosed AML pts, with DL1 determined to be the RP2D. The study is ongoing and actively enrolling pts; updated results will be presented at the meeting. Clinical trial information: NCT04075747. Research Sponsor: Jazz Pharmaceuticals.

Cellworks Omics Biology Model (CBM) to predict therapy response and identify biomarkers for all-*trans* retinoic acid (ATRA) benefit as addition to induction chemotherapy in adults with acute myeloid leukemia (AML). *First Author: Scott C. Howard, University of Tennessee Health Sciences Center, Memphis, TN*

Background: ATRA combined with arsenic trioxide revolutionized the treatment of APL. Based on promising *in vitro* data, several clinical trials evaluated ATRA combinations in non-APL AML, in which some patients seemed to benefit from the addition. Thus, predicting response *a priori* is imperative to determine the optimal treatment for each patient. The CBM was used to evaluate the impact of initial therapy with ATRA combined with cytarabine, etoposide, idarubicin (ATRA-CEI) to assess the biomarkers responsible for response in adults with AML. **Methods:** AML patients participating in clinical trial NCT00151242 had their leukemia sequenced as part of the trial, and genomic profiles were used for computational modeling by the CBM, which uses curated data about genomic aberrations from PubMed as input to generate disease-specific protein network maps and predict drug responses. Disease biomarkers unique to each patient were identified using biosimulation. Digital drug simulations were conducted by measuring the effect of ATRA-CEI on a composite cell growth score of cell proliferation, apoptosis and other hallmarks of cancer. ATRA-CEI was mapped to the patient genome along with a mechanism of action and validated based on the genomic profile and its biological consequences. **Results:** Of 171 patients treated with ATRA-CEI, 107 (63%) responded (R) and 64 did not (NR). A subset of 18 patients with favorable genomic features were found to be NR and their non-response was correctly predicted by CBM in all 18 cases. Mutations of *DNMT3A, EZH2, ASXL, FLT-3*, and GART amplification emerged as novel biomarkers of ATRA-CEI failure (only 37 of 107 responders (35%) with these findings, compared to 70 of 107 responders (65%) without these findings (p = 0.0027)). *DNMT3A, EZH2, ASXL1* loss of function mutations activate *FABP5*, a key mechanism of ATRA resistance, and also activate *ABCC1* (PgP), which reduces the efficacy of etoposide and idarubicin by upregulating *MDR1*. In general, monosomy 7 is expected to confer ATRA resistance due to the presence of *EZH2* and *KMT2E* gene deletions. Indeed, 18 of 32 patients with monosomy 7 did not respond. However, the 14 who responded had co-occurrence of deletions involving *IGFBP3, PMS2, HUS1, CDK5, XRCC2/4, AKR1B10,* and others that overcame ATRA resistance associated with monosomy 7 and were identified by CBM. Use of CBM helps avoid unnecessary use of ATRA in patients unlikely to respond (19% of cases) thus reducing toxicity and cost without changing efficacy, and also identifies those likely to respond, even when they have monosomy 7, where non-response is the norm. **Conclusions:** ATRA benefits a subset of patients with non-APL AML. CBM predicted response using computational modeling of all genetic alternations, which explains its success versus traditional one-gene-one-drug approaches. Research Sponsor: None.

Clinical utility of whole genome sequencing in hematological neoplasms. *First Author: Jesus Gutierrez-Abril, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Hematological neoplasms are often characterized by acute onset and rapid disease progression. Cytogenetics, FISH, SNP arrays, targeted DNA and RNA sequencing are performed to inform diagnosis, risk stratification and guide treatment decisions. Whole genome sequencing (WGS) offers the opportunity to comprehensively characterize all putative biomarkers in a single assay. However, a limitation in current WGS implementation is the requirement for a germline sample, as sources of control tissue are frequently contaminated with leukemic cells resulting in false negative calls. **Methods:** To evaluate the clinical utility and feasibility of WGS in the diagnostic work up of leukemias, we analyzed 57 B-cell acute lymphoblastic leukemia (B-ALL) from the UKALL14 trial (NCT01085617) with no informative biomarkers at diagnosis. WGS analysis was performed on the leukemic sample and a matching control sample (with minimal residual disease level of <1%). Using this dataset, we trained the development of an unmatched (uWGS) analytical workflow (Isabl) for a tumor only WGS study. This workflow was validated across 20 hematologic neoplasms (12 B-ALL, 6 AML and 2 T-ALL). **Results:** Among the 57 cases, 5 failed QC owing to low tumor content (<25%). Of the remaining 52, putative biomarkers of clinical relevance were identified by WGS in 69% (36/52). These included delineation of aberrant karyotypes where conventional chromosome banding failed (4/52), the detection of newly described fusion genes (such as *IGH-DUX4* and *EP300-ZNF384* in 21/52) and recurrent gene mutations (i.e. *PAX5* P80R, *ZEB2* H1038R in 11/52). uWGS workflow in our training dataset captured 86% of biomarkers identified in the matched analysis (3/3 ploidy, 21/22 fusion and 7/11 coding). Concordance between the matched and uWGS workflow for arm-level and focal copy number alterations (CNAs), structural variants (SVs) and annotated hotspot mutations were 94%, 84%, 83% and 100% respectively. Independent validation of the uWGS workflow across 20 myeloid and lymphoid neoplasms, recapitulated all clinically reported biomarkers (14/15 CNAs, 16/16 SVs) as well as captured two novel findings not previously detected in two B-ALL patients, to include a focal deletion in *BTG1* and the fusion gene *P2RY8-CRLF2*, as well as a *NOTCH1* translocation in T-ALL. **Conclusions:** Our findings demonstrate that comprehensive WGS allows for the detection of the same biomarkers as a range of clinical assays using a single test, as well as the opportunity to discover novel clinical and research findings to support future correlative research and biomarker development. Additionally, we developed and validated an uWGS workflow that allows WGS analysis of hematopoietic neoplasms at diagnosis, enabling detection and reporting of clinically relevant biomarkers. Retrospective analysis of a novel molecular genetic risk score, "MRplus", in BCR-ABL1 negative pediatric B-ALL: A single-center experience. *First Author: Sanjeev Kumar Gupta, Dr BRAIRCH, All India Institute of Medical Sciences, New Delhi, New Delhi, India*

Background: Currently, the molecular risk scoring is variably used in the management algorithms of B-ALL across various clinical cohorts. Unlike AML, the usage of molecular genetic abnormalities in the risk-stratification of B-ALL is limited and a consensus is yet to be reached. We have retrospectively analyzed the utility of molecular genetic risk criteria, previously described by Moorman et al. (2014), and Stanulla et al. (2018), in our cohort and hereby propose a novel molecular risk score, "MRplus", obtained by combining both criteria, as a useful way to improve the risk-stratification of BCR-ABL1 negative pediatric B-ALL. **Methods:** In this retrospective observational study, the genomic DNA of untreated BCR-ABL1 negative pediatric B-ALL cases was analyzed at baseline for copy number alterations of IKZF1, PAX5, CDKN2A/B, BTG1, RB1, ETV6, EBF1, ERG, pseudoautosomal region (PAR) genes– (CRLF2, CSF2RA, IL3RA), using multiplex ligation-dependent probe amplification (MLPA)- P335, P202 and P327 kits (MRC Holland). The cases were assigned a score- 0 for low and 1 for high genetic-risk as per the criteria by Moorman et al., and another score as per the criteria by Stanulla et al., 1 for IKZF1-plus cases and 0 for other cases. The final "MRplus" risk-score of 0 (low), 1 (intermediate) or 2 (high) was given by adding both these scores. All patients were treated using Indian Childhood Collaborative Leukemia Group protocol (ICICLE). The post-induction remission status, overall survival (OS) and event free survival (EFS) was noted for all patients. **Results:** Out of 320 cases with median age of 6 years (1-18 years), 141 (44.1%) cases had high genetic-risk (score 1) as per the Moorman's criteria. Thirty-two (10%) cases fulfilled the criteria of IKZF1plus (score 1) as per the criteria of Stanulla et al. The final "MRplus" score of 0, 1 and 2 was obtained in 179 (55.9%), 109 (34.1%) and 32 (10%) cases respectively. Out of these, 284 received treatment including 160, 101, and 23 cases with "MRplus" score 0, 1, and 2 respectively. The follow up period was upto 80 months with a median of 34.6 months. The post-induction remission rate was 90.6%, 78.2%, 73.9% ($p = 0.008$); 4-year OS 68%, 48%, 27% ($p < 0.001$); and 4-year EFS 57%, 36%, 19% ($p < 0.001$) in cases with "MRplus" score 0,1, and 2 respectively. **Conclusions:** The proposed novel "MRplus" scoring at baseline could identify three distinct risk- groups-low, intermediate and high, in BCR-ABL1 negative pediatric B-ALL. This may help in better identification of patients for alternative treatment approaches and also triage patients for further detailed genomic analysis for disease biology; with particular emphasis on those with intermediate and high "MRplus" score. TP53/NPM1-mutated acute myeloid leukemia as a molecularly distinct disease entity. *First Author: Frank J Scarpa, NeoGenomics Laboratories, Aliso Viejo, CA*

Background: TP53-mutated acute myeloid leukemia (AML) is a distinct disease entity associated with a dismal prognosis. This disease group is distinguishable by its low frequency of SNVs, unremarkable transcriptional signatures, and lower leukocyte and myeloblast counts compared to TP53 wildtype disease. Response to gold-standard hypomethylating agents is typically transient. NPM1 mutations in this disease subset are rare despite the fact that NPM1c has been shown to negatively regulate the tumor suppressive functions of p53.**Methods:** Bone marrow, peripheral blood, or FFPE tissue samples from 10,118 patients with suspected myeloid disease were sequenced using a dual DNA/RNA 297 gene myeloid panel. Results were validated in a separate independent dataset using a 54 gene TruSight myeloid panel (N = 2463). FISH/cytogenetic data was analyzed across myeloid disease. Patients with confirmed AML (n = 460) were included in the NGS portion of this study. Statistics were performed using Fisher's exact test for categorical variables and two-tailed T-test for continuous variables. **Results:** All TP53-mutated myeloid disease (n = 1282 / 10,118) was associated with fewer co-mutations except DNMT3A (13.4%; n = 172), and complex cytogenetics (36.4%; n = 134/381). TP53+/NPM1+ status across all myeloid disease was not associated with a complex karyotype (7.6% vs 38.5%; 1/13 vs. 133/368, p = 0.02). Among AML patients, NPM1+/TP53+ patients (n = 18) were more co-mutated with DNMT3A (33.3% vs. 10.3%, P = 0.01), FLT3 (33.33% vs. 2.5%, $P < 0.0001$), IDH1 (27.8% vs. 4.4%, P = 0.002), IDH2 (22.2% vs. 6.4%, P = 0.03); and PTPN11 (22.2% vs. 2.5%, P = 0.003) when compared to TP53+/NPM1- patients. NPM1+/TP53+ AML had more mutations in recurrently mutated genes (4.5 vs 2.1; $P < 0.0001$) than TP53+/NPM1- AML. **Conclusions:** TP53+/NPM1+ AML harbors molecular signatures which clearly distinguish it from ordinary TP53-mutated AML, and is more reflective of *de novo* and NPM1+ AML. Further clinical outcome studies are needed to determine the therapeutic and prognostic implications of this subset, and whether other TP53-mutated patients can be better risk stratified. Research Sponsor: None.

Predictors of clinical trial enrollment and impact on outcome in children and adolescents with acute lymphoblastic leukemia: A population based study. *First Author: Paul James Gibson, McMaster Children's Hospital, Hamilton, ON, Canada*

Background: Outcomes in pediatric acute lymphoblastic leukemia (ALL) have shown remarkable improvements in large part due to sequential clinical trials. Concerns however persist around whether access to clinical trials is equitable. It is also unclear whether patient outcomes are improved simply by enrolling on a clinical trial. Our objective was to therefore determine which patient and disease-related factors are associated with enrollment, and whether enrollment was associated with clinical outcomes among children and adolescents with ALL in a single-payer health system in Ontario, Canada. **Methods:** We included all Ontario patients diagnosed with ALL between 0-18 years of age from 2002-2012 treated at a pediatric center, identified through a provincial pediatric cancer registry. Clinical trial availability was determined by whether each patient's primary institution had an open frontline trial for which the patient was eligible at the time of their diagnosis, considering individual disease characteristics such as lineage, central nervous system (CNS) status and risk group. Demographic, disease, trial enrolment, and outcome data were obtained through chart abstraction. Logistic regression models determined factors associated with trial enrolment, while Cox proportional hazard models determined factors associated with event-free and overall survival (EFS, OS). **Results:** Of 858 patients, 693 (81%) were eligible for an open clinical trial at their time of diagnosis. 476 (69%) enrolled on a trial. In adjusted analyses, age > 15 years (odds ratio 0.4 vs. age 5-9, 95th confidence interval (95CI) 0.2-0.8; p = 0.01) and CNS3 disease (OR 0.38 vs. CNS1, 95CI 0.17-0.83; p = 0.01) were significantly associated with decreased likelihood of enrolment, while sex and neighborhood income quintile were not associated with enrolment. Adjusted for disease and demographic factors, clinical trial enrolment was not significantly associated with either EFS (hazard ratio (HR) 1.1, 95CI 0.7-1.7; p = 0.83) or OS (HR 1.3, 95CI 0.7-2.5; p = 0.44). **Conclusions:** The majority of patients with ALL eligible for available clinical trials at their time of diagnosis were enrolled. While no disparities in enrolment by income status were noted, adolescents were substantially less likely to participate in trials even within pediatric centers. Studies of mechanisms underlying this disparity are warranted in order to design and implement effective interventions targeting increased enrolment rates in this patient population. Our results however also suggest that clinical trial enrolment on its own is not associated with improved outcomes in the context of a single payer health system. Distress in a pandemic: The association of the coronavirus disease-2019 (COVID-19) pandemic with distress and quality of life in hematopoietic stem cell transplantation (HSCT). *First Author: Hermioni L. Amonoo, Dana–Farber Cancer Institute, Boston, MA*

Background: The global COVID-19 pandemic has drastically disrupted cancer care, potentially exacerbating patients' distress levels. Patients with hematologic malignancies undergoing HSCT may be especially vulnerable to this pandemic stress given their well-documented heightened psychological distress and impaired quality of life (QOL). However, the association of the COVID-19 pandemic with distress and QOL is not well understood. **Methods:** We conducted a cross-sectional analysis of data from 205 patients with hematologic malignancies undergoing HSCT who were enrolled in a multi-site, randomized supportive care trial. We compared baseline pre-HSCT distress (depression, anxiety, and posttraumatic stress disorder [PTSD] symptoms) and QOL between participants enrolled pre-COVID-19 (i.e., 03/2019-01/2020) and during the COVID-19 pandemic (i.e., 03/2020-01/2021). We used the Hospital Anxiety & Depression Scale, PTSD Checklist, and Functional Assessment of Cancer Therapy-Bone Marrow Transplant to assess symptoms of depression, anxiety, and PTSD, as well as QOL respectively. We used regression models adjusting for age, gender, race, relationship status, and cancer diagnosis to examine the relationship between the period of enrollment and patient-reported distress and QOL. **Results:** Prior to COVID-19, 124 participants enrolled, and 81 participants enrolled during the COVID-19 pandemic. The two cohorts had similar baseline demographic and disease risk factors. Most participants were non-Hispanic (n = 185; 90.2%), White (n = 138; 86.3%), and female (n = 131; 64.5%) with a mean (SD) age of 54.9 (11.7) years. In multivariate regression models, enrollment during COVID-19 was not associated with pre-HSCT depression (B = 0.004; 95% CI, -0.02 to 0.03; p = 0.73), anxiety (B = 0.008; 95% CI, -0.01 to 0.03; p = 0.44), PTSD (B = 0.004; 95% CI, -0.004 to 0.01; p = 0.35) symptoms or QOL (B = -0.003; 95% CI, -0.02 to 0.01; p = 0.68). **Conclusions:** Contrary to the widespread notion that the COVID-19 pandemic has worsened distress in patients with cancer, we found no differences in pre-HSCT distress or QOL in patients with hematologic malignancies undergoing HSCT prior to or during the COVID-19 pandemic. Our findings highlight the need to comprehensively explore the multifactorial causes (e.g., illness experience, treatment burden) of distress and QOL deficits in HSCT recipients irrespective of the COVID-19 pandemic. Research Sponsor: U.S. National Institutes of Health, U.S. National Institutes of Health.

Outcomes with COVID-19 in hematopoietic stem cell transplant and cellular therapy patients. *First Author: Muhammad Umair Mushtaq, Division of Hematologic Malignancies and Cellular Therapeutics, University of Kansas Medical Center, Kansas City, KS*

Background: The Coronavirus Disease 2019 (COVID-19) has caused over 25 million infections in the US with over 0.4 million deaths. Hematogenic stem cell transplant (HCT) or cellular therapy (CT) recipients have a high risk of mortality with COVID-19 due to profound immune dysregulation. We aimed to assess the outcomes with COVID-19 in HCT/CT recipients. **Methods:** A single-center prospective study was conducted, including all (n=40) adult HCT/CT patients who were diagnosed with COVID-19 at the University of Kansas from Apr 2020 to Jan 2021. Baseline and disease-related characteristics were ascertained from medical records. Data were analyzed using SPSS version 21 (SPSS Inc, Chicago, IL). Bivariate analyses, using chi-square and t-test, and logistic regression analyses were conducted. **Results:** The study included 40 COVID-19 patients (72.5% Oct 2020-Jan 2021), including allogeneic HCT (n=25), autologous HCT (n=13) and CAR-T CT (n=2) with median time since HCT/CT of 12.4 (1-201.9), 37.2 (0.4-118.7), and 3.8 (2.8-4.8) months. Seventy percent were Caucasians and 17.5 were Hispanics. Primary hematologic malignancy was myeloid (37.5%), lymphoid (35%) or plasma cell disorder (27.5%). Myeloablative conditioning was performed in 65% of patients. Donors were autologous (37.5%), matched sibling (17.5%), matched unrelated (22.5%) and haploidentical (22.5%). COVID-19 was mild (42.5%), moderate (42.5%) or severe (15%). Clinical findings included pneumonia (62.5%), hypoxia (25%) and ICU admission (17.5%) while therapies included remdesivir (47.5%), convalescent plasma (40%), dexamethasone (25%) and monoclonal antibodies (17.5%). Concurrent cancer treatment, other infections and active GVHD were reported in 25% (all myeloma), 20% and 32.5% of patients. After a median follow-up of 74 days (7-269), the mortality rate was 12.5% in all patients and 20% in allo-HCT patients. Significant predictors of COVID-19 severity included allogeneic HCT, concurrent immune suppression and elevated inflammatory markers. (Table). **Conclusions:** Hematopoietic stem cell transplant recipients have an increased risk of mortality with COVID-19. Our findings confirm the need for vaccination prioritization, close monitoring, and aggressive treatment in HCT/CT patients. Research Sponsor: None.

Characterizing advance care planning, palliative care utilization, and location of end-of-life for adult allogeneic hematopoietic stem cell transplant recipients. *First Author: Stephanie Hoffman, University of Michigan Rogel Cancer Center, Ann Arbor, MI*

Background: The impacts of advance care planning (ACP) on end-of-life (EOL) outcomes in allogeneic hematopoietic stem cell transplant (allo HCT) recipients are not well known. ACP includes advance directive (AD) completion, and palliative care (PC) consultation. Using these two components, we aimed to explore the current state of ACP and its impact on EOL outcomes in allo HCT recipients to provide the groundwork for future prospective studies. **Methods:** We performed a retrospective study of deceased adult patients who underwent allo HCT between December 2015-December 2019. We summarized patient characteristics, the rate of AD completion, PC consultation, and location of end-of-life (EOL). Univariate and multivariate analyses were performed to evaluate patient characteristics that may be associated with AD completion, PC consultation and assess the impact of these two factors on location of EOL. **Results:** See Table for summary of patient characteristics. Of the 125 patients included, we found that 66% (n = 82) completed ADs. All patients with ADs completed them prior to undergoing transplant and never modified them. The majority of patients (84%) with an AD expressed the desire to avoid life-sustaining treatment in the event of terminal illness or irreversible coma. PC was consulted for 46% (n = 58) of patients within 6 months prior to time of death (TOD). Regarding location of EOL, 30% of all patients died in the hospital (non-ICU), 20% in the ICU, 38% at home with hospice, and 10% in a hospice facility. Patients with ADs appeared more likely to die outside of the hospital compared to those without (53% vs. 44%, p = 0.4506). By multivariate analysis, there were no significant patient characteristics associated with the presence of an AD or PC consultation. After adjusting for age and comorbidity index, we found that patients with an AD were significantly more likely to die outside of the ICU (OR 3.0, 95% CI 1.2-7.5, p = 0.02), an effect that was further amplified in patients who both had an AD and received PC consultation at any point (n = 30, p = 0.0077). **Conclusions:** Our findings highlight the importance of ACP for EOL outcomes in the allo HCT population. While the rate of AD completion in our study population is higher than that of prior studies, future prospective studies aimed to improve the rate of ACP are needed. Research Sponsor: None.

Early results of phase 1 study of JSP191, an anti-CD117 monoclonal antibody, with non-myeloablative conditioning in older adults with MRD-positive MDS/AML undergoing allogeneic hematopoietic cell transplantation. *First Author: Lori S. Muffly, Stanford University, Stanford, CA*

Background: Myeloablative allogeneic hematopoietic cell transplantation (AHCT) is potentially curative for myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML), but toxicities of conditioning limit its use in older or frail patients. Non-myeloablative (NMA) conditioning achieves better tolerability, at the expense of higher rates of relapse. We have developed a first-in-class monoclonal antibody (mAb), JSP191, which inhibits stem cell factor binding to CD117 (c-Kit), thereby depleting normal and MDS/AML disease-initiating hematopoietic stem cells (HSC). In pre-clinical models, anti-CD117 mAbs potently synergize with low dose total body radiation (TBI) to deplete HSC and facilitate donor cell engraftment. We reasoned that adding JSP191 to a standard NMA conditioning of 2 Gy TBI and fludarabine (Flu) would be safe and result in depletion of measurable residual disease (MRD) in older adults with high-risk MDS/AML entering AHCT. **Methods:** We report on the first 6 enrolled subjects in our Phase 1 trial (NCT#04429191) of JSP191/TBI/Flu as AHCT conditioning in MDS/AML patients, ≥ 60 years, with MRD detected by cytogenetics (cyto), difference from normal flow cytometry (flow), and/or next-generation sequencing (NGS). Primary endpoints are safety and tolerability of JSP191/TBI/Flu and JSP191 pharmacokinetics. Secondary endpoints include engraftment, donor chimerism, MRD clearance, GVHD, NRM, EFS, and OS at 1 year. JSP191 at 0.6 mg/kg was administered intravenously; serum concentration of JSP191 was used to confirm timing to begin Flu at 30 mg/m^2/day x 3 days [Transplant Day (TD)-4, -3, -2] and TBI 2 Gy on TD0. Peripheral blood grafts from HLA-matched related or unrelated donors were administered on TD0 (10-13 days after JSP191). GVHD prophylaxis was tacrolimus, sirolimus, and mycophenolate mofetil. **Results:** All subjects are still on trial, and there have been no infusion toxicities and no JSP191-related serious adverse events. All subjects engrafted with neutrophil recovery TD+19 to TD+26, and showed ≥94% donor myeloid chimerism in the blood at TD+28. All 3 evaluable subjects with TD+90 follow up showed complete donor (≥95%) total and myeloid chimerism and MRD elimination (Table). **Conclusions:** These early results are the first to demonstrate that JSP191/TBI/Flu is safe, well-tolerated, and capable of clearing MDS/AML MRD in older adults undergoing NMA AHCT. Clinical trial information: NCT04429191. Research Sponsor: Jasper Therapeutics.

Phase 1 trial of anti-CD22 recombinant immunotoxin moxetumomab pasudotox combined with rituximab for relapsed/refractory hairy cell leukemia. *First Author: Robert J. Kreitman, Laboratory of Molecular Biology, NCI, NIH, Bethesda, MD*

Background: Anti-CD22 recombinant immunotoxin moxetumomab pasudotox (Moxe) is FDA-approved for hairy cell leukemia (HCL) patients who have received at least two prior systemic therapies including a purine nucleoside analog. In phase 3 testing the complete remission (CR) rate was 41%, and response was higher in patients with lower tumor burden and lower titers of antidrug antibodies (ADA). Phase 1 testing indicated that most CRs were without minimal residual disease (MRD) and eradication of MRD was associated with prolonged CR duration. Monoclonal antibody (Mab) rituximab binds to CD20 on HCL cells and induces apoptosis or immune-mediated killing, but as a single-agent achieved only 13% CRs in relapsed HCL requiring therapy. In a phase 1 trial to determine safety, rituximab was combined with Moxe, with the goal to help reduce tumor burden and to prevent or delay ADA by killing normal B-cells. **Methods:** To allow rituximab sufficient time to accomplish both goals, it was infused 3 days before day 1 of cycle 1 at 375 mg/m^2, and Moxe was given by 30-minute infusion on days 1, 3 and 5. On repeat cycles of Moxe days 1, 3 and 5, rituximab was given on day 1. Cycles were generally spaced 4 weeks apart. Moxe was begun at a lower dose, 30 rather than the 40 mcg/kg dose used in phase 3 in case the rituximab would increase its toxicity. Bone marrow aspirate flow cytometry, which can detect 0.002% HCL cells, was the most sensitive test used for MRD detection, much more sensitive than BRAF V600E digital droplet PCR (ddPCR) or bone marrow biopsy immunohistochemistry (IHC). Patients could receive 4 cycles past MRD-free CR, but not more than 8 cycles. **Results:** Three patients received Moxe at 30 mcg/Kg/dose and 6 received 40 mcg/Kg/dose, all without dose limiting toxicity (DLT). There was no evidence of hemolytic uremic syndrome or capillary leak syndrome. To prevent intravascular hypovolemia due to expected third spacing, patients were encouraged to drink one cup per hour of water or other fluid from days 1 to 8 and take dexamethasone 4 mg orally if headache or nausea prevented good oral hydration. Of the 9 patients, 7 (78%) achieved CR after 2 (n = 6) or 3 (n = 1) cycles, and achieved MRD-free CR after 2 (n = 3), 4 (n = 3) or 6 (n = 1) cycles. No patients became infected with COVID-19. **Conclusions:** This phase 1 trial met its primary endpoint of determining whether rituximab could be safely combined with Moxe and will enroll 4 additional patients to further access clinical activity. Further testing will determine whether addition of a CD20 Mab to Moxe significantly improves clinical outcome compared to Moxe alone, particularly long-term MRD-free CR rate. Clinical trial information: NCT03805932. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

The effect of body mass index on efficacy and safety of bosutinib or imatinib in patients with newly diagnosed chronic myeloid leukemia.

First Author: Tim H. Brümmendorf, Universitätsklinikum RWTH Aachen, Aachen, Germany

Background: Bosutinib (BOS) is approved for the treatment (Tx) of Philadelphia chromosome–positive (Ph+) chronic myeloid leukemia (CML) resistant/intolerant to prior therapy and newly diagnosed Ph+ chronic phase (CP) CML. Body mass index (BMI) was shown to influence Tx response with front-line dasatinib vs imatinib (IMA). We report the efficacy and safety of BOS and IMA by BMI in patients (pts) with newly diagnosed CP CML. **Methods:** In the open-label BFORE trial, pts were randomized to receive 400 mg once daily BOS or IMA. Outcomes were assessed according to baseline BMI ≥25 or = 25 kg/m^2. This post hoc analysis was based on the final 5-y analysis (database lock: June 12, 2020). **Results:** In the BOS and IMA arms, respectively, 149 (56.4%) vs 115 (43.6%) pts and 145 (54.3%) vs 122 (45.7%) pts had BMI ≥25 vs = 25. In both the BOS and IMA arms, median Tx duration and time on study was 55 mo for pts with BMI ≥25 or = 25; respective median dose intensity was 394 vs 393 mg/d and 400 vs 400 mg/d. Molecular response (MR) rates are shown in the table. Cumulative incidence of major MR was similar in pts with ≥25 vs = 25 receiving BOS (HR 0.99; 95% CI 0.74−1.31) or IMA (HR 1.09; 95% CI 0.81−1.47). Event-free survival (EFS) and overall survival (OS) rates at 60 mo are shown in the table. Most common reasons for Tx discontinuation were adverse events (AEs) (BOS 28.2 vs 20.0%; IMA 13.3 vs 10.7%) and lack of efficacy (BOS 5.4 vs 5.2%; IMA 16.1 vs 19.8%). In pts with BMI ≥25 vs = 25, dose reductions and interruptions due to Tx-emergent AEs (TEAEs) occurred in 43.6 % vs 46.2% and 66.4% vs 69.7% of pts with BOS and 24.5% vs 24.6% and 40.6% vs 50.8% with IMA. Any grade TEAEs in ≥30% of pts with BMI ≥25 vs = 25 were diarrhea (73.8 vs 73.1%), nausea (40.9 vs 31.9%), thrombocytopenia (30.9 vs 41.2%), increased alanine (37.6 vs 28.6%) and aspartate aminotransferase (30.2 vs 20.2%) with BOS and diarrhea (49.0 vs 29.5%), nausea (46.2 vs 37.7%), muscle spasms (33.6 vs 26.2%), neutropenia (14.7 vs 32.0%) and thrombocytopenia (10.5% vs 30.3%) with IMA. **Conclusions:** Efficacy of BOS was consistent in pts with BMI ≥25 or = 25; however, with IMA a low (vs high) BMI appeared to be associated with worse survival outcomes. Differences in certain TEAEs were observed between BMI subgroups in both treatment arms. Clinical trial information: NCT02130557. Research Sponsor: Pfizer Inc.

Novel application of Kaplan-Meier methods to model tolerance for nonadherence to imatinib in patients with chronic myeloid leukemia (CML) in the ADAGIO study.

First Author: Mavis Obeng-Kusi, Center for Health Outcomes and Pharmacoeconomic Research, and Department of Pharmacy Practice and Science, Tucson, AZ

Background: Although adherence to imatinib treatment has been shown to be critical for attaining treatment response among patients with CML, some studies have suggested a 7.3-9.9% nonadherence tolerance margin before loss of treatment effects. We aimed to model probabilistically the margin of tolerance required to ensure treatment response among patients prescribed imatinib and the margin, if any, before treatment response is at risk. **Methods:** We performed a post hoc analysis of the ADAGIO study conducted in Belgium on 169 evaluable patients (*Blood* 2009). Using the pill count ratio as, what in conventional survival analysis would be, the time variable, we modeled the cumulative likelihood of treatment response as a function of increasing pill count adherence. We applied Kaplan-Meier methods to model the likelihood of complete cytogenetic (CCyR), complete hematological (CHR), major molecular (MMR) and optimal (OR) (as defined by the European Leukemia Net) response as a function of 90-day pill count adherence. Kaplan-Meier methods thus estimated the tolerance for nonadherence to imatinib by calculating the 1 minus Kaplan-Meier estimate for treatment response. **Results:** Analyses (see Table) showed that ~100% adherence of prescribed dose is associated with probabilities (rounded) of 0.84 for CHR, 0.83 for CCyR, 0.82 for OR, and 0.77 for MMR; compared to, 0.37 (CHR and CCyR), 0.35 (OR), and 0.39 (MMR) at 90% adherence. (of 0.7698 (MMR). Increasing the intake of imatinib from 90% to 100% of the prescribed dose increased the likelihood of the various treatment responses by 1.95 to 2.35-fold. **Conclusions:** Our findings challenge any previously estimated tolerance for nonadherence. There is virtually no margin for nonadherence if the objective is to optimize the likelihood of treatment response, and only a minimal margin to avoid impaired treatment response. Under such adherence, response rates similar to those in the pivotal IRIS trial can be obtained. Clinicians must assess and promote patient adherence, and patients must be perfectly adherent. Research Sponsor: None.

Probability of treatment response as a function of 90-day pill count adherence.

Pill count ratio	Complete hematological response	Complete cytogenetic response	Major molecular response	Optimal response
90%	0.3746	0.3714	0.3938	0.3512
100%	0.8416	0.8335	0.7698	0.8236
Fold change	2.25	2.24	1.95	2.35

Outcomes before and after dose reduction in patients with newly diagnosed chronic myeloid leukemia receiving bosutinib or imatinib.

First Author: Michael W Deininger, University of Utah Health Care, Salt Lake City, UT

Background: Bosutinib (BOS) is approved for patients (pts) with Philadelphia chromosome-positive chronic myeloid leukemia (CML), at a starting dose of 400 mg QD in newly diagnosed pts in chronic phase (CP). This analysis evaluated the impact dose reduction has on the outcomes of BOS and imatinib (IMA) in pts with CP CML. **Methods:** In the open-label BFORE trial, 536 pts with newly diagnosed CP CML were randomized to receive 400 mg QD BOS (N = 268) or IMA (N = 268; 3 untreated). Dose could be reduced to 300 mg QD for toxicity. Following sponsor approval, dose reduction to BOS 200 mg QD was permitted for 4 wks maximum; after this time, dose escalation or treatment discontinuation was required. Maintenance of response after dose reduction was defined as having a response > 6 mo after the first reduction. Database lock: June 12, 2020, 5 y after the last pt enrolled. **Results:** In the BOS arm, dose reduction to 300 (without further reduction) or 200 mg QD was seen in 82 (31%) and 33 (12%) pts, and median time to dose reduction was 85 and 205 d. In the IMA arm, 50 (19%) pts had a dose reduction to 300 mg QD, and median time to dose reduction was 92 d. Most common (≥2% of pts) treatment-emergent adverse events (TEAEs) leading to dose reduction were increased alanine aminotransferase (8%), thrombocytopenia (7%), diarrhea (7%), increased lipase (6%), increased aspartate aminotransferase (4%), nausea (4%), neutropenia (3%), rash (3%) and abdominal pain (2%) with BOS, and neutropenia (4%) with IMA. Of the pts who remained on 400 mg QD BOS (n = 153) or IMA (n = 214), respectively, 120 (78%) and 139 (65%) achieved major molecular response (MMR). Among pts who had a BOS dose reduction to 300 mg QD, 51/82 (62%) had MMR > 6 mo after dose reduction: 14 (17%) maintained MMR before and after dose reduction and 37 (45%) achieved MMR for the first time after dose reduction. Seven (9%) pts had MMR before dose reduction but discontinued treatment before the next > 6 mo assessment. In the IMA arm, 32/50 (64%) pts had MMR > 6 mo after dose reduction: 9 (18%) maintained MMR before and after dose reduction and 23 (46%) achieved MMR for the first time after dose reduction. One (2%) pt had MMR before dose reduction but discontinued treatment before the next > 6 mo assessment and 1 (2%) pt lost a previously attained MMR after dose reduction. Among pts who had a BOS dose reduction to 200 mg QD, 12/33 (36%) had MMR > 6 mo after dose reduction: 7 (21%) maintained MMR before and after dose reduction and 5 (15%) achieved MMR for the first time after dose reduction. Six (18%) pts had MMR before dose reduction but discontinued treatment before the next > 6 mo assessment. Similar trends were seen for complete cytogenetic response. **Conclusions:** Management of TEAEs through BOS or IMA dose reduction enabled pts to continue treatment, with a substantial number of pts achieving MMR for the first time after dose reduction. Clinical trial information: NCT02130557. Research Sponsor: Pfizer Inc.

Health-related quality of life (HRQoL) in patients (pts) with myelodysplastic syndromes (MDS) in the Connect Myeloid Disease Registry.

First Author: Dennis A. Revicki, Outcomes Research Consulting, Sarasota, FL

Background: At diagnosis, disease risk and transfusion burden (TB) can impact HRQoL in pts with MDS. The impact of disease status and higher transfusion requirements on HRQoL has not been well studied. We used data from the Connect Myeloid Disease Registry, an ongoing, prospective, observational cohort study that includes adult pts with lower-risk (LR) and higher-risk (HR) MDS, to investigate factors influencing baseline (BL) and subsequent HRQoL. **Methods:** BL and Month 6 (M6) data from pts enrolled from Dec 12, 2013 to Mar 6, 2020 (data cutoff) were analyzed. Pts were stratified by International Prognostic Scoring System (IPSS) risk (LR, HR), treatment (Tx) within 45 days post-enrollment (no Tx, best supportive care [BSC], active Tx), and TB 16 weeks post-BL (non-transfusion dependent [NTD], low TB [LTB]; 1−3 transfusions, high TB [HTB]: ≥4 transfusions). Pts completed EQ-5D, FACT-An trial outcome index (TOI), and FACT-Fatigue (FACT-F) questionnaires at BL and quarterly thereafter. Clinically meaningful change, based on minimally important differences, was defined as a change of ±0.07 for EQ-5D, ±6 for FACT-An TOI, and ±3 for FACT-F. **Results:** At data cutoff, 830 (489 LR, 341 HR) pts were enrolled. Median age was 74 years. 278 pts received no initial Tx, 161 BSC, and 378 active Tx. At BL, 470 were NTD, 197 LTB, and 163 HTB. Of 670 pts still on-study at M6, 462 completed the questionnaires at both BL and M6. At BL, clinically meaningful differences were observed in FACT-An TOI and FACT-F scores, but not EQ-5D, between LR- and HR-MDS and the Tx subgroups. From BL to M6, no clinically meaningful changes were observed in mean scores for each questionnaire. For the TB subgroups, meaningful differences were observed at BL in FACT-An TOI and FACT-F scores, but not EQ-5D (Table). From BL to M6, meaningful decreases in scores were reported by 26%, 30%, and 35% of NTD, LTB, and HTB pts in EQ-5D, 41%, 43%, and 48% for FACT-An TOI, and 40%, 42%, and 48% for FACT-F; increases were reported by 19%, 19%, and 20% pts for EQ-5D, 31%, 32%, and 39% for FACT-An TOI, and 30%, 39%, and 40% for FACT-F. **Conclusions:** This preliminary analysis suggests that pts with HR-MDS, and transfusion-dependent pts, generally had worse HRQoL at BL, providing further support to initiating active Tx in pts with TB. Possible limitations of the analysis are lower completion rates in pts with more severe disease, and EQ-5D may not capture changes in these subgroups at M6. A longer follow-up may help delineate the impact of Tx on HRQoL assessments in pts with MDS. Clinical trial information: NCT01688011. Research Sponsor: Bristol Myers Squibb.

Comparison of dose modification strategies to address expected hematologic toxicities in treatment-naïve higher-risk (HR) MDS patients treated with venetoclax + azacitidine. *First Author: Jacqueline Suen Garcia, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Venetoclax (Ven) is a selective, potent BCL-2 inhibitor. Ven + azacitidine (Aza) were associated with a combined complete remission (CR)/marrow CR (mCR) rate of 79% in a phase 1b study of patients (pts) with HR-MDS. Here we compared two different dose modification strategies to manage expected hematologic toxicities in two safety expansion cohorts with similar follow-up periods. **Methods:** Pts ≥18y diagnosed with treatment-naïve IPSS intermediate-2 or high-risk MDS with ECOG ≤2 were enrolled. Aza 75 mg/m^2 (iv or subQ daily) was administered for 7 days (d) and Ven was administered at 400 mg for 14d in each 28d cycle. In both cohorts, dose modification during Cycle 1 was not recommended; dose modifications in subsequent cycles were prescribed for AEs. In Safety Expansion Cohort 1 (SE1), either Aza or Ven were initially reduced according to investigator's choice for significant neutrophil or platelet toxicity. Dose reductions per protocol were 33% for Aza and 50% for Ven (for 14d each cycle). In subsequent cycles, Ven duration could be shortened to 9d of each cycle. In Safety Expansion Cohort 2 (SE2), dose modification guidelines recommended stepwise reductions, first in Aza dose (first to 50 mg/m^2, then 36 mg/m^2) and subsequently in Ven duration to 7d of each cycle (Ven 400 mg). The impact of each dose modification strategy on safety and efficacy in SE1 *vs* SE2 was compared. Worsening of treatment-emergent adverse events (TEAE) grades from baseline (BL) was analyzed by cycle. Responses were evaluated using IWG 2006 criteria. Analyses included all pts who received ≥1 dose of study drug. **Results:** We compared 22 pts in SE1 and 21 pts in SE2 with median (range) follow-up of 7.5 (1.0–8.9) and 7.9 (1.8–10.1) mos, respectively. A similar frequency of ≥ G3 hematologic TEAEs (approx %) were reported in SE1 and SE2, respectively, including anemia (14% and 33%), febrile neutropenia (46% and 48%), leukopenia (36% and 19%), neutropenia (55% and 48%) and thrombocytopenia (32% and 38%). Infections (59% and 38%) were more frequent in SE1 than SE2. In a longitudinal analysis, there were more TEAE grade increases from BL to Cycle 1 in SE2 vs SE1. This could be accounted by pts in SE1 and SE2 having unbalanced susceptibility to AEs at BL, as SE1 and SE2 pts received identical Aza + Ven doses in Cycle 1. Response rates were identical: 86% of pts in both SE1 and SE2 had CR or mCR. For pts with mCR, hematologic improvement occurred in 50% of SE1 and 46% of SE2 pts. **Conclusions:** No obvious hematologic differences were observed when reducing Aza before Ven (SE2) in MDS compared to investigator's choice (SE1). Both approaches had a similar acceptable safety profile without compromising efficacy for pts with HR-MDS. Clinical trial information: NCT02942290. Research Sponsor: AbbVie.

Model-based analysis to support dose selection of pevonedistat (PEV) combined with azacitidine (AZA) in patients (pts) with higher-risk myelodysplastic syndromes (MDS)/chronic myelomonocytic leukemia (CMML) and acute myeloid leukemia (AML). *First Author: Xiaofei Zhou, Millennium Pharmaceuticals, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA*

Background: PEV+AZA has been studied in higher-risk MDS/CMML and AML, with encouraging efficacy and an acceptable safety profile without added myelosuppression. This pooled analysis was performed to evaluate the impact of PEV exposure on safety and efficacy. **Methods:** Data from three studies (NCT01814826, NCT02782468 and NCT02610777) were used in the PEV exposure–safety analyses, including ≥ grade 3 neutropenia (NEU3), febrile neutropenia (FN), ≥ grade 3 thrombocytopenia, ≥ grade 3 alanine aminotransferase elevation, ≥ grade 3 aspartate aminotransferase elevation and ≥ grade 3 treatment-emergent adverse event (TEAE3), in pts with higher-risk MDS/CMML and AML who received PEV+AZA. Data from NCT02610777 were used for exposure–efficacy analyses, including overall survival (OS), event-free survival (EFS), complete response (CR) and CR+partial response (PR), in pts with higher-risk MDS/CMML who received PEV+AZA. The exposure metrics for individual pts were derived from a previously developed population pharmacokinetic model with pooled data from eight phase 1/2 studies. PEV exposure–safety relationships for the toxicity endpoints, exposure–CR and exposure–CR+PR, were estimated by logistic regression. Age, sex, race, baseline Eastern Cooperate Oncology Group (ECOG) Performance Status score and disease type were evaluated as covariates. Cox proportional-hazards models were used to evaluate the PEV exposure–survival for higher-risk MDS/CMML, with age, sex, baseline ECOG PS score, Revised International Prognostic Scoring System score (IPSS-R) and disease type as potential covariates. **Results:** In total, 135 pts (median age, 74 years; male, 64%; Caucasian, 82%) and 41 pts (median age, 74 years; male, 76%; Caucasian, 90%; median IPSS-R, 5.5) were included in PEV exposure–safety and exposure–efficacy analyses, respectively. PEV exposure was significantly related to the incidence of NEU3 (p = 0.003), FN (p = 0.02) and TEAE3 (p = 0.02), supporting PEV dose reductions for pts with treatment-related toxicities. Relationships between PEV exposures and CR, CR+PR, EFS or OS indicated consistent clinical benefit across ranges of PEV exposure following a starting dose of 20 mg/m^2. **Conclusions:** The association between exposure and safety supports PEV dose reductions for pts with treatment-related toxicities. The exposure–efficacy analyses indicated consistent clinical benefit across ranges of PEV exposure following a starting dose of 20 mg/m^2. These results support a favorable benefit–risk profile of the 20 mg/m^2 PEV dose on days 1, 3 and 5 in combination with AZA 75 mg/m^2 for 7 days in 28-day cycles. Clinical trial information: NCT01814826, NCT02782468, NCT02610777. Predictors of hypomethylating agent discontinuation among patients with higher-risk myelodysplastic syndromes. *First Author: Amer Methqal Zeidan, Yale University School of Medicine and Yale Cancer Center, New Haven, CT*

Background: Real-world studies have shown that persistence with intravenous (IV) and subcutaneous (SC) hypomethylating agents (HMAs) among patients (pts) with higher-risk myelodysplastic syndromes (MDS) is poor, with over one-third of treated pts receiving <4 cycles or having a ≥90-day gap in therapy, despite recommendations for at least 4-6 cycles to elicit response in absence of progression/unacceptable toxicity. Survival outcomes have also been shown to be worse, and direct medical costs higher, among HMA non-persistent vs persistent pts. We explored factors associated with early discontinuation of HMA therapy in this population. **Methods:** This was a retrospective cohort study among pts from the 2010-2016 SEER-Medicare linked database with a diagnosis of refractory anemia with excess blasts (RAEB; a surrogate for higher-risk MDS) from 2011-2015. Included pts had to have received HMA therapy and have ≥12 months' continuous follow-up after diagnosis. Discontinuation was defined as stopping HMA therapy before 4 cycles. Multivariable logistic regression was used to assess predictors of HMA discontinuation. **Results:** In total, 664 pts with RAEB and treated with HMAs were included. Overall, 193 (29%) discontinued before 4 cycles; of these, 91 (47%) discontinued after 1 cycle, 57 (30%) 2 cycles, and 45 (23%) 3 cycles. Compared with pts continuing for ≥4 cycles, pts discontinuing before 4 cycles were generally older and more likely to be single/separated/divorced/widowed, have more comorbidities, and have poor performance status (PS) (Table). These trends were most pronounced among pts discontinuing HMA therapy after only 1 cycle vs ≥4 cycles (Table). In multivariable analysis, age 71-75 vs ≥80 y (odds ratio [OR] 0.556, p=0.017) and poor PS (OR 1.585, p=0.019) remained significant predictors of HMA discontinuation. Among treatment-related factors, the most statistically significant association with HMA discontinuation was observed for GCSF use (OR 0.453, p<0.001). Number of pills/day was not a predictor of HMA discontinuation (OR 1.009, p=NS). **Conclusions:** In this real-world study, almost one-third of RAEB pts treated with IV/SC HMAs discontinued before 4 cycles, with almost half of these pts discontinuing after only 1 cycle. Predictors of HMA discontinuation included older age and poor PS. Novel approaches are needed to improve persistence with HMA therapy, particularly among these higher-risk groups. Research Sponsor: Taiho Oncology, Inc.

Using tissue microarray to detect inflammasome signaling components that contribute to the pathogenesis of myelodysplastic syndrome. *First Author: Tony Kurian, Moffitt Cancer Center & University of South Florida, Tampa, FL*

Background: Myelodysplastic syndromes (MDS) are characterized by aberrant maturation, ineffective hematopoiesis, cytopenia, and progression to acute myeloid leukemia. MDS pathogenesis is multifactorial and potentially linked to constitutive innate immune stimulation converging upon the NLRP3 inflammasome to induce pyroptosis, a caspase-1 dependent cell death. Inflammasome assembly is initiated by both *cell-extrinsic* stimuli including S100A9, the TLR4 and CD33 ligand, and *cell-intrinsic* danger signals licensing caspase-1 which activates IL1b and beta-catenin resulting in cell death and cellular proliferation leading to maturation and differentiation blocks. Further, EYA2 has been suggested to be an inflammasome activator, whereas cPLA2 has been suggested to be an inhibitor. The purpose of this study is to determine whether immunohistochemistry (IHC) may be utilized to assess expression of inflammasome components. **Methods:** An IRB protocol was approved prior to initiating this study. We retrospectively identified 43 low risk MDS patients. A tissue microarray (TMA) was constructed utilizing MDS bone marrow biopsy samples (2-3 representative cores per sample). IL-1, S100A9, EYA2, cPLA2, beta-catenin, and TLR4 expression were assessed by IHC after validation of each antibody. IHC expression was scored independently by two hematopathologists by calculating scores (product of staining intensity x percent expression). IHC expression was compared using Spearman correlation estimate. Demographic and clinical data were collected and correlated with IHC expression using Kruskal-Wallis test, Spearman correlation, and Logrank test. **Results:** Patients were median 72 years of age, 67% men and included 47% MDS-MLD, 35% MDS-RS, 14% MDS-SLD, 2% MDS del5q and 2% MDS-U. IL-1 expression correlated with beta-catenin expression, r = 0.42, 95% CI 0.115 to 0.658 (p = 0.007). There was a trend towards significance between IL-1 and cPLA2, r = 0.30 (p = 0.067); S100A9 and cPLA2, r = 0.31 (p = 0.052); and S100A9 and EYA2, r = 0.31 (p = 0.057). Percentage EYA2 expression correlated with blast count, r = 0.425 (p = 0.008). The IHC expression of these antigens did not correlate with WHO MDS subclassification, IPSS, R-IPSS, disease progression, or survival (p > 0.05). **Conclusions:** IHC staining of inflammasome activators using TMA may allow better characterization of molecular pathways contributing the MDS pathogenesis. A correlation was seen between expression of antigens known to be increased downstream of NLRP3 inflammasome activation. Furthermore, increased expression of EYA2 correlated with blast count. A future study will compare expression patterns between normal, low risk MDS and high risk MDS samples and correlate these findings with clinical outcome data to further elucidate the pathogenesis of MDS and identify potential targetable markers for novel therapeutic strategies. Outcomes of allogeneic hematopoietic cell transplantation in patients with myelofibrosis: A systematic review and meta-analysis. *First Author: Jan Philipp Bewersdorf, Yale University School of Medicine, New Haven, CT*

Background: Allogeneic hematopoietic cell transplant (allo-HCT) remains the only potentially curative therapeutic modality for patients with primary or secondary myelofibrosis (MF). However, many patients (pts) are ineligible for allo-HCT and transplant-related mortality can be substantial. Data on the efficacy and safety of allo-HCT are mixed and largely derived from retrospective studies. **Methods:** To synthesize the available evidence, we conducted a systematic review and meta-analysis searching Cochrane Library, Google Scholar, Ovid Medline, Ovid Embase, PubMed, Scopus, and Web of Science Core Collection from inception to October 11, 2020 for studies on allo-HCT in MF. Databases were searched using a combination of controlled vocabulary and free text terms for relevant studies on the efficacy and safety of allo-HCT in pts with primary and secondary MF. This study protocol has been registered on PROSPERO (CRD42020188706). Random-effects models were used to pool response rates for the co-primary outcomes of 1-year, 2-year and 5-year overall survival (OS). **Results:** We identified 4247 studies after duplicate removal. 393 studies were assessed as full-texts for eligibility and 43 studies (38 retrospective, 1 prospective study, 4 phase II clinical trials) with 8739 pts were included in this meta-analysis. Study quality was limited by the absence of randomized clinical trials and retrospective design of most studies. Rates of 1-year, 2-year, and 5-year OS were 66.7% (95% confidence interval: 63.5-69.8%), 64.4% (57.6-70.6%), and 55.0% (51.8-58.3%), respectively. Rates of 1-year, 2-year, and 5-year non-relapse mortality were 25.9% (23.3-28.7%), 29.7% (24.5-35.4%), and 30.5% (25.9-35.5%), respectively. Among evaluable studies, rates of 1-year, 2-year, and 5-year relapse-free survival were 65.3% (56.5-73.1%), 56.2% (41.6-69.8%), and 53.6% (39.9-66.9%), respectively. Adverse events related to all-HCT were manageable with rates of acute and chronic graft-versus-host disease in 44.0% (39.6-48.4%; grade III/IV: 15.2%) and 46.5% of patients (42.2-50.8%; extensive or moderate/severe: 26.1%), respectively. Subgroup analyses did not show any significant difference between conditioning regimen intensity (myeloablative vs reduced-intensity), median patient age, and proportion of DIPSS-intermediate-2/high pts. **Conclusions:** Given the poor prognosis of patients not receiving transplant and in the absence of curative non-transplant therapies, our results support consideration of allo-HCT for eligible pts with MF. However, additional studies in pre- and post-allo-HCT setting are necessary to enhance patient selection (e.g. by incorporation of molecular markers), to optimize transplant strategies (e.g. peri-transplant ruxolitinib, conditioning regimens, and donor selection), symptom management and decrease non-relapse mortality. Association of transfusion independence with improved overall survival in myelofibrosis patients receiving momelotinib. *First Author: Ruben A. Mesa, UT Health San Antonio, San Antonio, TX*

Background: Momelotinib (MMB) is a potent JAK1, JAK2 and ACVR1 inhibitor with clinical activity against the hallmark features of myelofibrosis (MF), namely anemia, constitutional symptoms and splenomegaly, across the continuum of JAKi naïve or previously JAKi treated intermediate/high risk MF patients as demonstrated in the previously conducted Phase 3 SIMPLIFY-1 & -2 clinical trials (S1, S2). S1 enrolled JAKi-naïve patients with MF (n = 432) double-blind randomized 1:1 to MMB or ruxolitinib (RUX). S2 enrolled patients with MF with hematological toxicity during prior RUX therapy (n = 156) randomized 2:1 to open-label MMB or best available therapy (BAT; consisting of RUX in 88% of patients). In both trials, following the 24-week randomized treatment (RT) period, patients could continue MMB (MMB→MMB) and those randomized to RUX/BAT could cross-over to MMB (RUX/BAT→MMB) for extended treatment (ET). Previously published data from the SIMPLIFY studies demonstrate robust overall survival (OS) for MMB-treated patients in S1 and S2 (median not reached and 34.3 months, respectively) with a maximum follow up of approximately 5 years and median of 2.9 years in S1 and 2.3 years in S2. **Methods:** OS data for patients receiving MMB in S1 and S2 are reported here for subgroups defined by Week 24 (W24) transfusion independence (TI) responders vs non-responders, and also other efficacy endpoints. Survival was estimated using KM analysis with descriptive log-rank tests for comparison applied (all p-values are descriptive). **Results:** As previously reported, W24 TI rates were higher in the MMB arms of S1 (67% vs 49%) and S2 (43% vs 21%). In S1, W24 TI responders in the MMB group show an OS advantage, with median OS not reached and 3-year survival of 80% (HR = 0.30; p = 0.0001) compared to MMB TI non-responders. Similarly in S2, W24 TI responders in the MMB group show a trend toward better OS compared to TI non-responders (HR = 0.57; p = 0.0652). The HRs in S1 for MMB responders vs non-responders for W24 SRR and TSS were 0.59 (p = 0.0904) and 0.65 (p = 0.1657), respectively. Alternative analyses using OS defined from W24 demonstrated consistent results. **Conclusions:** These new analyses suggest JAKi naïve patients receiving MMB who maintain or achieve TI at W24 have favorable OS compared to MMB TI non-responders, with a similar trend observed in S2. These findings are consistent with anemia and transfusion dependency being key predictors of shortened OS in MF and suggest that TI response at W24 may become a surrogate for clinical benefit, supporting the clinical relevance of MMB's differentiated pro-erythropoietic ACVR1 inhibition. Clinical trial information: NCT01969838. Research Sponsor: Sierra Oncology / Gilead Sciences.

Clinical characteristics, treatment patterns, and overall survival of real-world patients with idiopathic multicentric Castleman disease. *First Author: Aaron B. Cohen, Flatiron Health, New York, NY*

Background: Castleman disease (CD) has three subtypes: Unicentric (UCD), Human herpesvirus-8 associated multicentric (HHV-8 MCD) and idiopathic multicentric (iMCD). Outcomes for patients with iMCD are poor and treatment options are limited, with only one FDA-approved therapy (siltuximab in April 2014). Further, the lack of CD-specific ICD codes until 2017 has limited real-world evaluation. We identified iMCD patients in an electronic health record (EHR)-derived dataset and described their clinical characteristics, treatment patterns, and real-world overall survival (rwOS). **Methods:** Patients with a possible diagnosis of CD as of 8/31/20 were identified from the nationwide deidentified Flatiron Health EHR-derived database using patient-level structured data (e.g., ICD-9/10 codes) and unstructured data (e.g., clinician notes), curated via technology-enabled manual abstraction to confirm CD diagnosis and treatments received. Descriptive statistics summarized patient characteristics and treatment patterns. Patients without structured data within 90 days after diagnosis were excluded from treatment patterns analyses. 5-year rwOS rate was estimated from diagnosis date using the Kaplan-Meier estimator. **Results:** 747 patients with possible CD were identified, of whom 453 were confirmed to have CD by abstraction (172 UCD, 100 iMCD, 36 HHV-8 MCD, and 145 unclassified). IMCD patients were predominantly female (53%), white (58%), and treated at community sites (70%). Of the 52 iMCD patients with evidence of structured data within 90 days after diagnosis and who had at least one documented line of therapy, the most common first-line therapies were siltuximab-based therapy (42.3%), rituximab monotherapy (36.5%), and chemotherapy-based treatment (13.5%). Among 28 iMCD patients with evidence of second-line therapy, the most common treatment was rituximab monotherapy (35.7%). Among 60 iMCD patients diagnosed on or after siltuximab approval in April 2014 (including those without evidence of any treatment), 26 (43%) received siltuximab at some point. 5-year rwOS rate for the 100 iMCD patients was 75% [95% CI: 63-89%]. **Conclusions:** This is the first study to utilize a large EHR-derived database to describe characteristics, treatment patterns, and overall survival of iMCD patients in real-world practice. Less than half of iMCD patients diagnosed on or after the date of FDA approval for siltuximab received it at some point. Future work should focus on characterizing the drivers of poor patient outcomes. Research Sponsor: Flatiron Health, an independent subsidiary of the Roche Group.

Phenotypes and prognostic factors in adults with Langerhans cell histiocytosis. *First Author: Gaurav Goyal, University of Alabama at Birmingham, Birmingham, AL*

Background: Langerhans cell histiocytosis (LCH) can manifest as single system (SS) disease, multisystem (MS) disease, or pulmonary LCH (smoking-related). There is a paucity of data on prognostic factors including risk organ (RO) involvement (liver, spleen, and bone marrow) in adult LCH, which we sought to address in this study. **Methods:** Single-center retrospective study of patients ≥18y diagnosed with LCH from 1998 to 2020. Univariate and multivariate analyses for progression free survival (PFS) and overall survival (OS) were conducted using age, sex, organ involvement, LCH subtype, year of diagnosis, BRAF V600E status, and treatments. **Results:** We included 219 patients with LCH; median age 43y (range 19-88), females 51%, SS unifocal (23%), SS multifocal (6%), pulmonary (31%) and MS (40%). Commonly involved organs included lung (53%), bone (42%), skin (24%), pituitary (16%), and CNS (12%). BRAF V600E was positive in 40/88 (46%). Median follow-up duration was 6.1y (95% CI, 5.1- 7.1). On univariate analysis, factors associated with worse PFS were bone LCH, RO involvement, multifocal/MS LCH, and radiation therapy alone; those with worse OS included RO involvement, MS disease, BRAF V600E+, and age ≥45y at diagnosis. In multivariate analysis, BRAF V600E and age ≥45y at diagnosis were associated with worse mortality (Table). Median PFS was not reached (NR-NR) for SS unifocal LCH, 5mo (0-12.7) for SS multifocal LCH, 110mo (84.7-135.3) for pulmonary LCH, and 27mo (17.2-36.8) for MS LCH. 5-year OS was 97.4% for SS unifocal LCH, 100% for SS multifocal LCH, 96.1% for pulmonary LCH, and 79.9% for MS LCH. 41 (18.7%) developed a second primary malignancy (SPM), of which 11 were hematologic neoplasms. There was a trend towards a higher prevalence of SPMs in patients with BRAF V600E (28% vs. 17%; p = 0.22). **Conclusions:** In our large single-center study, PFS for multifocal and MS LCH was worse than SS unifocal or pulmonary LCH. RO involvement was not associated with outcomes in multivariate analysis. Overall prognosis was excellent for all subtypes except MS LCH. BRAF V600E and older age were associated with worse OS. The prevalence of SPMs was very high and needs to be explored further. Research Sponsor: None.

$BRAF^{V600E}$ frequency and impact on outcomes in adults with langerhans cell histiocytosis. *First Author: Aldo A. Acosta-Medina, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Langerhans cell histiocytosis (LCH) is an inflammatory myeloid neoplasm manifesting as unifocal, multifocal, multisystem (MS) or pulmonary LCH (smoking-related). In pediatric LCH, somatic $BRAF^{V600E}$ prevalence is reported at 55-70%, and associated with increased risk of multisystem disease and early treatment failure. Our aim was to describe the prevalence of $BRAF^{V600E}$ mutation and evaluate its association with clinical manifestations and outcomes in adults with LCH. **Methods:** A retrospective review of adult patients diagnosed with LCH consecutively seen at Mayo Clinic from 2011 to 2020 was performed.Evaluation of association of $BRAF^{V600E}$ mutational status and clinical factors was conducted by the Chi-square test for independence. Progression-free survival (PFS) and overall survival (OS) were analyzed via the Kaplan Meier method and compared with the log-rank test to assess the effect of $BRAF^{V600E}$. **Results:** Of the total LCH cohort (n= 128), 88 patients with available $BRAF^{V600E}$ results were included in the study. Median age at diagnosis was 41y (range 19 - 88); 52.3% were male. 40 (45.5%) patients had a $BRAF^{V600E}$ mutation. Increasing age was associated with $BRAF^{V600E}$ (10-year increase OR 1.42, 95%CI 1.07-1.89; p= 0.017). No correlation was observed between $BRAF^{V600E}$ status and site of disease, risk organ (RO: liver, spleen, marrow) involvement, or MS disease. Patients with $BRAF^{V600E}$ were 4 times more likely to receive targeted therapy (*BRAF* inhibitor) than non-$BRAF^{V600E}$ patients (p= 0.018). After a median follow up of 46 mo (95% CI 30.8-61.2), PFS was similar between $BRAF^{V600E}$ and non-$BRAF^{V600E}$ patients (p= 0.167). However, patients with $BRAF^{V600E}$ had a worse 3-year OS compared with non-$BRAF^{V600E}$ patients (84% vs. 97.1%, p= 0.027). Patients who died had a significantly higher age at LCH diagnosis (median 62 vs. 38 years; p= 0.0002). **Conclusions:** In our cohort of adults with LCH, $BRAF^{V600E}$ was less frequent than reported in pediatric literature and was associated with worse OS. The frequency of $BRAF^{V600E}$ was positively correlated with increasing age. Contrary to reports in pediatric LCH, there were no significant associations between $BRAF^{V600E}$ and high-risk or multisystem disease. Research Sponsor: None.

TPS7051 **Poster Session**

A phase 4 study to evaluate outpatient blinatumomab in patients with minimal/measurable residual disease (MRD) positivity (+) of B-cell precursor acute lymphoblastic leukemia (BCP-ALL). *First Author: Sharif Khan, Saint Francis Hospital, Inc, Greenville, SC*

Background: The prognosis for adults with relapsed or refractory BCP-ALL is poor. MRD+ is the strongest predictor of relapse. Blinatumomab, a CD3/CD19-directed BiTE® (bispecific T-cell engager) molecule, is an effective treatment for patients with MRD+.[1] Blinatumomab is administered as a continuous intravenous infusion (cIV) 28 days per cycle. Severe adverse events (AEs) such as cytokine release syndrome (CRS) and neurologic toxicity (NT) may occur; thus, hospitalization is recommended for the first 3 days of cycle 1 and the first 2 days of cycle 2 for MRD+ patients. However, the incidence of severe AEs is low in MRD+ BCP-ALL patients (CRS: 2%, NT: 13%).[1] We believe that with the use of effective digital monitoring devices, blinatumomab can be safely administered for the entire 28-day cIV cycle as an outpatient. **Methods:** Adult patients (n = 45) with BCP-ALL in complete remission and MRD+ (≥0.1% blasts) are being enrolled at 25 planned treatment sites, endpoint: grade ≥3 AE during monitoring (Amgen NCT04506086). Patient suitability for blinatumomab and outpatient monitoring is established. Patients will receive 2-4 cycles of blinatumomab. Cycles are initiated in the outpatient setting, digital monitoring devices activated and attached, and patients sent home. Once home, patients set up the home hub and real-time remote data transfer to the healthcare professional (HCP) begins. The devices are worn continuously, 24 hours a day for the first 3 days of cycle 1 and the first 2 days of cycle 2 only. Devices: Current Health's Wearable Monitoring System (CHWMS) is an FDA-cleared platform for wireless and wearable health monitoring of patients at home. The CHWMS provides continuous oxygen saturation, respiratory rate, and heart rate; an axillary temperature sensor is worn and provides continuous temperature. Patients manually measure blood pressure every 3-6 hours around the clock. Patients have an integrated mobile device (tablet) to initiate contact with the HCP if needed. HCP/designee has a mobile device (smart phone) and receives vital signs as a constant live feed transmitted from the CHWMS device. The CHWMS platform generates a loud audible alert based on pre-specified vital sign alarming thresholds or if there is an interruption in data transfer. HCP may initiate direct audio and video contact with the patient, assess the patient's condition, and make an appropriate intervention. HCP may also initiate patient contact in the absence of an alert. Patients are required to have a caregiver present during the entire period of outpatient monitoring. Patients have a full set of replacement devices as well as a 24/7 hotline for device support. Trial enrollment is underway. This study may generate feasibility data on the effectiveness of home monitoring during blinatumomab infusion in patients with MRD+ BCP-ALL. [1]Gökbuget, *Blood*, 2018. Clinical trial information: NCT04506086. Research Sponsor: Amgen Inc.

TPS7052 **Poster Session**

V2 Trial: A phase I study of venetoclax and CPX-351 for young patients with relapsed/refractory acute leukemia. *First Author: Laura Agresta, Michigan State University College of Human Medicine, East Lansing, MI*

Background: Despite significant advances in therapy for acute myeloid leukemia (AML), 30-40% of young patients will relapse, after which prognosis is poor. In young patients, curative-intent salvage therapy involves intensive re-induction followed by hematopoietic stem cell transplant. Recently, the COG Phase II study of CPX-351 (liposomal cytarabine:daunorubicin, Vyxeos™) in pediatric patients with AML in first relapse (NCT02642965) demonstrated a CR/CRi rate of 81.3%. Separately, our first-in-pediatrics CPX-351 Phase I (NCT01943682) showed 48% in a heavily pre-treated pediatric cohort with multiply relapsed and refractory (R/R) AML. Our integrated pilot study of single cell RNA sequencing (scRNA-seq) done before, during, and after CPX-351 showed p53 targets over time with enrichment for genes regulating apoptosis (ex.: FAS, BAX), suggesting blasts may be primed for apoptosis following CPX-351. Venetoclax is a small molecule inhibitor of the anti-apoptotic protein BCL-2, a regulator of apoptotic balance in some leukemias. Based on our preclinical data, we developed a Phase I study to investigate venetoclax with CPX-351 for the treatment of young patients with R/R acute leukemias. **Methods:** The V2 Trial (NCT03826992) is a single-institution Phase I study to evaluate the safety and tolerability of venetoclax with CPX-351 in patients ages 1-39 years with R/R acute leukemias. Inclusion diagnoses include AML, mixed phenotype acute leukemia (MPAL), *KMT2A*-rearranged acute lymphoblastic leukemia (ALL), and T-ALL. Exclusion criteria include CNS status 3, bone marrow failure syndromes, and prior cardiotoxic exposures above acceptable risk thresholds. Subjects receive a single course of CPX-351 at the FDA approved adult dose on Days 1, 3, 5 with concurrent daily venetoclax. In the dose exploration phase, venetoclax dosing is 400 mg daily (or allometrically-scaled equivalent) for 21 (Dose Level 0) or 14 days (Dose Level -1) using a rolling 6 design. Primary endpoints are determination of the recommended phase 2 dose of venetoclax in combination with CPX-351 and description of toxicities. Secondary endpoints include estimations of $CR/CR_p/CR_i$ +/- MRD negativity in the context of a phase I study and evaluation of therapy-related cardiac dysfunction. Correlative studies include analysis of venetoclax pharmacokinetics with concomitant CPX-351. At the initial dose level, DLT were encountered and the study is now continuing enrollment at Dose Level -1. Clinical trial information: NCT03826992. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology, Cincinnati Children's Hospital Medical Center internal funding.

TPS7053 **Poster Session**

A prospective phase I/IIa trial to evaluate the safety and efficacy of GTA002, an off-the-shelf, *ex vivo*-cultured allogeneic NK cell preparation in patients with acute myeloid leukemia in complete morphological remission who have measurable residual disease. *First Author: Michael Heuser, Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany*

Background: Acute myeloid leukemia (AML) is a malignant disease with poor long-term prognosis in patients who cannot achieve morphological and molecular remission. Although insights into AML biology and treatment modalities have improved over recent years and even though many patients achieve morphological complete remission (CR), most are still relapsing. These relapses are due to residual leukemia stem cells that can be identified as minimal/measurable residual disease (MRD), with MRD serving as a predictive factor for relapse and mortality. Elimination of MRD in patients having reached CR is seen as essential for optimal and persistent clinical responses. A promising approach is the development of adoptive immunotherapies aimed at directly eradicating tumor cells using T-cells or natural killer (NK) cells. NK cells are part of the body's innate immune system and play a key role in controlling viral infections and conducting tumor immunosurveillance. Furthermore, NK cells can be applied clinically in an allogeneic setting, enabling the supply of high numbers of immune effector cells, which were not exposed to cytotoxic chemotherapeutics. A proprietary *ex vivo* expansion and differentiation method in a fully closed, automated manufacturing platform was developed to generate GTA002, an "off-the-shelf" (allogeneic), cryopreserved NK cell preparation, generated from CD34+ hematopoietic stem and progenitor cells derived from umbilical cord blood. The safety and tolerability of the product was already demonstrated in a Phase I trial in elderly patients with AML (PMLA25) (Dolstra et al. 2017). **Methods:** We are currently conducting a prospective 2-stage, open-label, single arm, multicenter Phase I/IIa trial to evaluate the safety and efficacy of GTA002 in 33 adults with AML who are in CR with MRD and who are not proceeding to allogeneic HSCT (ClinicalTrials.gov Identifier: NCT04632316). Patients enrolled in the clinical trial receive a lymphodepleting conditioning regimen consisting of cyclophosphamide and fludarabine (Cy/Flu) followed by up to 3 NK cell infusions 4 days apart and will be followed up for 12 months. The dose escalation stage of the trial will assess the safety and tolerability of repeat NK cell infusions in a 3+3 design with 3 cohorts and a cumulative dose range of 325 to 3,000 $x10^6$ viable NK cells. The expansion stage will evaluate the safety, tolerability and efficacy of NK cell infusions in 24 additional subjects. The primary efficacy endpoint is the cumulative incidence of the MRD response and secondary efficacy endpoints include the duration of the MRD response, event-free survival, overall survival and cumulative incidence of relapse. Enrollment in the first cohort (one single NK cell infusion) started in December 2020. Clinical trial information: EudraCT number 2019-003686-17. Research Sponsor: Glycostem Therapeutics BV.

TPS7054 **Poster Session**

Phase 3 VERONA study of venetoclax with azacitidine to assess change in complete remission and overall survival in treatment-naïve higher-risk myelodysplastic syndromes. *First Author: Amer Methqal Zeidan, Yale University School of Medicine and Yale Cancer Center, New Haven, CT*

Background: Patients with higher-risk myelodysplastic syndromes (HR-MDS) experience peripheral cytopenias, disease progression to acute myeloid leukemia, and high mortality with expected median overall survival of less than 2 years. Allogeneic hematopoietic cell transplantation (allo-HCT) is the only potentially curative treatment. Patients ineligible for transplantation are treated with hypomethylating agents such as azacitidine (Aza), which is not curative and provides limited improvement in clinical benefit. Venetoclax (Ven) is a selective, potent, oral B-cell lymphoma-2 (BCL-2) inhibitor that is approved in the U.S. in combination with hypomethylating agents for treating older or comorbid patients with newly diagnosed acute myeloid leukemia ineligible for intensive chemotherapy. Ven is approved in the U.S. as first-line treatment for chronic lymphocytic leukemia or small lymphocytic lymphoma. For patients with treatment-naïve HR-MDS, Ven + Aza demonstrated manageable safety and a combined complete remission (CR)/marrow CR (mCR) rate of 79% in a single arm phase 1b study (NCT02942290). To confirm these benefits, the VERONA study, a randomized, double-blind, phase 3 study (NCT04401748) of patients with treatment-naïve HR-MDS, will assess the safety and efficacy of Ven combined with Aza including CR rate and overall survival. **Methods:** Patients (≥18 years) with newly diagnosed HR-MDS per WHO 2016 classification with = 20% bone marrow blasts per marrow biopsy/aspirate at screening will be enrolled at ~200 sites globally (~500 patients). Patients must have intermediate risk or higher IPSS-R (score > 3), ECOG ≤2, and be hematopoietic stem cell transplant (HSCT) eligible without any pre-arranged donor, or HSCT ineligible without a plan for HSCT at Study Day 1. *De novo* patients without prior hypomethylating agents, chemotherapy for MDS, or allogenic stem cell transplantation are eligible. Patients will be randomized 1:1 to receive placebo or Ven 400 mg oral tablet once daily on Days 1-14, both in combination with Aza 75 mg/m^2 (intravenous or subcutaneous) on Days 7-0-0 or Days 5-2-2 per 28-days. Patients will receive study treatment until disease progression, unacceptable toxicity, HCT, withdrawal of consent, or discontinuation. The primary endpoints are CR rate (as adjudicated by investigator) per IWG 2006 criteria and overall survival. Secondary outcomes are red blood cell transfusion independence, platelet transfusion independence, change in fatigue as measured by Patient-Reported Outcomes Measurement Information System (PROMIS)-fatigue SF 7a scale score, time to deterioration in physical functioning domain of EORTC QLC-C30 scale, overall response (CR + partial response), and modified overall response (CR + mCR + partial response). Exploratory objectives are predictive biomarkers and pharmacokinetics. Clinical trial information: NCT04401748. Research Sponsor: AbbVie.

TPS7055 **Poster Session**

Magrolimab + azacitidine versus azacitidine + placebo in untreated higher risk (HR) myelodysplastic syndrome (MDS): The phase 3, randomized, ENHANCE study. *First Author: Guillermo Garcia-Manero, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MDS is a clonal myeloid disorder characterized by cytopenia and ineffective hematopoiesis. The median age of diagnosis is approximately 70 yrs of age and prognosis and treatment are guided by the Revised International Prognostic Scoring System (IPSS-R) criteria. Patients with intermediate, high and very high risk MDS (HR-MDS) have a median overall survival (OS) of 0.8 to 3.7 years. Despite the high unmet need in this patient population, azacitidine (AZA) is the only approved therapy for HR-MDS which has improved overall survival in clinical trials to date. However, these agents lead to low complete response (CR) rates (10-17%) with limited OS (= 2 years), indicating a need for alternative therapy. Magrolimab is a first-in-class monoclonal antibody that blocks the macrophage inhibitory immune checkpoint CD47, a "do not eat me" signal overexpressed on tumor cells. Binding of magrolimab to CD47 leads to phagocytosis of tumor cells. AZA increases expression of prophagocytic "eat me" signals, facilitating synergy with magrolimab. In an ongoing phase 1b study, the combination of magrolimab + AZA led to high response rates (ORR 91%, with a CR of 42%) and an acceptable safety profile without significant immune-related adverse events. ENHANCE (NCT04313881) is a phase 3 trial comparing the efficacy and safety of magrolimab + AZA with that of AZA + placebo (PBO) in previously untreated patients with HR-MDS. **Methods:** Patients ≥18 years old with previously untreated intermediate to very high risk MDS by IPSS-R are eligible for ENHANCE. Randomization is 1:1 to magrolimab + AZA or AZA + PBO with no crossover allowed. Magrolimab or placebo is administered intravenously (IV) with an initial 1 mg/kg priming dose to mitigate on target anemia. An intra-patient dose escalation regimen up to 30 mg/kg is then administered through Cycle 1, 30 mg/kg weekly dosing in Cycle 2, with 30 mg/kg Q2W dosing occurring in Cycle 3 and beyond. AZA is administered per regional prescribing information. Patients may remain on treatment until disease progression, relapse, loss of clinical benefit, or until unacceptable toxicities occur. Two primary efficacy endpoints are CR rate and OS. For patients undergoing allogeneic stem cell transplantation (ASCT), data for the CR rate will be censored at the time of ASCT and OS will be censored at the last known alive date. Secondary efficacy endpoints include RBC transfusion independence rate, event-free survival, minimal residual disease-negative rate, time to AML transformation, and patient-reported Functional Assessment of Cancer Therapy (FACT)-Anemia response rate. Biomarkers of immune cell recruitment, immune cell signaling, and bone marrow penetration of magrolimab will also be explored. Planned enrollment is approximately 520 patients globally, which began in September 2020. Accrual is ongoing. Clinical trial information: NCT04313881. Research Sponsor: Gilead Sciences, Inc.

TPS7056 **Poster Session**

IMerge: A phase 3 study to evaluate imetelstat in transfusion-dependent subjects with IPSS low or intermediate-1 risk myelodysplastic syndromes that are relapsed/refractory to erythropoiesis-stimulating agent treatment. *First Author: Uwe Platzbecker, Department of Hematology and Cell Therapy, University Clinic Leipzig, Leipzig, Germany*

Background: Current treatment options for red blood cell (RBC) transfusion-dependent (TD) patients (pts) with lower risk (LR) myelodysplastic syndromes (MDS) relapsed after or refractory to erythropoiesis-stimulating agents (ESAs) have limited efficacy and durability; new approaches are needed. Imetelstat is a first-in-class telomerase inhibitor that targets cells with short telomeres and active telomerase, characteristics observed in MDS pts across all disease stages. IMerge (MDS3001) is a Phase 2/3 global study of imetelstat for TD pts with non-del(5q) LR MDS post ESA therapy. The results from Phase 2 part indicated that imetelstat achieved durable RBC transfusion independence (RBC-TI) and the most frequently reported adverse events were manageable and reversible grade ≥3 cytopenias. Among 38 pts with median follow-up of 24 months, 8-week, 24-week and 1-year TI rates were 42%, 32% and 29%, respectively; these responses were seen across different LR MDS subtypes. Median TI duration was 20 months and the longest TI was 2.7 years. A high and durable hematologic improvement-erythroid (HI-E) rate of 68% for a median duration of 21 months were also achieved. Reduction of variant allele frequency of mutations by imetelstat treatment was observed in some pts and correlated with clinical benefits (Platzbecker et al EHA 2020; Steensma et al JCO 2020). These results support the Phase 3 part of the trial. **Methods:** IMerge is two-part, Phase 2/3 study (ClinicalTrials.gov: NCT02598661). The Phase 3 part of the study is open for enrollment to adult pts with International Prognostic Scoring System (IPSS) low or intermediate-1 risk, non-del(5q) MDS who are TD, are relapsed after or refractory to ESAs, and have not received treatment with lenalidomide or hypomethylating agents. The study is a randomized (2:1) double-blind, placebo-controlled trial to compare efficacy of imetelstat vs placebo that will enroll approximately 170 pts and will be conducted at approximately 120 centers in North America, Europe, Asia and Middle East. Imetelstat is administered as 2-hour IV infusion every 4 weeks at 7.5 mg/kg. The primary endpoint of the study is to assess the rate of RBC-TI lasting ≥8 weeks. Secondary endpoints include safety, rate of RBC-TI ≥24 weeks, time to RBC-TI start, RBC-TI duration, rate of HI-E, the amount and relative change in RBC transfusions, rate of CR or PR, overall survival, progression of MDS, pharmacokinetics, and quality of life. Biomarkers relevant to the mechanism of action of imetelstat will be assessed to demonstrate target inhibition and their association with clinical responses. Cytogenetics and mutation analyses will be performed to evaluate the impact of imetelstat on reduction/depletion of malignant clones leading to disease modification. The study is currently recruiting pts. Clinical trial information: NCT02598661. Research Sponsor: Geron Corporation.

TPS7057 **Poster Session**

BOREAS: A global phase 3 study of KRT-232, a first-in-class murine double minute 2 (MDM2) inhibitor in *TP53*^{WT} relapsed/refractory (R/R) myelofibrosis (MF). *First Author: Srdan Verstovsek, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The prognosis for patients (pts) with MF who have primary resistance to or who have progressed after treatment with ruxolitinib (RUX) is poor (median OS is ~13 months), highlighting the unmet need for novel treatments in this setting. MDM2 is a key negative regulator of the tumor suppressor protein p53 that is overexpressed in CD34+ cells in MF pts. Elevated MDM2 expression attenuates p53 activity, resulting in proliferation of malignant CD34+ cells. KRT-232 is a potent, selective, orally available MDM2 inhibitor that restores p53 function resulting in apoptosis of malignant stem and progenitor cells. KRT-232 has the potential to demonstrate disease-modifying effects in MF pts who are R/R to prior JAK inhibitor (JAKi) therapy. The FDA has granted KRT-232 Fast Track designation for the treatment of JAKi R/R MF. Clinical proof-of-concept for KRT-232 in R/R MF was established in phase 2 of this study. Once-daily dosing of KRT-232 at 240 mg (Day 1-7 of 28-day cycle) yielded a best spleen volume reduction (SVR) ≥35% by central review in 16% of pts, best total symptom score (TSS) response > 50% in 30% of pts, and 87% reduction of CD34+ cells in peripheral blood at Week 24. Spleen responses were superior in pts who were off RUX vs those on RUX at baseline imaging (best SVR ≥35%: 29% vs 0%). KRT-232 demonstrated a tolerable safety profile that included prophylaxis for nausea/vomiting (Al-Ali. EHA 2020). **Methods:** BOREAS is a randomized, controlled, open-label, global phase 3 study in MF pts (primary MF/post–polycythemia vera MF/post–essential thrombocythemia MF) who are R/R to JAKi. Pts aged ≥18 y with confirmed MF per WHO criteria, intermediate-1, 2, or high-risk disease (per DIPSS), ECOG performance status ≤2, adequate hematologic function (platelets ≥50 x 10^9/L), and wild-type p53 will be enrolled; pts with JAKi treatment = 28 d before baseline MRI/CT will be excluded. Pts will be randomized (2:1) to KRT-232 (240 mg on Day 1-7/28-day cycle; n = 188) or best available treatment (BAT; n = 94) and stratified by MF type (primary vs secondary) and baseline TSS (≤10 vs > 10). BAT options include hydroxyurea, chemotherapy, or supportive care (including; but not limited to: corticosteroids and androgens); treatment selection is at the discretion of the investigator. Pts in BAT arm with documented disease progression at any time (spleen volume increase ≥25% from baseline or confirmed leukemic transformation) or those who complete Week 24 assessments may crossover to the KRT-232 arm. Primary endpoint is rate of SVR ≥35% by MRI/CT at Week 24 (central review). Key secondary endpoints are ≥50% reduction in TSS rate at Week 24 (per MFSAF v4.0), PFS, OS, best overall SVR ≥35%, and duration of spleen response. Enrollment is planned at 137 sites in 21 countries in North and South America, Europe, and Asia-Pacific (ClinicalTrials.gov: NCT03662126). Clinical trial information: NCT03662126. Research Sponsor: Kartos Therapeutics, Inc.

TPS7058 **Poster Session**

A phase 3, randomized, double-blind, placebo-controlled study of ruxolitinib plus parsaclisib in patients with JAK- and PI3K-inhibitor treatment-naïve myelofibrosis. *First Author: Abdulraheem Yacoub, University of Kansas Medical Center, Westwood Campus, Westwood, KS*

Background: Ruxolitinib (JAK1/JAK2 inhibitor) significantly improves outcomes in patients with myelofibrosis (MF); however, a subset of patients may experience a suboptimal response. Recent phase 2 data showed that addition of PI3Kδ inhibitor parsaclisib to ruxolitinib monotherapy resulted in additional alleviation of MF symptoms and splenomegaly in patients with MF (Yacoub. EHA2020. S216). This phase 3, randomized, double-blind study (INCB 50465-313; NCT04551066), evaluates the combination of ruxolitinib and parsaclisib in patients with MF who are naïve to Janus kinase (JAK) and PI3K inhibitor therapies. **Methods:** Eligible patients are aged $\geq$18 years with a diagnosis of primary MF, post-polycythemia vera MF, or post-essential thrombocythemia MF, have a Dynamic International Prognostic Scoring System (DIPSS; Passamonti. Blood. 2010;115:1703-1708) risk category of at least Intermediate (INT)-1, palpable spleen $\geq$5 cm below left subcostal margin; total symptom score $\geq$10 at screening, ECOG PS 0–2, and life expectancy $\geq$24 weeks. Patients will be excluded if they previously received therapy with any JAK inhibitor, any PI3K inhibitor, any experimental or standard drug therapy for MF $\leq$3 months of first study dose and/or lack of recovery from all toxicities related to previous therapies to grade $\leq$1, have recent history of inadequate bone marrow reserve (eg, platelet count = 50×10^9/L) or have inadequate liver or renal function at screening. Approximately 440 patients will be randomized (1:1) to ruxolitinib plus parsaclisib 5 mg QD or ruxolitinib plus matching placebo, with stratification at randomization by DIPSS risk category (high vs INT-2 vs INT-1) and platelet count ($\geq100\times10^9$/L vs 50 to = 100×10^9/L inclusive). Treatment will begin on Day 1, with starting ruxolitinib dose level determined by baseline platelet count, and will continue as long as treatment is tolerated and discontinuation criteria are not met. When the last enrolled patient has completed 24 weeks of treatment, the study will be unblinded and patients randomized to ruxolitinib plus placebo who have adequate hematology parameters will be able to crossover to receive parsaclisib together with continued ruxolitinib. The primary objective is the evaluation and comparison of spleen volume at Week 24 for patients who received ruxolitinib plus parsaclisib versus ruxolitinib plus placebo. Secondary objectives include evaluation and comparison of patient-reported MF symptoms, overall survival, time to onset and duration of response in spleen volume, and safety and tolerability for ruxolitinib plus parsaclisib versus ruxolitinib plus placebo. Sites are opening across the United States, Europe, Asia, and New Zealand. Clinical trial information: NCT04551066. Research Sponsor: Incyte Corporation.

7500 **Oral Abstract Session**

First results of a head-to-head trial of acalabrutinib versus ibrutinib in previously treated chronic lymphocytic leukemia. *First Author: John C. Byrd, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: Increased selectivity of the Bruton tyrosine kinase inhibitor (BTKi) acalabrutinib (Aca) vs ibrutinib (Ib) may improve tolerability. We conducted an open-label, randomized, non-inferiority, phase 3 trial to compare Aca vs Ib in patients (pts) with chronic lymphocytic leukemia (CLL). **Methods:** Previously treated CLL pts with del(17p) or del(11q) by central lab were randomized to receive oral Aca 100 mg BID or Ib 420 mg QD (stratified by del(17p) status, ECOG PS [2 vs ≤1], and number of prior therapies [1–3 vs ≥4]) until progression or unacceptable toxicity. Primary endpoint was progression-free survival (PFS) as assessed by IRC; secondary endpoints of all grade atrial fibrillation (AF), grade ≥3 infection, Richter transformation, and overall survival (OS) were assessed in hierarchical order. **Results:** 533 pts (Aca, n=268; Ib, n=265) were randomized (median age 66 y; median 2 prior therapies; del(17p) 45.2%; del(11q) 64.2%). At a median follow-up of 40.9 mo (range 0.0–59.1), Aca was noninferior to Ib with a median PFS of 38.4 mo in both arms (HR 1.00; 95% CI 0.79–1.27). Aca was statistically superior to Ib in all-grade AF incidence (9.4% vs 16.0%; *P*=0.023). Among the other secondary endpoints, incidences of grade ≥3 infection (Aca: 30.8%, Ib: 30.0%) and Richter transformation (Aca: 3.8%, Ib: 4.9%) were comparable between arms. Median OS was not reached in either arm (HR 0.82 [95% CI 0.59–1.15]), with 63 (23.5%) deaths in the Aca arm and 73 (27.5%) in the Ib arm. Among any-grade AEs in ≥20% of pts in either arm, Aca was associated with a lower incidence of hypertension (9.4%, 23.2%), arthralgia (15.8%, 22.8%), and diarrhea (34.6%, 46.0%) but a higher incidence of headache (34.6%, 20.2%) and cough (28.9%, 21.3%). AEs led to treatment discontinuation in 14.7% of Aca- vs 21.3% of Ib-treated pts. Among any-grade events of clinical interest, cardiac, hypertension, and bleeding events were less frequent with Aca (Table). **Conclusions:** In this first head-to-head trial of BTKis in CLL, Aca demonstrated non-inferior PFS with less cardiotoxicity and fewer discontinuations due to AEs vs Ib. Clinical trial information: NCT02477696. Research Sponsor: Acerta Pharma, a member of the AstraZeneca Group.

Selected events of clinical interest.

Fixed-duration (FD) first-line treatment (tx) with ibrutinib (I) plus venetoclax (V) for chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL): Primary analysis of the FD cohort of the phase 2 captivate study. *First Author: Paolo Ghia, Università Vita-Salute San Raffaele and IRCCS Ospedale San Raffaele, Milan, Italy*

Background: CAPTIVATE (PCYC-1142) is a multicenter phase 2 study of first-line I+V in CLL. We previously reported results from the Minimal Residual Disease (MRD) cohort wherein undetectable MRD (uMRD) was achieved in over two-thirds of patients (pts) with 12 cycles of I+V, and 30-mo PFS rates were ≥95% irrespective of subsequent randomized treatment (Wierda, ASH 2020). We now present results from the FD cohort, evaluating fixed-duration tx with I+V. **Methods:** Pts aged ≤70 y with previously untreated CLL/SLL received 3 cycles of I then 12 cycles of I+V (I 420 mg/d orally; V ramp-up to 400 mg/d orally). Primary endpoint was CR rate, including CR with incomplete recovery (CRi); secondary endpoints were ORR, duration of response, uMRD rate ($<10^{-4}$ by 8-color flow cytometry), PFS, OS, tumor lysis syndrome (TLS) risk reduction, and adverse events (AEs). **Results:** 159 pts were enrolled (median age 60 y). High-risk features included del(17p)/*TP53* mutation, 17%; del(11q), 18%; complex karyotype, 19%; and unmutated IGHV, 56%. 147 (92%) and 149 (94%) pts completed planned tx with I and V, respectively. Median time on study was 27.9 mo (range, 0.8–33.2). With fixed-duration I+V, CR rate was 55% (95% CI 48–63) in the overall population and was consistent across high-risk subgroups. Of the 88 pts who achieved CR, 78 (89%) had durable CR (duration ≥1 y); 1 died 7 mo after CR, and 9 with <1 y follow-up were not evaluable. ORR was 96%. Best uMRD response was achieved in 77% of pts in peripheral blood (PB) and 60% of pts in bone marrow (BM). 24-mo PFS was 95%; 24-mo OS was 98%. Results were similar in pts without del(17p) (n=136) (Table). In pts with del(17p)/*TP53* mutation (n=27), CR rate was 56%, uMRD rate was 81% (PB) and 41% (BM), and 24-mo PFS was 84% (95% CI 63–94). Of 34 pts with high baseline TLS risk based on tumor burden, 32 (94%) shifted to medium or low risk after I lead-in; no TLS occurred. AEs were primarily grade 1/2. Most common grade 3/4 AEs were neutropenia (33%), hypertension (6%), and neutrophil count decreased (5%). AEs led to discontinuation of I in 4% and V in 2%. **Conclusions:** First-line I+V is an all-oral, once-daily, chemotherapy-free, fixed-duration regimen that provides deep, durable responses in pts with CLL/SLL, including those with genomic high-risk features. CR, uMRD rates, PFS, and OS appear favorable. The safety profile of I+V was consistent with known AEs for each agent; no new safety signals were identified. Clinical trial information: NCT02910583. 7502 **Oral Abstract Session**

First-in-human study of lisaftoclax (APG-2575), a novel BCL-2 inhibitor (BCL-2i), in patients (pts) with relapsed/refractory (R/R) CLL and other hematologic malignancies (HMs). *First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL*

Background: The BCL-2i venetoclax is active in certain HMs but can increase the risk of tumor lysis syndrome (TLS), requiring a 5-week dose ramp-up for CLL patients. Cases of severe neutropenia with venetoclax treatment have also been reported. Lisaftoclax is a novel, potent, selective BCL-2i that is active against HMs and is under clinical development. **Methods:** This first-in-human global phase I dose study assessed the safety, PK, PD, efficacy, and MTD/RP2D of lisaftoclax in patients with R/R CLL and other HMs. Lisaftoclax was orally administered daily in a 28-day cycle. Patients with CLL or intermediate-high TLS risk were initiated on a daily ramp-up schedule until the assigned dose before the study cycles. **Results:** On January 7, 2021, 35 pts had been enrolled and treated with lisaftoclax at doses ranging from 20 to 1,200 mg, with a median (range) of 2 (1-13) prior lines of treatment, and had diagnoses of R/R CLL or SLL (n = 15), MM (n = 6), FL (n = 5), WM (n = 4), and either AML, MCL, DLBCL, MDS, or HCL (n = 1 each). No DLT has been observed, even though 1,200 mg was considered as the highest dose treated. The MTD has not been reached, and no laboratory or clinical TLS has been reported. Any grade TRAEs in > 10% of pts included neutropenia (22.9%) and anemia (17.1%; hematologic), and fatigue (28.6%), diarrhea (17.1%), and nausea (11.4%; nonhematologic). Grade >3 TRAEs were neutropenia (14.3%) and thrombocytopenia, leukopenia, lymphopenia, fatigue, and nausea (2.9% of pts each). In CLL/SLL pts, grade 3-4 TRAEs included neutropenia (13.3%) and thrombocytopenia (6.7%), which did not cause treatment-related discontinuation. In all, 12 of 35 pts (34.3%) had non-treatment-related SAEs, and only two pts experienced > 1 SAE. With a median (range) treatment of 7 (3-20) cycles, 12 of 14 evaluable R/R CLL/SLL pts achieved PR, for an ORR of 85.7% and a median (range) time to response of 3 (2-7) cycles. Absolute lymphocyte counts (ALCs) were reduced at lisaftoclax doses as low as 20 mg/day. The preliminary PK profile showed that exposures increased with lisaftoclax doses from 20 to 1,200 mg (average half-life: 4-5 hours). On BH3 profiling, lisaftoclax rapidly triggered changes in BCL-2 complex in CLL/SLL pt samples, which were consistent with rapid clinical reductions in ALCs. **Conclusions:** Lisaftoclax was well tolerated up to 1,200 mg/day. No TLS was observed, even with the daily ramp-up schedule. There were no significant new or unmanageable safety findings, and the ORR in R/R CLL/SLL pts was 85.7%. Grade 3-4 TRAEs were infrequent, even at dose levels of 800 mg and above. BCL-2i lisaftoclax offers a treatment alternative for patients with R/R CLL/SLL and other HMs, with a daily ramp-up schedule that may be more pt "user friendly" and a favorable preliminary safety profile. ECOG-ACRIN E1411 randomized phase 2 trial of bendamustine-rituximab (BR)-based induction followed by rituximab (R) ± lenalidomide (L) consolidation for Mantle cell lymphoma: Effect of adding bortezomib to front-line BR induction on PFS. *First Author: Mitchell Reed Smith, GW University, Washington, DC*

Background: Optimal initial therapy for mantle cell lymphoma (MCL) remains uncertain. The randomized phase 2 NCTN trial E1411 tested if progression-free survival (PFS) is prolonged by addition of bortezomib (V) (1.6 mg/m2 SC/IV days 1, 8) to bendamustine-rituximab (BVR vs BR) induction and/or by addition of lenalidomide (L) to rituximab (LR vs R) consolidation. Here we report efficacy and toxicity of induction BVR vs BR. **Methods:** 373 pts, accrued 2012–16, stratified by MIPI and age (≥60) received 1 of 4 arms: A) BR induction x 6 followed by R x 2 yrs, B) BVR followed by R, C) BR followed by LR or D) BVR followed by LR. Eligible pts had untreated MCL, ≥ age 18 (amended from ≥60 when S1106 for < 65 closed), ECOG PS 0-2 and adequate hematologic and organ function. Pts without progressive disease during induction proceeded to consolidation. Primary induction objective was whether adding bortezomib (BVR) (Arms B + D) to BR (Arms A + C) improves PFS, irrespective of consolidation R vs LR. Design of 360 eligible treated pts would provide 93.8% power to detect 10% improvement in 2-yr PFS from 70% hypothesized for BR, corresponding to 37.4% reduction in hazard using stratified log-rank test at 1-sided 10% alpha. Efficacy population was 179 (BVR) and 180 (BR), induction treatment completed in 144 vs 153, progressive disease during induction 6 vs 7 and registration to consolidation 140 vs 145. **Results:** Baseline demographics did not differ between the groups, with median age 67 (range 42-90) and 13% < 60 yr, 73% men, ECOG PS 0-1 97%, MIPI Low/Med/Hi 37/29/34%. Estimated PFS at 2 yrs 79.6% BVR (95% CI 73.8-85.9) vs 74.5% BR (95% CI 68.2-81.4) (1-sided stratified log-rank p = 0.268). With median PFS follow-up 51 mos, median PFS estimated at 64.1 and 64.0 mos. Overall response rate (ORR) for BVR was 88.9% (CR 65.5%) vs 89.5% (CR 60.5%) BR (z-test 1 sided p = 0.577 for ORR). Treatment related deaths during induction were 2 in BVR (cardiac arrest, hepatitis) and 1 in BR (tumor lysis). Grade ≥ 3 toxicities were 88.1% (163/185) BVR vs 77.5% (145/187) BR. For BVR vs BR grade ≥ 3 neutropenia occurred in 52 vs 39 pts, though febrile neutropenia (7 vs 6), anemia (7 vs 8) and thrombocytopenia (18 vs 16) did not differ. Peripheral neuropathy (PN) grade 2 was 8 sensory for BVR vs 2 sensory/1 motor for BR, while grade 3 PN was 6 sensory/1 motor for BVR vs 0 with BR. The only non-hematologic grade ≥ 3 toxicity in > 5% of pts was rash (9 vs 12 pts). **Conclusions:** Bortezomib did not significantly improve the primary endpoint of PFS when added to BR as initial MCL therapy. ORR and CR rates at end of induction were also similar. Follow-up continues to assess the entire treatment regimen, including consolidation R vs LR, but the PFS > 5 yrs, high ORR and MRD negativity rate (Smith et al ASH 2019) in this BR-based trial support BR as a platform for MCL induction therapy. Clinical trial information: NCT01415752. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Real-world (RW) treatment (tx) patterns and outcomes of 3,455 previously untreated mantle cell lymphoma (MCL) patients (pts) in U.S. routine clinical practice.

First Author: Peter Martin, Weill Cornell Medicine, New York-Presbyterian Hospital, New York, NY

Background: MCL is a non-Hodgkin lymphoma with heterogeneous biology and outcomes. We characterized RW tx patterns and outcomes of MCL pts to identify factors associated with outcomes in the US. **Methods:** This retrospective study included adult MCL pts diagnosed Jan 2011-Nov 2020 in the nationwide Flatiron Health EHR-derived deidentified database. Pt characteristics, tx patterns, time to next tx (rwTTNT, defined as start of first-line [1L] tx to subsequent tx or death) and rwOS were evaluated. **Results:** 3455 pts were included, 85.3% from a community oncology setting. In 2946 (85.2%) pts with documented 1L MCL tx, median age was 69.5 y (range 27.7-85.3); 9.5% had blastoid/pleomorphic MCL. 262 (39.6%) and 235 (35.6%) of 661 pts with available MCL international prognostic index (MIPI) had intermediate and high risk, respectively. 150/1253 pts (12.0%) with available ECOG PS had PS $\geq$ 2. Chemoimmunotherapy was the most common 1L tx, including BR in 1223 (41.5%), R-CHOP in 512 (17.4%) and cytarabine (ara-C)-containing tx in 414 (14.1%). 667 pts received R maintenance (MR). In 1036 pts $<$ 65 y, 243 pts received 1L stem cell transplant (SCT), mainly autologous. In 1L-treated pts, with median follow-up of survivors of 45.3 mos (range 0.03-117.2), median rwTTNT was 24 mos; 36-mo rwOS was 67%. The Table shows tx received and outcomes by age and SCT status. MVA analyses showed age $\geq$ 65 y, ECOG PS $\geq$ 2, LDH/ULN $\geq$ 1, WBC $\geq$ 10 $\times$ 10^9/L, bulky disease ($\geq$ 5 cm) and blastoid/pleomorphic morphology were associated with shorter rwTTNT and rwOS; MR was independently associated with longer rwTTNT and rwOS. In pts $<$ 65 y who were alive and did not initiate subsequent tx within 6 mos of 1L tx ("SCT-eligible"), 36-mo rwTTNT and rwOS were similar between pts treated with vs without SCT: 65% vs 59% and 86% vs 85%, respectively. **Conclusions:** In this large RW cohort of primarily community-based US practices, median 1L rwTTNT for MCL pts was ~ 2 y. BR was the most commonly used 1L tx. SCT was uncommon even in pts $<$ 65 y, suggesting RW considerations may influence SCT eligibility and availability. Also, SCT was not clearly associated with rwOS. As with other reports, older age and high-risk disease features were predictive of worse outcome in RW, while MR appeared to be associated with better outcomes. Outcomes across the board appear worse than prospective trials, suggesting a need to focus on developing tx that can be delivered effectively in the community setting. Research Sponsor: Janssen Research and Development.

The combination of venetoclax, lenalidomide, and rituximab in patients with newly diagnosed mantle cell lymphoma induces high response rates and MRD undetectability.

First Author: Tycel Phillips, University of Michigan Medical School, Ann Arbor, MI

Background: MCL is a rare lymphoma without a standard of care but several regimens have demonstrated clinical activity, the majority based on traditional chemotherapy. We hypothesized that adding venetoclax (V) to R2 would be safe and effective in MCL pts irrespective of age, morphology or stage. Here we present safety and efficacy data from the on-going phase 1b study of R2 + V in pts with newly diagnosed MCL. **Methods:** This multi-center phase 1 study (NCT03523975) enrolled pts aged $\geq$18 yrs with untreated MCL. The primary objective was to characterize the safety and tolerability of R2 + V and determine the MTD. During induction (12 months (m)) pts received lenalidomide (L) 20 mg daily on day 1-21, Rituximab (R) was given weekly during c1 then on day 1 of every even cycle, V was escalated over 4 weeks to 400 mg beginning day 8. Each cycle is 28 days (d). The DLT period was 42 d beginning C1D8. In maintenance, R every 8 weeks for 36m, L at 10 mg or half of last dose during induction for 24 m and V for minimum 12 m. No pts have been transplanted. Pts with progression (PD) came off study. MRD was analyzed in parallel with scans during induction by clonoSEQ assay (Adaptive Biotechnologies). **Results:** As of Feb. 1st, 2021, we have enrolled all 28 planned pts on study. Pt characteristics/responses are summarized in Table. Among the 28 pts who have received at least one dose, the median treatment duration so far is 278d (IQR 170-560), with 24 pts still on treatment (Tx). 1 pt is off from a unrelated condition. All pts escalated to V 400 mg w/o any DLTs noted. Treatment-emergent adverse events (TEAEs) were reported in 100% of pts, and grade 3+ TEAEs were reported in 26 (93%) patients. The most common all-grade TEAEs ($\geq$50% of pts), regardless of relationship to study Tx, were fatigue, neutropenia and diarrhea. Grade $\geq$3 TEAEs reported in $\geq$50% pts were neutropenia (68%) and thrombocytopenia (50%). No pts have withdrawn or d/c Tx due to AEs. There was one grade 5 event, in a non-evaluable pt, related to a PE that occurred prior to DLT period. In the 28 evaluable pts the ORR (CR/PR) was 96% (27/28 pts) with CR/CRu of 89%. Of the responding pts, two had PD, one w/ CR and one w/ PR. All pts with PD had baseline *TP53* mutation. MRD testing was successful in all pts. At time of submission 20 of 28 (71%) were MRD - at 10^{-6}. **Conclusions:** Interim results show that at the MTD the combination of V 400 mg daily, L 20 mg, with R is safe with a manageable toxicity profile and a high ORR and MRD - in pts with newly diagnosed MCL. Safety data is consistent with the AE profile noted for each drug without any unexpected or unique AEs. Updated results including BH3 profiling will be presented at the meeting. Clinical trial information: NCT03523975. Research Sponsor: Abbvie, Rogel Cancer Center.

Myeloablative versus non-myeloablative consolidative chemotherapy for newly diagnosed primary central nervous system lymphoma: Results of CALGB 51101 (Alliance).

First Author: Tracy Batchelor, Brigham and Women's Hospital, Boston, MA

Background: Optimal consolidative therapy for primary central nervous system lymphoma (PCNSL) is not defined. Avoidance of whole brain radiation may reduce risk of neurotoxicity. Non-radiation consolidative options include myeloablative chemotherapy with autologous stem cell transplantation (HDT/ASCT) or non-myeloablative chemotherapy. **Methods:** This is a randomized phase 2, National Clinical Trials Network study of induction methotrexate (MTX) (8 g/m^2 days 1, 15), temozolomide (TMZ) (150-200 mg/m^2 D7-11), and rituximab (RTX) (C1 D3, 10, 17, 24 and C2 D3, 10) in four 28-day cycles followed by one cycle of cytarabine (ARA-C) (2 g/m^2 BID, D1, 2) (MTRA). After induction, patients (pts) received consolidation with thiotepa (5 mg/kg BID, D -5, -4) plus carmustine (400 mg/m^2, day -6) and ASCT (Arm A) or one cycle of ARA-C (2 g/m^2 BID, D1-4) plus infusional etoposide (40 mg/kg over 96h) (Arm B). Pts were stratified on age and performance status and randomized 1:1 before induction. The primary endpoint was progression-free survival (PFS) from randomization. With 110 pts, there was 84% power to detect an improvement in PFS using a log-rank test (1-sided α= 10%), assuming a median PFS of 3 months for pts who progress during induction, and a median PFS of 2 years (yrs) for Arm B and 4.5 yrs for Arm A consolidation. This report includes the results for the primary endpoint analysis. **Results:** 113 pts (median age 61 yrs, range 33-75) were randomized (Arm A: 57, Arm B: 56) across 27 centers. 108 eligible pts who received induction therapy were included in the primary endpoint analysis (Arm A: 54, Arm B: 54). 72/108 pts started consolidation and 70/72 completed consolidation per protocol (Arm A: 36, Arm B: 34). With a median follow-up of 3.8 years, median PFS from randomization was 6 yrs (95% CI 3.9-not reached) in Arm A vs 2.4 yrs (95% CI 0.6-not reached) in Arm B (p = 0.02). However, more pts randomized to Arm B went off treatment before consolidation due to progression or death (28% vs 11%, p = 0.05). PFS landmarked at start of consolidation demonstrated a trend for improved PFS favoring Arm A (HR 0.58, 95% CI 0.25-1.36; p = 0.21). Median OS was not reached in either arm, and 3-yr estimates were 83% (95% CI 69-91; Arm A) vs 72% (95% CI 57-82; Arm B). Toxicities were similar between arms with no treatment-related mortality during consolidation. **Conclusions:** MTRA induction followed by myeloablative consolidation (Arm A) had improved PFS vs MTRA induction followed by non-myeloablative consolidation (Arm B), though more progressions or deaths leading to treatment discontinuation prior to consolidation in Arm B were noted. Both consolidation regimens were well-tolerated with encouraging PFS and OS in newly-diagnosed PCNSL. Support: U10CA180821, U10CA180882; https://acknowledgments.alliancefound.org. CALGB 50801 (Alliance): PET adapted therapy in bulky stage I/II classic Hodgkin lymphoma (cHL).

First Author: Ann S. LaCasce, Dana-Farber Cancer Institute, Boston, MA

Background: Bulky disease is associated with inferior outcomes in patients with early stage cHL. Historically, most patients (pts) receive chemotherapy followed by radiotherapy (RT), which is associated with long-term toxicity. We tested a PET-adapted approach to reduce the need for RT in pts with early PET-negative (PET-) disease and escalate therapy in pts with PET-positive (PET+) disease. **Methods:** Eligible pts aged 18-60 years (yrs) had stage IA-IIB cHL with disease bulk $>$10 cm or $>$.33 max intrathoracic diameter on chest x-ray. Pts received 2 cycles of doxorubicin-bleomycin-vinblastine-dacarbazine (ABVD) followed by centrally reviewed PET. PET- was defined as Deauville of 1-3. Pts who achieved a negative PET scan (PET2-) received 4 additional cycles of ABVD. PET2+ pts received 4 cycles of escBEACOPP plus 30 Gy involved-site radiation therapy. The primary endpoint was progression-free survival (PFS) estimated from PET2. With 93 pts and assuming 30% PET2+, there was 80% power to rule out that PFS of PET2+ pts was substantially inferior to PFS of PET2- pts (HR 4.1, 3-yr PFS 40% vs 80%) if the true PFS of PET2+ pts was closer to that of PET2- pts (HR 2.29, 3-yr PFS 60% vs 80%) with one-sided alpha=0.15. With few events and mature follow-up, we report results 3 yrs after the last pt was enrolled. **Results:** Between May 2010 and October 2017, 101 pts enrolled. Excluding 6 ineligible pts (3 without baseline DLCO, 2 did not meet definition of bulk, 1 stage IIIB) and 1 pt without PET2, 94 were evaluable. 78% of pts were PET2- (73 PET2-, 21 PET2+). Median age was 30 yrs (range: 18 to 58) and 53.2% were female. Distribution of stage was: 1A - 7.4%, IB - 2.1%, IIA – 39.4%, IIB - 51.1%; 61.9% PET2+ pts had stage IIB disease. Therapy was generally well tolerated. Grade $>$ 3 neutropenia occurred in 86% of pts with 8% of PET2- and 10% of PET2+ with grade $>$ 3 febrile neutropenia. 3-yr PFS estimates were 93.1% (95% CI: 87.4-99.1%) in PET2- pts, 89.7% (95% CI: 77.2-100.0%) in PET2+ pts (HR=1.01, 85% upper bound 2.32), and 92.3% (95% CI: 87.0-98.0%) for all pts. The protocol-defined primary endpoint was met as the PFS hazard ratio for PET2+ vs PET2- was less than 4.1 (one sided p=0.04). With a median follow-up of 5.5 yrs, 3 PET2- pts died (HL, anaplastic astrocytoma and COPD) and 1 PET2+ died of progressive disease. 3-yr overall survival (not a primary or secondary outcome of the study) estimates were 98.6% (95% CI: 95.9-100.0%) in PET2- pts, 94.4% (95% CI: 85.4-100.0%) in PET2+ pts (HR: 1.2, 95% CI: 0.12, 11.60), and 97.7% (95% CI: 94.7-100.0%) for all pts. **Conclusions:** Excellent PFS outcomes were observed in all pts using a PET-adapted approach that allowed omission of RT in 78% of pts. In addition, PET2+ pts treated with escalation to BEACOPP and consolidative RT did not have inferior outcomes. Efficacy and safety of tisagenlecleucel (Tisa-cel) in adult patients (Pts) with relapsed/refractory follicular lymphoma (r/r FL): Primary analysis of the phase 2 Elara trial. *First Author: Stephen J. Schuster, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: Most pts with r/r FL experience multiple relapses and progressively worse clinical outcomes with each line of therapy, underlining a need for novel therapies. Tisa-cel has demonstrated durable responses and manageable safety in adult pts with r/r diffuse large B-cell lymphoma. Here we report the primary analysis of ELARA, an international, single-arm phase 2 trial of tisa-cel in adult pts with r/r FL. **Methods:** Eligible pts (≥18 y) had r/r FL (grades [Gr] 1-3A) after ≥2 lines of therapy or had failed autologous stem cell transplant. Bridging therapy was permitted followed by disease assessment prior to tisa-cel infusion. Pts received tisa-cel ($0.6\text{-}6\times10^8$ CAR+ viable T cells) after lymphodepleting chemotherapy. The primary endpoint was complete response rate (CRR) by central review per Lugano 2014 criteria. Secondary endpoints included overall response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), safety, and cellular kinetics. Predefined primary analysis occurred when ≥90 treated pts had ≥6 mo of follow-up. **Results:** As of September 28, 2020, 98 pts were enrolled and 97 received tisa-cel (median follow-up, 10.6 mo). At study entry, median age among treated pts was 57 y (range, 29-73), 85% had stage III-IV disease, 60% had a FLIPI score ≥3, 65% had bulky disease, and 42% had LDH > upper limit of normal. The median number of prior therapies was 4 (range, 2-13); 78% of pts were refractory to their last treatment (76% to any ≥2 prior regimens) and 60% progressed within 2 y of initial anti-CD20–containing treatment. Of 94 pts evaluable for efficacy, the CRR was 66% (95% CI, 56-75) and the ORR was 86% (95% CI, 78-92). CRRs/ORRs were comparable among key high-risk subgroups. Estimated DOR (CR) and PFS rates at 6 mo were 94% (95% CI, 82-98) and 76% (95% CI, 65-84), respectively. Of 97 pts evaluable for safety, 65% experienced Gr ≥3 adverse events within 8 weeks post-infusion, most commonly neutropenia (28%) and anemia (13%). Any-grade cytokine release syndrome (per Lee scale) occurred in 49% of pts (Gr ≥3, 0%). Any-grade neurological events (per CTCAE v4.03) occurred in 9% of pts (Gr 3, 0%; Gr 4, 1 pt and recovered). Three pts died from progressive disease. Cellular kinetic parameters for tisa-cel were estimated using transgene levels (by qPCR) in peripheral blood. C_{max} and $AUC_{0\text{-}28d}$ were similar between responders (CR or partial response) and non-responders (stable or progressive disease). Maximum transgene levels were reached by a median of 10 days in responders and 12.9 days in non-responders; transgene persistence was detected up to 370 days and 187 days, respectively. **Conclusions:** These data demonstrate the efficacy and acceptable safety of tisa-cel in pts with r/r FL, including high-risk pts after multiple lines of prior therapy, and suggest that tisa-cel may be a promising therapy for pts with r/r FL. Clinical trial information: NCT03568461. Research Sponsor: Novartis.

7509 **Poster Discussion Session**

Acalabrutinib ± obinutuzumab versus obinutuzumab + chlorambucil in treatment-naïve chronic lymphocytic leukemia: Elevate-TN four-year follow up. *First Author: Jeff Porter Sharman, Willamette Valley Cancer Institute and US Oncology Research Center, Eugene, OR*

Background: Early results from ELEVATE-TN (NCT02475681) at a median follow-up of 28.3 mo demonstrated superior efficacy of acalabrutinib (A) ± obinutuzumab (O) compared with O + chlorambucil (Clb) in patients (pts) with treatment-naïve (TN) chronic lymphocytic leukemia (CLL) (Sharman et al. Lancet 2020;395:1278-91). Results from a 4-year update are reported here. **Methods:** Pts received A±O or O+Clb. Crossover to A monotherapy was permitted in pts who progressed on O+Clb. Investigator-assessed (INV) progression-free survival (PFS), INV overall response rate (ORR), overall survival (OS), and safety were evaluated. **Results:** 535 pts (A+O, n=179; A, n=179; O+Clb, n=177) were randomized with a median age of 70 y; 63% had unmutated IGHV and 9% del(17p). At a median follow-up of 46.9 mo (range, 0.0–59.4; data cutoff: Sept 11, 2020), the median PFS was not reached (NR) for A+O and A pts vs 27.8 mo for O+Clb pts (both $P<0.0001$). In pts with unmutated IGHV, the median PFS was NR (A+O and A) vs 22.2 mo among O+Clb pts (both $P<0.0001$). In pts with del(17p), the median PFS was NR (A+O and A) vs 17.7 mo for O+Clb ($P<0.005$). Estimated 48-mo PFS rates were 87% for A+O, 78% for A, and 25% for O+Clb. Median OS was NR in any treatment arm with a trend towards significance in the A+O group (A+O vs O+Clb, $P=0.0604$); estimated 48-mo OS rates were 93% (A+O), 88% (A), and 88% (O+Clb). ORR was significantly higher with A+O (96.1%; 95% CI 92.1–98.1) vs O+Clb (82.5%; 95% CI 76.2–87.4; $P<0.0001$); ORR with A was 89.9% (95% CI 84.7–93.5; $P=0.035$ vs O+Clb). Complete response/complete response with incomplete hematologic recovery (CR/CRi) rates were higher with A+O (26.8%/3.9%) vs O+Clb (12.4%/0.6%); 10.6%/0.6% had CR/CRi with A. Common adverse events (AEs) and AEs of interest are shown in the Table. Overall treatment discontinuation rates were 25.1% (A+O), 30.7% (A), and 22.6% (O+Clb); the most common reasons were AEs (12.8%, 12.3%, 14.7%, respectively) and progressive disease (4.5%, 7.8%, 1.7%). Most pts (77.4%) completed O+Clb treatment. **Conclusions:** With a median follow-up of 46.9 mo (~4y), the efficacy and safety of A+O and A monotherapy was maintained, with an increase in CR since the interim analysis (from 21% to 27% [A+O] and from 7% to 11% [A]) and low rates of discontinuation. Research Sponsor: None.

7510 **Poster Discussion Session**

Copanlisib + rituximab versus rituximab + placebo in patients with relapsed follicular (FL) or marginal zone lymphoma (MZL): Subset analysis from the phase III CHRONOS-3 trial. *First Author: Matthew J. Matasar, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Rituximab (R) monotherapy is an approved treatment for patients (pts) with relapsed indolent NHL (iNHL) who have a prolonged progression-free and treatment-free interval after last R-based therapy or who are unwilling/unfit to receive chemotherapy. Copanlisib (C) is a PI3K inhibitor approved as monotherapy in pts with relapsed FL who have progressed after ≥2 systemic therapies. The recent Phase III CHRONOS-3 study in pts with relapsed iNHL treated with C+R vs placebo (P)+R (NCT02367040) met its primary endpoint with a significant 48% reduction in the risk of disease progression or death (Matasar et al. AACR 2021). We report here a pre-planned subset analysis in pts with relapsed FL or MZL. **Methods:** Pts with relapsed iNHL who were progression- and treatment-free for ≥12 months (mo) after last R-based therapy or ≥6 mo if unwilling/unfit to receive chemotherapy were randomized 2:1 to receive C+R or P+R. C 60 mg/P was given i.v. on days 1, 8, and 15 (28-day cycle); R 375 mg/m^2 was given i.v. on days 1, 8, 15, and 22 of cycle 1 and on day 1 of cycles 3, 5, 7, and 9. Primary endpoint was centrally assessed progression-free survival (PFS) by Cheson 2014 criteria. Secondary endpoints included objective response rate (ORR), duration of response (DoR), complete response rate (CRR), time to progression (TTP), and treatment-emergent adverse events (TEAEs). All randomized pts were assessed for efficacy; pts were assessed for safety if they received ≥1 dose of C/P or R. The data cut-off date was August 31, 2020. **Results:** From a total dataset of 458 iNHL pts, 250 pts with FL/MZL (184 FL/66 MZL) were randomized to C+R and 120 (91 FL/29 MZL) to P+R. Median age was 62 years (range 28-91) and the arms were well balanced. With a median follow-up of 18.5 mo, C+R significantly reduced the risk of disease progression/death vs P+R (HR = 0.55 [95% CI 0.40, 0.76]; 1-sided p = 0.0001); median PFS was 22.2 mo (95% CI 19.1, 33.1) vs 15.4 mo (95% CI 11.0, 19.2), respectively. Median TTP was 27.5 mo for C+R vs 15.4 mo for P+R (HR = 0.500; 1-sided p = 0.00001). ORRs were 82.4% (CRR 37.6%) for C+R and 50.8% (CRR 18.3%) for P+R; median DoR was 23.9 mo vs 17.9 mo, respectively. Most common TEAEs (all grades [G]/G3+) in pts with FL/MZL receiving C+R (n = 249) were hyperglycemia (72.7%/59.0%), hypertension (53.8%/43.0% [all G3]), and diarrhea (35.3%/5.6% [all G3]). For pts receiving P+R (n = 116), the most common TEAEs were hyperglycemia (23.3%/7.8% [all G3]), hypertension (19.8%/8.6% [all G3]), neutropenia (18.1%/13.8%), and upper respiratory tract infection (18.1%/0%). **Conclusions:** C+R demonstrated superior efficacy vs P+R in pts with relapsed FL/MZL and had a manageable safety profile, consistent with C and R as monotherapy. Copanlisib is the first PI3K inhibitor to be safely combined with R in relapsed FL/MZL, representing a potential new therapeutic option. Clinical trial information: NCT02367040. Obinutuzumab (G)-atezolizumab (atezo)-lenalidomide (len) for the treatment of relapsed/refractory (R/R) follicular lymphoma (FL): Final analysis of a phase Ib/II trial. *First Author: Nilanjan Ghosh, Hematologic Oncology and Blood Disorders, Levine Cancer Institute/Atrium Health, Charlotte, NC*

Background: G-len has promising activity and manageable toxicity in R/R FL (Morschhauser et al. 2019). We report the final analysis of an open-label, multicenter, Phase Ib/II trial (NCT02631577) that evaluated the immunomodulatory triplet G-atezo-len in pts with R/R FL. **Methods:** An initial 3+3 dose-escalation to identify the Phase II len dose was followed by an expansion phase with G-atezo-len. Enrolled pts (aged ≥18 years) received induction with 6, 28-day cycles of G 1000 mg IV on Day [D] 1, 8, and 15 of Cycle [C] 1 and D1 of C2–6, atezo 840 mg IV on D1 and 15 of C2–6, and len 15/20 mg (dose escalation) or 20 mg (expansion) orally on D1–21 of C1–6. Responders received 24 months (mos) of maintenance with G 1000 mg D1 every 2 mos, atezo 840 mg D1–2 every mo, and len 10 mg D1–21 mos 1–12. The primary endpoint was complete response at end of induction by PET-CT assessed by Independent Review Committee (modified Lugano 2014 criteria; Morschhauser et al. ICML 2019). Exploratory endpoints described herein included progression-free survival (PFS), overall survival (OS), and duration of response (DOR). Adverse events (AEs) were also assessed. **Results:** At the final analysis (October 7, 2020), 38 pts had completed the trial. Median age was 62 years, 26% had a high-risk FLIPI score, 45% were refractory to their last line of therapy, and 37% had progression of disease within 24 mos of their first-line of therapy (POD24). Median treatment duration was 26 mos (range: 0.4–30). The 36-mo PFS rate for the overall population (median observation time, 35.9 mos; range: 3–47) was 64% (95% CI, 45–79), OS was 85% (95% CI, 70–93), and median DOR was 38 mos (95% CI, 35–NE). 36-mo PFS rates for the following subgroups are provided in the table: double refractory (rituximab and an alkylator); with/without POD24; minimal residual disease (MRD) +/-. In total, 32 pts (84%) had a Grade 3/4 AE (majority hematologic), and 18 (47%) had a serious AE. Five pts (13%) during induction and six pts (16%) during maintenance had an AE that led to discontinuation of any drug. Two fatal AEs were reported (1 merkel carcinoma, 1 sarcomatoid carcinoma; both unrelated to any study drug). The most common atezo AEs of special interest were hyperthyroidism (13%), hypothyroidism (11%), increased ALT and AST (both 8%), increased lipase (8%), and hepatocellular injury (5%). **Conclusions:** G-atezo-len is efficacious in pts with R/R FL, with data from the final analysis suggesting a potential for improved outcomes versus the G-len doublet. AEs were consistent with the safety profile of the individual drugs. Clinical trial information: NCT02631577. Research Sponsor: This study was sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of all authors, was provided by A. Lynch, PhD, of Ashfield MedComms, an Ashfield Health Company, and funded by F. Hoffmann-La Roche Ltd.

36-mo PFS rates.

	Subgroup						
	MRD- (N=16)	MRD+* (N=5)	Double refractory (N=12)	Not double-refractory (N=20)	With POD24 (N=12)	Without POD24 (N=20)	Overall (N=32)
36-mo PFS rate, % (95% CI)	79 (48–93)	0	70 (33–89)	67 (40–84)	64 (30–85)	73 (46–88)	64 (45–79)

*All pts progressed before 36 mos; median PFS was 10.7 mos (range: 1.8–18).

Polatuzumab vedotin (Pola) + rituximab (R) + lenalidomide (Len) in patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL): Primary analysis of a phase 1b/2 trial.

First Author: Catherine S. Magid Diefenbach, Perlmutter Cancer Center at NYU Langone Health, New York, NY

Background: The combination of Pola-R-Len may enhance anti-tumor response in R/R DLBCL. We report the primary analysis of the R/R DLBCL cohort in a Phase 1b/2 study (GO29834; NCT02600897). **Methods:** Pts received induction with 6 x 28-Day (D) cycles (C) of: Pola 1.8mg/kg intravenous (IV; C1−6: D1); R 375mg/m^2 IV (C1−6: D1) and oral Len 10–20mg (dose escalation) or recommended Phase 2 dose (RP2D) daily on D1–21. Pts with a response at end of induction (EOI) received 6 months (mo) consolidation with R 375mg/m^2 (D1 every 2 mo) and Len 10mg (D1–21 monthly). Primary endpoints were safety/tolerability and positron emission tomography (PET)-complete response (CR) rate at EOI by independent review committee (IRC) by modified Lugano criteria. **Results:** At primary analysis (Sep 08, 2020), 57 pts were enrolled. Median age was 71 years (range 28–92); male (67%); Ann Arbor Stage III–IV (86%); International Prognostic Index 3–5 (60%); median 2 prior therapies; prior bone marrow transplant (11%); prior CAR-T therapy (5%); primary refractory (49%) and refractory to last therapy (65%). Grade 3–4 adverse events (AEs) were experienced by 75% of pts, most commonly, neutropenia (58%), thrombocytopenia (14%), infections (14%) and anemia (11%). AEs led to Len dose reduction in 25% and interruption in 63% of pts. One Grade 5 treatment-related AE (neutropenic sepsis) was reported. In total, 49 pts were treated at RP2D (Pola 1.8mg/kg + Len 20mg). IRC PET-CR rate at EOI was 29% (Table). A best overall response (BOR) assessed by investigator (INV) was seen in 36/49 (74%) pts with 17/49 (35%) pts achieving a CR; of these, 14/17 (82%) remain in remission at the cutoff date. Median duration of response (DOR) was 8.1 mo (95% confidence interval [CI]: 4.7–not evaluable [NE]). After a median follow-up of 9.7 mo, median progression-free survival (PFS) and overall survival (OS) were 6.3 mo (95% CI: 4.5–9.7) and 10.9 mo (95% CI: 7.4–NE), respectively. **Conclusions:** Our study of the novel triplet combination, Pola-R-Len, demonstrates a tolerable safety profile. This first efficacy report of Pola-R-Len shows promising activity in a difficult-to-treat R/R DLBCL population, particularly in pts achieving CR, a large proportion of whom remain in remission at the cutoff date. Further evaluation of Pola-R-Len and the impact of consolidation therapy is warranted to address the significant unmet need in this patient population. Clinical trial information: NCT02600897. Research Sponsor: Study sponsored by F. Hoffmann-La Roche Ltd/Genentech, Inc. Third-party editorial assistance, under direction of authors, was provided by Angela Rogers, PhD, of Ashfield MedComms, an Ashfield Health company, and funded by F. Hoffmann-La Roche Ltd.

7513 **Poster Discussion Session**

Long-term analyses from L-MIND, a phase II study of tafasitamab (MOR208) combined with lenalidomide (LEN) in patients with relapsed or refractory diffuse large B-cell lymphoma (R/R DLBCL).

First Author: Johannes Düll, Medizinische Klinik und Poliklinik II, Universitätsklinik Würzburg, Würzburg, Germany

Background: L-MIND (NCT02399085) is an ongoing, open-label, Phase II study of tafasitamab (MOR208), an Fc-modified, humanized, anti-CD19 monoclonal antibody, plus LEN in ASCT-ineligible patients (pts) with R/R DLBCL. Primary analyses and 2-year efficacy results were previously presented; we report an updated efficacy analysis with ≥35 months follow up (cut-off: October 30, 2020). **Methods:** Pts were aged ≥18 years with ASCT-ineligible R/R DLBCL, had 1–3 prior systemic therapies (Tx), including ≥1 CD20-targeting regimen, with an ECOG status of 0–2. Pts received 28-day cycles (C) of tafasitamab (12 mg/kg IV), once weekly during C1–3, with a loading dose on Day 4 of C1, then every 2 weeks (Q2W) during C4–12. LEN (25 mg PO) was administered on Days 1–21 of C1–12. After C12, progression-free pts received tafasitamab Q2W until disease progression. The primary endpoint was objective response rate (ORR), assessed by IRC. Secondary endpoints included duration of response (DoR), progression-free survival (PFS) and overall survival (OS). **Results:** Eighty of 81 enrolled pts received tafasitamab + LEN and were included in the full analysis set (1 prior Tx, n=40; 2+ prior Tx, n=40). At data cut-off, the overall ORR was 57.5% (n=46/80), including complete response (CR) in 40% of pts (n=32/80) and partial response (PR) in 17.5% of pts (n=14/80) (Table). Kaplan-Meier estimates: median DoR=43.9 months (95% CI: 26.1–not reached [NR]), and NR in pts who achieved a CR (95% CI: 43.9–NR); median PFS=11.6 months (95% CI: 6.3–45.7), with median follow-up 33.9 months; median OS=33.5 months (95% CI: 18.3–NR), with median follow-up 42.7 months. There were no unexpected toxicities or new safety signals. **Conclusions:** Combination Tx with tafasitamab + LEN followed by tafasitamab monotherapy provided durable responses in pts with R/R DLBCL not eligible for ASCT, with a manageable safety profile. These long-term data indicate the potential of tafasitamab + LEN followed by extended tafasitamab monotherapy in achieving prolonged remission and survival benefit in this patient population, especially at first relapse. Clinical trial information: NCT02399085. Research Sponsor: MorphoSys AG, Planegg, Germany.

Multicenter phase II study of romidepsin plus lenalidomide for patients with previously untreated peripheral T-cell lymphoma (PTCL).

First Author: Jia Ruan, Weill Cornell Medicine and New York Presbyterian Hospital, New York, NY

Background: PTCL are aggressive malignancies associated with poor prognosis when treated with cytotoxic chemotherapy. Novel agents, such as HDAC inhibitor romidepsin and immunomodulatory agent lenalidomide, have shown clinical activities as single agents and in combination in R/R PTCL. We hypothesize that upfront treatment with these agents is an effective and well-tolerated option to defer chemotherapy, particularly in patients who are not candidates for intensive approach. We report the findings of the first chemo-free combination of romidepsin plus lenalidomide as initial treatment for PTCL (ClinicalTrials.gov-NCT02232516). **Methods:** Patients with untreated PTCL who were over 60 or noncandidates for chemotherapy based on comorbidity CIRS score were eligible. Treatment was initiated with romidepsin 10 mg/m2 IV on d 1, 8, 15, and lenalidomide 25 mg PO on d 1-21 of 28-day cycle for up to 1 year, unless discontinued prior due to POD, toxicities, or withdrawal of consent. The primary objective was to evaluate ORR per Cheson criteria. Secondary objectives included safety, PFS, OS, DOR, and delay to chemotherapy. The sample size was 20 evaluable patients, which allows to estimate the underlying true response rate with the margin of error of an approximate 95% confidence interval equal to 0.22, assuming the true ORR = 0.5. **Results:** The study enrolled 29 subjects at 3 US centers, including 16 (55%) AITL, 11 (38%) PTCL-NOS, 1 ATLL and 1 EATCL. The median age was 75 (range 49-84), and M:F ratio was 1:1. Nineteen (66%) had stage III/IV disease, 23 (79%) had elevated LDH, and 9 (31%) had IPI 3-5. Treatment was well tolerated with expected side effects. Grade 3-4 hematologic toxicities included neutropenia (45%), thrombocytopenia (34%) and anemia (28%). Grade 3-4 non-hematologic toxicities included hyponatremia (45%), hypertension (38%), hypoalbuminemia (24%), fatigue (17%), hyperglycemia (14%), hypokalemia (14%), dehydration (10%), lung infection (10%) and sepsis (10%). At a median follow-up of 8 months, 20 subjects were evaluable with at least one response assessment, and received a median treatment of 6 cycles. The ORR was 75% (95%CI: 50.9%, 91.3%) with CR at 30% (11.9%, 54.3%). For AITL, the ORR was 85% (54.6%, 98.1%) with CR at 38% (13.9%, 68.4%). Median DOR was 4.2 months for all responders, and 14.3 months for CR patients. The estimated 1-yr PFS was 54.3% with 3-yr PFS at 36.2%, and the estimated 1-yr OS was 76.0% with 3-yr OS at 51.3%. Two subjects moved onto consolidative ASCT in remission, and 4 received additional cytotoxic chemotherapy after progression. **Conclusions:** This study provides the first demonstration that chemo-free biologic combination of romidepsin and lenalidomide is feasible and effective as initial therapy for PTCL patients who are not candidates for cytotoxic chemotherapy. These data justify further evaluation of such novel agents as a frontline strategy. Clinical trial information: NCT02232516. Research Sponsor: BMS/Celgene.

7515 **Poster Discussion Session**

Outcomes in ZUMA-5 with axicabtagene ciloleucel (axi-cel) in patients (pts) with relapsed/refractory (R/R) indolent non-Hodgkin lymphoma (iNHL) who had the high-risk feature of progression within 24 months from initiation of first anti-CD20–containing chemoimmunotherapy (POD24).

First Author: Caron A. Jacobson, Dana-Farber Cancer Institute, Boston, MA

Background: POD24 is an indicator of poor survival in iNHL (Casulo & Barr. *Blood*. 2019). In the ZUMA-5 Phase 2 study of axi-cel anti-CD19 CAR T-cell therapy in pts with R/R iNHL, overall response rates (ORR) after 17.5 months median follow-up were similarly high in those with and without POD24 (93% and 92%; Jacobson et al. ASH 2020. #700). Here, we report updated outcomes with longer follow-up in pts with POD24 in ZUMA-5. **Methods:** Adults with R/R follicular lymphoma (FL) or marginal zone lymphoma (MZL) after ≥2 lines of therapy underwent leukapheresis followed by conditioning therapy and axi-cel infusion (2×10^6 CAR T cells/kg). Axi-cel–treated pts with available data on progression after an anti-CD20 mAb + alkylating agent were included. The updated efficacy analysis occurred when ≥80 treated pts with FL had ≥18 months follow-up. **Results:** Of 129 pts at baseline, 81 pts (63%; 68 FL, 13 MZL) had POD24 and 48 pts (37%; 40 FL, 8 MZL) did not have POD24. Median prior lines of therapy in pts with and without POD24 were 3 and 3.5, respectively. High-risk characteristics of pts with and without POD24 included stage III/IV disease, 83% and 94%; ≥3 FLIPI, 44% and 43%; high tumor bulk (GELF), 51% and 44%; and refractory disease, 77% and 63%, respectively. With 23.3 months median follow-up, ORR among efficacy-evaluable pts with POD24 (n = 61) and without POD24 (n = 37) was 92% each (complete response rates, 75% and 86%). At data cutoff, 52% of pts with POD24 and 70% without POD24 had ongoing responses. Median duration of response, progression-free survival, and overall survival were not reached in pts with and without POD24; 18-month estimated rates were 60% and 78%, 55% and 84%, and 85% and 94%, respectively. Incidences of Grade ≥3 adverse events were similar in pts with and without POD24 (84% and 88%), including cytopenias (69% and 65%) and infections (15% and 21%). Grade ≥3 cytokine release syndrome (CRS) occurred in 9% and 2% of pts with and without POD24, respectively; Grade ≥3 neurologic events (NEs) occurred in 17% of pts each. Median times to onset were similar in pts with and without POD24 for CRS (4 days each) and NEs (8 days and 7 days); median durations of CRS (7 days and 5 days) and NEs (11 days and 13 days) were also similar between groups. In efficacy-evaluable pts with FL, median peak CAR T-cell levels were similar in pts with and without POD24 (35.8 cells/μL and 34.5 cells/μL). Peak levels of key inflammatory biomarkers and axi-cel product attributes were generally similar in pts with and without POD24. **Conclusions:** Axi-cel showed a high rate of durable responses in pts with POD24 iNHL, a population with high-risk disease. Efficacy results, as well as safety and pharmacological profiles, appeared largely comparable between groups, with the exception of PFS rates. Clinical trial information: NCT03105336. Research Sponsor: Kite, a Gilead Company.

Preliminary safety and efficacy of PBCAR0191, an allogeneic, off-the-shelf CD19-targeting CAR-T product, in relapsed/refractory (r/r) CD19+ NHL. *First Author: Bijal D. Shah, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Although autologous CD19-directed CAR T products have demonstrated unprecedented efficacy in chemorefractory patients, manufacturing failure or delays remain important barriers to care, limiting utility for those with more rapidly growing disease and/or impaired T cell fitness. Here, we present an update to preliminary safety, efficacy, and correlative data for the subjects dosed with at least 3 x 10^6 CAR-T+ cells/kg, or equivalent, of PBCAR0191, an off-the-shelf allogeneic CAR T product. **Methods:** Subjects were required to have evaluable CD19+ r/r NHL, adequate organ function, 2+ prior treatment regimens, and no active GvHD, CNS disease, infections or active medical issues. Prior stem cell transplant and/or CAR-T therapy were allowed. All subjects were lymphodepleted prior to administration of PBCAR0191with either standard (sLD; 30/500mg/m2/day x 3 days fludarbine/cyclophosphamide) or enhanced (eLD; 30 x 4 days and 1000mg/m2/day x 3 days flu/cy) lymphodepletion. Correlative laboratory samples were taken at baseline and while patients remained on study for CAR T cell expansion, persistence, response to treatment and safety assessments. **Results:** As of February 2021, 13 subjects were evaluable meeting these criteria. Demographics, baseline disease characteristics, and prior therapy data are presented in the table. Median time from eligibility confirmation to PBCAR0191 infusion was 6.5 days (1 day to start LD). To date, most adverse events (AE) reported were mild, with no cases of GvHD or Grade ≥3 CRS/ ICANS. PBCAR0191 related serious AEs were reported for 31% (4/13) of the subjects and 1 subject (9%) died of Febrile neutropenia on day 42 after treatment. Infections and cytokine release related AEs occurred at higher frequency in the eLD group. Efficacy of PBCAR0191 in 13 NHL subjects with available 28 day follow up is presented in the table. Peak PBCAR0191 expansion was increased 56-fold and was associated with CR rate of 71% in eLD group versus 33% in sLD group. Duration of response assessment is ongoing. **Conclusions:** PBCAR0191 has demonstrated dose and LD-dependent cell expansion kinetics with encouraging anti-tumor activity. Host-versus-graft rejection may have a role in depth and durability of response. CR rates with PBCAR0191 are preliminarily comparable to those observed with autologous CAR T in this population. Updated response durability assessment will be presented at the time of the meeting. Clinical trial information: NCT03666000. Research Sponsor: Precision BioSciences.

Engineered immunostimulatory cells can convert PBMCs from chronic lymphocytic leukemia (CLL) patients into potent tumor killing immune cells. *First Author: Joshua W. Keegan, Brigham and Women's Hospital and Harvard Medical School, Boston, MA*

Background: Alloplex Biotherapeutics has developed a cellular therapeutic that uses ENgineered Leukocyte ImmunoSTimulatory cell lines called ENLIST cells to activate and expand populations of tumor killing effector cells from human peripheral blood mononuclear cells (PBMCs). This process leads to a 300-fold expansion of NK cells, CD8+ T cells, NKT cells, and TCR$\gamma\delta$ T cells that are called SUPLEXA cells, which will be cryopreserved and transferred back into patients as an autologous immune cell therapy for cancer. In this study, PBMCs from CLL patients were used to generate SUPLEXA cells as a first approach to comparatively profile SUPLEXA cells from cancer patients and normal healthy volunteers (NHVs). **Methods:** ENLIST cell lines were engineered by expressing curated immunomodulatory proteins in the SK-MEL-2 melanoma cell line. Two million (M) PBMCs from 10 CLL patients or 2 NHVs were incubated with 0.4 M freeze/thaw killed ENLIST cells for 5 days in XVIVO-15 medium with 2% heat-inactivated human AB serum (XAB2) and then split 1:15 in XAB2 containing IL-7 and IL-15 to expand. After 9 days, SUPLEXA cells were harvested and cryopreserved. **Results:** Original PBMCs and matched SUPLEXA cells from each donor were thawed and characterized by mass cytometry (CyTOF) using a 47-marker antibody panel. CyTOF staining results of PBMCs from CLL patients demonstrated approximately 95% leukemia cells and few T cells, NK cells, B cells, and monocytes. CyTOF staining of SUPLEXA cells from all 10 CLL patients showed expansion of NK cells (17%), CD8 T cells (11%), and CD4 T cells (7.5%) that were similar in phenotype to SUPLEXA cells from NHVs showing high expression of granzymes and perforin that are indicative of potent tumor cell killing activity. Cancer cells in the original CLL PBMC samples were reduced to 0.78%. However, a population of non-T/non-B cells (60% ± 9.5%) was detected in SUPLEXA cells from all CLL patients that require further characterization. Next, SUPLEXA cells from CLL and NHV patients were comparatively tested for tumor cell killing activity at 2:1, 1:1, and 1:2 effector to target cell (MEL-14 melanoma cells expressing RFP) ratios. Percent killing of tumor cells by SUPLEXA cells prepared from CLL patients (77.8% ± 2.6% at 2:1) and NHVs (81.5% ± 0.3% at 2:1) were nearly identical at all effector to target ratios. **Conclusions:** We demonstrate for the first time that PBMCs from CLL patients can be converted into SUPLEXA cells despite low numbers of normal immune cells at baseline and the known immunologic impairment present in CLL patients. Importantly, SUPLEXA cells derived from CLL patients acquire potent tumor killing activity that is indistinguishable from SUPLEXA cells prepared from NHVs. Taken together, these findings support the feasibility of converting PBMCs from CLL patients with low percentages of NK and T cells into an autologous cellular therapy for cancer. Research Sponsor: Alloplex Biotherapeutics.

Subcutaneous epcoritamab in patients with relapsed/refractory B-cell non-Hodgkin lymphoma: Safety profile and antitumor activity. *First Author: Michael Roost Clausen, Vejle Hospital, Vejle, Denmark*

Background: Epcoritamab is a CD20xCD3 bispecific antibody that induces T-cellmediated killing of CD20positive malignant B-cells. We present updated data, including progression-free survival (PFS) from the dose escalation part of the first-in-human phase 1/2 study of epcoritamab in pts with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (B-NHL; NCT03625037). **Methods:** Adults with R/R CD20+ B-NHL received flat-dose 1 mL SC epcoritamab (step-up dosing approach) in 28-day cycles (q1w: cycles 12; q2w: cycles 36; q4w thereafter) until disease progression or unacceptable toxicity. Step-up dosing and standard prophylaxis were used to mitigate severity of cytokine release syndrome (CRS). **Results:** At data cut off (1/31/2021), 68 pts with B-NHL were enrolled across histologies including diffuse large B-cell lymphoma (DLBCL; n = 46 [67.6%]; de novo and transformed), follicular lymphoma (FL; 12 [17.6%]), mantle cell lymphoma (MCL; 4 [5.9%]), and others (6 [8.8%]). Majority were heavily pretreated (median [range] prior lines: DLBCL, 3 [16]; FL, 4.5 [118]); including prior CAR-T (n = 6) and prior ASCT (n = 10). At median follow-up of 14.1 mo (DLBCL, 10.2 mo; FL, 15.2 mo), treatment was ongoing in 15 (22%) pts. Most common treatment-emergent adverse events (AEs) were pyrexia (69%), CRS (59%), and injection site reaction (47%). CRS events were all grade 1 or 2 and most occurred in cycle 1; neurotoxicity was limited (6%; grade 1: 3%; grade 3: 3%; all transient). One case of tumor lysis syndrome was observed (1.5%; grade 3); there were no cases of febrile neutropenia or treatment-related death. Overall response is shown for DLBCL ≥12 mg and ≥48 mg and FL ≥12 mg, corresponding to the minimal efficacy threshold (Table). Responses deepened over time (PR converted to CR: DLBCL, 6 pts; FL, 3 pts). Median time to response was 1.4 mo (DLBCL) and 1.9 mo (FL). Among DLBCL pts achieving CR with ≥6 mg (n = 11), none relapsed while on treatment. The median PFS for pts with DLBCL ≥12 mg (n = 22) was 9.1 mo (95% CI: 1.6, NE; median follow-up 9.3 mo) and for pts with DLBCL ≥48 mg (n = 11) median PFS was not reached (median follow-up 8.8 mo). Updated analyses will be presented. **Conclusions:** With longer follow-up, SC epcoritamab demonstrated substantial single-agent activity, inducing deep and durable clinically meaningful responses, with a consistent safety profile. Notably no severe (grade ≥3) CRS events, no febrile neutropenia, and limited neurotoxicity was observed. Clinical trial information: NCT03625037. Research Sponsor: This study was funded by Genmab A/S and AbbVie Inc.

Glofitamab step-up dosing (SUD): Complete response rates in updated efficacy data in heavily pretreated relapsed/refractory (R/R) non-Hodgkin lymphoma (NHL) patients (pts). *First Author: Carmelo Carlo-Stella, Humanitas University and Humanitas Research Hospital, Milan, Italy*

Background: Glofitamab (RG6026), a T-cell-engaging, bispecific, full-length antibody, allows bivalent binding to CD20 (B-cells), and monovalent binding to CD3 (T-cells). In NP30179 (NCT03075696), an ongoing multicenter, Phase I dose-escalation and expansion study, 0.6–25mg glofitamab fixed-dosing with obinutuzumab pretreatment (Gpt), showed high, durable complete responses and manageable safety in heavily pretreated R/R NHL (Dickinson, et al. EHA 2020). Glofitamab SUD, in addition to Gpt, allowed dose escalation up to 30mg to maximize efficacy, while mitigating cytokine release syndrome (CRS) (Hutchings, et al. JCO 2021). We present updated efficacy data from glofitamab monotherapy SUD cohorts. **Methods:** Gpt (1000mg) was given to pts 7 days pre-glofitamab initial dose. Intravenous SUD of glofitamab was given on Day (D) 1 and 8 of Cycle (C) 1 and then at the target dose from C2D1 (2.5/10/16mg or 2.5/10/30mg); treatment continued for up to 12 cycles, every 21 days. Response rates were based on the Lugano criteria (Cheson, et al. JCO 2014). **Results:** Fifty-two pts received glofitamab SUD; 17 and 35 pts received 2.5/10/16mg and 2.5/10/30mg, respectively. Twenty-eight pts (53.8%) had aggressive NHL (aNHL) and 24 pts had indolent NHL (iNHL). Pts had a median age of 68 (44–85) years and received a median of 3 (1–12) prior lines of therapy. Forty (76.9%) and 38 (73.1%) pts were refractory to their most recent and any prior CD20 therapy, respectively. After a median follow-up of 6.3 months, an updated efficacy analysis was conducted on December 1, 2020. For pts with aNHL (N = 28), the best overall response (OR) and complete metabolic response (CMR) rates were 64.3% and 57.1%, respectively; a trend of improved response was observed with increased target dose, with a CMR rate of 71.4% at 2.5/10/30mg (N = 14). Notably, 4/5 pts (80%) with mantle cell lymphoma (2.5/10/16mg, n = 2; 2.5/10/30mg, n = 2) had CMR. For aNHL, 13/16 CMRs are ongoing, with 8 CMRs lasting > 3 months. For pts with iNHL (N = 24), OR and CMR rates were 79.2% and 70.8%, respectively; 14/17 CMRs are ongoing, with 10 CMRs lasting > 3 months. As of August 3, 2020, common adverse events (52 pts) were CRS (63.5%), neutropenia (38.5%), and pyrexia (32.7%). CRS was mostly confined to C1: 24/50 pts had CRS after 2.5mg; 20/49 pts after 10mg; 2/16 and 8/32 pts had CRS after 16 and 30mg (C2D1), respectively. Grade [Gr] 1 and 2 CRS was reported in 18 (34.6%) and 12 (23%) pts, respectively; 3 pts had Gr 3 CRS; none had Gr 4/5 events (ASTCT 2019). Updated data, including biomarker data on baseline CD20 expression and CD8 levels in the tumor, will be presented. **Conclusions:** Updated data for glofitamab monotherapy SUD show higher preliminary response rates than previously reported in pts with R/R NHL who have failed multiple lines of therapy. CRS was mostly manageable, of low grade, and confined to the first cycle of treatment. Clinical trial information: NCT03075696. Research Sponsor: NP30179 is sponsored by F. Hoffmann-La Roche Ltd. 7520 **Poster Discussion Session**

Promising tolerability and efficacy results from dose-escalation in an ongoing phase Ib/II study of mosunetuzumab (M) with polatuzumab vedotin (Pola) in patients (pts) with relapsed/refractory (R/R) B-cell non-Hodgkin's lymphoma (B-NHL).

First Author: L Elizabeth Budde, City of Hope National Medical Center, Duarte, CA

Background: Mosunetuzumab (M), a full-length, humanized, IgG1 bispecific antibody targeting CD20 and CD3, has shown promising efficacy and safety as monotherapy for R/R B-NHL (NCT02500407; Assouline, et al. ASH 2020). The combination of M with the anti-CD79b antibody-drug conjugate, Pola, showed synergistic anti-lymphoma activity in a mouse xenograft model. These data supported a Phase Ib/II, open-label, multicenter trial of M-Pola for R/R B-NHL (GO40516, NCT03671018). Here we present early clinical data from the Phase Ib cohort. **Methods:** Pts with R/R follicular lymphoma (FL, grade [Gr] 1–3a) or aggressive NHL (aNHL), including *de novo* diffuse large B-cell lymphoma (DLBCL), transformed FL (trFL) and FL Gr 3b (FL3b), received Cycle (C) 1 step-up doses of M on Day (D) 1 (1mg) and D8 (2mg), the target dose on C1D15, then continued at the target dose on C2D1 onwards. M was given every 21 days for eight cycles (or 17 cycles if stable disease or a partial response after C8). Pola (1.8mg/kg) was given with M on D1 of each cycle for six cycles. **Results:** As of November 17, 2020, 22 pts had received M-Pola (M target doses: 9mg, n=7; 20mg, n=3; 40mg, n=6; 60mg [with D1 dose of 30mg from C3 onwards], n=6). Pts had DLBCL (n=12), FL (n=3), FL3b (n=3) and trFL (n=4). Pt characteristics include: median age of 70 (38–81) years; median of 3 (1–10) prior lines of therapy; 7 (32%) pts had prior CAR-T therapy; 17 (77%) and 19 (86%) pts had disease refractory to last prior therapy and prior anti-CD20 therapy, respectively. Median follow-up duration was 9.6 (0.7–23.7) months. The most frequent treatment-related adverse events (AEs) were neutropenia (45.4%), fatigue, nausea and diarrhea (all 36.4%). Cytokine release syndrome (CRS) was observed in 2 pts (9.1%; both Gr 1 by ASTCT 2019 criteria). One dose-limiting toxicity (Gr 3 new onset atrial fibrillation) was observed in the 40mg cohort. The maximum tolerated dose was not exceeded. The most common Gr ≥3 and serious AEs were both neutropenia, observed in 8 (36.4%) and 3 (13.6%) pts, respectively. Two (9.3%) Gr 5 AEs occurred: sudden cardiac death (n=1) and respiratory failure (n=1); neither was deemed treatment related. No immune effector cell-associated neurotoxicity was observed. The Table shows preliminary efficacy data. Preliminary efficacy in the dose-escalation cohort. **Conclusions:** These data indicate that M-Pola has an acceptable safety profile, with no Gr ≥2 CRS observed, and promising efficacy in pts with R/R NHL with predominantly aggressive disease. The Phase II expansion cohort in R/R DLBCL is ongoing, with no mandatory hospitalization required. Clinical trial information: NCT03671018. Research Sponsor: Study GO40516 is sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under direction of authors, was provided by Katie Buxton and Khalida Rizi of Ashfield MedComms, and funded by F. Hoffmann-La Roche Ltd/Genentech, Inc.

Effect of time to relapse on overall survival (OS) in mantle cell lymphoma (MCL) patients (pts) following frontline high-dose therapy and autologous hematopoietic cell transplantation (autoHCT).

First Author: Peter A. Riedell, The University of Chicago, Chicago, IL

Background: In MCL, outcomes are heterogeneous and the clinical significance of the timing of relapse following autoHCT and its impact on OS is not well defined. Using the CIBMTR database, we evaluate the effect of post-autoHCT time to relapse on OS over time. **Methods:** Adult MCL pts treated with up to two lines of rituximab-based induction therapy followed by first autoHCT within 1-year of diagnosis were identified between 2000-2018. Primary outcomes included OS and post-relapse OS. A dynamic landmark analysis was performed at 6-month intervals following autoHCT to evaluate the impact of relapse on OS while adjusting for significant patient- and disease-related variables. Post-relapse OS was evaluated in pts who experienced relapse. **Results:** Of the 461 pts included in the analysis, the median age was 60 years (range 29-78), 57% had a KPS of ≥ 90, 83% had stage III-IV disease at diagnosis, and 76% had extranodal involvement. BEAM was the most common conditioning regimen (58%) and 23% of pts received post-autoHCT maintenance rituximab. With a median follow-up of 67 months, the 5-year progression-free survival was 45.8% with a 5-year OS of 69.6%. On multivariate analysis, age ≥60 years was associated with worse OS (HR= 1.55, 95% CI 1.08-2.24, p=0.0191) at all landmark timepoints. Additionally, the impact of relapse on OS varied with time (p=0.006) and was greatest at the 6-month (HR=7.68), 12-month (HR=6.68), and 18-month (HR=5.81) landmark timepoints. The risk of death for relapsing pts decreased with time and was mirrored by an improvement in adjusted OS for both relapsing and non-relapsing pts. In total, 9.3% of patients relapsed prior to the 18-month landmark timepoint. Relapse at the 6-month, 12-month, and 18-month landmark timepoints correlated with a poor median post-relapse OS of 9 months, 24 months, and 34 months, respectively (Table). Conversely, patients relapsing after the 18-month landmark timepoint experienced a median post-relapse OS ranging from 44-67 months. **Conclusions:** In MCL, early relapse (< 18-months) following autoHCT defines a high-risk group with inferior post-relapse OS. This population should be considered for clinical trials or novel therapeutic approaches including early utilization of chimeric antigen receptor T-cell therapy. Research Sponsor: U.S. National Institutes of Health.

Median OS of relapsing and non-relapsing patients following frontline autoHCT for MCL.

Progression-free survival at 24 months as a landmark after autologous stem cell transplant in relapsed or refractory diffuse large B-cell lymphoma.

First Author: Aung M. Tun, The University of Kansas Cancer Center, Westwood, KS

Background: Patients with newly diagnoseddiffuse large B-cell lymphoma (DLBCL) who achieve event-free survival at 24 months (EFS24) following immunochemotherapy (IC) have excellent overall survival (OS) similar to that of age- and sex-matched general population. The standard of care for patients with relapsed or refractory (RR) DLBCL following frontline IC is salvage therapy followed by autologous stem cell transplant (ASCT). The goal of this study is to evaluate the role of progression-free survival (PFS) at 24 months (PFS24) as a landmark after ASCT in patients with RR DLBCL. **Methods:** Patients with RR DLBCL after frontline R-CHOP or R-CHOP-like IC who underwent salvage therapy and ASCT at Mayo Clinic or University of Iowa between 07/2000 and 4/2020 were identified from institutional lymphoma transplant databases. Clinical characteristics, treatment information, and outcome data were abstracted. Post-ASCT PFS, OS, and post-relapse survival (PRS) were plotted by Kaplan-Meier method, and cumulative incidences of relapse vs non-relapse mortality (NRM) and different causes of death were compared accounting for competing events. Statistical analyses were performed in EZR v1.54. **Results:** A total of 437 patients were identified. Median age at ASCT was 61 years (range 19-78), and 280 (64%) were male. After a median post-ASCT follow up of 8.0 years (95% CI 7.2-8.7), 215 patients had a relapse (or disease progression), 180 within 2 years and 35 after 2 years. For the entire cohort, post-ASCT relapse rate was much higher than NRM rate (48.1 vs 9.1% at 5-year). Median PFS and OS after ASCT was 2.7 and 5.4 years, respectively. Lymphoma was the primary cause of death after ASCT. In contrast, for patients who had achieved PFS24 (n = 220), rates of post-PFS24 relapse and NRM were similar (14.8% and 12.3% at 5-year). Median PFS and OS after achieving PFS24 was 10.0 and 11.5 years, respectively. Lymphoma related and unrelated death rates were similar after achieving PFS24 (Table). For all patients who had a post-ASCT relapse, median PRS was 0.7 years (95% CI 0.5-0.9), and late relapse (> 2 vs ≤2 years after ASCT) was associated with better PRS (median 2.3 [1.7-4.8] vs 0.5 [0.3-0.7] years, p < 0.001). **Conclusions:** Post-ASCT PFS24 is an important prognostic predictor of post-ASCT outcomes in patients with RR DLBCL following frontline IC. Research Sponsor: None.

7523 **Poster Session**

Up to seven years of follow-up in the RESONATE-2 study of first-line ibrutinib treatment for patients with chronic lymphocytic leukemia.

First Author: Paul M. Barr, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY

Background: Ibrutinib, a once-daily Bruton's tyrosine kinase inhibitor, is the only targeted therapy with significant progression-free survival (PFS) and overall survival (OS) benefit in multiple randomized phase 3 studies versus established therapies in patients (pts) with previously untreated chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). Extended long-term follow-up data for the RESONATE-2 study of first-line ibrutinib vs chlorambucil in older pts with CLL/SLL are reported. **Methods:** In the phase 3 RESONATE-2 study, older pts (≥65 years [y]) with previously untreated CLL/SLL and without del(17p) (N=269) were randomly assigned 1:1 to once-daily single-agent ibrutinib 420 mg until disease progression (PD) or unacceptable toxicity (n=136) or chlorambucil 0.5–0.8 mg/kg up to 12 cycles (n=133). Outcomes included PFS, OS, overall response rate (ORR), and safety. Long-term responses were investigator-assessed per 2008 iwCLL criteria. **Results:** With up to 7y of follow-up (median, 74.9 months; range, 0.1–86.8), significant PFS benefit was sustained for pts treated with ibrutinib vs chlorambucil (hazard ratio [HR] 0.160 [95% confidence interval (CI): 0.111–0.230]). At 6.5y, PFS was 61% in pts treated with ibrutinib vs 9% in pts treated with chlorambucil. This PFS benefit was observed across all subgroups, including in ibrutinib-treated pts with high-risk genomic features of unmutated IGHV (HR 0.109 [95% CI: 0.063–0.189]) or del(11q) (HR 0.033 [95% CI: 0.010–0.107]). OS at 6.5y was 78% with ibrutinib treatment. ORR was 92% for ibrutinib-treated pts with complete response (CR/CRi) rate increasing to 34% with this follow-up. Ongoing rates of grade ≥3 adverse events (AEs) of interest remained low for hypertension (5–6y interval: 5%, n=4; 6–7y: 4%, n=3) and atrial fibrillation (5–6y: 1%, n=1; 6–7y: 1%, n=1); no grade ≥3 major hemorrhage occurred in 5–7y. Dose reductions due to grade ≥3 AEs occurred in 1% (n=1) of pts during the 5–6y and 6–7y intervals. Across full follow-up, 31 pts had dose reductions due to any-grade AEs of whom 22/31 (71%) had resolution or improvement the AE. Primary reason for discontinuations in 5–7y was PD (5–6y: 5%, n=4; 6–7y: 6%, n=4). Any-grade AEs leading to discontinuations were seen in 3% (n=2) of pts from 5–6y and none in 6–7y. With over 7y of follow-up, 47% of pts remain on single-agent ibrutinib. **Conclusions:** Extended long-term data from RESONATE-2 demonstrate the sustained PFS and OS benefit of first-line ibrutinib treatment for pts with CLL, including for pts with high-risk genomic features. Responses continue to deepen over time. Rates of grade ≥3 AEs of interest continued to be low at up to 7y follow-up and further discontinuations and dose reductions due to AEs were rare; most AEs leading to dose reduction resolved or improved. Ibrutinib remains well tolerated with no new safety signals observed. Clinical trial information: NCT01722487, NCT01724346. Survival trends in chronic lymphocytic leukemia in the era of oral targeted therapies in the United States: SEER database analyses (1985 to 2017). *First Author: Neda AlRawashdh, University of Arizona, Tucson, AZ*

Background: The survival of chronic lymphocytic leukemia (CLL) patients has progressively improved after the approval of new targeted therapy for first-line treatment and relapsed disease. We performed a corresponding analysis from the U.S. population-based SEER database (1973–2017) to explore the trend of survival and the effect of advanced CLL treatment on overall survival in CLL patients. **Methods:** Data were extracted from SEER*Stat for all patients 15 years or older with a primary diagnosis of CLL with or without subsequent cancers. A period analysis was performed to estimate the 5- and 10-year relative survival rates for patients diagnosed (dx) during different calendar periods from 1985 to 2017, based on gender and age at time of diagnosis (15–44, 45–54, 55–64, 65–74, 75–84, 85 years or older). A mixture cure model was used to examine the proportion of long-term survivors per gender and age category among CLL patients diagnosed between 1985 and 2015. Cox proportional hazard modeling was used to calculate the hazard ratios (HRs) of death adjusted for gender and age at diagnosis for two cohorts: (a) diagnosed in 2000–2003 and followed to 2012; (b) 2004–2007 and followed to 2015. **Results:** For males, the 5-year age-adjusted relative survival rate improved progressively from 72.0% (dx 1985-1989) to 88.2% (dx 2010-2014); for females, from 76.8% (dx 1985-1989) to 90.8% (dx 2010-2014). The corresponding 10-year age-adjusted relative survival rates were 47.3% (dx 1985-1989) and 72.5% (dx 2005-2009) for males; and 58.2% (dx 1985-1989) and 78.7% (dx 2005-2009) for females. The table below shows the proportions of long-term survivors for the 1985–2017 cohort as estimated in the mixed cure model. The HRs (95%CI) of death for cohort (b) in comparison to cohort (a) were 0.58 (0.43–0.78), 0.58 (0.48–0.70), 0.57 (0.49–0.67), 0.68 (0.54–0.85); and 0.83 (0.68–1.02) for age categories of 45–54, 55–64, 65–74, 75–84, and 85 years or old. **Conclusions:** Survival is significantly improved by calendar period among patients diagnosed after 2004 and treated in the era of advanced therapies. Females and younger patients had a higher probability of long term survival. Future studies should consider such covariates as treatment type, disease stage and genetics. Research Sponsor: None.

Estimated cure proportions for CLL patients diagnosed between 1985-2015.

Age	Overall cured proportion (95%CI)	Cured proportion in males (95%CI)	Cured proportion in females (95%CI)
45-54	0.43 (0.38-0.49)	0.35 (0.29-0.42)	0.59 (0.52-0.64)
55-64	0.41 (0.37-0.44)	0.35 (0.32-0.39)	0.50 (0.46-0.54)
65-74	0.12 (0.10-0.70)*	0.08 (0.007-0.98)	0.16 (0.12-0.22)
75-84	0.003 (0.001-0.98)*	no cure	0.14 (0.11-0.20)
85+	0.02 (0.001-0.99)*	no cure	0.06 (0.02-0.26)

*Indicates a high variation in CLL survival per gender.

Updated results of the selective Bruton tyrosine kinase (BTK) inhibitor TG-1701, as monotherapy and in combination with ublituximab and umbralisib (U2) in patients (pts) with B-cell malignancies. *First Author: Chan Cheah, Sir Charles Gairdner Hospital, Comprehensive Cancer Centre, Nedlands, Australia*

Background: TG-1701 is a selective, covalent BTK inhibitor administered once daily (QD). Both the "U2" combination (anti-CD20 mAb ublituximab + the PI3Kδ-CK1ε inhibitor umbralisib) and BTK inhibition are highly active in treatment-naïve (TN) and relapsed/refractory (R/R) CLL, each having previously demonstrated superiority over standard chemoimmunotherapy. Here we report the results of the dose escalation of TG-1701 monotherapy and TG-1701+U2. **Methods:** Pts with R/R CLL and lymphoma were enrolled in a Ph 1 study initially evaluating dose escalation (DE) of oral TG-1701 QD continuously administered in 28-day cycles (100, 200, 300, and 400 mg). After characterizing the safety profile of TG-1701 monotherapy, we implemented a parallel DE arm of TG-1701+U2. Select dose levels of TG-1701 monotherapy were expanded in CLL, MCL and Waldenström's (WM) . All pts were treated until disease progression. The primary objectives are to characterize the safety profile and define the recommended Ph 2 doses for the drugs alone and in combination. **Results:** As of 03 February 2021, 123 pts were treated with TG-1701: 25 in the monotherapy DE arm, 61 in the 200 mg disease-specific cohorts (20 CLL [5 TN], 21 MCL [4 TN], 20 WM [8 TN]), 20 in the 300 mg CLL cohort (4 TN), and 17 in the 1701+U2 DE arm. The median # of prior therapies was 1 (range, 1 - 10). All pts were BTKi-naïve. All 123 pts were evaluable for safety. TG-1701 was well tolerated and the maximum tolerated dose (MTD) for monotherapy was not reached at 400 mg (demonstrating near 100% saturation of the BTK at all dose levels studied). Treatment emergent adverse events (TEAE) of clinical interest included atrial fibrillation (AF 4.0% of pts, G $\geq$3 in 1 case), G $\geq$3 hypertension (2.4%), and bleeding events (18.7%, all G1-2). No cases of ventricular tachyarrhythmia were reported. TEAEs leading to TG-1701 dose reduction occurred in 6.5% of pts. TEAEs leading to treatment discontinuation occurred in 1.6% of pts (AF, COVID-19). At the data cut-off, 119 pts were evaluable for response, including 40 in DE (Table). The median duration of response has not been reached among responders overall. The median follow-up (mFU range) was 15.9 mos (1.3 - 28.6+) in DE and 8.5 mos (1.4 -15.6+) in disease-specific cohorts. **Conclusions:** TG-1701 exhibits an encouraging safety and efficacy profile. The combination of 1701+U2 has been well tolerated and dose escalation continues. The combination shows enhanced depth of response over TG-1701 monotherapy. Recruitment to this study continues. Response per investigator review by treatment group. Clinical trial information: NCT03671590. Research Sponsor: TG Therapeutics.

Identification of genetic markers associated with ibrutinib-related cardiovascular toxicity. *First Author: Issam Hamadeh, Department of Hematologic Malignancies and Blood Disorders, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Cardiovascular side effects (CVSEs: atrial fibrillation, hypertension, etc.) are common in patients with chronic lymphocytic leukemia (CLL) treated with ibrutinib and often lead to dose reductions or discontinuation. However, the etiology of ibrutinib related CVSEs has not been elucidated. This study sought to interrogate the association between ibrutinib related CVSEs and polymorphisms in genes of the Bruton Tyrosine Kinase (BTK) signaling pathway (identified through Ingenuity Pathway Analysis) **Methods:** Newly diagnosed and relapsed patients with CLL who underwent treatment with ibrutinib between December 2019 and November 2020 at Levine Cancer Institute were identified. Buccal swabs were collected through an IRB approved specimen collection protocol. Data extraction included: demographics, CLL stage, cytogenetics, previous treatments, ibrutinib start dates and dose, drug related SEs, and other medications. DNA isolated from buccal swabs was genotyped for 40 single nucleotide polymorphisms (SNPs) in *GATA4, SGK1, KCNQ1, KCNA4, NPPA* and *SCN5A* genes using a custom NGS panel. Logistic regression analysis evaluated the association between SNPs and CVSEs. **Results:** In 50 evaluable patients, the median age was 71 years (range:48-90) and 50% received frontline ibrutinib monotherapy. CVSEs occurred in 20% of patients (n=10). In univariate analysis, 4 SNPs in 3 genes were significantly associated with CVSEs (Table). Because the genes were in the same pathway, a genetic risk score was developed which indicated that patients with at least 2 SNPs had a 12-fold increase in risk of CVSEs (Table). **Conclusions:** Our findings provide insights into the genetic determinants of ibrutinib related CVSEs. If replicated in a larger study, this will facilitate utility of pharmacogenetic testing (for *GATA4, KCNQ1* and *KCNA5* polymorphisms) as a clinical tool to individualize ibrutinib treatment. Research Sponsor: Atrium foundation.

Herpes zoster in chronic lymphocytic leukemia: Effect of vaccination and treatment. *First Author: Nirav Antao, Saint Louis VA Medical Center, St. Louis, MO*

Background: Patients with Chronic Lymphocytic Leukemia (CLL) are susceptible to infections due to impaired humoral immunity as a complication of the disease, treatments received and age at diagnosis. Herpes zoster (HZ) is a painful, vesicular rash from reactivation of varicella-zoster virus that is common in immunocompromised patients. While HZ vaccines can reduce both varicella-zoster reactivation and post-herpetic neuralgia, vaccination rates are low. The aim of this study is to determine the effect of vaccination on rates of HZ infection in patients with CLL. **Methods:** We identified patients diagnosed with CLL between September 1999 and October 2015 using Veterans Administration Central Cancer Registry (VACCR). Pharmacy records were used to identify patients who received treatment for CLL and HZ. HZ events were defined as patients with International Classification of Diseases 9th Revision (ICD-9) codes for HZ infection (053) or prescriptions of acyclovir or valacyclovir at a dose of 1500 mg/day or higher or famciclovir at a dose of 1000 mg/day or higher without a diagnosis of Herpes simplex or Bell's palsy, or an ICD-9 code and prescription above. Cox proportional hazards regression model was used to assess the association between vaccination as a time-varying exposure and developing HZ while controlling age at CLL diagnosis, co-morbidity score, and receipt of first and second line chemotherapy. The study was approved by the St. Louis VA Medical Center institutional review board. **Results:** A cohort of 7155 patients with CLL was identified using VACCR. 2640 patients (36.9%) and 1161 patients (16.2%) received first and second line chemotherapy respectively. Mean age at first chemotherapy was 69.5 years. We detected 1115 cases of HZ (15.6%) using ICD-9 codes, prescriptions or both. 615 patients (8.6%) received HZ vaccinations. Patients with HZ were younger (mean 68.0 vs. 69.8 years, $p < 0.001$), had similar co-morbidities, and were more likely to get treatment for CLL (58.1% vs. 33.0%, $p < 0.001$). Using a time-varying analysis, there was a trend for HZ vaccine to decrease the risk of developing HZ (HR 0.71, 95% CI 0.49-1.04, $p = 0.082$). When adjusting for age and co-morbidity, patients with CLL treated with first line chemotherapy had a higher risk of HZ (HR 2.34, 95% CI 2.02-2.71, $p < 0.001$) compared to those never receiving therapy. Second line chemotherapy increased risk of HZ (HR 1.32, 95% CI 1.13-1.55, $p < 0.001$) beyond first line treatment. **Conclusions:** HZ is prevalent in patients with CLL and affects younger patients who require chemotherapy. The risk of developing HZ increases in recipients of first and second line chemotherapy. In the time-varying analysis, there was a trend towards decreased infection in patients who received HZ vaccination. Further studies in a more modern cohort that assess infection risk using a larger vaccinated group with the newer and more effective HZ vaccine are warranted. Research Sponsor: None.

Brentuximab vedotin with chemotherapy in adolescents and young adults (AYAs) with stage III or IV Hodgkin lymphoma: A subgroup analysis from the phase 3 Echelon-1 study. *First Author: Howland E. Crosswell, Bon Secours Hematology Oncology, Bon Secours, St. Francis Health System, Greenville, SC*

Background: Hodgkin lymphoma (HL) is a rare disease that commonly occurs in adolescents and young adults (AYAs) which is typically defined as 15 to 39 years. Given their young age at presentation, key factors in treatment selection include a high cure rate and limiting long-term toxicities. Brentuximab vedotin (Adcetris®; A) is a CD30-directed ADC approved in combination with doxorubicin, vinblastine, and dacarbazine chemotherapy (A+AVD) for adults with previously untreated stage III/IV cHL based on results from the phase 3 ECHELON-1 trial. Recent 5-year data demonstrated a significantly improved PFS per investigator (INV) vs doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD) (HR, 0.69; 95% CI, 0.54–0.9; P = 0.003) (Straus 2020). Here we describe key efficacy and safety results for AYA pts enrolled in ECHELON-1. **Methods:** ECHELON-1 (N = 1334) is a global, open-label, multicenter, randomized trial of pts with previously untreated stage III/IV cHL. A total of 771 AYAs (57.8%) received either A+AVD (n = 396) or ABVD (n = 375) with a PET scan after cycle 2 (PET2). An analysis of PFS (time from randomization to progression or death from any cause) per INV was conducted. **Results:** After a median follow-up of 60.7 months (95% CI, 60.4-61.0), there was a 36% reduction in the risk of progression or death in AYAs receiving A+AVD vs ABVD (HR 0.64; 95% CI, 0.45-0.92; P = 0.013) with a 5-year PFS of 86.3% vs 79.4%, respectively, similar to the ITT population. The PFS benefit of A+AVD vs ABVD was independent of PET2 status; PET2 positivity (Deauville 4-5) was 6% and 8%, respectively. On the A+AVD arm, 81 AYAs (20%) had at least 1 subsequent anticancer therapy vs 96 AYAs (26%) on the ABVD arm; 26 AYAs (7%) received subsequent high dose chemotherapy and autologous stem cell transplant vs 32 AYAs (9%) on the A+AVD and ABVD arms, respectively. Resolution or improvement of peripheral neuropathy (PN) were similar in both arms; 224 AYAs (88%) on the A+AVD had resolution or improvement of PN vs 133 AYAs (89%) on the ABVD arm. Ongoing PN was predominantly Gr 1 (62%) and Gr 2 (26%), with 8 AYAs (13%) on the A+AVD arm and 1 AYA (5%) on the ABVD arm reporting ongoing Gr 3 PN. Finally, 7 AYAs (1.8%) and 5 AYAs (1.4%) on the A+AVD and ABVD arms, respectively, reported a secondary malignancy. Subsequent pregnancies were reported in female pts (44 A+AVD; 26 ABVD) and partners of male pts (31 A+AVD; 30 ABVD). No stillbirths were reported. All but 1 pt in each arm was < 40. **Conclusions:** Consistent with the ITT population, AYAs treated with A+AVD compared to ABVD had a durable PFS benefit at this significant 5-year milestone. No impact on the rate of secondary malignancies and a numerically greater number of pregnancies were observed, outcomes of interest to AYAs. Additionally, the majority of PN events improved or resolved over time. A+AVD should be considered a treatment option for AYAs with stage III/IV cHL. Clinical trial information: NCT01712490. Research Sponsor: Seagen Inc., Takeda.

7529 **Poster Session**

A phase II study of penpulimab, an anti-PD-1 antibody, in patients with relapsed or refractoryclassic Hodgkin lymphoma (cHL). *First Author: Yuqin Song, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Lymphoma, Peking University Cancer Hospital & Institute, Bejing, China*

Background: Penpulimab is a humanized IgG1 monoclonal antibody (mAb) that blocks PD-1 binding to PD-L1. Penpulimab, with its unique binding epitope, was engineered to eliminate Fc-mediated effector function that compromises anti-tumor immune cell function, and to optimize receptor occupancy by improving duration of drug binding. Fc-mediated effector functions, such as ADCC/ADCP, have been observed in most IgG4 anti-PD-1 mAbs but is absent in penpulimab, thereby potentially reducing the occurrence of immune-related adverse reactions. Penpulimab also demonstrated a slower PD-1 antigen binding off-rate than marketed anti-PD-1 mAbs, thereby resulting in better cellular activity and higher receptor occupancy. Penpulimab's numerous contacts with N58 glycosylation on the BC loop of PD-1 may also contribute to a slower binding off-rate. These structural differentiations of penpulimab enhance its anti-tumor activity and produce a superior safety profile. **Methods:** AK105-201 is a multicenter, single-arm, open-label study of penpulimab in relapsed/refractory (R/R) cHL. All pts received penpulimab 200 mg Q2W until progression or unacceptable toxicity. Eligible pts had prior autologous stem cell transplant (ASCT) or at least 2 lines of prior chemotherapy. The primary endpoint was ORR based on the Lugano 2014 criteria as assessed by an independent review committee (IRC). Key secondary endpoints included CR rate, DCR, PFS, duration of response (DoR), safety, and tolerability. **Results:** As of 8 November 2020, of 94 pts (59.6% male, median age 32.0 yrs [31-71], 26.6% was ECOG 1) enrolled, 56 pts remained on treatment, 4 pts completed 24-months treatment and 25 had discontinued (17 due to disease progression, 3 due to AE). After a median follow-up of 15.8 months, the IRC-assessed ORR in the 85 pts evaluable for efficacy was 89.4% (95% CI: 80.8%, 95.0%). A total of 40 patients (47.1%) achieved CR. Median duration of response was not reached with range from 1.7 to 24.5+ months. Median PFS was not reached with 12-months PFS rate was 72.1% (95% CI: 60.5%, 80.8%). Treatment-related adverse events (TRAEs, with unlikely-related events included) occurred in 97.9% of pts (≥ G3 in 26.6% [25/94], treatment discontinuation in 5.3% [5/94]). Treatment-related SAEs occurred in 10.6%. Most frequent TRAEs (≥20%) were hypothyroidism (31.9%), upper respiratory tract infection (25.5%), fever (24.5%), and ALT elevations (23.4%). Grade ≥3 TRAEs reported in ≥2 pts were platelet count decreased (3.2%), hyperlipemia (3.2%), rash (3.2%), neutrophil count decreased (2.1%). Grade 3 immune-related AEs (irAEs) were reported in 4.3%: IgA nephropathy, pneumonitis, rash, psoriasis (each n = 1) and no G4 or G5 irAEs reported. **Conclusions:** Penpulimab was shown to be highly active in achieving in a CR rate of 47.1% in pts with R/R cHL while demonstrating lower rates of SAEs, TRAEs leading to discontinuation, and Grade ≥3 irAEs. Clinical trial information: NCT03722147. Research Sponsor: Akeso Biopharma Inc.

Salvage therapies in transplant-eligible relapsed classic Hodgkin lymphoma, are novel regimens better? *First Author: Sanjal Desai, Mayo Clinic, Rochester, MN*

Background: Clinical trials of novel salvage therapies (ST) have encouraging outcomes for relapsed/refractory classic Hodgkin lymphoma (R/R cHL) eligible for autologous stem cell transplant (ASCT). In this observational study, we report efficacies and outcomes of different ST in ASCT-eligible R/R cHL. **Methods:** Consecutive ASCT-eligible R/R cHL pts at 3 Mayo Clinic sites were included. Demographics and clinical variables at relapse were recorded by medical records review. Time to event endpoints were defined from relapse. Univariate associations were confirmed in multivariate models of age, sex, B symptoms, stage, bulky disease (BD, single mass > 6 cm) extra nodal disease (END), primary refractory disease (PRD) and early relapse (ER, within 1 year). **Results:** From Jan 2008 to May 2020, 207 ASCT-eligible pts with R/R cHL were included. Median age was 33 (24-43) years, 53% were male, 52% had advanced stage, 24% had BD, 36% had B symptoms, 41% had END, 11% had PRD and 43% had ER. All patients received ST and underwent ASCT; 43 (21%) received 2 ST, 14 (7%) 3 ST and 4 (0.5%) received 4 ST. 6 groups of ST were identified: ifosfamide, carboplatin and etoposide (ICE), bendamustine/brentuximab (BBV), brentuximab vedotin (BV), gemcitabine-based therapy (Gem), checkpoint inhibitor (CPI), and others. Table lists response to first line ST. BBV had significantly higher overall response rate (ORR) and complete response (CR) as first ST in univariate and multivariate models. 114 (79%) after ICE, 30 (97%) after BBV, 15 (56%) after BV, 25 (76%) after Gem, 8 (73%) after CPI and 15 (79%) after other ST underwent ASCT. Higher number of pts were bridged to ASCT after BBV than ICE ($p<0.01$). 110 (53%) went to ASCT in CR, 74 (36%) in partial response (PR) and 11% in progressive disease (PD). 43 received BV maintenance (BVm) after ASCT. Pts going to ASCT in PR or PD had significantly lower progression free survival (PFS) compared to pts in CR (2 yr PFS: 62%, 18% vs 77%, respectively, $p<0.0001$) in univariate and multivariate models. There was no difference in PFS and overall survival (OS) by type of ST. BVm was associated with higher PFS (HR 0.3 (CI_{95} 0.2-0.8)) and higher number of ST was associated with lower OS (HR 2 (CI_{95} 1.4-3)) in multivariate model ($p<0.001$). For pts transplanted in CR, there was no significant difference in PFS and OS by type of ST but higher number of ST predicted lower OS (HR 2.4 (CI_{95} 1.2-3.5), $p<0.01$). **Conclusions:** Type of ST did not predict survival, response to and number of ST did. For pts with CR, number of ST not type of ST predicted survival. BBV had higher response rates, higher rates of bridge to ASCT, and may be a preferable ST than ICE. Large, randomized trials are needed to evaluate efficacy of BBV compared to ICE. Research Sponsor: None.

A phase Ib study of a PI3Kδ inhibitor Linperlisib in patients with relapsed or refractory peripheral T-cell lymphoma. *First Author: Jie Jin, First Hospital Affiliated Zhe Jiang Medical University, Hangzou, China*

Background: PI3Kδ inhibitors have been shown to have important roles in blocking mitogenic and survival signaling within the tumor cell and the tumor microenvironment and activate antilymphoma immune responses. Linperlisib is an oral highly selective small molecule inhibitor of PI3Kδ and has been demonstrated to be well-tolerated with a favorable PK profile in patients with lymphomas at the RP2D. This phase Ib study is evaluating the efficacy and safety of Linperlisib in relapsed or refractory peripheral T-cell lymphoma (PTCL), a highly aggressive malignancy with few treatment options for patients. **Methods:** Eligible PTCL patients who must have received at least 1 prior systemic conventional therapy were administrated Linperlisib 80mg orally once daily (RP2D) in 28 days cycle until disease progression, unacceptable toxicity, or withdrawal from the study. Tumor response was assessed by IWG 2007 criteria with CT performed every 2 cycles. The primary endpoint was the overall response rate (ORR), and the secondary endpoint was toxicity assessed by NCI-CTCAE5.0. **Results:** As of February 2, 2021, 36 PTCL patients were enrolled in this exploratory trial. Most patients were stage III (38.2%) or IV (50%). Of the 27 evaluable patients to date, the PTCL histologies were PTCL-NOS (n=12), AITL (n=10), ALCL (n=3), NKTCL (n=1) and MEITL (n=1). 19 of the 27 evaluable patients had Investigator confirmed responses for a 70.4% ORR including 25.9% CR (7pt) and 44.4% PR (12pt). In the major subtypes, ORR was 50% (6/12) PTCL-NOS and 80% (8/10) AITL, respectively. A disease control rate of 100% was observed, and most responses occurred by first assessment at C2D28. One subject who had a CR at C2D28 is currently in cycle 9 and continuing on Linperlisib. 36 patients experienced at least 1 AE in the trial, with 95% of AEs ≤ grade 2. Consistent with previously treated lymphoma patients, no unexpected toxicities were observed. The most common TRAEs (≥10%) were neutrophil count decreased (55.6%), leukocyte count decreased (33.3%), hypertriglyceridemia (22.2%), aspartate aminotransferase increased (16.7%), hypercholesterolemia (16.7%), alanine aminotransferase increased (11.1%), creatinine increased (11.1%), rash (11.1%), thrombocyte count decreased (11.1%) and electrocardiogram T wave abnormal (11.1%). No AE grade 4 was observed. 6 patients (16.7%) experienced at least one SAE, in which 4 (11.1%) SAEs were considered to be drug-related, including neutrophil count and leukocyte count decreased (2.8%), gastritis (2.8%), and pneumonia (5.6%). **Conclusions:** The oral PI3Kd inhibitor Linperlisib had significant activity in patients with relapsed or refractory PTCL. Toxicities with Linperlisib therapy were generally tolerable and manageable. Further efficacy and safety is being evaluated. Clinical trial information: NCT04108325. Research Sponsor: Shanghai Yingli Pharmaceutical Co., Ltd.

CD19 CAR T-cell product type independently impacts CRS and ICANS severity in patients with aggressive NHL. *First Author: Jordan Gauthier, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: CD19-targeted chimeric antigen receptor-engineered (CD19 CAR) T cells achieve high response rates in patients (pts) with relapsed or refractory (R/R) aggressive B-cell non-Hodgkin lymphoma (NHL), but are limited by cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Pivotal trial data suggested distinct toxicity risks across CD19 CAR T-cell products, but differences in pt and disease characteristics may have confounded these observations. Thus, we assessed the independent impact of 3 CD19 CAR T-cell products (axicabtagene ciloleucel[axicel], tisagenlecleucel [tisacel], and JCAR014) on CRS and ICANS severity in 136 pts with R/R aggressive NHL. **Methods:** We retrospectively analyzed aggressive NHL pts treated at our institutions with cyclophosphamide and fludarabine lymphodepletion (LD) followed by CD19 CAR T-cell therapy. Axicel and tisacel pts were treated off trial using commercial products. JCAR014 (defined-composition 4-1BB-costimulated CD19 CAR T cells) was administered in all pts at the dose of $2x10^6$/kg on a phase I/II clinical trial (NCT01865617). CRS and ICANS were graded according to the ASTCT criteria and CTCAE 4.03, respectively. We used multivariable proportional odds logistic regression to model CRS and ICANS grade. **Results:** The CAR T-cell product was axicel, tisacel, or JCAR014 in 50%, 28%, and 22% of pts, respectively. Compared to axicel pts, we observed higher preLD LDH levels in tisacel and JCAR014 pts, and lower preLD albumin with tisacel ($p < 0.001$) with comparable age and hematopoietic cell transplantation comorbidity (HCT-CI) indexes across CAR T-cell products. Higher day-28 overall response rate by Lugano criteria was observed after axicel (71%) compared to tisacel (56%) and JCAR014 (53%). Adjusting for age, HCT-CI, preLD LDH, preLD albumin, CAR T-cell product type was associated with CRS severity (tisacel versus [vs] axicel, OR = 0.45, p = 0.05; JCAR014 vs axicel, OR = 0.29, p = 0.005;). Age had limited or no impact on CRS severity (OR 95%CI, 0.97-1.02), while the effect of HCT-CI was undetermined (OR 95%CI, 0.85-1.27). In a multivariable model including the same covariates as above, CAR T-cell product type (tisacel vs axicel, OR = .14, $p < .001$; JCAR014 vs axicel, OR = 0.31, p = 0.009), preLD LDH (OR, 3.96 per log10 increase; p = 0.04) and age (OR per 10-year increase, 1.32; p = .06) were associated with ICANS severity. Interaction effect testing suggested effect modification of age by the CAR T-cell product type (tisacel/JCAR014 versus axicel, p = 0.06); using a multivariable model including this interaction term, the predicted probabilities of grade ≥3 ICANS in a 70 year-old after axicel, tisacel, and JCAR014 were 40%, 6%, and 8%, respectively. **Conclusions:** CAR T-cell product type independently impacts CRS and ICANS severity in NHL pts. Our findings provide key insights to guide patient and CAR T-cell product selection. Research Sponsor: U.S. National Institutes of Health.

Update of a phase II, multicenter study of high-dose chemotherapy with autologous stem cell transplant followed by maintenance romidepsin for T-cell lymphoma. *First Author: Niloufer Khan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Peripheral T-cell lymphomas (PTCL) have suboptimal outcomes with conventional chemotherapy. Autologous hematopoietic stem cell transplant (AHCT) is a therapeutic strategy for patients in first complete or partial remission (CR1 or PR1), with median progression-free survival (PFS) after AHCT of 36-48% by intent to treat (d'Amore et al JCO 2012, Reimer et al JCO 2009). Romidepsin (romi) is a histone deacetylase inhibitor approved for treatment of relapsed/refractory T-cell lymphoma. We present updated data of the first multicenter study to evaluate PFS of patients (pts) receiving maintenance therapy with romi after AHCT. **Methods:** This was a phase 2, open-label, investigator-initiated study (expected PFS 45%, desired PFS 70%; success achieved if 15 or more pts out of 25 were progression-free at 2 years post-AHCT). 26 pts transplanted in CR1 or PR1 were evaluable for the primary endpoint of 2-year PFS (Cohort 1, Table). An exploratory cohort (Cohort 2, n=7) enrolled pts either transplanted ≥ CR/PR2 (n=5) or with high risk histologies (n=2). Pts underwent AHCT with carmustine, etoposide, cytarabine and melphalan (BEAM) conditioning. Maintenance romi 14 mg/m2 started days 42-80 post AHCT; every other week through 6 mon, every 3 weeks through 1 year and every 4 weeks through 2 years post AHCT. PFS was estimated by Kaplan-Meier. **Results:** 47 pts consented; 13 did not receive romi (no AHCT, n=2; relapse before romi, n=3; cardiac comorbidity, n=3, patient declined, n=5). 1 consented pt did not have PTCL. 15 out of the first 25 pts in Cohort 1 were progression free after 2 years; median follow up of 31 mon (21 - 36 mon). Estimated 2-year PFS was 62% (45-83%, 95% CI); median PFS 30 mon (12.0- NA, 95% CI). In Cohort 2, estimated 2-year PFS was 43% (18 – 100, 95% CI); median follow up of 30 mon (range, 24 – 37 mon); median PFS 14 mon (5 – NA, 95% CI). Across cohorts, 5 pts required dose reduction. The most common toxicities (≥10% of pts, all grades) were fatigue (n=24, 73%), decreased platelets (n=16, 48%) and anemia (n=16, 48%). **Conclusions:** While the study did not meet its desired primary efficacy endpoint, maintenance romi was well-tolerated with an estimated 2-year PFS of 62%, greater than historical data. A larger, randomized study would be needed to determine the superiority of this approach. Clinical trial information: NCT01908777. Research Sponsor: Celgene.

Polatuzumab vedotin + obinutuzumab + venetoclax in patients with relapsed/refractory (R/R) follicular lymphoma (FL): Primary analysis of a phase 1b/2 trial. *First Author: Rajat Bannerji, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Polatuzumab vedotin (Pola) + obinutuzumab (G) demonstrated activity and tolerability in a Phase 1b/2 trial of patients (pts) with R/R FL (Phillips, et al. Blood 2016). Preclinical studies with venetoclax (Ven) showed that concurrent treatment with Pola promotes MCL-1 degradation, a known mechanism of resistance to Ven, and enhances *in vivo* anti-tumor efficacy (Amin, et al. AACR 2020). Here, we report the primary safety/efficacy analysis with Pola-G-Ven in a Phase 1b/2 study of pts with R/R FL (GO29833; NCT02611323). **Methods:** Pts received induction treatment every 21 days (D) x six cycles (C) of: Pola 1.4–1.8mg/kg intravenously (IV) in dose escalation (DE) or recommended Phase 2 dose (RP2D) on D1; G 1000mg IV (C1: D1, D8, D15; C2–6: D1); and oral Ven 200–800mg (DE or RP2D; D1–21). Pts with complete response/partial response/stable disease (CR/PR/SD) at end of induction (EOI) received maintenance with G (1000mg on D1 every 2 months [mo] for 24 mo) and Ven (200–800mg daily) for 8 mo. Primary endpoints were safety/tolerability and positron emission tomography (PET)-CR rate at EOI by independent review committee (IRC) using modified Lugano criteria. **Results:** At the primary analysis (Oct 05, 2020), 74 pts were enrolled. Median pt age was 64 years (range 36–78); male (57%); Ann Arbor Stage III–IV (86%); FL International Prognostic Index high risk ≥3 (55%); bulky disease ≥7cm (16%); prior lines of therapy ≥2 (74%); refractory to: last prior therapy (51%), any prior anti-CD20 therapy (55%), both anti-CD20 therapy and an alkylating agent (double refractory; 55%). Grade 3–4 adverse events (AEs) were experienced by 73% of pts; most commonly, neutropenia (39%), thrombocytopenia (19%), and infections (16%; mainly pneumonia). AEs led to dose reduction in 38% and interruption in 68% of pts (mainly modifications to Ven). One fatal AE was reported (pneumonia). In total, 49 pts were treated at RP2D (Pola 1.8mg/kg + Ven 800mg) and were evaluable for efficacy. PET-CR rate at EOI by IRC was 57% (Table). With a median follow-up of 14.4 mo (range 8.2–28.4), the 12-mo progression-free survival (PFS) was 73% (95% confidence interval: 59.4–86.9). Median PFS was not reached. **Conclusions:** The safety profile of Pola-G-Ven is consistent with the known profiles of the individual drugs. Response rates at EOI with Pola-G-Ven are encouraging in this R/R FL patient population. Additional follow-up is needed to assess PFS benefit during maintenance treatment and beyond. Clinical trial information: NCT02611323. Research Sponsor: The GO29833 study was sponsored by F. Hoffmann-La Roche Ltd and Genentech, Inc. Comparative efficacy of tisagenlecleucel (tisa-cel) and lisocabtagene maraleucel (liso-cel) in patients with relapsed/refractory diffuse large B-cell lymphoma (r/r DLBCL). *First Author: Stephen J. Schuster, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: Chimeric antigen receptor T-cell therapies tisa-cel and liso-cel are effective treatments for r/r DLBCL (Schuster 2019, Abramson 2020). This study compared efficacy outcomes of tisa-cel and liso-cel in r/r DLBCL using matching-adjusted indirect comparison (MAIC). **Methods:** Individual patient-level data (IPD) from JULIET (tisa-cel; NCT02445248; 02/2020 datacut) were weighted to match the patient population in TRANSCEND (liso-cel; NCT02631044; 08/2019 datacut). Baseline prognostic factors available in both trials were adjusted for age, sex, histology, ECOG performance status [ECOG PS], left ventricular ejection fraction, radiologic sum of product diameters, lactate dehydrogenase, prior stem cell transplantation [SCT], use of bridging therapy, and number of and refractoriness to prior therapies, in the MAIC. Overall survival (OS), progression-free survival (PFS), complete response (CR) rate, and overall response (OR) rate were compared. Primary analyses compared infused patients in JULIET (N=106, excluding 8 without lymphodepleting chemotherapy [LDC] and 1 large cell neuroendocrine carcinoma) with efficacy-evaluable set in TRANSCEND (N=256, infused patients). A scenario analysis compared JULIET infused to TRANSCEND primary analysis set (PAS) (N=133, dose level 2, excluding those with ECOG PS 2, prior allogeneic SCT, primary mediastinal B-cell lymphoma, follicular lymphoma [FL] 3B, or transformation from indolent lymphoma besides FL). Sensitivity analyses included JULIET patients with only fludarabine-based LDC or only adjusted significantly different baseline prognostic factors. Safety outcomes were not compared because adverse event management has evolved and differed between the two trials; MAIC is unable to adjust for such differences. **Results:** After adjusting for differences in baseline characteristics, OS, PFS, and CR were comparable between tisa-cel infused patients and the liso-cel efficacy-evaluable set (Table). The results were consistent across all scenario and sensitivity analyses. OR rate trended higher in the TRANSCEND efficacy-evaluable set (72.7% vs. 62.9%, p=0.07) and was higher in TRANSCEND PAS than in the respectively matched JULIET infused set (74.4% vs. 60.9%, $p < 0.05$). **Conclusions:** The MAIC results indicate there is no evidence suggesting differences in OS, PFS and CR between tisa-cel and liso-cel in r/r DLBCL. Analyses using IPD from both trials and/or real-world evidence are warranted to confirm these findings. Research Sponsor: Novartis Pharmaceutical Corporation.

MAIC of Tisa-cel Infused vs. Liso-cel Efficacy-evaluable set.

	Tisa-cel vs. liso-cel (95% CI); p-value
OS, hazard ratio (HR)	1.12 (0.62, 2.05); p=0.71; 1-year OS rate: 55.1% vs 57.9%
PFS, HR	1.16 (0.64, 2.09); p=0.63; 1-year PFS rate: 47.4% vs 44.1%
CR, rate difference	-5.4% (-15.5%, 4.7%); p=0.29
OR, rate difference	-9.7% (-20.0%, 0.6%); p=0.07

Favorable tumor immune microenvironment (TME) and robust chimeric antigen receptor (CAR) T-cell expansion may overcome tumor burden (TB) and promote durable efficacy with axicabtagene ciloleucel (axi-cel) in large B-cell lymphoma (LBCL). *First Author: Justin Chou, Kite, A Gilead Company, Santa Monica, CA*

Background: Axi-cel is an autologous anti-CD19 CAR T-cell therapy approved for patients (pts) with relapsed/refractory LBCL after ≥2 prior systemic therapies. In the pivotal ZUMA-1 study, pts with high pretreatment (preTx) TB (estimated by sum of product diameters [SPD]) had lower peak CAR T-cell expansion normalized to TB and less frequent durable response rates vs pts with low TB (< 30% vs > 60%, respectively; *Blood Adv.* 2020;4:3268). The number of $CD8^+$ and $CCR7^+CD45RA^+$ product T cells infused and favorable immune contexture in preTx TME were also associated with axi-cel response (*Blood Adv.* 2020;4:3268; Galon et al. ASCO 2020. #3022). As potential barriers to axi-cel efficacy are not fully elucidated, we systematically analyzed preTx TME characteristics, including myeloid-related biomarkers and product attributes, to identify such challenges in ZUMA-1 pts with high TB. **Methods:** Samples from evaluable pts in ZUMA-1 Phase (Ph) 1 and Ph2 Cohorts (C) 1–3 were analyzed (NCT02348216; Ph1 and Ph2 C1+2, ≥2-y follow-up; C3, ≥6-mo follow-up). PreTx immune TME was analyzed by multiplex immunohistochemistry (n = 18) and gene expression analysis (n = 30) as previously described (Rossi et al. AACR 2018. #LB-016; Galon et al. ASCO 2020. #3022). CAR T-cell product characteristics and other covariates were evaluated as previously described (*Blood Adv.* 2020;4:3268). Correlative analyses of these covariates with clinical outcomes were performed by Wilcoxon or Kruskal-Wallis test. Median TB (by SPD) from ZUMA-1 Ph1 and Ph2 C1+2 was used as a cutoff for high (> 3721 mm^2) vs low (≤3721 mm^2) TB. Durable response refers to pts in ongoing response at time of data cutoff. **Results:** PreTx immune TME features related to suppressive myeloid-related activity, most notably *ARG2*, *TREM2*, and *IL-8* gene expression, were elevated in pts who failed to respond or relapsed without documented loss of CD19 expression. *ARG2* and *TREM2* levels in preTx biopsies were negatively associated with $CD8^+$ T-cell density. Pts with high TB who achieved durable response had low preTx *ARG2* and *TREM2* levels in TME and enhanced CAR T-cell expansion after axi-cel compared to pts with high TB who relapsed. High ratio of T-cell to suppressive myeloid cell markers (T/M ratio) in preTx biopsies associated positively with CAR T-cell expansion (peak and peak normalized to TB) and durable response in pts with high TB. **Conclusions:** Axi-cel may overcome high TB in pts with a favorable immune TME alongside robust CAR T-cell expansion. Favorable immune TME is characterized by reduced suppressive myeloid cell activity (low *ARG2* and *TREM2* expression) and increased T/M ratio. These data suggest possible actionable strategies to overcome high TB in the context of CAR T-cell therapy. [JC and VP contributed equally] Clinical trial information: NCT02348216. Research Sponsor: Kite, a Gilead Company.

Combination of sintilimab, anlotinib and pegaspargase "sandwich" with radiotherapy in localized natural killer/T cell lymphoma: A multicenter, phase 2 study. *First Author: Zhiming Li, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: NK/T-cell lymphoma (NKTL) is a rare and distinct subtype NHL. Most newly diagnosed NKTL cases were localized-stage. For localized NKTL, RT alone is inadequate due to high systemic failure rate. Chemoradiation has been increasingly applied. However, current chemotherapy (CT) regimens have severe toxicity and infection, which reduce the completion of RT and patients' medical compliance. Therefore, novel regimens with mild toxicity are needed. Sintilimab, a fully human anti-PD-1 monoclonal antibody, has showed encouraging antitumor efficacy in pts with r/r NKTL. Anlotinib, a multiple-targeted TKI that mainly blocks VEGF/VEGFR pathway, has been approved for several solid tumor types in china. Anti-angiogenesis therapy could improve efficacy of ICI in multiple tumor types. This multicenter, single-arm, phase 2 study aims to evaluate the efficacy and safety of sandwich chemoradiotion of sintilimab combined with anlotinib and pegaspargase (PEG-ASP) in newly diagnosed localized NKTL pts. **Methods:** Patients with pathologically confirmed previously untreated stage NKTL were enrolled. All enrolled patients received 3 cycles of sintilimab (200mg D1 ivdrip) combined with anlotinib (12mg po D1-14) and PEG-ASP (2500U/m^2 D1) every 3 weeks followed by RT, then received additional 3 cycles of combination therapy as described above. The primary endpoint was overall response rate (ORR) by LUGANO 2014 criteria. **Results:** A total of 39 pts were enrolled, and 24 pts eligible for response evaluation (70.8% men; median age, 46 y [range 20-64]; 58.3% stage). According to PINK-E system, 8 pts (33.3%) were identified as intermediate risk group and 16 patients were low risk group. 23 of 24 patients completed protocol-specified therapeutic schemes, one patient discontinued the study after the second cycle due to disease progression. ORR was 95.8% (23/24, 95%CI: 76.9%-84.1%). Surprisingly, all the responded patients achieved CR, while 66.7% (16/24, 95%CI: 44.7%-83.6%) patients achieved CR after the second cycle. Median PFS and OS have not been reached. 1-year OS and PFS was 100% and 95.8%, respectively. All grade TRAEs occurred in 84.6% of all enrolled patients and 92.1% were grade 1-2. The most common TRAE was lymphocytopenia (9.9%). Of note, grade 3-4 hematological toxicity was reported in only one patient (4.2%). All AEs were resolved after symptomatic treatment, without systematic corticosteroid intervention. **Conclusions:** Sintilimab combined with anlotinib and PEG-ASP upfront and after radiotherapy was effective and could be well tolerated in localized NKTL, achieving promising CRR and rapid and long-term remission with mild toxicity. Further investigation of survival outcome is warranted. Clinical trial information: NCT03936452. Research Sponsor: None.

Safety and efficacy of VIP152, a CDK9 inhibitor, in patients with double-hit lymphoma (DHL). *First Author: Victor Moreno, START Madrid-FJD, Fundación Jiménez Díaz Hospital, Madrid, Spain*

Background: PTEFb/CDK9-mediated transcription of short-lived anti-apoptotic survival proteins and oncogenes like MCL-1 and MYC plays a critical role in a variety of cancers. VIP152 (formerly BAY 1251152), a potent and highly selective CDK9 inhibitor, has been evaluated in a Phase 1 dose-escalation study in patients with advanced cancer. The maximum tolerated dose was 30 mg once weekly administered in consecutive 21-day cycles, based on neutropenia as the dose-limiting toxicity (JCO 2018;36:2507; NCT02635672). DHL is defined as dual rearrangement of the MYC gene and either the BCL2 or BCL6 genes; the resulting overexpression of MYC and BCL2/BCL6 make it particularly difficult to treat. Patients with DHL have a poor prognosis and no standard of care. Considering the impact of CDK9 inhibition on MYC, an exploratory cohort of patients with DHL was added to the study. **Methods:** Patients with refractory or relapsed DHL were eligible. VIP152 was administered once weekly as a 30-minute IV infusion on Days 1, 8 and 15 of a 21-day cycle. Tumor response was assessed according to the revised Cheson criteria (2007). **Results:** To date a total of 7 patients have been enrolled and were evaluable at the time of data cutoff (24NOV2020). The patients were mostly men (6/7 pts, 86%) with a median (range) age of 70 (58-84) years. All patients received ≥2 prior therapies, including 2 patients with bone marrow transplant. Three of 7 patients (29%) had ≥3 prior therapies. The median time on treatment was 22 days (range 8-1361 days). The most common adverse events of any grade were: constipation, fatigue, nausea (each 3/7 pts, 43%) and abdominal pain, diarrhea, lymphocyte count decrease, neutrophil count decrease, skin infection, tumor pain, and vomiting (each 2/7 pts, 29%). Most were Grade 1 and Grade 2. The Grade 3 adverse events were fatigue, lymphocyte count decrease, neutrophil count decrease (each 1/7 pts, 14%) and tumor pain (2/7 pts, 29%). One Grade 4 lymphocyte count decrease was reported. Two patients had a serious adverse event (Grade 3 syncope and Grade 3 tumor pain). Two patients had dosing held for an adverse event; however, no patient withdrew from treatment due to any adverse events. One death occurred due to disease progression. Pharmacodynamic biomarker analysis showed significant reduction of MYC, PCNA, and MCL-1 mRNA in all patients across multiple timepoints. Antitumor activity consisted of 2 complete metabolic responses in 7 patients (29%) based on investigator-assessed FDG-PET scans. Due to the COVID pandemic, the patients withdrew consent after 3.7 and 2.3 years, respectively, of treatment. Both patients were in complete metabolic response. **Conclusions:** VIP152 had a manageable safety profile, on-target pharmacodynamic activity and signs of durable monotherapy antitumor activity in patients with DHL. These encouraging results warrant further evaluation of VIP152 in patients with MYC-driven lymphoma and solid tumors. Clinical trial information: NCT02635672. Research Sponsor: Bayer AG.

Lenalidomide plus rituximab in patients with rituximab-resistant indolent B-cell and mantle cell lymphomas: 10-year follow-up. *First Author: Aditi Gupta, University of Pennsylvania Health System, Philadelphia, PA*

Background: Lenalidomide (len) plus rituximab is now a standard-of-care option for indolent B-cell non-Hodgkin lymphomas (iNHL) and mantle cell lymphomas (MCL). We previously demonstrated the efficacy of len plus rituximab in patients (pts) with rituximab-refractory iNHL and MCL (Chong *et al.* Clin Can Res 2015). We now report the longest experience to date with this regimen. **Methods:** We conducted an open-label phase II trial in pts with iNHL or MCL and rituximab resistance, defined as failure to respond or progression of disease within 6 months (mo) of rituximab or a rituximab-containing regimen. Pts received len 10 mg daily for 8 weeks, followed by 4 weekly doses of rituximab 375 mg/m^2 and continued len maintenance until disease progression, toxicity or pt choice. **Results:** 50 pts (30 FL, 14 MCL, 2 MZL, 4 SLL) were treated between 2008-2012. Median follow-up was 10.5 years (yr). Pts received a median of 3 prior therapies (range: 1–7). Progression free survival (PFS) for all pts at 5 and 10 yrs was 20.0% [95%CI 8-35] & 13% [95%CI 3-30%]; 5- and 10-yr response duration (RD) was 27% [95% CI 12-46] and 18% [95% CI 4-40], respectively; 5- and 10-yr overall survival (OS) was 58% [95%CI 43-70] and 45% [95%CI 30-58], respectively. 5-yr OS from the time pts were deemed rituximab-resistant is 64.0% and 10-yr OS 51.9%. For pts with FL, 5- and 10-yr PFS were both 13%, and 5- and 10-yr OS were 60% and 40%. For MCL, 5- and 10-yr PFS were both 25% and 5- and 10-yr OS were 50% and 36%. At 10.5 yr, 4 pts (2 FL, 1 MCL, 1 MZL) remain in complete remission (CR), 3 of whom discontinued len at 7.0-yr, 8.8-yr and 10.1-yr in CR. 1 pt with FL discontinued study in CR after 11.6-yr but continues on commercial len at 5 mg daily. The most common grade 1–2 adverse events (AEs) requiring dose reductions were neuropathy (n = 3) and diarrhea (n = 5), which all resolved with dose reduction. The most common grade 3–4 AEs requiring dose reductions were neutropenia (n = 6, 12%) and tumor flare (n = 3, 6%). Pts discontinued therapy due to toxicity at a median of 4.9 mo (range 0.3–25.7) from len start due to grade 3–4 rash (n = 2), grade 2 abdominal pain (n = 1), and grade 3–4 thrombocytopenia (n = 2). Only 1 patient discontinued len after > 1 yr (25.7 mo) due to persistent diarrhea. The pt who developed grade 2 abdominal pain was retreated with len without recurrence of pain and sustained a second CR for 5 yrs. 5 (10%) pts developed secondary cancers at a median of 15.5 mo (range: 0.8–50.5) from starting len, including 2 hematological (acute myeloid leukemia, B-acute lymphoblastic leukemia) and 3 solid cancers (NSCLC, renal cell carcinoma, prostate cancer). Prior to enrollment, 4/5 of the patients with secondary cancers had received alkylating agents and 3/5 had received anthracyclines. **Conclusions:** These data represent the longest reported outcomes for len plus rituximab in NHLs. We demonstrate durable responses and a manageable safety profile with rituximab plus low-dose len. Clinical trial information: NCT00783367. Research Sponsor: Celgene.

7540 **Poster Session**

First-MIND: A phase Ib, open-label, randomized study to assess safety of tafasitamab (tafa) or tafa + lenalidomide (LEN) in addition to R-CHOP in patients with newly diagnosed DLBCL. *First Author: David Belada, 4th Department of Internal Medicine–Hematology, University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic*

Background: Tafasitamab is a humanized, Fc-modified anti-CD19 monoclonal antibody that enhances antibody-dependent cellular cytotoxicity and phagocytosis. It is FDA-approved with LEN for adult patients (pts) with relapsed/refractory (R/R) DLBCL ineligible for autologous stem cell transplantation. First-MIND (NCT04134936) is a Phase Ib, open-label, randomized study of tafa + R-CHOP or tafa + LEN + R-CHOP in newly diagnosed DLBCL. **Methods:** Eligible pts were ≥18 years, treatment-naïve, with histologically confirmed DLBCL not otherwise specified, international prognostic index (IPI) 2–5 and ECOG performance status (PS) 0–2. Pts with known double- or triple-hit and transformed lymphoma were excluded. Treatment (Tx) comprised six 21-day cycles of tafa (12 mg/kg IV, Day [D] 1, 8, 15) + R-CHOP (arm A) or tafa (12 mg/kg IV, D1, 8, 15) + LEN (25 mg orally, D1–10) + R-CHOP (arm B). G-CSF and VTE prophylaxis was mandatory. Primary objective is safety; secondary objectives are ORR, PET-CR rate at end of Tx, PFS, long-term safety, pharmacokinetics, immunogenicity. **Results:** From Dec 2019 to Aug 2020, 83 pts were screened in Europe and the US; 66 were randomized (33 per arm). Data cut-off for this analysis: 9 Dec 2020; study is ongoing. Median age was 64.5 years (range 20–86). Overall, 30% (20/66) of pts were ≥70 years and many had high-risk disease: IPI 2 29%, IPI 3 46%, IPI 4 26%. ECOG PS: 47% of pts were ECOG PS 0, 44% PS 1, 9% PS 2. Most pts had stage III/IV disease (92%); 46% had bulky disease. All pts experienced a treatment-emergent adverse event (TEAE). Grade ≥3 neutropenia and thrombocytopenia occurred in 54.5% and 12.1% (arm A) and 66.7% and 30.3% (arm B) of pts, respectively (Table). Serious TEAEs occurred in 42.4% (arm A) and 51.5% (arm B) of pts. There were three deaths, unrelated to tafa and/or LEN (sepsis, urosepsis, and COVID-19 pneumonia). R-CHOP dose intensity was maintained in both arms. Among 60 pts who completed tumor assessments after cycle 3, ORR was 89.7% (arm A) and 93.5% (arm B). **Conclusions:** These data suggest R-CHOP + tafa or tafa + LEN is tolerable in pts with Tx-naïve DLBCL and that R-CHOP dosing is not affected. Toxicities are similar to those expected with R-CHOP or R-CHOP + LEN. Updated safety and early efficacy data will be presented at the conference. Clinical trial information: NCT04134936. Research Sponsor: MorphoSys AG, Planegg, Germany.

Preliminary results of a phase I trial of FT516, an off-the-shelf natural killer (NK) cell therapy derived from a clonal master induced pluripotent stem cell (iPSC) line expressing high-affinity, non-cleavable CD16 (hnCD16), in patients (pts) with relapsed/refractory (R/R) B-cell lymphoma (BCL). *First Author: Paolo Strati, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: FT516 is an investigational, NK cell cancer immunotherapy derived from a clonal master iPSC line. FT516 is engineered with a novel hnCD16 Fc receptor, demonstrated preclinically to maximize antibody-dependent cellular cytotoxicity (Zhu et al. Blood 2020). FT516 can be mass produced and made available off-the-shelf for broad pt access and multi-dose administration. **Methods:** This is a Phase I trial of FT516 combined with rituximab (R) in pts with R/R BCL. Treatment consists of 2 cycles, each with 3 days lympho-conditioning (fludarabine 30 mg/m^2 and cyclophosphamide 500 mg/m^2) and 1 dose of R followed by 3 weekly infusions of FT516 (planned doses 30-900 million/dose) with IL-2 (6 MIU after each FT516 dose). The primary objective is to identify the incidence of dose-limiting toxicity (DLT)/dose cohort and the recommended Phase II dose using a standard 3+3 design. Additional objectives include safety, tolerability, preliminary activity, pharmacokinetics, and immunogenicity. **Results:** Six pts (5 DLBCL, 1 FL, median age 65.5 y) have completed (5) or discontinued (1) study treatment after the DLT period (data cutoff 9 Dec 2020): 2 received 30 million cells/dose, 3 received 90 million cells/dose, and 1 received 300 million cells/dose. All pts received > 1 prior R-containing regimen, and median number of prior therapies was 3 (range 2-6), including CAR-T in 3 pts. FT516 was primarily administered in the outpatient setting. No FT516-related Grade ≥3 adverse events (AEs) or serious AEs, and no events of cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), or graft-versus-host disease (GvHD) of any grade were reported. DLT (Grade 4 neutrophil count decreased, not recovered to baseline by D29) was reported in the first pt at 30 million cells/dose and R dosing of 375 mg/m^2 weekly x 4/cycle, resulting in modification of R dosing to once/cycle; no DLTs were observed with modified R dosing. Most common all grade AEs in ≥3 pts: fatigue (4 pts) and decreased appetite, nausea, neutrophil count decreased, and headache (3 pts each). Grade ≥3 AEs in ≥2 pts: neutrophil count decreased (3 pts) and febrile neutropenia and platelet count decreased (2 pts each); none considered related to FT516. Host anti-product B- or T-cell immunogenicity was not observed. Three of 4 pts treated at ≥90 million cells/dose achieved objective response (2 complete responses [CRs] and 1 partial response). **Conclusions:** Administration of up to 6 doses of FT516 cells, including up to 300 million cells/dose, appears to be safe and tolerable, without CRS, ICANS, or GvHD. Activity was observed, including CRs, in heavily pretreated pts. Dose escalation is ongoing. Updated clinical and translational data will be presented. Clinical trial information: NCT04023071. Research Sponsor: Fate Therapeutics, Inc.

Survival trends of older adult patients with diffuse large B-cell lymphoma: A National Cancer Database analysis. *First Author: Xavier Andrade-Gonzalez, Mayo Clinic, Rochester, MN*

Background: 60-70% of patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL) can be cured with R-CHOP or R-CHOP-like immunochemotherapy. However, patients ≥80 years of age were either excluded or underrepresented in modern DLBCL trials, and their outcomes are understudied. The aim of this study is to define the survival trends and risk factors for inferior survival in older adult patients with DLBCL. **Methods:** Patients with newly diagnosed DLBCL were identified from the National Cancer Database (2004-2017, representing the rituximab era). Clinical characteristics, treatment, and outcomes were compared between patients ages ≥ 80, 65-79, and < 65 years. The Kaplan-Meier method and Cox proportional hazards model were used for survival analysis. **Results:** A total of 231,756 patients with newly diagnosed DLBCL were identified; 46,250 (20%) were ≥80 years, 87,702 (38%) were 65-79 years, and 97,904 (42%) were < 65 years. Patients ≥80 years were more likely to have a higher Charlson-Deyo Comorbidity Index score (CDS) (CDS ≥2, 12% vs 11% vs 8%, p = 0.001), less likely to receive systemic chemotherapy (63% vs 83% vs 89%, p < 0.001), and more likely to receive treatment at a non-academic center (71% vs 65% vs 48%, p < 0.001), compared to patients 65-79 and < 65 years, respectively. Median overall survival (OS) was significantly worse for patients ≥80 years compared to patients 65-79 years (11.6 vs 61.0 months, p = 0.001) and patients < 65 years (11.6 vs 178.1 months, p = 0.001). During the study period, the median OS had only minimally improved for patients ≥80 years (10.6 months in 2004-2007 vs 11.5 months in 2008-2011 vs 12.3 months in 2012-2016, p = 0.006). In contrast, the OS improvement appears more meaningful in patients 65-79 years (median in months: 51 vs 61.2 vs 65.9, p = < 0.001) and patients < 65 years (median in years: 14.6 vs 11.3 vs not reached, p < 0.001) in the prespecified intervals (2004-07, 2008-11, and 2012-16). In multivariate analysis, the most substantial risk factor for worse survival in patients ≥80 years was not receiving systemic therapy (hazard ratio [HR] = 3.26, 95%CI = 3.01-3.54, p = 0.001). Other risk factors associated with worse survival included high-risk IPI score (HR = 2.16, 95%CI = 1.96-2.39, p = 0.001), CDS score ≥2 (HR = 1.56, 95%CI = 1.40-1.73, p = 0.001), male sex (HR = 1.16, 95%CI = 1.09-1.24, p = 0.001), B symptoms at diagnosis (HR = 1.16, 95%CI = 1.08-1.25, p = 0.001), and treatment at a non-academic center (HR = 1.1, 95%CI = 1.01-1.20, p = 0.001). **Conclusions:** Patients ≥ 80 years of age with DLBCL have a significantly inferior survival which has not meaningfully improved in recent years. More than 1/3 of patients ≥ 80 years did not receive systemic therapy. Older adult patients with DLBCL should be assessed for fitness for chemotherapy using validated geriatric assessment tools. Novel therapeutic strategies with favorable safety profiles are urgently needed for this expanding patient population. Research Sponsor: None.

CNS relapse in DLBCL patients below 60 years treated with R-ACVBP, R-CHOEP, or R-CHOP: A joint analysis of LYSA and GLA/DSHNHL. *First Author: Catherine Thieblemont, AP-HP at Saint-Louis Hospital, Hematooncology, Paris University, Paris, France*

Background: Central nervous system (CNS) relapse occurs in 2-6% of DLBCL patients (pts) increasing to 10% or more in high-risk groups. Intrathecal (IT) or intravenous high-dose methotrexate (HD MTX) have limited if any prophylactic impact on CNS relapse. To address the role of systemic first-line therapy in pts tolerating intensified strategies (R-ACVBP, R-(Mega)CHOEP, R-CHO(E)P), we compared CNS relapses occurring in a large cohort of pts ≤60 years. **Methods:** We conducted a retrospective analysis including previously untreated pts with DLBCL by central review, age 18-60 years, from multicenter clinical trials conducted by LYSA and GLA/DSHNHL (Table). We assessed the risk of CNS relapse in matched cohorts based on the aaIPI. **Results:** A total of 2203 pts were included. Median age was 47 years (18-60). 455 pts were treated with R-ACVBP, 444 with R-(Mega)CHOEP, 1304 with R-CHOP. Distribution of CNS IPI was not significantly different comparing R-ACVBP to R-CHO(E)P groups within aaIPI categories (Table). PFS and OS were comparable according to treatment within aaIPI groups, also adjusted for prognostic factors. No CNS events occured during observation time of 3 years in pts with aaIPI 0. In pts with aaIPI 1, no CNS event occured in the R-ACVPB arm, the 3y-cumulative incidence of CNS relapse for pts treated with R-CHO(E)P group was 1.0% (95%CI 0.3-1.7). In pts with aaIPI 2,3 and intermediate/high CNS IPI, four (1.6%) treated with R-ACVBP experienced relapse in the CNS compared to 15 (3.9%) pts treated with R-(Mega)CHO(E)P (3y-cumulative incidence 1.6% (95%CI 0-3.2) vs. 4.0% (95%CI 2.0-6.0). **Conclusions:** CNS relapse was extremely rare in younger DLBCL pts with aaIPI 0 or 1; prophylactic measures are not warranted. In pts with aaIPI 2,3 (and intermediate/high CNS-IPI), only 4 (1.6%) CNS relapses were seen with the R-ACVBP while 15 (3.9%) relapses did occur after R-(Mega)CHO(E)P. This analysis underlines the important role of the systemic therapy in controling CNS relapse. Research Sponsor: None.

Atezolizumab + obinutuzumab + venetoclax in patients with relapsed or refractory indolent non-Hodgkin's lymphoma (R/R iNHL): Primary analysis of a phase 2 trial from LYSA. *First Author: Charles Herbaux, Centre Hospitalier Régional Universitaire de Lille, Institute of Hematolog-Tranfusion, Lille, France*

Background: R/R iNHL treatment remains challenging. Atezolizumab (ATE) and obinutuzumab (OBI) are monoclonal antibodies acting respectively to inhibit T-lymphocyte exhaustion or by inducing lymphoma cells cytotoxicity, whereas venetoclax (VEN) is a small molecule inhibiting BCL-2. Combining tumor-targeted therapies with agents that enhance anti-tumor immunity represents an attractive treatment paradigm. This LYSA sponsored multicenter phase 2 trial (NCT03276468) evaluated ATE, OBI and VEN combination in R/R B-cell lymphomas. Herein, we present primary efficacy and safety data from the iNHL cohort including Follicular Lymphoma (FL) and Marginal Zone Lymphomas (MZL). **Methods:** Patients ≥18 years with biopsy-confirmed R/R FL and MZL who failed at least one line of therapy were eligible. OBI was given IV at 1 g on day (D) 1, 8 and 15 of cycle (C) 1 and on D1 from C2 to C8 every 3 weeks. ATE was given IV, 1.2 g every 3 weeks, started at D2 of C1, then administered at D2 of each cycle for 24 cycles. VEN was given orally at 800 mg/D at full dose, starting on D8C1 for 24 cycles. The primary endpoint was the Overall Response Rate (ORR) evaluated by Lugano criteria at the end of induction (EOI) after 8 cycles of ATE, OBI and VEN (M6) or at premature treatment discontinuation. **Results:** At the time of the primary analysis (08 Jan 2021), 78 patients were enrolled. *FL cohort* (n = 58): the median follow-up was 14.5 months. Main baseline characteristics were: Ann Arbor Stage III/IV, 85.7%; FLIPI HR, 47.3%; > 2 prior lines of therapy, 32.1%; and exposed to ASCT, 30.4%. The ORR on PET scan at EOI was measured at 53.6% [41.8%-65.1%], including 30.4% of CMR. 37 patients (63%) received the full induction treatment. *MZL cohort* (n = 20; 13 nMZL, 5 eMZL, 2 sMZL): the median follow-up was 11.9 months. Main baseline characteristics were: Ann Arbor Stage IV, 100%; bone marrow infiltration, 38.9%; ≥ 2 extra-nodal sites, 50%; and > 2 prior lines of therapy, 22.2%. The ORR on CT scan at EOI was measured at 66.76% [44.6%-84.4%], including 16.7% of CR and 50.0% PR. 11 patients (55%) received the full induction treatment. At time of the present analysis, responses in the 2 cohorts seem durable with only 21,4% of responders who have reported relapse/progression. Out of the 78 pts, a total of 55 (70.5%) pts experienced grade 3–4 adverse event (AE) and 1 patient experienced an AE that led to discontinuation of any drug. Main AE of grade 3 or more were hematologic cytopenias, with only one febrile neutropenia (1.3%). Three pts experienced immune-related AE (1 grade 2 myositis and 2 grade 3 colitis), no tumor lysis syndrome was observed. **Conclusions:** ATE, OBI and VEN triplet appears to be well tolerated, with no unexpected toxicity brought by the combination. The ORR at EOI seems to be comparable to other innovative regiments in this setting, with durable responses to date. Clinical trial information: NCT03276468. Research Sponsor: None.

7545 **Poster Session**

Obinutuzumab short-duration infusion (SDI) in previously untreated advanced follicular lymphoma: Results from the end of induction analysis of the phase IV GAZELLE study. *First Author: Miguel Angel A. Canales Albendea, Hospital Universitario La Paz, Madrid, Spain*

Background: Obinutuzumab (G)-chemotherapy (chemo) has demonstrated improved progression-free survival compared with rituximab (R)-chemo in previously untreated advanced follicular lymphoma (FL). G is currently administered by IV infusion over ~3–4 hours. A shorter duration of infusion in Cycle (C) 2 and subsequent cycles, as is standard practice with R, could improve convenience for patients (pts) and efficiency for infusion facilities. We report the primary analysis of the prospective, open-label, multicenter, single-arm, Phase IV, GAZELLE study (NCT03817853), which evaluated the safety of G administered as a 90-minute (min) SDI from C2 onwards in pts with FL. **Methods:** Pts with previously untreated FL received G (1000mg) intravenously on Day (D) 1, 8, and 15 of C1, and on D1 thereafter, plus chemo (bendamustine, CHOP, or CVP) for 6–8 cycles. In C1, pts received G at the standard infusion rate. Pts without a Grade (Gr) ≥3 infusion-related reaction (IRR) in C1 were eligible to receive G as a 90-min SDI from C2. Pts with a Gr 3 IRR in C1 received the standard G infusion in C2, and were eligible for G SDI in subsequent cycles if no Gr ≥3 IRRs occurred. Pts with a second Gr 3/4 IRR discontinued G. At the end of induction (EOI), responding pts received maintenance G (1000mg) as SDI for 2 years or until disease progression (PD). The primary endpoint was incidence of Gr ≥3 IRRs during C2. IRRs were defined as any event occurring ≤24 hours from infusion judged to be related to treatment. Secondary endpoints included adverse events (AEs) and investigator-assessed overall response rate at EOI. **Results:** As of December 3, 2020, 113 pts had received study treatment. Median age was 62.0 years, 50.4% were male, 61.9% had stage IV FL, and 45.1% were classified as high-risk FLIPI. Of the 110 pts who were eligible for G SDI from C2, no pt experienced a Gr ≥3 IRR with SDI in C2 (Table). One pt experienced a Gr 3 IRR with SDI in C5, presenting hypertension. All other IRRs with SDI were Gr 1/2. No Gr 4/5 IRRs were reported. Other AEs were similar to those observed in previous studies. At the clinical cut-off date, 104 pts had a CT imaging-based response assessment at EOI and 9 pts had no response assessment; 76/113 (67.3%) had a complete response, 22 (19.5%) had a partial response, and six (5.8%) had PD. **Conclusions:** In GAZELLE, G SDI in C2 and beyond appeared to be safe. No Gr 3 IRRs were observed in C2 and only one Gr 3 IRR was reported in subsequent cycles. The safety profile of G SDI was comparable with the established profile of G in advanced FL. Clinical trial information: NCT03817853. Research Sponsor: GAZELLE was sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of all authors, was provided by Aisling Lynch and Louise Profit of Ashfield MedComms, and was funded by F. Hoffmann-La Roche Ltd.

Duration of response to loncastuximab tesirine in relapsed/refractory diffuse large B-cell lymphoma by demographic and clinical characteristics: Subgroup analyses from LOTIS 2. *First Author: Paolo Caimi, University Hospitals Cleveland Medical Center/Case Western Reserve University, Cleveland, OH*

Background: Outcomes for patients with refractory/relapsed diffuse large B-cell lymphoma (R/R DLBCL) are poor, particularly for those with high-risk clinical characteristics. There remains an unmet need for new treatment options for these patients. Loncastuximab tesirine (Lonca) is an antibody-drug conjugate comprising a humanized anti-CD19 antibody conjugated to a potent pyrrolobenzodiazepine dimer toxin. LOTIS 2 was a pivotal Phase 2 study that demonstrated substantial single-agent anti-cancer activity of Lonca in patients with R/R DLBCL. Efficacy and safety data were presented at ASH 2020 (Caimi *et al*, ASH 2020; abstract 1183). Here we present subgroup analyses of duration of response (DoR) to Lonca by demographic and clinical characteristics. **Methods:** Adult patients with R/R DLBCL who had received ≥2 prior therapies were enrolled in this Phase 2, multicenter, single-arm, open-label study of single-agent Lonca (150 μg/kg every 3 weeks for 2 doses, followed by 75 μg/kg thereafter for up to 1 year). The primary analysis has previously been reported, with a primary endpoint of overall response rate (ORR). Patients are being followed-up every 12 weeks for up to 3 years. DoR was a key secondary efficacy endpoint, defined as time from the first documentation of response (central review) to disease progression or death. We analyzed pre-specified demographic and clinical characteristic subgroups for DoR. **Results:** As of data cut-off (August 6, 2020), ORR in the total population (N = 145) was 48.3% (24.8% had complete response [CR] and 23.4% had partial response [PR]). Median DoR (mDoR) for the 70 responders was 12.58 months. mDoR for patients with CR and PR was 13.37 months and 5.68 months, respectively. Overall, subgroups with high-risk characteristics for poor prognosis had a DoR comparable to the whole study population. mDoR for patients with double-/triple-hit DLBCL was 13.37 months, with advanced stage disease was 12.58 months, and with transformed disease was 12.58 months. The mDoR for older patients was longer than for younger patients (≥75 years, 13.37 months; 65 to < 75 years, 12.58 months; < 65 years, 9.26 months). Patients with DLBCL refractory (defined as no response to therapy) to first-line, most recent line, and all prior lines of therapy had mDoRs of 9.63 months, 9.26 months, and 9.63 months, respectively. **Conclusions:** Durable responses were observed with the recommended Phase 2 dose regimen of Lonca in heavily pre-treated patients and those at high risk of poor prognosis, including older patients and those with double-/triple-hit, advanced stage, transformed, and primary refractory DLBCL. Updated DoR data will be presented at the meeting. Clinical trial information: NCT03589469. Research Sponsor: ADC Therapeutics SA.

Outcomes with KTE-X19 in patients (pts) with relapsed/refractory (R/R) mantle cell lymphoma (MCL) in ZUMA-2 who had progression of disease within 24 months of diagnosis (POD24). *First Author: Michael Wang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: KTE-X19 is an autologous anti-CD19 CAR T-cell therapy approved in the US and EU for the treatment of R/R MCL. In the ZUMA-2 study of KTE-X19 in R/R MCL, the objective response rate (ORR) at a median 17.5-mo follow-up was 92% (67% complete responses [CR]; Wang et al. ASH 2020 #1120). Here, we report results in pts with or w/o POD24, an indicator of poor outcomes (Visco et al. *Br J Haematol* 2019). **Methods:** Eligible pts with R/R MCL underwent leukapheresis and conditioning chemotherapy followed by a single infusion of KTE-X19. Efficacy results are reported for the 60 treated pts with ≥1 y of follow-up (median 17.5 mo); safety results are presented for all 68 treated pts. **Results:** High-risk disease characteristics were common in pts with (n=33) and w/o POD24 (n=35), although pts with POD24 had higher tumor burden and lactate dehydrogenase (LDH) levels, and more had blastoid type MCL (Table). ORR in pts with (n=28) and w/o POD24 (n=32) was 93% and 91%, with CR rates of 61% and 72%. In pts with and w/o POD24, median progression-free survival (PFS) was 11.3 mo (range, 0.9–30.3) and 29.3 mo (range, 0–35.9). Medians for duration of response (DOR) and overall survival (OS) were not reached in either group. Most common Grade ≥3 adverse events (AEs) in pts with vs w/o POD24 were neutropenia (91% vs 80%), thrombocytopenia (61% vs 46%), and anemia (55% vs 51%); Grade ≥3 cytokine release syndrome (CRS) and neurologic events occurred in 9% vs 20% and 27% vs 34%, respectively. There were no cases of Grade 5 CRS, KTE-X19–related secondary cancers, or replication-competent retrovirus in either group. In pts with vs w/o POD24, median peak CAR T-cell levels and median area under the curve were 53.4 cells/μL (range, 0.2–2566) and 583.4 cells/μL (range, 1.8–27,743.6) vs 112.4 cells/μL (range, 0.2–2589) and 1588.3 cells/μL (range, 3.8–27,238.7); by 12 mo, B cells were detectable in 8/11 (73%) vs 7/15 pts (47%) in ongoing response. **Conclusions:** KTE-X19 provided a high CR rate across all pts, with median DOR and OS not reached. Pts with POD24 had more aggressive high-risk disease characteristics (tumor burden, LDH levels, and blastoid MCL) and generally lower CAR T-cell expansion and PFS vs pts w/o POD24. Earlier intervention with CD19-directed CAR T-cell therapy may benefit pts with MCL with known high-risk factors. Clinical trial information: NCT02601313. Research Sponsor: Kite, a Gilead Company.

Updated outcomes with axicabtagene ciloleucel (axi-cel) retreatment (reTx) in patients (pts) with relapsed/refractory (R/R) indolent non-Hodgkin lymphoma (iNHL) in ZUMA-5. *First Author: Julio C. Chavez, University of South Florida H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: ZUMA-5 is a Phase 2 study of axi-cel anti-CD19 CAR T-cell therapy in pts with R/R iNHL (follicular lymphoma [FL]; marginal zone lymphoma [MZL]). In the primary analysis, 11 pts (9 FL; 2 MZL) were retreated with axi-cel, achieving an overall response rate (ORR) of 100% (91% complete response [CR] rate) at a median follow-up of 2.3 mo post-reTx, with no Grade ≥3 cytokine release syndrome (CRS) or neurologic events (NEs; Chavez et al. ASH 2020. #2036). Here, we report updated clinical and translational outcomes with longer follow-up in pts retreated with axi-cel in ZUMA-5. **Methods:** Eligible pts with FL or MZL had R/R disease after ≥2 lines of therapy. Pts were considered for reTx if they progressed after a response at mo 3, had no evidence of CD19-negative relapse in biopsy, had no axi-cel neutralizing antibodies, and had no Grade 4 CRS or NEs with 1st Tx. Retreatment was per investigator discretion. At both Txs, pts received axi-cel (2×10^6 CAR T cells/kg) after conditioning chemotherapy. **Results:** As of 9/14/2020, 13 pts with iNHL (11 FL; 2 MZL) received axi-cel reTx, with 2 pts retreated after the primary analysis. Before their 1st Tx, pts had median 4 prior lines of therapy; 85% had stage 3–4 disease; 82% had FLIPI of ≥3; 46% were POD24; 77% had refractory disease. Among the 13 retreated pts, 85% had a CR to 1st Tx. Median 1st duration of response (DOR) was 8.2 mo. Detectable CD19 was confirmed in all evaluable biopsies from retreated pts at relapse, and median time from 1st Tx to reTx was 10.6 mo. Following reTx, the ORR was 100% (77% CR rate). After a median follow-up of 11.4 mo, the median DOR had not yet been reached; 46% of retreated pts had ongoing responses at data cutoff. At 1st Tx, CRS occurred in 9 pts (5 Grade 1, 4 Grade 2); NEs occurred in 5 (3 Grade 1, 1 Grade 2, 1 Grade 3). At reTx, CRS occurred in 8 pts (6 Grade 1, 2 Grade 2); NEs occurred in 4 (3 Grade 1, 1 Grade 2). Median peak levels of biomarkers typically associated with severe CRS and NEs were similar at reTx and 1st Tx (IL-6, 7.7 vs 5.7 pg/mL; IL-2, 1.8 vs 0.9 pg/mL; IFN-γ, 62.9 vs 64.2 pg/mL). In the 11 retreated pts with FL, tumor burden (median sum of product diameters [SPD]) was lower before reTx vs 1st Tx (1416 vs 4770 mm^2). Engraftment index (CAR T-cell expansion relative to SPD) is an indirect proxy for effector:target ratio and a key covariate of response to axi-cel (Locke et al. *Blood Adv.* 2020). Though median peak CAR T-cell levels appeared lower at reTx vs 1st Tx (5.2 vs 14.3 CAR+ cells/μL blood), engraftment index was similar (0.003 vs 0.005 cells/μL×mm2). **Conclusions:** Axi-cel reTx achieved deep and durable responses, with an acceptable safety profile. Tumor CD19 positivity was maintained at relapse, and engraftment index was similar at both Txs, comparing favorably to previous reports in aggressive lymphomas (Locke et al. ASCO 2020. #8012). These data suggest axi-cel reTx is a promising option for pts with R/R iNHL. Clinical trial information: NCT03105336. Research Sponsor: Kite, a Gilead Company.

NVG-111, a novel ROR1xCD3 bispecific antibody for non-Hodgkin lymphoma. *First Author: David Granger, NovalGen Ltd , London, United Kingdom*

Background: Receptor tyrosine kinase-like Orphan Receptor 1 (ROR1) is a type I transmembrane protein is highly expressed on an array of haematological and solid tumours. NVG-111 is a humanised, tandem scFv ROR1xCD3 bispecific antibody previously shown to elicit potent killing of tumour cells *in vitro* and *in vivo* by engaging a membrane-proximal epitope in the Wnt5a-binding Frizzled domain of ROR1 and redirecting T cell activity. The *in vitro* potency and pharmacodynamic responses to NVG-111 were assessed to support progression to a first-in-human study. **Methods:** The potency of NVG-111 *in vitro* was determined by evaluating the concentration response for cytotoxicity, T cell activation, and cytokine release in co-cultured Jeko-1 and unstimulated human T cells. Comparative data were generated for the marketed CD19xCD3 bispecific antibody, blinatumomab. Potency data for NVG-111 were used together with allometric scaling from murine PK studies to inform planned clinical doses. **Results:** NVG-111 demonstrated T cell-dependent cytotoxicity, T cell activation and levels of cytokine release similar in potency to blinatumomab. Cytotoxic responses of both NVG-111 and blinatumomab were more potent than T cell activation and cytokine release. Dose response curves for NVG-111 showed a decrease in activity beyond the concentration of maximal response (ie "hook effect"). We hypothesise this is due to receptor saturation, inhibiting synapse formation. NVG-111 has progressed to a Phase 1/2 first-in-human study in patients with debulked, relapsed/refractory chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL), the drug given as add-on to ≥2nd line therapy with a Bruton's tyrosine kinase inhibitor, or venetoclax. Phase 1 includes escalating doses of 0.3 to 360 μg/day via continuous infusion over 3 cycles (each 21 days on, 7 days off) to establish safety, PK, pharmacodynamics (PD) and recommended phase 2 dose (RP2D). Predicted exposure at 0.3 μg/day is ~EC_{20} for cytotoxicity *in vitro* and below the lowest EC_{10} for cytokine release. PD biomarkers in the study include systemic cytokines. Phase 2 will study efficacy and safety of the RP2D in CLL and MCL, with primary endpoint complete response rate; other efficacy endpoints include minimal residual disease and progression free survival. **Conclusions:** NVG-111 shows potent T-cell mediated lymphoma cell cytotoxicity *in vitro* at concentrations well below those associated with extensive cytokine release. NVG-111 is in an ongoing Phase 1/2 study and may present a novel option for adoptive immunotherapy in patients with non-Hodgkin lymphoma and potentially other cancers. Clinical trial information: 2020-000820-20. Research Sponsor: NovalGen Ltd.

Efficacy and safety of the PI3Kδ inhibitor zandelisib (ME-401) on an intermittent schedule (IS) in patients with relapsed/refractory follicular lymphoma (FL) with progression of disease within 24 months of first-line chemoimmunotherapy (POD24). *First Author: John M. Pagel, Swedish Cancer Institute, Seattle, WA*

Background: FL patients (pts) with POD24 have poorer survival and may benefit from novel therapies at relapse. Zandelisib, a potent, selective, and structurally differentiated oral PI3kδ inhibitor was evaluated in a dose escalation/expansion Phase 1b study for FL demonstrating a high objective response rate (ORR) and well tolerated when given on IS (J Clin Oncol 2020;38:#8016). We report here results based on POD24 status (NCT02914938). **Methods:** Eligible pts had ≥1 prior therapy, adequate bone marrow and organ function, ECOG performance status ≤2, and no prior PI3K therapy. Zandelisib was administered at 60 mg once daily for 8 weeks followed by IS on days 1-7 of each subsequent 28-day cycle, either as monotherapy or with rituximab at 375 mg/m^2 for 8 doses in Cycles 1-6. Treatment was continued until disease progression, intolerance, or withdrawal of consent. Imaging scans were obtained after 2 and 6 cycles, and then every 6 cycles. Response was reported based on Lugano criteria. **Results:** 37 FL pts were enrolled and received zandelisib on IS as monotherapy (N = 18) or in combination with rituximab (N = 19). Median number of prior therapies = 2 (range, 1-5). The ORR was 86.5% (32/37) with 27% CR (complete response). In the monotherapy group the ORR and CR were 77.8 % (14/18) and 27.8% and with rituximab 94.7% (18/19) and 26.3% respectively. Median duration of response (DOR) among all pts was not reached with a median follow-up of 16.9 months (mos) (1.2-33.1+). 22 pts (59%) were POD24, of which 15 (68%) had ≥2 prior lines of therapy. Despite more refractory disease, ORR among the POD24 pts was 81.8% (Table). Zandelisib on IS was well tolerated. 3 pts (8%) discontinued therapy due to an adverse event (AE) for any cause. Grade (Gr) 3 AE of special interest (AESI) were 2 (5.4%) diarrhea, 2 (5.4%) colitis, 3 (8.1%) rash, 3 (8.1%) ALT elevation, 1 (2.7%) AST elevation and no pulmonary infection. **Conclusions:** Zandelisib administered on IS as monotherapy or with rituximab resulted in a high-rate of durable responses in FL, both in POD24 and non-POD24 groups and therapy was well-tolerated with low rate of Gr 3 class-related AESI and discontinuation rate due to AE's. Zandelisib as monotherapy is being evaluated in a global Phase 2 study in FL and MZL after failure of 2 prior therapies (NCT03768505). A Phase 3 study of zandelisib plus rituximab in FL and MZL after failure of prior immunochemotherapy will begin enrollment in 2021. Clinical trial information: NCT02914938. Research Sponsor: MEI Pharma, Inc.

Long-term follow-up results of a phase II study of dose-adjusted (DA)-EPOCH-R with high-dose methotrexate (HD-MTX) for newly diagnosed stage II-IV CD5-positive diffuse large B-cell lymphoma (CD5+ DLBCL). *First Author: Kana Miyazaki, Mie University Graduate School of Medicine, Tsu, Japan*

Background: CD5+ DLBCL is characterized by a poor prognosis and frequent central nervous system (CNS) relapse after standard immunochemotherapy. In the primary analysis of our multicenter phase II study of DA-EPOCH-R/HD-MTX for newly diagnosed stage II-IV CD5+ DLBCL, the 2-year (yr) progression-free survival (PFS) was 79% and the 2-yr CNS relapse rate was 9% at a median follow-up of 3.1 yrs (Miyazaki, et al. 2020). The aim of this preplanned 5-yr follow-up was to assess PFS, overall survival (OS), the CNS relapse rate, and late toxicity. **Methods:** A total of 47 patients (pts) with newly diagnosed stage II-IV CD5+ DLBCL between 20-75 yrs old and ECOG PS of 0-3 were enrolled. The treatment included 4 cycles of DA-EPOCH-R followed by 2 cycles of HD-MTX ($3.5\ g/m^2$) and 4 additional cycles of DA-EPOCH-R. Intrathecal administration of MTX and/or cytarabine was not allowed. 45 (96%) pts completed the protocol treatment. The data were updated as of December 1, 2020. **Results:** The median follow-up of alive pts was 6.0 yrs (range, 5.0-7.7). The pts' characteristics were as follows: age, 37-74 yrs (median, 62); male, 38%; ECOG PS > 1, 4%; stage III/IV, 57%; IPI HI/H, 47%; CNS-IPI high, 21%; and ABC/GCB/unclassified (n = 46), 85%/9%/7%. The 5-yr PFS and OS were 72% (95% CI, 57-83%) and 79% (95% CI, 64-88%), respectively. The 5-yr PFS and OS of pts with CD5+ ABC DLBCL (n = 39) were 72% and 74%, respectively. The 5-yr CNS relapse rate in all 47 pts was 9% (95% CI, 3-22%). There were no CNS relapse events after the primary analysis. Neither grade 3/4 late adverse events nor cardiac events of any grade were observed. Possible second malignancies were recorded in 6 (13%) pts. Among them, one pt who received R-ICE as salvage therapy experienced acute myeloid leukemia. The other 2 pts had colon cancers treated with endoscopic polypectomy/mucosal resection. **Conclusions:** Both the survival benefit and safety of DA-EPOCH-R/HD-MTX were maintained during a 5-yr follow-up, indicating the excellent efficacy, and safety of this approach as a first-line therapy for CD5+ DLBCL. Clinical trial information: UMIN000008507. Research Sponsor: Japan Agency for Medical Research and Development, AMED.

7552 **Poster Session**

Real-world evidence of axicabtagene ciloleucel (Axi-cel) for the treatment of large B-cell lymphoma (LBCL) in the United States (US). *First Author: Caron A. Jacobson, Dana-Farber Cancer Institute, Boston, MA*

Background: Axi-cel is approved in the US for the treatment of adult patients with relapsed or refractory LBCL after 2 or more lines of systemic therapy. Post-market long term follow up study of commercial Axi-cel recipients using the Center for International Blood and Marrow Transplant Research was recently completed. **Methods:** From October 2017 to August 2020, 1,500 Axi-cel recipients from 79 centers were enrolled. Of these, 1001 patients with at least 6 months of follow-up were included in this analysis. Outcomes include complete and overall responses rates (CR and ORR), duration of response (DOR), progression-free and overall survival (PFS and OS), cytokine release syndrome (CRS) (Lee D 2014 and American Society for Transplantation and Cellular Therapy [ASTCT]), immune effector cell associated neurotoxicity syndrome (ICANS), hematologic recovery and subsequent neoplasm (SN). Subgroup analysis by sensitivity to therapy, defined as responsive to the last line of therapy prior to Axi-cel. Median follow-up was 12 months (range, 6-28 months). **Results:** The median age overall was 62 years, 37% were ≥ 65 years, 83% with Eastern Cooperative Oncology Group (ECOG) performance score 0-1, 28% with transformed lymphoma, 14% with high grade lymphoma, 29% with prior autologous transplant, and 66% with chemotherapy-resistant disease prior to Axi-cel. The median time from diagnosis to Axi-cel infusion was 15 months. Best ORR was 70% (CR 53%). Landmark analysis of patients in CR at 6 months post Axi-cel demonstrates a low number of subsequent progression/death events. With respect to outcomes for chemotherapy-sensitive disease versus resistant disease, the ORR, CR, 12-month PFS and OS were 78% vs. 66%, 60% vs. 48%, 55% (95% CI, 48-62%) vs. 40% (95% CI, 37-44%), and 70% (95% CI, 63-76%) vs. 54% (95% CI, 50-58%), respectively. CRS of any grade was reported in 83% of patients. Incidence of Grades ≥ 3 CRS was 10% according to Lee et al 2014, and 13% according to ASTCT Consensus Grading. Median time to any grade CRS was 4 days (range, 1-28 days), and 93% of CRS cases resolved with a median duration of 7 days (range, 1-121 days). ICANS were reported in 576 (57%) patients, grade >3 was 26%. The median time to onset of ICANS was 7 days (range, 1-82 days), and 86% resolved with a median duration of 9 days (range, 1 to 115 days). Twenty-nine patients (2.9%) reported SN: hematologic (N = 17), solid tumors (N = 12). **Conclusions:** This is the largest report on Axi-cel in the real-world setting and demonstrates consistent efficacy outcomes and further characterizes safety outcomes. Patients in CR at 6 months have sustained disease control with low number of relapse events. Although patients with therapy-sensitive disease experience better outcomes than patients with therapy-resistant, the overall outcomes on both groups of patients are favorable. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

7553 **Poster Session**

Initial results of the combination of PI3Kδ inhibitor zandelisib (ME-401) and the BTK inhibitor zanubrutinib in patients (pts) with relapsed or refractory (R/R) B-cell malignancies. *First Author: Jacob Drobnyk Soumerai, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Dual inhibition of PI3Kδ and BTK pathways may overcome existing or acquired monotherapy resistance. Dual inhibition of these pathways displays synergistic activity in cell lines that is evident even at suboptimal concentrations [Blood 2015;125(14):2306-09]. Zandelisib is a potent, selective, and structurally differentiated oral PI3Kδ inhibitor (i), and zanubrutinib is an oral BTKi. Based on their efficacy as monotherapy, we hypothesized that the combination of zandelisib and zanubrutinib can be well tolerated and may improve the depth and durability of responses. We evaluatedthis combination therapy in pts with R/R B-cell malignancies to determine the optimal dose and schedule for further evaluation in disease-specific expansion cohorts (NCT02914938). **Methods:** This is a multi-cohort Phase 1b study enrolling pts with FL, CLL, MZL, MCL, DLBCL, or high grade B-cell lymphoma (HGBCL), ≥1 prior therapy, adequate bone marrow and organ function, ECOG performance status ≤2, and no prior PI3Ki or BTKi therapy. For this combination therapy, two dose levels were evaluated in 28-day cycles: Cohort 10A: zandelisib 60 mg once daily for 2 cycles followed by an intermittent schedule (IS) on days 1-7 of subsequent 28-day cycles and zanubrutinib 160 mg twice daily (bid). Cohort 10C: zandelisib 60 mg on days 1-7 starting in Cycle 1 and zanubrutinib at 80 mg bid. Dose limiting toxicity (DLT) observation period was 28 days for cohort 10A and extended to 56 days for cohort 10C. Response was assessed at month 3, 7, 13 and then every 6 months until progression. **Results:** 20 pts treated, 7 in cohort 10A and 13 in cohort 10C: 8 FL, 5 CLL, 2 DLBCL, 2 HGBCL, 2 MZL, and 1 MCL. Median age 70 years (range, 44-85) and median prior therapies 2 (1-8). Median follow-up of 2.9 months (0.5-17.4+). There were no DLT in cohort 10A, grade (Gr) ≥3 adverse events (AE) occurred after day 28 in 4 pts, including Gr 4 neutropenia (1 pt), Gr 3 neutropenia, fatigue and CMV colitis (1 pt), Gr 3 AST/ALT and rash (1 pt) and Gr 3 AST/ALT (1 pt). In cohort 10C, 2 pts had DLT with Gr 3 AST/ALT in Cycle 2, with 1 pt successfully resuming both drugs and 1 discontinued treatment due to recurrence of Gr 3 AST/ALT upon rechallenge. Other Gr 3 AE were all laboratory findings: 1 pt (CLL) had laboratory TLS, neutropenia and thrombocytopenia and 2 pts (FL, DLBCL) had neutropenia. Response rate was 100% (2 CR 14 PR) in the following 16 pts with indolent NHL and MCL evaluable for response: FL (2 CR, 6 PR), CLL (5 PR), MCL (1 PR) and MZL (2 PR). No pt with aggressive B-cell lymphomas has responded. **Conclusions:** The combination of zandelisib 60 mg on IS from Cycle 1 and zanubrutinib 80 mg bid is well tolerated and achieves a high ORR in R/R indolent B-cell malignancies. This schedule is being evaluated in expansion cohorts in R/R FL and MCL. Clinical trial information: NCT02914938. Research Sponsor: None.

Outpatient practice pattern and remote patient monitoring for axicabtagene ciloleucel CAR-T therapy in patients with aggressive lymphoma. *First Author: Radhika Bansal, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Chimeric antigen receptor T-cell therapy (CAR-T) are commonly administered inpatient due to concern for early onset cytokine release syndrome (CRS), especially with axicabtagene ciloleucel (axi-cel). We report Mayo Clinic Rochester experience for hospital-based outpatient (HBO) management of patients (pts) receiving axi-cel and identify opportunities for improvement. HBO is closely integrated with inpatient practice and includes the same specialty trained clinical team. It is the first point of contact 24/7 for pts and triage evaluations. Lymphodepletion chemotherapy and CAR-T infusion is given on HBO followed by daily monitoring till day 8 and thereafter, as clinically needed until admission criteria is met. **Methods:** We retrospectively analyzed database of pts who received axi-cel between 1/2018 and 1/2021. After 06/2020, remote patient monitoring (RPM) tools were implemented to collect patient-reported neurologic symptoms and vital signs via bluetooth-enabled devices 4 times daily through month 1. Adverse data trends are addressed by the HBO team. **Results:** Among 72 recipients, 89% received their cells outpatient; 8% remained outpatient for the entire month. CRS and neurotoxicity incidence were comparable to those reported from CIBMTR. Median time to first admission was 2 days (Table). Use of bridging therapy, increased CRP and LDH were associated with early admission (≤3 days). Median time to tocilizumab, steroid, oxygen support, vasopressor was 4 days after admission. Half of HBO visits required intervention such as blood transfusions, IV medications through the first month. Nine pts had enrolled in RPM to date; with 8 having evaluable data. With 4 scheduled entries/day, a median of 1 entry/day was skipped and 2 entries/day were answered incompletely. An average of 57 additional unscheduled entries were generated per pt. Among a median of 373 (range 91-522) readings per pt over the first month, 4% (2%-20%) of the readings generated alerts. An average of 4 alerts were seen within 48 hours prior to admission. Data including additional subjects will be presented at ASCO meeting. **Conclusions:** We report a feasible outpatient care model for management of axi-cel recipients with safe outcomes. Clinical characteristics associated with more aggressive disease are associated with likelihood of early admission. Early RPM experience suggest use of digital tools could improve monitoring compliance and may predict evolution to symptoms requiring escalation of care. Research Sponsor: None.

Vaccine titers in lymphoma patients receiving chimeric antigen receptor T-cell therapy. *First Author: Radhika Bansal, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: While CAR-T therapy is not myelo-ablative, patients with aggressive lymphoma treated with CD19 chimeric antigen receptor T cell therapy (CAR-T) are lymphodepleted and have prolonged B cell aplasia. The impact of CAR-T on immunologic protection from vaccine-preventable diseases (and thus the need to revaccinate) is not known. We report the vaccine titers of patients treated with axicabtagene ciloleucel (axi-cel) at Mayo Clinic. **Methods:** Retrospective chart review of adult lymphoma patients who received axi-cel from 9/2018 to 9/2020 for anti-viral and anti-bacterial titers prior to CAR-T infusion and at month 3 (MO3) post CAR-T. **Results:** Prior to CAR-T therapy, positive titer rate was highest for tetanus and lowest for Strep pneumoniae (Strep PNA) (Table). Similar trends were seen whether patients had stem cell transplant (ASCT) within 2 years of CAR-T (i.e. within immunization timeframe post ASCT) or not (Table). Compared to patients who had ASCT, those who did not had higher rate of positive titer for Strep PNA and lower rate for hepatitis B, Mumps, and VZV. The same trend for seropositive rate were observed at MO3 post CAR-T. Patients with IgG<400 mg/dl received IVIG supplement for prophylaxis. Among the 23 patients who received IVIG, variable rate of conversion from negative to positive titers were seen for measles (1/2, 50%), mumps (2/3, 67%), rubella (2/3, 67%), varicella-zoster (VZV, 3/3, 100%), hepatitis A (6/6, 100%), hepatitis B (6/7, 86%) and Strep PNA (0/10, 0%). For patients who did not receive IVIG prophylaxis, there was one loss of seropositivity for Strep PNA (1/4, 25%). **Conclusions:** The presence of protective vaccine titers is variable for patients receiving CAR-T, regardless of recent ASCT. The loss of protective titers post CART was low. IVIG variably impacted vaccine titer status. Immunization remains important for patients with ASCT prior to CART, without completion of post ASCT immunization protocol. Further study is needed to inform the need for immunization and optimal timing post CART. Research Sponsor: None.

Phase 1/2 study of cirmtuzumab and ibrutinib in mantle cell lymphoma (MCL) or chronic lymphocytic leukemia (CLL). *First Author: Hun Ju Lee, Department of Lymphoma and Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cirmtuzumab (Cirm) is a humanized monoclonal antibody that inhibits the tumor promoting activity of ROR1 and had demonstrated additive/synergistic activity with many anti-cancer agents including ibrutinib (Ibr). **Methods:** Patients (Pts) with relapsed or refractory (RR) MCL or treatment naïve (TN) or RR CLL were enrolled. In Part 1 (Dose Escalation), doses of Cirm IV q2wks x5 then q4wks of 2-16 mg/kg and 300 or 600 mg were examined. Safety of Cirm alone was assessed during the first 28 days, then Ibr was started at approved doses for each indication. Cirm 600 mg IV q2wks x3 then q4wks in combination with Ibr starting day 0 was chosen as the recommended dosing regimen for use in Part 2 (Expansion) and Part 3 (CLL only, Cirm/Ibr vs. Ibr alone). **Results:** Twelve evaluable MCL pts were enrolled into Part 1, and 5 into Part 2. Median number of prior regimens was 2 (1-5), including pts relapsing after Ibr (4), auto-SCT (3), auto-SCT/ allo-SCT (1), auto-SCT/CAR-T (1). In CLL, 34 evaluable pts (12 TN and 22 RR) enrolled into Part 1 (18) or Part 2 (16). At least 74% of CLL pts in Parts 1 and 2 were high risk as determined by unmutated IGHV, del17p, and/or del11q. In Part 3, 22 evaluable pts received Cirm/Ibr (15) or Ibr (7). As of the 30OCT2020 safety cut-off for MCL and CLL, common TEAEs (all grades) included diarrhea (41%), contusion (39%), fatigue (39%), URI (31%), hypertension (25%) arthralgia (23%). Grade ≥3 neutropenia was 13% and thrombocytopenia 1%. There were no Cirm dose reductions or discontinuations for toxicity. Overall, Cirm did not appear to negatively impact the safety of Ibr. Efficacy (MCL): As of the 02FEB2021 efficacy cutoff, the best response of 17 evaluable pts in Parts 1 and 2 included an objective response rate (ORR) of 82%, 41% CR/CMR, 41% PR, 12% SD, and 6% PD. CR/CMR remain durable from 8-28+ mos**.** Most responses occurred rapidly after ~3 mos of Cirm/Ibr. Notably, responses were achieved in all pts who received prior SCT+/- CAR-T (4CR, 1PR) or prior Ibr (2CR, 2PR). At a median follow-up of 14.6 mos, the median PFS (mPFS) had not been reached (NR) (95% CI: 17.5, NA). Efficacy (CLL): The best response of 34 evaluable pts in Parts 1 and 2 included 91% ORR, 3% CR, 88% PR/PR-L, 9% SD, 0% PD. In Part 3, both arms achieved 100% ORR (all PRs). At a median follow-up of 20.2 mos, the mPFS was NR (95% CI: NA, NA), and the PFS estimate at 24 months was 95% for R/R, and 87% for TN, respectively, for evaluable CLL pts receiving Cirm/Ibr. **Conclusions:** Cirm/Ibr is a well-tolerated, active regimen in both MCL and CLL. For MCL, the mPFS of NR (95% CI: 17.5 , NA) and CRR (41%), with all CRs remaining without PD, compare favorably to mPFS of 12.8 mos (95% CI 8.5-16.6) and CRR (20%) reported for single agent Ibr (Rule 2017). For CLL, the high ORR and PFS are encouraging, particularly for RR CLL. The study is ongoing, with MCL enrollment expanded to study Cirm + Ibr in pts who have had a suboptimal response to an Ibr regimen, or who have failed other approved BTKi agents. Clinical trial information: NCT03088878. Research Sponsor: Oncternal Therapeutics, Inc., Other Foundation.

Survival outcomes, treatment toxicity, and healthcare utilization in older adults with aggressive non-Hodgkin lymphoma (NHL). *First Author: Mitchell W. Lavoie, Massachusetts General Hospital, Boston, MA*

Background: Aggressive NHLs frequently affect older adults, and are often treated with intensive systemic therapy that is potentially curative but can cause substantial toxicities. Although balancing treatment efficacy with the risk of complications is critically important for older adults with NHL, few studies have described these patients' survival outcomes, rates of toxicities, and healthcare utilization. **Methods:** We conducted a retrospective analysis of adults > 65 years diagnosed with aggressive NHL and treated with systemic therapy at Massachusetts General Hospital from 4/2000-7/2020. We abstracted patient demographic and clinical information, survival outcomes, treatment toxicity (rates and grade), and healthcare utilization outcomes (intensive care unit [ICU] admissions and unplanned hospitalizations within six months of treatment initiation) from the electronic health record. Using multivariable logistic regression, we examined patient and disease factors associated with rates of grade 3+ non-hematologic toxicity and unplanned hospitalization. **Results:** Of 295 patients (median age = 73 years [age 65-69: 32.5%; age 70-74: 26.1%; age 75-79: 20.0%; age 80+: 21.4%], 39.0% female), most had advanced stage disease (59.5%) and an ECOG performance status of 0 or 1 (83.1%). The most common diagnosis was de novo diffuse large B-cell lymphoma (DLBCL) or grade 3B follicular lymphoma (69.2%). Most common therapies were CHOP (65.8%) and EPOCH (17.0%) with or without Rituximab. With a median follow up of 5.9 years, 5-year overall survival (OS) was 74.2%. Among patients age 65-69, 70-74, 75-79, and 80+ years, 5-year OS by age group were 82.1%, 72.2%, 73.5%, and 66.3%, respectively. Overall, 42.4% had grade 3+ toxicity, while 8.1% had grade 4 or 5 toxicity. The rates of unplanned hospitalization and ICU admission during the first 6 months of therapy were 41.0% and 6.1%, respectively. In multivariable analysis, hypoalbuminemia (OR 4.22, 95%, $p < 0.001$) and number of comorbidities (OR 1.75, $p < 0.001$) were associated with a greater likelihood of grade 3+ toxicity. Hypoalbuminemia (OR 2.76, $p = 0.003$), number of comorbidities (OR 1.61, $p = 0.001$), and receipt of EPOCH (OR 5.41, $p = 0.012$) were associated with a greater likelihood of unplanned hospitalization. **Conclusions:** The majority of older adults receiving upfront therapy for aggressive NHL survive beyond 5 years, yet nearly half experience substantial treatment toxicities and unplanned hospitalizations. Our findings underscore the need to develop supportive care interventions to enhance the care experience for older adults with NHL. Research Sponsor: Leukemia and Lymphoma Society.

Prognostic role of lymphocyte to monocyte ratio in patients treated with CAR-T for aggressive lymphoma. *First Author: Henan Zhang, Mayo Clinic, Rochester, MN*

Background: A low absolute lymphocyte to monocyte ratio (ALC/AMC) has been found to predict decreased survival in lymphoma patients receiving chemotherapy and stem cell transplant. We report its clinical significance and additional cellular phenotype changes in patients receiving chimeric antigen receptor T-cell (CART) therapy. **Methods:** Records were reviewed for patients (pts) who received axicabtagene ciloleucel between 6/2016 and 12/2020. Receiver operator curve was generated using nominal logistic regression to predict CR as best response. Survivals were calculated using Kaplan- Meier method. Blood immune phenotype were assayed by multiparametric flow. Principle component analysis (PCA) was performed using ClusterVis. **Results:** Low ALC/AMC (≤0.8) prior to lymphodepletion (LD) chemotherapy on day -5 was associated with lower CR rate (AUC=0.68, Table). Our cohort of 81 pts had similar baseline characteristics except that noted in Table. Low ALC/AMC ratio is associated with shorter EFS and OS (EFS: 2.6 vs. 6.4 months, P<0.0001; OS: 5.3 months vs. not reached, P=0.0006), respectively. Prognostic association remained significant in multivariate analysis including ASCT, bridging therapy and CRP. Interestingly, compared to the high ALC/AMC group, the low ALC/AMC group had decreased CD8 Tem, increased CD16+CCR2+ monocytes and increased monocytes' producing IL12, IL-10, and IL-1β (n=26). Unsupervised PCA identified 3 clusters: 1. Low ALC/AMC, all non-CR; 2. High ALC/AMC, some non-CR; 3. High ALC/AMC, all CR. Compared to cluster 1 and 2, cluster 3 had increased CD4 Tnaive, CD8 Tcm and IL-17 producing CD4 T and NK cells. **Conclusions:** ALC/AMC is a clinically accessible test that is strongly associated with CAR-T response and survival. Immune characterization revealed that the biologic effect is not just associated with cell ratio. Increased inflammation has been found to negatively impact CAR-T response, with some cytokines known to be from the myeloid lineage. We show that CRP is elevated in the low ALC/AMC group with increased cytokine production by monocytes. In addition, presence of T cell subset and IL-17 producing cells, before LD, are associated with clinical response. Further investigation on optimizing host immunity may help improve clinical outcome with CAR-T. Research Sponsor: Center for Individualized medicine Mayo Clinic.

Efficacy and safety of zanubrutinib versus rituximab-based chemoimmunotherapy in Waldenström macroglobulinemia (WM): Matching-adjusted indirect comparisons. *First Author: Jorge J. Castillo, Bing Center for Waldenström Macroglobulinemia, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Given a lack of WM randomized trials directly comparing zanubrutinib with chemoimmunotherapy, this study aimed to indirectly compare zanubrutinib with bendamustine-rituximab (BR) and with dexamethasone-rituximab-cyclophosphamide (DRC) separately through matching-adjusted indirect comparisons (MAIC). **Methods:** MAIC were conducted to re-weight the individual data of 102 WM patients (83 relapsed/refractory [R/R] and 19 treatment-naïve [TN]) treated with zanubrutinib in the ASPEN trial (NCT03053440) so that the weighted average baseline characteristics of patients treated with zanubrutinib matched those of 71 R/R patients treated with BR, and 72 TN patients treated with DRC separately. Matching variables for MAIC with BR included age, prior lines of therapy, IgM concentration, International Prognostic Scoring System for WM score, and extramedullary disease (EMD); and for MAIC with DRC included age, platelet count, hemoglobin concentration, and EMD. Kaplan-Meier curves of progression-free survival (PFS) and overall survival (OS) of comparators were digitized to re-create patient-level data. Comparisons of survival and adverse event incidence between treatments were conducted using Cox proportional hazards models and modified Poisson models. **Results:** Compared to DRC, zanubrutinib was associated with longer PFS (hazard ratio [HR]: 0.39 [95% confidence interval 0.18-0.82] and 0.35 [0.14-0.86] pre- and post-matching, respectively) and longer OS (HR: 0.56 [0.20-1.53] and 0.47 [0.14-1.62] pre- and post-matching, respectively), and insignificantly higher incidences of neutropenia (risk ratio [RR]: 1.63 [0.71-3.77] and 1.47 [0.58-3.74] pre- and post-matching, respectively). Compared to BR, zanubrutinib was associated with longer PFS (HR: 0.32 [0.15-0.69] and 0.37 [0.15-0.91] pre- and post-matching, respectively), longer OS (HR: 0.31 [0.12, 0.80] and 0.29 [0.10-0.85] pre- and post-matching, respectively), lower incidences of neutropenia (RR: 0.45 [0.26-0.78] and 0.50 [0.27-0.91] pre- and post-matching, respectively) and lower incidences of pneumonia (RR: 0.18 [0.02-1.55] and 0.26 [0.03-2.28] pre- and post-matching, respectively). **Conclusions:** Zanubrutinib demonstrated longer PFS than DRC, and longer PFS and OS than BR in WM, before and after matching adjustment based on patient characteristics. Research Sponsor: BeiGene, Ltd.

Immune priming with nivolumab followed by nivolumab and rituximab in first-line treatment of follicular lymphoma: The phase 2 1st FLOR study. *First Author: Eliza Anne Hawkes, Austin Health and Olivia Newton-John Cancer Research Institute, Heidelberg, Australia*

Background: Standard of care immunochemotherapy in front-line (1L) follicular lymphoma (FL) is highly efficacious but not without significant toxicity. High rates of grade 3-5 adverse events (AEs), primarily infection and bone marrow suppression, are experienced in up to 75% of patients. A more tolerable but equally effective approach is required. PD-1 inhibition, in combination with rituximab (R), increases T cell anti-tumour effect & enhances NK cell antibody dependent cell cytotoxicity, with proven efficacy in relapsed FL. The concept of 'priming' the immune system with nivolumab (N) prior to tumour-directed therapy has rationale and evidence, but the safety of this approach in 1L FL is not described. **Methods:** '1st FLOR' (NCT03245021) is an open-label, multi-centre, phase 2, Simon's 2-stage study of N + R (N = 39). Key eligibility were stage III-IV grade 1-3A FL requiring 1L systemic therapy; ECOG ≤2; adequate organ function. All patients (pts) receive induction N 240mg IV 2-weekly for 4 cycles. Pts with complete response (CR) receive 4 further cycles of 240mg IV N monotherapy then 12 cycles of maintenance N 480mg IV 4-weekly. Pts with < CR had 240mg N plus 375mg/m^2 IV R 2-weekly for 4 cycles followed by maintenance N+R (N 480mg 4 weekly for 12 cycles; R 12 weekly for 8 cycles). Primary endpoint (EP) was ≥ G3 toxicity rate during induction. Secondary EPs; response rate by Lugano response criteria, overall toxicity, PFS, OS. **Results:** Between September 2017 to March 2020, 39 pts were enrolled. Baseline characteristics included median age of 54 (range: 28-79). stage IV disease in 67%, B Symptoms & bulk (≥7cm) in 23% each, intermediate-high risk FLIPI in 74%. The primary EP was met, with only 16 pts (41%) having ≥G3 toxicity at end of induction. Non-immune AEs were predominantly G1-2; most commonly infection (67%) & fatigue (64%). G3-4 Immune-related AEs were infrequent and included pancreatitis plus hepatitis (N = 1), pancreatitis alone (N = 1), rash (N = 1), transaminitis (N = 2), hypocortisolism (N = 1), hyperglycaemia (N = 3) and asymptomatic lipase/amylase increase (N = 3). Median follow-up was 17.5 months (range: 7-39). Overall response rate was 92% (36/39) with CR in 54% (21/39). Median time to CR was 5 months (m) (range: 2-25). Nine pts (23%) discontinued treatment; 7 due to progressive disease (1 pt died of transformed FL), 2 developed constitutional symptoms (1 stable disease, 1 partial response). In 25 evaluable pts, 12m PFS & OS is 72% (CI 51-88) & 96% (CI 80-100). Biomarker analysis is in progress. **Conclusions:** Immune-priming with single-agent N, then combination N+R in 1L FL is associated with favourable toxicity and high ORR & CR rates potentially providing an alternative to chemotherapy. Treatment free remission (TFR) and overall response rate (ORR) results in patients with relapsed/refractory Waldenstrom's macroglobulinemia (WM) treated with CLR 131. *First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL*

Background: Phospholipid ethers (PLE) provide a novel mechanism to specifically target tumor cells leveraging high lipid raft content in their cell membranes. PLE/phospholipid drug conjugates are specifically designed to have high affinity to lipid rafts which upon binding results in trans-membrane flipping with the ability to deliver an attached warhead directly to the cytosol. CLR 131 (I-131-CLR1404) is a novel PLE molecule armed with I-131 resulting in targeted tumor cell radiotherapy which is being examined in relapsed or refractory WM through an open-label, Phase 2 trial, CLOVER-1 (NCT02952508). **Methods:** The primary objective of this study is to determine the efficacy and safety of CLR 131 in select B-cell malignancies. Eligibility criteria for WM pts include receipt of at least 2 prior treatment regimens unless ineligible to receive standard agents and have measurable disease: either IgM or extramedullary disease. CLR 131 is administered in up to 4 IV infusions (15-20 min) over 3 months. Adverse events (AEs) are graded by NCI-CTCAE v4.03; responses are assessed by the VIth WM Criteria for Response Assessment [Owen 2013]. **Results:** 6 pts with WM were enrolled in the study with data current as of 8 Jan 2021. The median age was 69 (range 54-81) with 4 females and 2 males who had a median of 2 prior regimens (range 1-5) and received a mean total body dose of 92.76 mCi CLR 131. 3 of 6 patients were MYD88 wild type (WT) of which 2 were dual WT (MYD88 WT & CXCR4 WT). The overall response rate (ORR) was 100% and the major response rate (MRR) was 83%, including 1 pt with a CR, 4 PR, and 1 MR. For those pts who were dual WT, the MRR was 100% and 1 pt who was MYD88 WT (CXCR4 is unknown) had a complete response. The median time to initial response was 48 days. Median duration of response (DOR) and treatment free remission (TFR) have not been reached; ongoing mean DOR is 335 days and mean TFR is 384 days. 100% of MYD88 WT patients have exceeded 6.5 months of follow up with average TFR of 18.1 months. The primary treatment emergent AEs in pts with WM included fatigue and cytopenias, in line with prior experience with CLR 131 in other B-cell malignancies. The most commonly observed cytopenias included Grade 3 or 4 thrombocytopenia (100%), neutropenia (83%), anaemia (66%) and decreased white blood cell count (33%). Of note, no cases of bleeding or febrile neutropenia were observed. **Conclusions:** Initial results for CLR 131 show efficacy across multiple WM patient genotypes including dual WT patients with durable DOR and TFR after 2 to 4 infusions. CLR 131 represents a novel and promising approach to the treatment of MYD88 WT patients who have a historical median time to progression of 1.3 years. These encouraging data led to the pivotal global CLOVER-WaM trial (N=50) in WM patients who have failed or had a suboptimal response to a Bruton Tyrosine Kinase inhibitor. CLOVER-WaM is currently enrolling. Clinical trial information: NCT02952508. Research Sponsor: Cellectar Biosciences.

A novel index using inflammatory markers improves the diagnosis of hemophagocytic lymphohistiocytosis in patients with hematologic malignancies. *First Author: Adi Zoref Lorenz, Hematology Institute, Meir Medical Center, Sackler faculty of medicine, Tel Aviv University, Kfar Saba, Israel*

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening inflammatory syndrome that may accompany hematologic malignancies (HM). The diagnosis of HLH in patients with HM (HM-HLH) is confounded by a number of factors: the most commonly used HLH-2004 diagnostic criteria are derived from studies in infants while the Hscore used in adults is not specific for HMs; moreover, most parameters in these scoring systems may reflect features of the underlying HM rather than HLH associated inflammation; and finally specific diagnostic cutoff values for laboratory abnormalities in HM-HLH have not been defined. We therefore conducted a study to optimize the HLH-2004 laboratory thresholds for the diagnosis of HM-HLH. **Methods:** A multi-center retrospective study in adult patients with HM in whom testing for HLH was performed. HM-HLH was defined as fulfillment of 5/8 HLH-2004 diagnostic criteria. We established the optimal diagnostic cutoff levels for HLH-2004 laboratory parameters using receiver operating curves (ROC) and combined the best performing parameters into a combined index, using binary logistic regression. We then created a clinical decision tree using a Classification and Regression Tree (CART) analysis with all available parameters, using cross validation. We also determined the prognostic value of our combined diagnostic tool. **Results:** 225 adults were analyzed (112 with HM-HLH per HLH-2004 and 113 with HM only). 35% of patients were evaluated for HLH routinely upon HM diagnosis. Soluble CD25 (sCD25) and ferritin best discriminated HM-HLH from HM, with an area under the curve (AUC) of 0.83 for each. ROC analysis demonstrated an optimal cutoff of > 4190 U/mL for sCD25 (sensitivity/specificity 91%/69%) and an optimal cutoff of > 2636 ng/ml for ferritin (sensitivity/specificity 64%/86%) for HM-HLH. We term the combination of elevated sCD25 and ferritin using optimized cutoff levels the 'optimized HLH inflammatory' (OHI) index. This OHI index was highly specific for the diagnosis of HM-HLH (specificity of 92%, sensitivity 79%). CART analysis demonstrated that OHI index positivity was sufficient to diagnose HM-HLH. In patients without a positive OHI index an Hscore > 168 and either splenomegaly or triglycerides > 279 ng/dL can still diagnose HM-HLH. By following this decision pathway, approximately 92% of patients were accurately classified based on HLH-2004. Furthermore, the OHI was better (odds ratio (OR) 7.9; 95% confidence interval (CI) 4.2-14.6) than Hscore >169 (OR 5.5; CI 3.9-9.6) and > 5/8 HLH-2004 (OR 5.3; CI 3-9.3) at predicting mortality at 1 year. **Conclusions:** The OHI index derived here is a simple tool that can accurately diagnose HLH and predict mortality in patients with hematologic malignancies. Some patients may not need full HLH workup before intervening with therapy that is HLH directed and not only malignancy directed. Research Sponsor: None.

Post-transplant lymphoproliferative disorder in kidney transplant patients: A multicenter report. *First Author: Elise A. Chong, Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Post-Transplant Lymphoproliferative Disorder (PTLD) is a complication of transplantation that often arises due to reactivation of the Epstein-Bar Virus (EBV). Given the rarity of this disease, a full understanding of its presentation and optimal therapies has yet to be determined. **Methods:** A multicenter retrospective analysis was performed utilizing data from kidney transplant patients (pts) who developed PTLD at the Hospital of the University of Pennsylvania and the Cleveland Clinic. The association between categorical variables and clinical response were assessed via Fisher's exact testing. **Results:** 117 pts had diagnoses of PTLD after kidney transplantation. The median age at PTLD diagnosis was 52 yrs (range 17-89 yrs), and the median time from transplantation to diagnosis was 3.6 yrs (range: 7 days-36 yrs). Pt characteristics included: 84% Caucasian, 57% male, and 11% combined kidney and pancreas transplant patients. 68% pts had received unrelated donor transplants; 41% had prior rejection episodes. PTLD histology was 72% monomorphic and 28% polymorphic. Polymorphic PTLD was more likely to be EBV+ than monomorphic PTLD (81% vs. 54%, p = 0.05). At diagnosis, immunosuppression included: steroids (95%), mycophenolate (44%), azathioprine (40%), sirolimus (30%), cyclosporine (46%), and/or tacrolimus (45%). Common PTLD symptoms included fever (34%), pain (38%), weight loss (30%), fatigue (30%), and/or mass (26%). The most common sites of involvement were lymph nodes (64%), kidney allograft (22%), and/or GI tract (17%). At diagnosis, 61% of patients' tumors were EBV+ and 59% of patients had elevated serum LDH. Overall, the majority of pts responded to first-line PTLD therapy, with 61% CR and 14% PR. Reduction of immunosuppression (RI) alone (36% of pts) led to 48% CR and 12% PR; RI with rituximab (16%) led to 47% CR and 7% PR; and RI with chemotherapy (14%) resulted in 58% CR and 42% PR. Patients treated with RI as well as resection (n = 18) of their limited stage disease had better outcomes (p = 0.05). Overall survival for all patients was 10.7 years (95%CI: 5.2-13 years). PTLD patients < 40 yrs were more likely to achieve CR after first line therapy (p < 0.001), have allograft involvement (p = 0.003), and have a polymorphic histology (p = 0.002). Allograft involvement tended to occur sooner after transplant (p = 0.001) and was more likely to present with allograft failure (p = 0.007). PTLD with allograft involvement had better response to first therapy than regular PTLD (p = 0.007) and often responded well to complete resection and RI. **Conclusions:** Pts with PTLD may achieve a CR through different initial therapies. Younger patients and those able to undergo complete resection of disease and RI had better prognoses. Allograft involvement by PTLD carries a good prognosis and should be identified and treated differently from other presentations. Research Sponsor: None.

Phased variants improve DLBCL minimal residual disease detection at the end of therapy. *First Author: David Matthew Kurtz, Stanford Cancer Institute, Stanford, CA*

Background: Detection of circulating tumor DNA (ctDNA) has prognostic value in diverse tumors, including DLBCL. Despite uses for assessing molecular response to therapy, current methods using immunoglobulin or hybrid-capture sequencing have suboptimal sensitivity, particularly when disease-burden is low. This contributes to a high false negative rate at key milestones such as at the end of therapy (EOT; Kumar A, *ASH* 2020). We explored the utility of detecting multiple mutations (phased variants, PVs) on individual cell-free DNA (cfDNA) strands to improve MRD in DLBCL. **Methods:** We applied Phased Variant Enrichment and Detection Sequencing to track PVs from 485 specimens from 117 DLBCL patients undergoing first-line therapy. We sequenced cfDNA prior to, during, and after therapy to assess the prognostic value of MRD. We compared the performance of PhasED-Seq to current techniques, including SNV-based CAPP-Seq and duplex sequencing. **Results:** To establish its detection limit for ctDNA, we compared the background error-profile of of PVs and SNVs in cfDNA sequencing from healthy subjects. PV-detection by PhasED-Seq demonstrated a lower background profile than SNVs, even when considering duplex molecules (n = 12; 8.0e-7 vs 3.3e-5 and 1.2e-5; $P < 0.0001$). We also assessed analytical sensitivity within a ctDNA limiting dilution series from 3 patients, simulating tumor fractions from 0.1% to 0.00005% (1:2,000,000). PhasED-Seq outperformed SNV-based methods and duplex sequencing for recovery of expected tumor content below 0.01% ($P < 0.0001$ and $P = 0.005$ respectively by paired t-test). We then explored disease detection in clinical samples. We identified SNVs and PVs from pretreatment tumor or plasma and followed these variants in serial cfDNA. Using SNV-based methods, 40% and 59% of patients had undetectable ctDNA after 1 or 2 cycles (n = 82 and 88). However, 24% and 25% of these cases had detectable ctDNA by PhasED-Seq. Importantly, MRD detection by PhasED-Seq was prognostic for event-free survival even in patients with undetectable ctDNA by SNVs. We next explored the utility of PhasED-Seq at the EOT in 19 subjects, 5 of whom experienced eventual disease progression. While only 2/5 cases with progression had detectable disease at EOT using SNVs, PhasED-Seq detected all 5/5 cases. PhasED-Seq also correctly identified all patients (14/14) without clinical relapse as having no residual disease, including one patient who discontinued therapy after 1 cycle due to toxicity, but remains in remission > 5 years after this single treatment. This resulted in superior classification of patients for EFS using PVs compared with SNVs (C-statistic: 0.98 vs 0.60, $P = 0.02$). **Conclusions:** Tracking PVs results in significantly lower background rates than SNV-based approaches, enabling detection to parts per million range. PhasED-Seq improves on disease detection in DLBCL at the EOT, allowing possible MRD-driven consolidative approaches. IL-1 receptor antagonist for prevention of severe immune effector cell-associated neurotoxicity syndrome. *First Author: Caspian Oliai, UCLA Medical Center, Los Angeles, CA*

Background: Progress in chimeric antigen receptor (CAR) T-cell therapy has included reduction in life-threatening toxicity. Rates of severe cytokine release syndrome (CRS) have declined from 50% in early trials to 7% in the most recent real-world experience. However, rates of severe immune effector cell-associated neurotoxicity (ICANS) associated with axicabtagene ciloleucel (Axicel) remain unchanged. IL-1 is a major driver of ICANS pathophysiology that is produced upstream of IL-6. The IL-1 receptor antagonist, Anakinra, can prevent neurotoxicity in animal models when given at fever onset. We present our early experience of the first 13 participants enrolled into a phase II trial evaluating Anakinra to prevent severe ICANS (NCT4205838). **Methods:** This investigator-sponsored trial included adults eligible for standard-of-care Axicel for large B-cell lymphoma after ≥2 lines of intensive chemoimmunotherapy. Participants received Anakinra 100 mg SQ q6h x 12-36 doses until ICANS returned to grade ≤1. The trigger to initiate Anakinra was any grade ICANS or grade ≥3 CRS in the absence of ICANS. A protocol modification, made after the first 3 participants were treated, changed the trigger for Anakinra to grade ≥2 CRS. In addition to Anakinra, all participants received standard-of-care interventions for CRS and ICANS. The primary objective is to estimate the efficacy of Anakinra in preventing severe ICANS (grade ≥3) according to ASTCT 2018 consensus grading. **Results:** To date, 13 participants have been enrolled, and 7 met criteria to initiate Anakinra and received the first dose prior to severe ICANS. Median age was 56 years (range, 23-84 years). Of the 7 participants whom received Anakinra prior to severe ICANS, only 1 of 7 (14%) developed grade 3 ICANS. The most common adverse event was injection site reaction, which peaked at grade 2. There were no unexpected toxicities. Once the protocol was amended to initiate Anakinra for grade ≥2 CRS (N = 4), no participant developed severe ICANS, and only one participant met the institutional standard to receive corticosteroids (Table). **Conclusions:** Anakinra is feasible to initiate in the non-prophylactic setting in patients at increased risk for severe ICANS. These early results demonstrate potential to reduce severe ICANS associated with Axicel to a rate similar to other CAR T-cell products, and to reduce corticosteroid use. Further enrollment to the pre-planned sample size of N=36 is required to demonstrate statistical efficacy. Serum IL-1 analysis is also ongoing. Clinical trial information: NCT4205838. Research Sponsor: John Timmerman, MD study investigator-sponsor.

Randomized, phase III study of early intervention with venetoclax and obinutuzumab versus delayed therapy with venetoclax and obinutuzumab in newly diagnosed asymptomatic high-risk patients with chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL): EVOLVE CLL/SLL study (SWOG S1925, NCT#04269902). *First Author: Deborah Marie Stephens, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Currently, asymptomatic patients with CLL/SLL are observed without treatment until development of symptoms or cytopenias. Historically, early intervention studies with chemoimmunotherapy have not resulted in an overall survival (OS) benefit and have resulted in toxicity. The introduction of targeted therapies, such as venetoclax and obinutuzumab (VO), have provided tolerable/efficacious options for CLL patients. In the CLL14 study, *symptomatic* CLL patients receiving frontline therapy with VO had longer progression-free survival (PFS) and deeper remissions [more minimal residual disease-undetectable (MRDu)] compared with those receiving chlorambucil and obinutuzumab (Fischer 2019). The CLL-International Prognostic Index (CLL-IPI; Table) is a validated prognostic model to predict which patients are highest risk for a shorter time to first therapy and shorter OS. We aim to use VO as early intervention in *asymptomatic*, high-risk patients with CLL to potentially lengthen OS and thus alter the natural history of the disease. **Methods:** On 12/14/20, we activated the S1925 study for adult patients with CLL or SLL, who were diagnosed within 12 months of enrollment. Eligible patients have a CLL-IPI score ≥ 4 (Table) or complex cytogenetics (≥3 cytogenetic abnormalities) and do not meet any criteria for initiation of treatment by the International Working Group for CLL (IWCLL; Hallek 2018) guidelines. Enrolled patients are randomized in a 2:1 manner to early versus delayed (at the time IWCLL indication for treatment is met) therapy with VO. VO is administered for a fixed duration of 12 months as previously described (Fischer 2019). The primary endpoint is OS. We hypothesize that early intervention with VO will improve the rate of 6-year OS from 60% to 80%. This design requires 222 eligible patients for 88% power (2-sided α=0.05) for the primary comparison. To allow for 10% ineligibility, we will enroll 247 patients. Estimated accrual time is 4 years. Secondary endpoints include: rates of response, PFS, and relapse-free survival; safety; time to 2nd CLL-directed therapy; and quality of life (FACT-Leukemia total score). The primary translational objective is to evaluate the prognostic association between OS and peripheral blood MRD status at 15 months after treatment initiation by flow cytometry. Additional exploratory objectives include the association of other clinical outcomes, baseline prognostic factors, and IWCLL-defined response with MRD status at multiple timepoints. Currently, enrollment is open. Clinical trial information: NCT04269902. Research Sponsor: U.S. National Institutes of Health.

A phase 3 study to evaluate the efficacy and safety of tafasitamab plus lenalidomide and rituximab versus placebo plus lenalidomide and rituximab in patients with relapsed/refractory (R/R) follicular lymphoma (FL) or marginal zone lymphoma (MZL). *First Author: Laurie Helen Sehn, BC Cancer Centre for Lymphoid Cancer and University of British Columbia, Vancouver, BC, Canada*

Background: Most patients with the indolent non-Hodgkin lymphoma (NHL) subtypes FL or MZL respond to first-line treatment but relapse is common, and there is no single standard treatment for patients with R/R FL or MZL. Tafasitamab is an Fc-engineered humanized monoclonal antibody (mAb) against CD19 which is broadly expressed in FL and MZL, and regulates B-cell proliferation via B-cell receptor signaling. In preclinical studies, tafasitamab has shown activity against NHL cell lines in combination with rituximab (anti-CD20 mAb) and lenalidomide (LEN). Tafasitamab monotherapy has shown promising clinical activity in a phase 2a study in patients with R/R NHL (NCT01685008), with an ORR of 29% (n/N = 10/34) in patients with FL and 33% (n/N = 3/9) in patients with MZL. In an ongoing phase 2, single-arm study (L-MIND, NCT02399085), tafasitamab plus LEN followed by tafasitamab alone demonstrated an ORR of 57.5% (n/N = 46/80) in patients with R/R diffuse large B-cell lymphoma (FDA approved indication). These preclinical and clinical observations from phase 2 trials suggest a potential clinical benefit of tafasitamab plus LEN and rituximab for patients with R/R FL or MZL. **Methods:** This phase 3 double-blind, placebo-controlled, randomized study is designed to investigate whether tafasitamab plus LEN and rituximab provides improved clinical benefit compared with LEN and rituximab in patients with R/R FL or R/R MZL. Patients will be randomized 1:1 to receive tafasitamab (12 mg/kg IV on days 1, 8, 15, and 22 of a 28-day cycle [cycles 1–3], then days 1 and 15 [cycles 4–12]) plus LEN (20 mg PO QD, days 1–21/ cycle for 12 cycles) and rituximab (375 mg/m^2 IV on days 1, 8, 15, and 22 of cycle 1, then day 1 of cycles 2–5), or placebo (0.9% saline solution IV) plus LEN and rituximab. The primary study endpoint is PFS (investigator assessed [INV] by Lugano 2014 criteria) for patients with FL. Key secondary endpoints are PFS (INV) in overall population (FL and MZL), PET-CR rate (INV) at end of treatment (4–8 weeks after last treatment) and OS in patients with FL. Inclusion criteria include age ≥18 y, histologically confirmed FL (grade 1, 2, or 3a) or MZL (nodal, splenic, or extranodal), documented R/R disease, ≥1 prior systemic anti-CD20 therapy (including anti-CD20 refractory disease), ECOG PS ≤2, adequate systemic organ function, and high tumor burden (per GELF criteria). Exclusion criteria include prior rituximab plus LEN treatment, history of radiotherapy for other diseases (≥25% of bone marrow), nonhematologic malignancy, congestive heart failure (LVEF < 50%), active systemic infection, known CNS lymphoma, or severe immunocompromised state. inMIND (NCT04680052, EudraCT2020-004407-13) is currently enrolling patients; planned enrollment is 528 patients with R/R FL and 60–90 patients with R/R MZL. Clinical trial information: NCT04680052. Research Sponsor: Incyte Corporation.

TPS7569 **Poster Session**

Phase 3 trial (GCT3013-05) of epcoritamab versus standard of care in patients with relapsed or refractory diffuse large B-cell lymphoma (DLBCL). *First Author: Catherine Thieblemont, Assistance Publique & Hôpitaux de Paris (APHP), Hopital Saint-Louis, Hemato-Oncologie, Université de Paris, Paris, France*

Background: Patients (pts) with DLBCL who are refractory to/or have relapsed (R/R) after treatment with chemotherapy and anti-CD20 monoclonal antibody (mAb) have a poor prognosis. There is a need for new treatment options to improve outcomes. Epcoritamab, a novel subcutaneous (SC) bispecific antibody, binds to CD3 on T-lymphocytes and CD20 on B-cell non-Hodgkin lymphoma (NHL) cells to induce potent and selective killing of malignant CD20+ B-cells. In an ongoing phase 1/2 dose-escalation trial in heavily pretreated pts with B-cell NHL (N = 68), epcoritamab demonstrated a tolerable safety profile and substantial single-agent anti-tumor activity, with a complete response (CR) rate of 55% and an overall response rate (ORR) of 91% in pts with R/R DLBCL (at ≥48 mg doses; n = 12) (NCT04663347; Hutchings, ASH, 2020). Furthermore, all 4 evaluable R/R DLBCL pts previously treated with chimeric antigen receptor T-cell (CAR-T) therapy achieved an objective response with 2 achieving CR. These encouraging data support the potential for epcoritamab to improve clinical outcomes in pts with R/R DLBCL. Here we describe the phase 3 trial of epcoritamab versus standard of care (SOC) treatments in pts with R/R DLBCL (NCT04628494). **Methods:** GCT3013-05 is a randomized, open-label, worldwide, multicenter, phase 3 study designed to evaluate the efficacy of epcoritamab versus investigator's choice of SOC with R-GemOx (rituximab, gemcitabine, oxaliplatin) or BR (bendamustine, rituximab) in adults with R/R disease of one the following CD20+ B-cell NHL histologies: I) DLBCL, not otherwise specified including de novo DLBCL or DLBCL histologically transformed from follicular lymphoma; II) "double-hit" or "triple-hit" DLBCL (high-grade B-cell lymphoma, with MYC and BCL2 and/or BCL6 translocations); or III) follicular lymphoma grade 3B. Other key eligibility criteria include: ≥1 line of prior chemotherapy that included treatment with an anti-CD20 mAb, Eastern Cooperative Oncology Group performance status 0–2, and prior failure of/ineligibility for autologous stem cell transplantation. Prior CAR-T therapy is allowed. A total of 480 pts will be randomized 1:1 to receive either SC epcoritamab at the recommended phase 2 dose (28-day cycles; weekly, biweekly, or monthly schedule depending on cycle number) until disease progression or unacceptable toxicity; or up to 4 cycles of biweekly treatment with intravenous (IV) R-GemOx (8 doses); or up to 6 cycles of IV BR (6 doses; dosing every 3 weeks). The primary endpoint is overall survival. Key secondary endpoints include progression-free survival, ORR, duration of response, time to response, and safety. The study is currently enrolling in Australia, Belgium, Denmark, France, Spain, and will open for enrollment in additional countries. Clinical trial information: NCT04628494. Research Sponsor: This study was funded by Genmab A/S and AbbVie Inc.

TPS7570 **Poster Session**

A phase 1 dose escalation and cohort expansion study of the safety and efficacy of allogeneic CRISPR-Cas9–engineered T cells (CTX110) in patients (Pts) with relapsed or refractory (R/R) B-cell malignancies (CARBON). *First Author: Joseph McGuirk, Department of Blood and Bone Marrow Transplant, The University of Kansas Medical Center, Kansas City, KS*

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common form of non-Hodgkin lymphoma (NHL), and although > 50% of pts achieve long-term remission with first-line therapy, pts with R/R disease as well as those with R/R grade 3b follicular lymphoma (FL), double-, or triple-hit high-grade lymphomas have poor long-term outcomes (Crump 2017; Kahl 2016; Jain 2012). Autologous (auto) chimeric antigen receptor (CAR) T cell therapy has provided additional options for pts with R/R disease, but only when leukapheresis and manufacturing prove feasible (Jacobson 2020). Allogeneic (allo) CAR-T cells were designed specifically to address these unmet needs by using healthy donor T cells to produce a readily available product and remove the need for bridging chemotherapy. We are currently investigating the safety and efficacy of CTX110, an allo anti-CD19 CAR-T cell product modified by using CRISPR/Cas9-editing to disrupt the endogenous T-cell receptor (TCR) alpha constant (TRAC) locus in order to remove TCR expression and disrupt β_2-microglobulin, which eliminates major histocompatibility complex (MHC) class I expression. Disruption of the TCR should significantly reduce or eliminate risks of graft-versus-host disease and elimination of MHC class I expression may increase CAR-T cell persistence by mitigating CTX110 rejection. In addition, the anti-CD19 CAR transgene construct is precisely inserted into the TRAC locus. **Methods:** The Phase 1 CARBON trial (NCT04035434) is an open-label, multicenter, global study evaluating the safety and efficacy of CTX110 in pts ≥18 y with R/R DLBCL NOS, double- or triple-hit DLBCL, or transformed or grade 3b FL with ≥2 prior lines of therapy or who are ineligible for/refused prior auto hematopoietic stem cell transplant (HSCT). Pts who received prior auto CAR-T or allo HSCT are excluded. Pts will receive lymphodepleting chemotherapy with fludarabine 30mg/m^2 and cyclophosphamide 500mg/m^2 for 3 days, followed by CTX110 infusion. In part A, dose escalation will be performed using a 3+3 design. Upon completion of dose finding, the cohort will be expanded to further assess safety signals and efficacy including the primary efficacy endpoint of overall response rate. Key secondary efficacy endpoints include duration of response, progression-free survival, and overall survival. The trial is currently open and enrolling. Clinical trial information: NCT04035434. Research Sponsor: CRISPR Therapeutics.

TPS7571 **Poster Session**

Brentuximab vedotin in combination with lenalidomide and rituximab in subjects with relapsed or refractory diffuse large B-cell lymphoma (DLBCL) (Trials in Progress). *First Author: Nancy L. Bartlett, Division of Oncology, Washington University School of Medicine, St. Louis, MO*

Background: The majority of patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) who relapse after HSCT, or who are not candidates for HSCT have poor outcomes and are in need of novel therapies. Brentuximab vedotin (BV) is a CD30-directed ADC and preclinical data provide a strong rationale for combining BV, lenalidomide, and rituximab in the treatment of R/R DLBCL. In addition, in a phase 1 trial in which 37 pts with R/R DLBCL were treated with BV + lenalidomide, the ORR was 56.7% (73.3% in CD30+ pts; manuscript in preparation). The median duration of remission was 13.2 months in pts with a CR or PR and 11.7 months in pts with CR, PR, or stable disease > 6 months. The PFS and median OS were 11.2 months and 14.3 months, respectively and results were similar in the CD30+ and CD30 < 1% groups. The clinical activity and manageable safety profiles of BV, lenalidomide, and rituximab as single agents, make the combination a viable option in multiply relapsed and heavily pretreated pts. **Methods:** This is a randomized, double-blind, placebo-controlled, active-comparator, multicenter phase 3 study designed to evaluate the efficacy of BV vs placebo, in combination with lenalidomide + rituximab, in subjects with R/R DLBCL (NCT04404283). Prior to randomization, there will be a safety and PK run-in period where 6 pts will receive BV, lenalidomide + rituximab, and safety and PK will be evaluated after the first cycle of treatment; 6/6 subjects have been enrolled. Key eligibility criteria include: pts aged ≥18 with R/R DLBCL with an eligible subtype; ≥2 prior lines of therapy and must be ineligible for, or have declined, stem cell transplant, and chimeric antigen receptor T-cell (CAR-T) therapy; ECOG 0 to 2; fluorodeoxyglucose-avid disease by PET and bidimensional measurable disease of at least 1.5 cm by CT. Patients (n = 400) will be randomized 1:1 to receive either BV or placebo in combination with lenalidomide + rituximab and will be stratified by CD30 expression (positive [≥1%] versus < 1%), prior allogeneic or autologous stem cell transplant therapy (received or not), prior CAR-T therapy (received or not), and cell of origin (GCB or non-GCB). The primary endpoints are PFS per BICR in the ITT and CD30+ populations. Key secondary endpoints are OS in the ITT and CD30+ populations, and ORR per BICR. Other secondary endpoints include CR rate, duration of response, and safety and tolerability of the combination. Disease response will be assessed by BICR and the investigator according to the Lugano Classification Revised Staging System. Radiographic disease evaluations, including contrast-enhanced CT scans and PET, will be assessed at baseline, then every 6 weeks from randomization until Week 48, then every 12 weeks. PET is not required after CR is achieved. The trial is currently enrolling and will be open in 16 countries. Clinical trial information: NCT04404283. Research Sponsor: Seagen Inc.

TPS7572 **Poster Session**

ESCALADE: A phase 3 study of acalabrutinib in combination with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) for patients ≤65y with untreated non-germinal center B-cell–like (non-GCB) diffuse large B-cell lymphoma (DLBCL). *First Author: Laurie Helen Sehn, British Columbia Cancer Centre for Lymphoid Cancer, Vancouver, BC, Canada*

Background: R-CHOP remains the standard of care for DLBCL. Although most patients (pts) can be cured, 3540% will experience relapsed/refractory disease, leading to poor outcomes in the majority of pts. Covalent irreversible Bruton tyrosine kinase inhibitors (BTKi) have shown higher responses in pts with non-GCB DLBCL than with GCB DLBCL. In untreated non-GCB DLBCL pts, the phase 3 PHOENIX study (Younes et al. *J Clin Oncol.* 2019;37:1285-95) showed that addition of the BTKi ibrutinib to R-CHOP (R-CHOP-I) did not improve outcomes in the intent-to-treat population. However, pts age < 60y treated with R-CHOP-I had significantly improved progression-free survival (PFS) and overall survival (OS) compared with those receiving R-CHOP alone. Acalabrutinib (A) is a second-generation BTKi with enhanced kinase selectivity and potential for better efficacy and tolerability than first-generation BTKis. There is a strong rationale for combining A with R-CHOP in pts with untreated DLBCL, and safety of A + R-CHOP has been shown in a phase 1b/2 study (Davies et al. ASH 2020). The aim of this study is to determine if the addition of A to R-CHOP leads to improved PFS in pts age ≤65y with untreated non-GCB DLBCL. **Methods:** ESCALADE (ACE-LY-312; NCT04529772) is a phase 3, randomized, global, double-blind study of A vs placebo in combination with R-CHOP for treatment of newly diagnosed non-GCB DLBCL. The study is recruiting adults ≥18y and ≤65y with previously untreated DLBCL stage IIIV disease with a Revised International Prognostic Index (R-IPI) score of 25. Prior to randomization, all pts will receive an initial R-CHOP cycle (cycle 1) as standard-of-care treatment to prevent delays in therapy initiation. Based on central Gene Expression Profile (GEP) testing performed after enrollment, pts with non-GCB DLBCL (activated B-cell like or unclassified) will be randomized into 2 arms to receive A 100 mg twice daily plus R-CHOP or placebo plus R-CHOP from cycle 2 to cycle 6 followed by 2 additional cycles of rituximab + A or placebo (cycles 7 and 8). All pts will receive primary prophylaxis with granulocyte colony-stimulating factors accompanying all R-CHOP cycles. The study aims to randomize 600 pts (~300 per arm). The primary objective is to evaluate whether the addition of A to R-CHOP will prolong PFS. Secondary endpoints include event-free survival, complete response rate, OS, pharmacokinetics, and safety. Key exclusion criteria are central nervous system involvement, primary mediastinal lymphoma, high-grade B-cell lymphoma, diagnosis or treatment of malignancy other than DLBCL, and history of indolent lymphoma. Approximately 250 sites globally will enroll pts. Enrollment began in Q3 of 2020. Clinical trial information: NCT04529772. Research Sponsor: Acerta Pharma, a member of the AstraZeneca Group.

TPS7573 **Poster Session**

Coastal: A phase 3 study of the PI3Kδ inhibitor zandelisib with rituximab (R) versus immunochemotherapy in patients with relapsed indolent non-Hodgkin's lymphoma (iNHL). *First Author: Wojciech Jurczak, National Research Institute of Oncology, Kraków, Poland*

Background: Patients (pts) with iNHL treated with front-line immunochemotherapy may benefit from an alternative, chemotherapy-free regimen at relapse. Zandelisib, a potent, selective, and structurally differentiated oral PI3Kδ inhibitor, achieved an 87% response rate, with median duration of response not reached in iNHL when given as a monotherapy or in combination with R. A low rate ($<$ 10%) of Grade $\geq$ 3 immune-mediated adverse events of special interest associated with PI3kδ inhibitors is observed in patients administered zandelisib on an intermittent schedule (IS) (JCO 2020 38:15_suppl, 8016). An open-label, phase 2 study (TIDAL, NCT03768505) of zandelisib as monotherapy is ongoing in pts with relapsed/refractory follicular lymphoma (FL) and marginal zone lymphoma (MZL). **Methods:** The COASTAL study is a randomized, open-label, controlled multicenter phase 3 trial to investigate the safety and efficacy of zandelisib in combination with R versus standard immunochemotherapy in pts with iNHL. Key eligibility criteria: adults with relapsed or refractory FL or MZL who received $\geq$1 prior lines of therapy which must have included an anti-CD20 antibody in combination with chemotherapy or lenalidomide (L); at least one bi-dimensionally measured lesion $>$ 1.5 cm; adequate bone marrow, renal and hepatic function; ECOG performance status score of 0 to 1. Key exclusion criteria: histologically confirmed diagnosis of FL grade 3b or transformed disease; administration of 2 prior immunochemotherapy regimens; prior PI3K inhibitor therapy; known lymphomatous involvement of the central nervous system. Subjects will be randomized 1:1 to receive R-zandelisib or immunochemotherapy (R-CHOP or R-B) and stratified by type and number of prior treatment regimens, histology, and duration of treatment-free interval after last therapy. Zandelisib will be given in a 28-day cycle comprising of daily dosing for 2 cycles followed by IS dosing on days 1-7 of each 28-day subsequent cycle for a duration of 2 years. Rituximab or immunochemotherapy will be given for a total of 6 cycles. Disease response will be assessed by an Independent Response Review Committee according to the modified Lugano Classification. Radiographic tumor assessment will be performed approximately every 12 weeks for the first 9 months, every 16 weeks for the next 12 months, and every 24 weeks thereafter. The primary efficacy endpoint is progression-free survival. The major secondary endpoints include ORR, complete response rate, overall survival, and safety. The trial will enroll approximately 534 pts in ~200 sites globally and will begin enrollment in mid-2021. Clinical trial information: NCT04745832. Research Sponsor: MEI Pharma, Inc.

TPS7574 **Poster Session**

Phase 3 randomized study of loncastuximab tesirine plus rituximab versus immunochemotherapy in patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL): LOTIS-5. *First Author: Mehdi Hamadani, Division of Hematology and Oncology, Medical College of Wisconsin, Milwaukee, WI*

Background: Patients (pts) with DLBCL for whom frontline therapy is unsuccessful and who are ineligible for autologous stem cell transplantation have poor outcomes with salvage therapy. Single-agent loncastuximab tesirine (Lonca), an antibody-drug conjugate comprising a humanized anti-CD19 monoclonal antibody conjugated to a pyrrolobenzodiazepine dimer (PBD) toxin, showed antitumor activity and manageable toxicity in pts with R/R B-cell non-Hodgkin lymphoma in a Phase 1 trial (Hamadani et al. *Blood* 2020; blood.2020007512) and in pts with R/R DLBCL in a Phase 2 trial (Caimi et al. *Blood* 2020; 136(Suppl 1):35–37). Rituximab (R) is part of standard immunochemotherapy for DLBCL, both as frontline therapy and in subsequent treatments. LOTIS-5 aims to evaluate Lonca + R (Lonca-R) versus (vs) standard immunochemotherapy of R + gemcitabine + oxaliplatin (R-GemOx) in pts with R/R DLBCL. **Methods:** This is a Phase 3 randomized, open-label, 2-part, 2-arm, multicenter study (NCT04384484). A non-randomized safety run-in (Part 1) will compare the safety of Lonca-R with previous safety data for Lonca after the first 20 pts have completed Cycle 1. Part 2 will be started if no significant increase in toxicity occurs; ~330 pts will be randomized 1:1 to receive Lonca-R or R-GemOx. The primary objective of the study is to evaluate the efficacy of Lonca-R vs R-GemOx. The primary endpoint is progression-free survival by independent review. Secondary endpoints include overall survival; objective response rate; complete response rate; duration of response; frequency and severity of adverse events; changes from baseline in safety laboratory and clinical variables; concentration and pharmacokinetic parameters of Lonca (conjugated and total antibody, and unconjugated warhead); immunogenicity; and changes in patient-reported outcomes. Time-to-event endpoints will be assessed for the intent-to-treat population using a stratified log-rank test. The dosing regimen of Lonca-R in both parts of the study will be 150 μg/kg Lonca + 375 mg/m^2 R every 3 weeks (Q3W) for 2 cycles and then 75 μg/kg Lonca + 375 mg/m^2 R for 6 cycles. The dose regimen of R-GemOx in Part 2 will be 375 mg/m^2 R, 1000 mg/m^2 Gem, and 100 mg/m^2 Ox Q2W for 8 cycles. Key inclusion criteria include age $\geq$18 years; pathologic diagnosis of DLBCL (including pts with DLBCL transformed from indolent lymphoma) or high-grade B-cell lymphoma with *MYC* and *BCL2* and/or *BCL6* rearrangements; $\geq$1 line of prior systemic therapy; not a candidate for stem cell transplantation; and measurable disease per 2014 Lugano Classification. The study opened in September 2020 and enrollment is ongoing. The trial design was presented at 62nd American Society of Hematology Annual Meeting and Exposition, December 5–8, 2020. Research Funding: ADC Therapeutics SA. Clinical trial information: NCT04384484. Research Sponsor: ADC Therapeutics SA.

TPS7575 **Poster Session**

A phase III trial evaluating glofitamab in combination with gemcitabine plus oxaliplatin versus rituximab in combination with gemcitabine and oxaliplatin in patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL). *First Author: Mark Hertzberg, Prince of Wales Hospital, Sydney, Australia*

Background: Prognosis is poor for patients with R/R DLBCL, particularly those who are ineligible for autologous stem cell transplant (ASCT) or who relapse after second-line therapy (Gisselbrecht C, et al. Br J Haematol 2018). While chimeric antigen receptor therapies have shown favorable response rates in R/R DLBCL, convenient off-the-shelf options are needed, especially for patients with rapidly progressing disease (Sermer D, et al. Blood Adv 2020). Glofitamab is a full-length, humanized, immunoglobulin G1 bispecific antibody with two regions that bind to CD20 (B cells) and one region that binds to CD3 (T cells). In an ongoing Phase I study in patients with R/R non-Hodgkin lymphoma, glofitamab monotherapy has induced high response rates with a manageable safety profile (NCT03075696; Hutchings M, et al. ASH 2020). Rituximab in combination with gemcitabine and oxaliplatin (R-GemOx) is widely used for patients with R/R DLBCL who are not eligible for ASCT (Mounier N, et al. Haematologica 2013). **Methods:** GO41944 (NCT04408638) is a Phase III, open-label, randomized trial designed to evaluate the safety and efficacy of glofitamab plus gemcitabine and oxaliplatin (glofit-GemOx) vs R-GemOx in patients with R/R DLBCL. Eligible patients must be aged $\geq$ 18 years, have histologically confirmed DLBCL (excluding transformed indolent disease, and high-grade B-cell lymphoma (BCL) with MYC and BCL2 and/or BCL6 rearrangements), and have received $\geq$ 1 prior systemic therapies; patients who have failed only one prior line of therapy must not be eligible for high-dose chemotherapy followed by ASCT. Prior treatment with GemOx, R-GemOx or a CD20xCD3 bispecific antibody is not permitted. Patients are randomized 2:1 to receive up to eight 21-day cycles of either glofit-GemOx (intravenous [IV], followed by up to four cycles of glofitamab monotherapy) or R-GemOx (IV). A single dose of obinutuzumab is administered seven days prior to the first glofitamab administration. Randomization is stratified by number of prior lines of therapy and outcome of last systemic therapy (relapsed vs refractory). The primary objective is overall survival from time of randomization. Secondary efficacy objectives include progression-free survival, complete and overall response rates, duration of response, and time to deterioration in physical functioning and fatigue, and in lymphoma symptoms. Safety objectives comprise rate of adverse events, change from baseline in targeted vital signs and clinical laboratory test results, and tolerability. Pharmacokinetic, immunogenicity and biomarker endpoints will also be explored. The study started on February 17, 2021; an estimated enrollment of 270 patients by the study completion date of March 2022 is anticipated. Clinical trial information: NCT04408638. Research Sponsor: Study GO41944 is sponsored by F. Hoffmann-La Roche Ltd/Genentech, Inc. Third-party medical writing assistance, under the direction of authors, was provided by Katie Buxton, BSc, of Ashfield MedComms, and funded by F. Hoffmann-La Roche Ltd/Genentech, Inc.

TPS7576 **Poster Session**

Randomized, double-blind, placebo-controlled phase 3 study of ibrutinib plus rituximab in patients with previously untreated marginal zone lymphoma (MZL). *First Author: Ariela Noy, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: First-line treatment options for patients with MZL include single-agent immunotherapy, chemotherapy, or chemoimmunotherapy. While chemoimmunotherapy has a higher toxicity profile than immunotherapy alone, it may lead to longer progression-free survival (PFS). Rituximab, an anti-CD20 antibody, is FDA approved for the first-line treatment of follicular lymphoma but not specifically for advanced MZL. Ibrutinib is a Bruton's tyrosine kinase inhibitor approved in the United States for patients with MZL who require systemic therapy and have received $\geq$1 prior anti-CD20-based therapy. The combination of ibrutinib and rituximab has proven effective and is well tolerated in other B-cell lymphomas; it may serve as an effective chemotherapy-free option for the treatment of previously untreated MZL. **Methods:** NCT04212013 is a multicenter, double-blind, placebo-controlled, randomized, phase 3 study designed to compare the efficacy of ibrutinib + rituximab vs placebo + rituximab in patients with previously untreated MZL. Adults ($\geq$18 y) with histologically documented MZL (splenic, nodal, and extranodal subtypes), no prior systemic treatment for MZL (prior splenectomy or other local surgical or radiation treatment allowed), measurable disease on CT scan, documented evidence of need for treatment, and Eastern Cooperative Oncology Group performance status $\leq$2 are eligible. Patients will be randomly assigned 1:1 to receive ibrutinib 560 mg once daily or placebo; all patients will also receive rituximab 375 mg/m^2 on days 1, 8, 15, and 22 of cycle 1. Subcutaneous dosing after dose 1 is allowed. Treatment with ibrutinib or placebo will continue for 30 mo or until disease progression, unacceptable toxicity, patient or investigator decision to withdraw, noncompliance, death, or study termination. Clinical assessments will occur every 4 weeks until week 13, at week 25, and then every 6 mo thereafter. Imaging assessments will be conducted at week 13, at week 25, and then every 6 mo thereafter. Response will be investigator assessed per the revised International Working Group for Non-Hodgkin Lymphoma (RECIL) criteria. At month 30, patients who have a complete response (CR) will discontinue treatment; patients who have a partial response (PR) or stable disease may continue treatment at investigator discretion. Safety will be assessed throughout the study and for 30 days after the last dose of study treatment. The primary endpoint is CR rate at month 30. Secondary endpoints include overall response rate (CR + PR), duration of response, PFS, overall survival, and safety. Enrollment has started and will continue until approximately 138 patients are enrolled. Clinical trial information: NCT04212013. Research Sponsor: Pharmacyclics LLC, an AbbVie Company.

8000 **Oral Abstract Session**

Upfront autologous stem cell transplantation (ASCT) versus carfilzomib-cyclophosphamide-dexamethasone (KCd) consolidation with K maintenance in transplant-eligible, newly diagnosed (NDTE) multiple myeloma (MM). *First Author: Kwee Yong, University College Hospital, London, United Kingdom*

Background: Upfront ASCT for NDTE MM remains under evaluation with high MRD rates following novel induction and consolidation (cons) strategies. Current phase 3 trials support ASCT, however these employ lenalidomide maintenance which predominantly benefits standard risk (SR) patients (pts). The CARDAMON trial investigated the role of ASCT using K based induction and maintenance. **Methods:** NDTE pts received 4 x KCd induction (K 20/56 mg/m^2 biweekly, C 500 mg D 1,8,15, d 40mg weekly) before 1:1 randomisation to ASCT or 4 x KCd cons. All received 18 months K maintenance (56mg/m^2 D1,8,15). Flow cytometric MRD (10^{-5}) was assessed post induction, pre-maintenance and at 6 months maintenance. Primary endpoints were ≥VGPR post induction and 2-year PFS from randomisation. 210 randomised pts were needed to exclude a 10% non-inferiority margin with 15% 1-sided alpha, 80% power. **Results:** 281 pts were registered, median age 59y (33–74), 24% high risk [t(4;14), t(14;16), t(14;20) or del(17p)]. Post induction, ≥VGPR rate was 58.5%, ORR was 87% with similar responses for high risk vs SR. 52 pts did not proceed to PBSCH (6 MR, 16 PD, 19 toxicity, 4 deaths: 3 infection, 1 cardiac event, 7 other). 109 were randomised to ASCT, 109 to KCd cons. ≥VGPR rate was 78.5% after cons and 80.0% after ASCT (p = 0.8). Median KCd cons dose was 55.5 mg/m^2, 99 (90.8%) pts completed 4 cycles, 104 (95.4%) pts received ASCT. After 2.6 years follow-up, median PFS was not reached for ASCT vs 3.8 years for cons (HR: 0.82 (70% CI 0.65, 1.05, p = 0.4). Observed 2-year PFS for ASCT was 75.5% vs 70.7% for cons; calculated difference in 2-year PFS rate (cons vs ASCT) was -4.5% (70% CI -9.2%, +1.1%, non-inferior). High risk pts had inferior outcomes to SR overall regardless of randomisation (2-year PFS ASCT: 52% vs 82% (HR 4.09); cons 48% vs 77% (HR 2.83)). 2 year PFS did not differ according to randomisation: SR 82% (ASCT) vs 77% (cons) HR: 1.29 (0.71-2.35); high risk: 52% (ASCT) vs 48% (cons) HR: 1.06 (0.50-2.23). MRD negativity post induction was 24.3% and similar by genetic risk. MRD negative rates were higher post ASCT (53.1%) than cons (35.8%) (p = 0.02) independent of genetics: SR 49% (ASCT) vs 36% (cons); high risk: 57% (ASCT) vs 32% (cons). G3+ adverse events to induction were infections (18.7%), hypertension (11.2%), anaemia (10.4%), cardiac disorders (3.6%), vomiting (2.2%), fatigue (2.2%), diarrhoea (1.8%). **Conclusions:** In NDMM receiving KCd induction and K maintenance, KCd cons was non-inferior to ASCT. High risk pts had inferior outcomes, that were not influenced by ASCT or cons randomisation. Clinical trial information: NCT02315716. Research Sponsor: Amgen.

	ASCT			Consolidation

Depth of response and minimal residual disease status in ultra high-risk multiple myeloma and plasma cell leukemia treated with daratumumab, bortezomib, lenalidomide, cyclophosphamide and dexamethasone (Dara-CVRd): Results of the UK optimum/MUKnine trial. *First Author: Martin F. Kaiser, The Institute for Cancer Research, London, United Kingdom*

Background: Patients with ultra high-risk (UHiR) newly diagnosed multiple myeloma (NDMM) and patients with plasma cell leukemia (PCL) continue to have dismal outcomes and are underrepresented in clinical trials. Recently, improved responses with anti-CD38 monoclonal antibody combination therapy have been reported for NDMM patients. We report here outcomes for NDMM UHiR and PCL patients treated in the OPTIMUM/MUKnine (NCT03188172) trial with daratumumab, cyclophosphamide, bortezomib, lenalidomide, dexamethasone (Dara-CVRd) induction, augmented high-dose melphalan (HDMEL) and ASCT. With final analysis follow-up surpassed in Feb 2021, we report here early protocol defined endpoints from induction to day 100 post ASCT. **Methods:** Between Sep 2017 and Jul 2019, 107 patients with UHiR NDMM by central trial genetic (≥2 high risk lesions: t(4;14), t(14;16), t(14;20), gain(1q), del(1p), del(17p)) or gene expression SKY92 (SkylineDx) profiling, or with PCL (circulating plasmablasts > 20%) were included in OPTIMUM across 39 UK hospitals. Patients received up to 6 cycles of Dara-CVRd induction, HDMEL and ASCT augmented with bortezomib, followed by Dara-VR(d) consolidation for 18 cycles and Dara-R maintenance. Primary trial endpoints are minimal residual disease (MRD) status post ASCT and progression-free survival. Secondary endpoints include response, safety and quality of life. Data is complete but subject to further data cleaning prior to conference. **Results:** Median follow-up for the 107 patients in the safety population was 22.2 months (95% CI: 20.6 – 23.9). Two patients died during induction due to infection. Bone marrow aspirates suitable for MRD assessment by flow cytometry (10^{-5} sensitivity) were available for 81% of patients at end of induction and 78% at D100 post ASCT. Responses in the intention to treat population at end of induction were 94% ORR with 22% CR, 58% VGPR, 15% PR, 1% PD, 5% timepoint not reached (TNR; withdrew, became ineligible or died) and at D100 post ASCT 83% ORR with 47% CR, 32% VGPR, 5% PR, 7% PD, 10% TNR. MRD status was 41% MRDneg, 40% MRDpos and 19% not evaluable post induction and 64% MRDneg, 14% MRDpos and 22% not evaluable at D100 post ASCT. Responses at D100 post ASCT were lower in PCL with 22% CR, 22% VGPR, 22% PR, 22% PD, 12% TNR. Most frequent grade 3/4 AEs during induction were neutropenia (21%), thrombocytopenia (12%) and infection (12%). Grade 3 neuropathy rate was 3.7%. **Conclusions:** This is to our knowledge the first report on a trial for UHiR NDMM and PCL investigating Dara-CVRd induction and augmented ASCT. Response rates were high in this difficult-to-treat patient population, with toxicity comparable to other induction regimens. However, some early progressions highlight the need for innovative approaches to UHiR NDMM. Clinical trial information: NCT03188172. Research Sponsor: Myeloma UK and research support by Celgene and Janssen.

8002 **Oral Abstract Session**

Carfilzomib-based induction/consolidation with or without autologous transplant (ASCT) followed by lenalidomide (R) or carfilzomib-lenalidomide (KR) maintenance: Efficacy in high-risk patients. *First Author: Francesca Gay, European Myeloma Network, Gimema, Italy*

Background: Cytogenetic abnormalities (CA) are one of the most powerful prognostic factors in multiple myeloma (MM). In the FORTE study, carfilzomib-lenalidomide-dexamethasone induction/consolidation with ASCT (KRd_ASCT) significantly improved progression-free survival (PFS) vs KRd without ASCT (KRd12, HR 0.64) or carfilzomib-cyclophosphamide-dexamethasone (KCd) plus ASCT (KCd_ASCT, HR 0.53). KR maintenance significantly improved PFS vs R (HR 0.63). **Methods:** MM patients (pts) were randomized to KRd_ASCT vs KCd_ASCT vs KRd12 and, thereafter, to KR vs R maintenance. Subgroup analyses according to FISH evaluated the impact of each single high-risk (HiR) CA [del17p, t(4;14), t(14;16), del1p and 1q gain (3 copies) or amp1q (≥4 copies)] and that of combined CA, defining HiR by the presence of ≥1 HiR CA and double-hit (DH) by the presence of ≥2 HiR CA. Pts negative for all the HiR CA were considered at standard risk (SR). The primary objective was the impact of treatment on PFS according to pt risk. **Results:** 396 out of 474 enrolled pts were included in the analysis with complete FISH data: 243 HiR, 105 DH and 153 SR. Among HiR pts, 60 had del17p, 65 t(4;14), 20 t(14;16), 44 del1p, 126 1q gain and 49 amp1q. SR pts benefited from intensification with KRd_ASCT vs KRd12 (HR 0.47, p = 0.05) and KCd_ASCT (HR 0.38, p = 0.01), with a 4-year PFS of 80%, 67% and 57%, respectively. In HiR pts, KRd_ASCT improved PFS vs KRd12 (HR 0.6, p = 0.04) and KCd_ASCT (HR 0.57, p = 0.01), with a 4-year PFS of 62%, 45% and 45%, respectively. The advantage with KRd_ASCT vs KRd12 (HR 0.53, p = 0.07) and KCd_ASCT (HR 0.49; p = 0.03) was also observed in DH pts (4-year PFS 55%, 31% and 33%, respectively). Analyses by single CA were limited by the small number of pts in each subgroup, but a trend towards a PFS benefit from KRd_ASCT vs KRd12 was seen in pts with del17p (HR 0.61, p = 0.3), t(4;14) (HR 0.59, p = 0.2) and 1q gain (HR 0.45, p = 0.02). In pts with del1p, KRd_ASCT (HR 0.24, p = 0.06) and KRd12 (HR 0.33, p = 0.09) showed superiority over KCd_ASCT, while amp1q pts had the worst outcome regardless of treatment (KRd_ASCT vs KCd_ASCT, HR 1.16, p = 0.73; KRd12 vs KCd_ASCT, HR 1.34, p = 0.45). KR improved PFS vs R in SR (3-year PFS 90% vs 73%, HR 0.42, p = 0.06), HiR (3-year PFS 69% vs 56%, HR 0.6, p = 0.04) and DH pts (3-year PFS 67% vs 42%, HR 0.53, p = 0.1). Despite the small subgroups, a beneficial trend with KR vs R was observed in pts with del17p (HR 0.59, p = 0.37), t(4;14) (HR 0.59, p = 0.3), 1q gain (HR 0.54, p = 0.07) and del1p (HR 0.23, p = 0.08), while amp1q pts showed the worst outcome and no benefit from KR vs R (HR 0.83, p = 0.7). **Conclusions:** KRd_ASCT and KR maintenance are highly effective in SR and also in HiR and DH pts, with impressive 4-year PFS from diagnosis (KRd_ASCT: HiR 62%, DH 55%) and 3-year PFS from maintenance (KR: HiR 69%, DH 67%), thus supporting their use in HiR pts, who represent an unmet medical need. Clinical trial information: NCT02203643. Research Sponsor: Amgen; Bristol-Myers Squibb (Celgene).

8003 **Oral Abstract Session**

Subcutaneous daratumumab + bortezomib, cyclophosphamide, and dexamethasone (VCd) in patients with newly diagnosed light chain (AL) amyloidosis: Updated results from the phase 3 ANDROMEDA study. *First Author: Efstathios Kastritis, Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Athens, Greece*

Background: Systemic AL amyloidosis is a plasma cell disease characterized by the deposition of insoluble amyloid fibrils causing organ dysfunction and death. Primary results from the ANDROMEDA study showed that addition of subcutaneous (SC) daratumumab (DARA) to the standard of care combination of bortezomib, cyclophosphamide, and dexamethasone (VCd) was superior to VCd alone, with higher rates of hematologic complete response (CR) and an acceptable safety profile. DARA-VCd was approved for newly diagnosed AL amyloidosis in January 2021. Here we present an update of the primary ANDROMEDA study results with longer follow-up. **Methods:** ANDROMEDA is a randomized, open-label, active-controlled phase 3 study. Adult patients (pts) with newly diagnosed AL amyloidosis were randomized 1:1 to DARA-VCd or VCd and were treated for 6 28-day Cycles (Cyc). Bortezomib (1.3 mg/m^2), cyclophosphamide (300 mg/m^2 maximum weekly dose 500 mg), and dexamethasone (40 mg) were given weekly. DARA SC was given weekly (Cyc 1–2) and every 2 weeks (wk) (Cyc 3–6). After Cyc 6, pts in the DARA-VCd group received DARA SC alone every 4 wk for up to 24 Cyc from first dose. Disease status was evaluated every 4 wk in Cyc 1–6 and every 8 wk after Cyc 7. The primary endpoint was overall hematologic CR rate in the intent-to-treat population. Secondary endpoints were major organ deterioration progression-free survival (PFS), organ response rate, time to hematologic response, survival, and safety. **Results:** Of 388 randomized pts, 195 were randomized to DARA-VCd and 193 to VCd. As of November 2020, the median treatment duration was 18.5 months (mo) for DARA-VCd and 5.3 mo for VCd; 78 pts (40%) in the DARA-VCd group were still on treatment. The overall hematologic CR rate continued to be higher with DARA-VCd than VCd (59% vs 19%; odds ratio [OR] 5.9; 95% CI 3.7–9.4; P< 0.0001). More pts achieved a very good partial response or better (≥VGPR) with DARA-VCd than VCd (79% vs 50%; OR 3.7; 95% CI 2.4–5.9; P< 0.0001). Among responders, median time from randomization to ≥VGPR was shorter for DARA-VCd than VCd (0.56 vs 0.82 mo). Cardiac response rates were higher with DARA-VCd than VCd at 6 mo (42% vs 22%) and at 12 mo (57% vs 28%); renal response rates were 54% vs 27% at 6 mo and 57% vs 27% at 12 mo. A total of 71 deaths occurred (DARA-VCd, n = 31; VCd, n = 40). From Cyc 7 onward in the DARA-VCd group, no grade 3/4 treatment-emergent adverse events occurred in ≥5% of pts. There were no systemic administration-related reactions with DARA-VCd after Cyc 6. Analysis of major organ deterioration PFS will be updated after ~200 events have occurred. **Conclusions:** Updated results from the ANDROMEDA study reinforce the clinical superiority of DARA-VCd over VCd in pts with newly diagnosed AL amyloidosis. Based on its recent approval, DARA-VCd represents a new standard of care in AL amyloidosis. Clinical trial information: NCT03201965. Research Sponsor: Janssen Research & Development, LLC.

8004 **Oral Abstract Session**

Daratumumab (DARA) maintenance or observation (OBS) after treatment with bortezomib, thalidomide and dexamethasone (VTd) with or without DARA and autologous stem cell transplant (ASCT) in patients (pts) with newly diagnosed multiple myeloma (NDMM): CASSIOPEIA Part 2. *First Author: Philippe Moreau, Hematology, University Hospital Hotel-Dieu, Nantes, France*

Background: D-VTd plus ASCT was approved for transplant-eligible (TE) NDMM based on part 1 of CASSIOPEIA. We report a prespecified interim analysis of CASSIOPEIA part 2: DARA maintenance vs OBS in pts with ≥partial response (PR) in part 1, regardless of induction/consolidation (ind/cons) treatment. **Methods:** CASSIOPEIA is a 2-part, randomized, open-label, phase 3 study in TE NDMM. Pts received 4 cycles ind and 2 cycles cons with D-VTd or VTd. 886 pts who achieved ≥PR were rerandomized to DARA 16 mg/kg IV Q8W for up to 2 yr (n = 442) or OBS (n = 444) until progressive disease per IMWG. Pts were stratified by ind (D-VTd vs VTd) and depth of response (minimum residual disease [MRD] status and post cons response ≥PR). Primary endpoint was progression-free survival (PFS) after second randomization. This interim analysis assessed efficacy and safety after 281 PFS events. A preplanned hierarchical procedure tested key secondary endpoints: time to progression (TTP), ≥complete response (CR), MRD negativity rates by NGS and overall survival (OS). **Results:** At median follow-up of 35.4 mo, median PFS was not reached (NR) with DARA and 46.7 mo with OBS (HR 0.53; 95% CI 0.42–0.68; P <0.0001). PFS advantage for DARA was consistent across most subgroups. However, a prespecified analysis showed significant interaction with ind/cons treatment arm (P< 0.0001). PFS HR for DARA vs OBS was 0.32 (95% CI 0.23–0.46) in the VTd arm and 1.02 (0.71–1.47) in the D-VTd arm. Median TTP was NR for DARA vs 46.7 mo for OBS (HR 0.49; 95% CI 0.38–0.62; P <0.0001). More pts in the DARA vs OBS arm achieved ≥CR (72.9% vs 60.8%; OR 2.17; 95% CI 1.54–3.07; P <0.0001). MRD negativity (in ≥CR pts at 10^{-5}) was 58.6% with DARA vs 47.1% with OBS (OR 1.80; 95% CI 1.33–2.43; P= 0.0001). Median OS was NR in either arm. Most common (≥2.5%) grade 3/4 adverse events (AEs) with DARA vs OBS were pneumonia (2.5% vs 1.4%), lymphopenia (3.6% vs 1.8%), and hypertension (3.0% vs 1.6%). Serious AEs occurred in 22.7% (DARA) vs 18.9% (OBS) of pts; the most common (≥2.5%) was pneumonia (2.5% vs 1.6%). 13 (3.0%) pts discontinued DARA due to an AE. The rate of infusion-related reactions was 54.5% (DARA-naïve pts) and 2.2% (prior DARA pts); 90% were grade 1/2.Second primary malignancies occurred in 5.5% (DARA) vs 2.7% (OBS) of pts. **Conclusions:** CASSIOPEIA part 2 demonstrated a clinical benefit of DARA maintenance in TE NDMM pts, with significantly longer PFS for DARA vs OBS. With current follow-up, maintenance PFS benefit appeared only in pts treated with VTd as ind/cons. Pts who received D-VTd ind/cons with or without DARA maintenance achieved similar PFS; longer follow-up is needed for PFS2 and OS. DARA significantly increased deeper response and MRD negativity rates vs OBS, and was well tolerated with no new safety signals. Clinical trial information: NCT02541383. Research Sponsor: Janssen Research & Development, LLC.

Ciltacabtagene autoleucel, a B-cell maturation antigen (BCMA)-directed chimeric antigen receptor T-cell (CAR-T) therapy, in relapsed/refractory multiple myeloma (R/R MM): Updated results from CARTITUDE-1. *First Author: Saad Zafar Usmani, Levine Cancer Institute/Atrium Health, Charlotte, NC*

Background: CARTITUDE-1 (NCT03548207) is a phase 1b/2 study evaluating ciltacabtagene autoleucel (cilta-cel; JNJ-68284528), a CAR T-cell therapy with two BCMA–targeting single-domain antibodies, in patients (pts) with R/R MM. Here, we report updated results in pts with a longer duration (median 12.4 months) of follow-up. **Methods:** Eligible pts had MM and received ≥3 prior regimens or were double refractory to a proteasome inhibitor (PI) and immunomodulatory drug (IMiD), and had received a PI, IMiD, and anti-CD38 antibody. After apheresis, bridging therapy was permitted. Pts received a single cilta-cel infusion (target dose: 0.75×10^6 CAR+ viable T cells/kg; range $0.5\text{-}1.0\times10^6$) 5–7 days (d) after lymphodepletion (300 mg/m^2 cyclophosphamide, 30 mg/m^2 fludarabine daily for 3 d). The primary objectives were to characterize cilta-cel safety, confirm the recommended phase 2 dose (RP2D; phase 1b), and evaluate efficacy (phase 2). Cytokine release syndrome (CRS) was graded by Lee *et al* (Blood 2014) and neurotoxicity by CTCAE, v5.0 (in phase 1b). CRS and ICANS were graded by ASTCT criteria (in phase 2). Here, Lee *et al* and CTCAE v5.0 were mapped to ASTCT for CRS and ICANS, respectively. **Results:** As of Sept 1, 2020, 97 pts with a median of 6 prior lines received cilta-cel. Overall response rate per independent review committee (primary endpoint) was 97% (95% CI, 91–99), with 67% achieving stringent complete response (sCR). Median time to first response was 1 month (range, 1–9), and median time to CR or better was 2 months (range, 1–15). Responses deepened over time, and median duration of response was not reached. Of 57 pts evaluable for minimal residual disease (MRD) assessment, 93% were MRD-negative at 10^{-5}. The 12-month progression-free survival (PFS) and overall survival rates (95% CI) were 77% (66–84) and 89% (80–94), respectively; median PFS was not reached. Grade 3/4 hematologic AEs ≥20% included neutropenia (95%), anemia (68%), leukopenia (61%), thrombocytopenia (60%), and lymphopenia (50%). CRS occurred in 95% of pts (4% grade 3/4), with median time to onset of 7 d (range, 1–12), and median duration of 4 d (range, 1–14, excluding 1 pt with 97-d duration). CRS resolved in all but one with grade 5 CRS/haemophagocytic lymphohistiocytosis. CAR T-cell neurotoxicity occurred in 21% of pts (grade ≥3, 10%). Fourteen deaths occurred during the study after cilta-cel infusion: none within the first 30 days, 2 within 100 days; and 12 more than 100 days post infusion, of which 5 were due to disease progression, and 4 due to treatment-related AEs. **Conclusions:** A single infusion of cilta-cel yielded early, deep, and durable responses in heavily pretreated pts with MM, with a manageable safety profile at the RP2D. Cilta-cel is under further investigation in other MM populations in earlier lines of therapy and in outpatient settings. Clinical trial information: NCT03548207. Efficacy and safety of elranatamab (PF-06863135), a B-cell maturation antigen (BCMA)-CD3 bispecific antibody, in patients with relapsed or refractory multiple myeloma (MM). *First Author: Nizar J. Bahlis, Arnie Charbonneau Cancer Institute, University of Calgary, Calgary, AB, Canada*

Background: Elranatamab (PF-06863135) is a humanized bispecific monoclonal antibody (IgG2a) that targets BCMA, a member of the tumor necrosis factor receptor superfamily expressed in MM, and CD3 on T cells. We reported results for intravenous (IV) dosing (Raje et al. Blood. 2019;134(S1):1869) and now update for subcutaneous (SC) dosing from the ongoing Phase 1 study (MagnetisMM-1). **Methods:** Patients (pts) received elranatamab at 80, 130, 215, 360, 600, and 1000μg/kg SC weekly. A modified toxicity probability interval method was used for escalation, with monitoring for dose-limiting toxicity (DLT) to end of the first cycle. Treatment-emergent adverse events (TEAEs) were graded by Common Terminology Criteria for Adverse Events (v4.03), and cytokine release syndrome (CRS) by American Society for Transplantation and Cellular Therapy criteria (Lee et al. Biol Blood Marrow Transplant. 2019;25:625). Response was assessed by International Myeloma Working Group criteria. Pharmacokinetics, cytokine profiling, and T cell immunophenotyping were performed. **Results:** 30 pts had received elranatamab as of 4-Aug-2020 at 80 (n = 6), 130 (n = 4), 215 (n = 4), 360 (n = 4), 600 (n = 6), or 1000 (n = 6) μg/kg SC weekly. Pts had a median of 8 prior treatments; 87% had triple refractory disease, 97% had prior anti-CD38 therapy, and 23% had prior BCMA-directed antibody drug conjugate or chimeric antigen receptor T cell therapy. The most common all causality TEAEs included lymphopenia (n = 24, 80%; 20% G3, 60% G4), CRS (n = 22, 73%; none > G2), anemia (n = 17, 57%; 43% G3, 3% G4), injection site reaction (n = 16, 53%; none > G2), thrombocytopenia (n = 16, 53%; 23% G3, 17% G4), and neutropenia (n = 12, 40%; 17% G3, 17% G4). Both CRS and immune effector cell-associated neurotoxicity syndrome (n = 6, 20%) were limited to ≤G2 with median durations of 2 and 1.5 days, respectively. No DLT was observed. Exposure increased with dose, and T_{max} ranged from 3–7 days. Cytokine increases occurred with the first dose, and increased T-cell proliferation was observed in peripheral blood. The overall response rate (ORR) for doses ≥215μg/kg was 75% (n = 15/20) including partial response (PR; n = 6), very good PR (VGPR; n = 3), complete response (CR; n = 1), and stringent CR (sCR; n = 5). Median time to response was 22 days, and 3 of 4 pts (75%) with prior BCMA-directed therapy achieved response (VGPR, n = 2 and sCR, n = 1). Updated data, including duration of response, will be presented. **Conclusions:** Elranatamab demonstrated a manageable safety profile, and SC doses ≥215μg/kg achieved ORR of 75% with CR/sCR rate of 30%. These results demonstrate the safety and efficacy of SC elranatamab in this relapsed/refractory population and support ongoing development of elranatamab for pts with MM, both as monotherapy and in combination with standard or novel therapies. Clinical trial information: NCT03269136. Research Sponsor: Pfizer.

8007 **Oral Abstract Session**

Updated phase 1 results of teclistamab, a B-cell maturation antigen (BCMA) × CD3 bispecific antibody, in relapsed/refractory multiple myeloma (MM). *First Author: Amrita Y. Krishnan, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: BCMA-targeted immunotherapies offer considerable promise for relapsed/refractory MM. Teclistamab (JNJ-64007957) is a BCMA × CD3 bispecific IgG4 antibody that redirects CD3+ T cells to BCMA-expressing MM cells. We present updated results of patients (pts) treated at the recommended phase 2 dose (RP2D) in the first-in-human phase 1 study of teclistamab. **Methods:** Eligible pts had MM and were relapsed, refractory or intolerant to established therapies. Primary objectives were to identify the RP2D (part 1) and characterize safety and tolerability of teclistamab at the RP2D (part 2)**.** Teclistamab was given intravenously (IV; range 0.3–19.2 μg/kg [biweekly]; range 19.2–720 μg/kg [weekly]) or subcutaneously (SC; range 80.0–3000 μg/kg weekly) in different cohorts, with step-up dosing used for ≥38.4 μg/kg doses. Adverse events (AEs) were graded by CTCAE v4.03 (cytokine release syndrome [CRS] by Lee et al 2014). Response was assessed per IMWG criteria. **Results:** As of Feb 4, 2021, 156 pts received teclistamab (IV n = 84; SC n = 72). The RP2D, identified as weekly SC 1500 μg/kg teclistamab with 60.0 and 300 μg/kg step-up doses, was given to 40 pts (median follow-up 4.3 mo [range 1.1–10.4+]). Pts dosed at the RP2D (median age, 62.5 y [range, 39–84]; 65% male) had received a median of 5 prior lines of therapy (range 2–11; 100% triple-class exposed; 65% penta-drug exposed; 83% triple-class refractory; 35% penta-drug refractory; 85% refractory to their last line of therapy). There were no dose-limiting toxicities at the RP2D in part 1. The most common AEs at the RP2D were CRS (70%; grade 3/4 0) and neutropenia (60%; grade 3/4 40%); grade 1 neurotoxicity was reported in 1 (3%) pt. Median time to CRS onset was later with SC vs IV dosing (day after SC injection vs day of IV infusion). The overall response rate in response-evaluable pts treated at the RP2D (n = 40) was 65%; 58% achieved a very good partial response or better and 30% achieved a complete response (CR) or better; median time to first confirmed response was 1.0 mo (range 0.2–3.1). At the RP2D, median duration of response was not reached; 23 of 26 responders (88%), after median follow-up of 5.3 mo (range 1.2–10.4+), were alive and continuing on treatment with responses deepening over time. Of 14 evaluable pts across all cohorts, 9 with CR were minimal residual disease–negative at 10^{-6}. At the RP2D, teclistamab exposure was sustained across the dosing interval and exceeded target levels, and consistent T cell activation was observed. **Conclusions:** Teclistamab at the RP2D (weekly 1500 μg/kg SC) was well-tolerated and showed encouraging efficacy with durable, deepening responses, supporting further investigation as monotherapy and in combination with other agents. With the extended exposure profile at the RP2D and delayed and low-grade CRS observed with SC administration, alternative SC dosing strategies are being explored. Clinical trial information: NCT03145181. Research Sponsor: Janssen Research & Development, LLC.

8008 **Oral Abstract Session**

Updated results of a phase 1, first-in-human study of talquetamab, a G protein-coupled receptor family C group 5 member D (GPRC5D) × CD3 bispecific antibody, in relapsed/refractory multiple myeloma (MM).

First Author: Jesus G. Berdeja, Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN

Background: New immunotherapy targets in MM are needed as patients (pts) continue to relapse. The orphan receptor GPRC5D is expressed on malignant plasma cells in MM. Talquetamab (JNJ-64407564) is a bispecific IgG4 antibody that redirects T cell killing to MM cells by binding to the novel target, GPRC5D, and CD3. We present updated results of talquetamab at the recommended phase 2 dose (RP2D) from a phase 1 trial in relapsed/refractory MM. **Methods:** Eligible pts with MM who had relapsed or refractory disease or were intolerant to standard therapies received talquetamab intravenously (IV; range 0.5–180 μg/kg) or subcutaneously (SC; range 5.0–800 μg/kg) weekly or biweekly. Primary objectives were identification of the RP2D (part 1) and talquetamab safety and tolerability at the RP2D (part 2). Adverse events (AEs) were graded by CTCAE v4.03 (cytokine release syndrome [CRS] per Lee 2014). Response was assessed per IMWG criteria. **Results:** As of Feb 8, 2021, 174 pts received talquetamab, 102 by IV and 72 by SC; in parts 1 and 2, 28 pts were treated at the RP2D, identified as weekly SC 405 μg/kg, with 10.0 and 60.0 μg/kg step-up doses. Pts treated at the RP2D had a median age of 61.5 y (range 46–80) and a median of 5.5 prior lines of therapy (range 2–14; 100%/79% triple-class/penta-drug exposed; 71%/18% triple-class/penta-drug refractory; 86% refractory to last line of therapy; 21% with prior B-cell maturation antigen–directed therapy). No dose-limiting toxicities occurred at the RP2D in part 1. Most common AEs at the RP2D were CRS (79%; grade 3 4%; median time to onset: day after SC injection), neutropenia (64%; grade 3/4 54%), anemia (57%; grade 3/4 29%) and dysgeusia (57%; all grade 1/2); infections were reported in 32% of pts (grade 3/4 4%) and neurotoxicity in 7% (grade 3/4 0). In all, 75% of pts dosed at the RP2D had skin-related AEs (grade 3/4 0), including 18% with nail disorders. The overall response rate at the RP2D in response-evaluable pts (n = 24) was 63%, with 50% reaching very good partial response or better; 9/17 (53%) evaluable triple-class refractory pts and 3/3 (100%) penta-drug refractory pts had a response. Median time to first confirmed response at the RP2D was 1.0 mo (range 0.2–3.8); responses were durable and deepened over time (median follow-up 6.2 mo [range 2.7–9.7+] for responders at the RP2D). At the RP2D, exposure was maintained over the maximum EC_{90} target level from an ex vivo cytotoxicity assay, and consistent T cell activation was seen. **Conclusions:** At the RP2D of weekly 405 μg/kg SC, talquetamab showed a high clinical response rate and was well-tolerated in pts with relapsed/refractory MM; based on pharmacokinetic data, other SC dosing strategies are being explored. The promising efficacy, safety profile and convenience of SC dosing support monotherapy development and combination approaches with this novel agent. Clinical trial information: NCT03399799. Research Sponsor: Janssen Research & Developent, LLC.

MASS-FIX versus standard methods to predict for PFS and OS among multiple myeloma patients participating on the STAMINA trial.

First Author: Angela Dispenzieri, Division of Hematology, Mayo Clinic, Rochester, MN

Background: Measuring response among patients with multiple myeloma is essential for the care of patients. Deeper responses have been associated with better progression free survival (PFS) and overall survival (OS). Serum (SIFE) and urine immunofixation are the currently used markers for biochemical documentation of CR after which marrow is tested for plasma cell clearance. Next generation flow cytometry and sequencing are used to document the presence of minimal residual disease (MRD). Mass spectrometry of blood by MALDI (Mass-Fix) is a new simple, inexpensive, sensitive, and specific means of detecting monoclonal immunoglobulins. To better test the hypothesis that Mass-Fix is superior to existing methodologies to predict for survival outcomes—especially SIFE– samples from the STAMINA trial (NCT01109004), a trial comparing 3 transplant approaches among patients who have already received induction, were employed. **Methods:** Five-hundred and seventy-five patients were included. Samples from enrollment post-induction (post-I) and 1-year post enrollment (1YR) were tested when available. Four response parameters were assessed univariately: Mass-Fix, SIFE, complete response, and MRD by next generation flow cytometry. Mass spectrometry spectra were evaluated in a blinded fashion. Complete response was according to the 2006 International Myeloma Working Group criteria. Multivariate Cox proportional hazard models using stepwise regression were developed to explore the independent effect of the different response parameters on PFS and OS and interactions with other risk factors. **Results:** Of the 4 response measures, only MRD and Mass-Fix predicted for PFS and OS at multiple testing points on multivariate analyses (Table). Of the 4 post-I measurements, only MRD predicted for PFS; however, Mass-Fix was the only post-I measurement to predict for OS. Of all the 1-year measures, both 1YR Mass-Fix and 1YR MRD positivity predicted for inferior PFS and OS. In models including MRD and Mass-Fix, SIFE and CR were not prognostic for PFS or OS. **Conclusions:** Mass-Fix is a powerful means to track monoclonal proteins. The full utility of Mass-Fix was not exploited given the absence of a diagnostic sample and the fact that only serum (and not urine) was tested. Despite these limitations, it performed well at pre-induction and at 1 year. Mass-Fix provides a convenient and non-invasive means of predicting for myeloma outcomes. Clinical trial information: NCT01109004. Research Sponsor: This manuscript was prepared using BMT CTN 0702 Research Materials obtained from the NHLBI. This project was also supported by Grant Number P30 CA015083 and CA186781 from the National Cancer Institute and by the Predolin Foundation. Support for the clinic.

Analysis of minimal residual disease in bone marrow by NGF and in peripheral blood by mass spectrometry in newly diagnosed multiple myeloma patients enrolled in the GEM2012MENOS65 clinical trial.

First Author: Noemi Puig, Hematology Department, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Analysis of minimal residual disease (MRD) in the bone marrow (BM) of patients with multiple myeloma (MM) is accepted by the IMWG to evaluate treatment efficacy and is a well-established prognostic factor. However, there is an unmet need to explore the clinical value of MRD in peripheral blood (PB). **Methods:** Newly diagnosed MM patients enrolled in the GEM2012MENOS65 trial received six induction (Ind) cycles of bortezomib, lenalidomide, and dexamethasone (VRD) followed by autologous stem cell transplantation (ASCT) and 2 further cycles of consolidation (Cons) with VRD. MRD was analyzed in BM using Next Generation Flow (NGF) and in serum by Mass Spectrometry (MS) using IgG/A/M, κ, λ, free κ and free λ specific beads, both after Ind, at day 100 after ASCT, and after Cons. Sequential samples from the first 184 patients were analyzed. **Results:** Results of both methods were in agreement (NGF+/MS+ and NGF-/MS-) in 83% of cases post-Ind (152/184), 80% post-ASCT (139/174) and 76% post-Cons (128/169). Stratifying by the log range of MRD by NGF, discordances (NGF+/MS- and NGF-/MS+) seemed to increase at the lower MRD ranges, being 22%, 21% and 19% from $\geq 10^{-5}$ to $<10^{-4}$ and 21%, 21%, 23% at $\geq x10^{-6}$(post-Ind, ASCT and Cons, respectively). Analysis of discordances showed that they could be partly explained by the higher percentages of cases found to be positive by MS as compared by NGF at part of the time-points analyzed and at each log range of MRD. From $\geq 10^{-5}$ to $<10^{-4}$, MRD was detected by NGF in 36%, 28%, 20% of cases post-Ind, ASCT and Cons, respectively *vs* MS in 37%, 29%, 21% of them; at $\geq x10^{-6}$, NGF was positive in 11%, 14%, 19% of cases *vs* MS in 23%, 19% and 16% of them. Considering NGF as a reference, the negative predictive value (NPV) of MS per MRD range ($\geq 10^{-5}$ to $<10^{-4}$ and $\geq x10^{-6}$, respectively) was: post-Ind: 83% (p<0,0001), 94% (p=0,034); post-ASCT 86% (p<0,0001), 90% (p=0,022); post-Cons 89% (p<0,0001), 85% (p=0,0469). Despite these discordances, the prognostic value of each technique in terms of undetectable MRD and progression-free survival (PFS) was consistent at all time-points (Table) and further, discordant cases (NGF+/MS- and NGF-/MS+) did not display a significantly different PFS as compared to NGF-/MS- cases. **Conclusions:** The results of MRD assessed by NGF in BM and by MS in PB show a significant concordance and are associated with a similar prognostic value analyzed in terms of PFS. Given its high NPV, MRD in peripheral blood by MS provides a gateway for BM aspiration/biopsy and MRD assessment by NGF. Research Sponsor: PETHEMA-GEM.

Interim analysis of a phase 2 minimal residual disease (MRD)-adaptive trial of elotuzumab, carfilzomib, lenalidomide, and dexamethasone (Elo-KRd) for newly diagnosed multiple myeloma (MM).

First Author: Benjamin Avi Derman, University of Chicago, Chicago, IL

Background: The addition of a monoclonal antibody to triplet induction regimens in patients (pts) with MM with intent for autologous stem cell transplant (ASCT) has resulted in higher overall and deep response rates. In this study we are investigating the impact of the addition of Elo to KRd on complete response (CR) and/or MRD-negative rates in newly diagnosed MM regardless of transplant eligibility. **Methods:** Pts were enrolled from four MM Research Consortium sites into this phase 2 study. All patients receive 12 cycles of Elo-KRd in 28-day cycles: Elo per standard dosing, K 20/56/70 mg/m^2 days 1, 8 and 15, R 25 mg days 1-21, and dexamethasone 40 mg days 1, 8, 15, 22. ASCT eligible candidates can undergo stem cell collection after cycle 4 and then resume treatment; pts who elect to proceed to ASCT are censored for response at that time. Pts MRD(-) ($<10^{-5}$) by NGS after cycles 8 (C8) and 12 (C12) proceed to Elo-Rd until progression. Patients who convert from MRD(+) to MRD(-) between C8 and C12 receive an additional 6 cycles of Elo-KRd (total 18 cycles) followed by Elo-Rd, and pts MRD(+) after C12 receive an additional 12 cycles of Elo-KRd (total 24) followed by Elo-Rd. The primary endpoint of the study is sCR and/or MRD(-) rate after C8 E-KRd. MRD status was determined by ClonoSEQ next generation sequencing (NGS, $<10^{-5}$) [Adaptive Biotechnologies]. An improvement in the sCR and/or MRD(-) rate by NGS from a historical 30% to 50% at the end of C8 will be considered promising. **Results:** 44 pts are enrolled, 39 of whom are evaluable for response (cutoff Jan 10 2021). Median age is 62 years (range 43-81, 23% age >70) and 23 (52%) have high-risk cytogenetic abnormalities (HRCA) including 13 (30%) with >2 high-risk abnormalities (6 pts unknown cytogenetics). 34/39 (87%) have MRD trackable by clonoSEQ. The rate of sCR and/or MRD(-) by NGS at the end of C8 is 19/33 (58%), meeting the statistical threshold for establishing efficacy (2 pts censored for elective ASCT before C8 and 4 pts receiving therapy but have not reached C8). With a median follow-up of 24 months, estimated 2-year progression free survival is 87% (100% for standard risk, 79% for HRCA) and estimated 2-year overall survival is 89% (82% for HRCA). No pt who was MRD(-) by NGS after C8 has progressed, including 6 pts with HRCA. Serious adverse events occurred in 30 pts (68%). 89% experienced treatment emergent AEs, the most common (>10%) of which was pneumonia (14%). One pt had grade 5 myocardial infarction. **Conclusions:** Elo-KRd demonstrates tolerability consistent with known toxicities of these agents and met the primary endpoint of sCR and/or MRD(-) of >50% after 8 cycles. With longer follow-up, the study results may validate that an MRD-adaptive design for de-escalation of therapy in MM can generate deep responses while reducing treatment exposure. Clinical trial information: NCT02969837. Research Sponsor: Bristol Myers Squibb.

Prospective comparison of whole body MRI and FDG PET/CT for detection of multiple myeloma and correlation with markers of disease burden: Results of the iTIMM trial. *First Author: Martin F. Kaiser, Institute of Cancer Research, London, United Kingdom*

Background: Early and sensitive detection of bone marrow disease and stratified patient management according to clinical risk can confer survival advantages in multiple myeloma (MM). Whole body MRI (WB MRI) and Fluorodeoxyglucose (FDG) PET/CT are included in international guidelines for imaging in patients with a suspected diagnosis of MM. However prospective studies comparing detection of MM by contemporary WB MRI as per recent MY-RADS consensus against FDG PET/CT are lacking. We report here protocol-defined endpoints from the prospective iTIMM (NCT02403102) study, comparing WB MRI and PET/CT, their relationship with serum and bone marrow estimates of disease burden, as well as molecular tumor characteristics. **Methods:** Patients with newly diagnosed MM or at first relapse planned to receive chemotherapy and autologous stem cell transplantation were enrolled in iTIMM. Matched baseline WB MRI and FDG PET/CT were performed and baseline clinical data including tumor genetics collected. Scans were double reported for presence of focal and diffuse disease by expert MRI and PET/CT radiologists, blinded to each other's assessment. Paired methods were used to compare burden and patterns of disease on WB MRI compared to FDG PET/CT at baseline. Primary and secondary trial endpoints include relationship between post-treatment WB MRI response and progression-free survival, for which follow-up is ongoing. Exploratory endpoints include comparison of baseline WB MRI and PET/CT and their correlation with laboratory parameters, for which data is complete and reported here. **Results:** From May 2015 to March 2018, sixty patients (35 male; mean age 60 years) underwent baseline WB MRI as per MY-RADS consensus and FDG PET/CT. At least one focal lesion was detected in 50/60 patients (83.3%) by WB MRI and in 36/60 patients (60%) by PET/CT. WB MRI was more sensitive ($P< 0.05$) across anatomical regions except for ribs and cervical spine. Four patients in our study showed two or more focal lesions ≥5 mm only on WB MRI but not PET/CT. All lesions detected by WB MRI but not PET/CT resolved in follow-up scans after treatment, excluding false positives. In 49/60 (81.7%) patients, diffuse disease was detected by WB MRI, compared to 10/60 (16.7%) by PET-CT; WB MRI was more sensitive across all anatomical areas ($P< 0.05$). Plasma cell infiltration and paraprotein levels were significantly higher for patients with diffuse disease on WB MRI, but not on PET/CT. All genetically high-risk tumours, defined by t(4;14), t(14;16), del(1p), gain(1q) or del(17p), showed diffuse infiltration on WB MRI. **Conclusions:** WB MRI increases detection of focal and diffuse disease compared with FDG PET/CT, including improved detection of focal lesions meeting criteria for active disease as per International Myeloma Working Group diagnostic criteria, proposing it as a gold standard for tumor imaging in MM. Clinical trial information: NCT02403102. Research Sponsor: Cancer Research UK and NIHR Biomedical Research Centre at the Royal Marsden Hospital and Institute of Cancer Research.

8013 **Poster Discussion Session**

CARTITUDE-2: Efficacy and safety of ciltacabtagene autoleucel (cilta-cel), a BCMA-directed CAR T-cell therapy, in patients with progressive multiple myeloma (MM) after one to three prior lines of therapy. *First Author: Mounzer Agha, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Cilta-cel is a CAR T-cell therapy expressing two BCMA-targeting, single-domain antibodies designed to confer avidity. The multicohort, phase 2 CARTITUDE-2 study (NCT04133636) is evaluating cilta-cel safety and efficacy in various clinical settings for patients (pts) with MM and exploring suitability of outpatient administration. Here, we present initial results from Cohort A. **Methods:** Cohort A pts had progressive MM after 1–3 prior lines of therapy (LOT), including a proteasome inhibitor (PI) and immunomodulatory drug (IMiD), were lenalidomide refractory, and had no prior exposure to BCMA-targeting agents. A single cilta-cel infusion (target dose: 0.75×10^6 CAR+ viable T cells/kg) was given 5–7 days (d) after start of lymphodepletion (daily cyclophosphamide [300 mg/m^2] and fludarabine [30 mg/m^2] for 3 d). The primary objective was minimal residual disease (MRD) 10^{-5} negativity. Secondary outcomes were response rates (IMWG) and safety (per CTCAE; CRS and ICANS by ASTCT). **Results:** As of Feb 2021 data cutoff (median follow-up: 5.8 months [mo]; range: 2.5–9.8 mos), 20 pts (65% male; median age 60 years [38–75]) received cilta-cel; 1 pt was treated in an outpatient setting. Pts received a median of 2 prior LOT (1–3); 12 pts received < 3 prior lines and 8 received 3 prior LOT. All pts were exposed to PI, IMiD, and dexamethasone, 95% to alkylating agents, and 65% to daratumumab. The majority (95%) were refractory to the last LOT; 40% were triple refractory. Overall response rate was 95% (95% CI: 75–100), 75% (95% CI: 51–91) achieved stringent CR/CR, and 85% (95% CI: 62–97) achieved ≥VGPR. Median time to first response was 1.0 mo (0.7–3.3); median time to best response was 1.9 mo (0.9–5.1). Median duration of response was not reached. All pts (n = 4) with MRD-evaluable samples at 10^{-5} at data cutoff were MRD-negative. Hematologic AEs ≥20% were neutropenia (95%; gr 3/4: 90%), thrombocytopenia (80%; gr 3/4: 35%), anemia (65%; gr 3/4: 40%), lymphopenia (60%; gr 3/4: 55%), and leukopenia (55%; all gr 3/4). CRS occurred in 85% of pts; 10% were gr 3/4. Median time to CRS onset was 7 d (5–9), with a median duration of 3.5 d (2–11). CAR T-cell neurotoxicity occurred in 20% of pts (all gr 1/2). Three pts had ICANS (1 gr 1; 2 gr 2); median time to onset was 8 d (7–11) and median duration was 2 d (1–2). One pt had gr 2 facial paralysis; time to onset was 29 d with a duration of 51 d. One death occurred due to COVID-19 (assessed as treatment (tx)-related by investigator). Safety profile was manageable in the pt treated in an outpatient setting. **Conclusions:** A single cilta-cel infusion at the recommended phase 2 dose led to early and deep responses with a manageable safety profile in pts with MM who had 1–3 prior LOT. Updated efficacy and safety findings will inform suitability of outpatient tx in this and other cohorts of CARTITUDE-2 as well as the CARTITUDE-4 study. Clinical trial information: NCT04133636. 8014 **Poster Discussion Session**

Long-term follow-up results of a multicenter first-in-human study of the dual BCMA/CD19 Targeted FasT CAR-T GC012F for patients with relapsed/refractory multiple myeloma. *First Author: Hua Jiang, Shanghai Chang Zheng Hospital, Shanghai, China*

Background: The dual CAR-T GC012F developed on the novel FasT CAR-T platform targeting B cell maturation antigen (BCMA), and CD19 was designed to improve depth of response and overall efficacy for CAR-T as therapy for Multiple Myeloma. Here, we present updated data for study (NCT04236011; NCT04182581) including additional pts treated. **Methods:** From October 2019 to July 2020, 19 heavily pretreated Relapsed/Refractory Multiple Myeloma (RRMM) pts (age 27-71) with a median of 5 prior lines (range 2-9) received a single infusion of GC012F. 94.7% (18/19) were high risk (HR- defined by mSMART), 5 pts had extramedullary disease, 1 pts presented with plasma cell leukemia, and 15/19 were refractory to last therapy. 4/19 pts had received prior anti- CD38, 18/19 pts prior IMiD. 18/19 pts were refractory to PI, 17 pts to IMiD, 3 pts being primary refractory. After lymphodepletion over 2-3 days (30 mg/m^2/d, 300mg/ m^2/d Flu/Cy) CAR-T cells were administered as single infusion at 3 dose levels: 1x10^5/kg (DL1) n=1, 2x10^5/kg (DL2) n=9 and 3x10^5/kg (DL3) n=9. **Results:** As of Jan 12, 2021 cut-off, 19 pts were evaluated for response. Overall response rate (ORR) was 94.7% - all responses VGPR or better (94.7% - 16/18 sCR, 2/18 VGPR) with all pts MRD- by flow cytometry (10^{-4}-10^{-6}) - earliest response d 28 post infusion. 100% of pts achieved a reduction of paraprotein, 18/19 a 100% reduction. Best response was MRD- sCR in 16/19 patients (84.2%). In DL3 (n=9) 4 additional pts were response evaluable for 6 mth follow-up: 100% (9/9) of pts achieved MRD-sCR as best response, 87.5% (7/8) of response evaluable pts maintained MRD-sCR at landmark analysis of 6 mths. At data cut off, the median time to follow up was 13.8 mths (6.1-16.4) – median duration of response not yet reached. Cytokine Release Syndrome (CRS) and ICANs were graded by ASBMT criteria: grade 1-2 n=16 (84.2%), grade 3 n=2 (10.5%). Median duration of CRS was 4 d (1-8 d). No grade 4/5 CRS or ICANS were observed. 2 deaths occurred on study and were assessed as not related to therapy – one reported previously; one patient was diagnosed with pseudomonas pneumonia on Day 52, refused life-saving treatment and passed. CAR-T median Tmax was 10 d (range 8-14d), median peak copy number (Cmax) was 127548 (16,011-374,346) copies /ug DNA with long duration of persistence of up to 60 weeks at time of data cut off. Patients continue to be monitored for safety and efficacy. **Conclusions:** BCMA-CD19 dual FasT CAR-T GC012F showed early, deep and durable responses with a high ORR (94.7% - VGPR and better) including a high MRD- sCR rate (DL3=100%, n=9) in high risk RRMM pts including those refractory to anti-CD38, PI and IMIDs with a favorable safety profile consistent with previous findings. BCMA-CD19 dual FasT CAR-T GC012F may present a new treatment approach for patients with RRMM including those with high-risk features refractory to standard of care. Clinical trial information: NCT04236011; NCT04182581. Research Sponsor: Gracellbio.

8015 **Poster Discussion Session**

Phase 1 Study of CART-ddBCMA, a CAR-T therapy utilizing a novel synthetic binding domain, for the treatment of subjects with relapsed and refractory multiple myeloma. *First Author: Matthew J. Frigault, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: CART-ddBCMA is an autologous CAR-T cell therapy encoding a novel non-scFv synthetic binding domain targeting BCMA with a 4-1BB costimulatory motif and CD3-zeta T-cell activation domain. The novel binding domain is based on a computationally-derived triple-helix protein scaffold that is small (73 amino acids), stable, engineered to reduce immunogenicity, and can be modified to bind alternative targets. **Methods:** ARC-101 (NCT04155749), ARM 1 (CART-ddBCMA) is a Phase 1, multi-center, open-label, dose escalation trial enrolling subjects who have received ≥3 prior regimens, including proteasome inhibitor(s), immunomodulatory agent(s), and anti-CD38 antibody, or are triple-refractory. Subjects undergo lymphodepletion with fludarabine and cyclophosphamide, then receive CART-ddBCMA as a single infusion. Planned dose levels are 100, 300, and up to 900 x 10^6 CAR+ T cells. The primary endpoint is incidence of adverse events (AEs), including dose-limiting toxicities (DLTs). Secondary endpoints include clinical response per IMWG criteria, MRD, DOR, PFS, OS, and CAR-T cell kinetics. **Results:** As of 29 Jan 2021, 10 subjects received CART-ddBCMA, 9 subjects were evaluable, and 1 subject was pending assessment. Median age was 66 years [min:max 54 to 75]. 6 subjects received 100 x 10^6 CAR+ T cells, and 4 subjects received 300 x 10^6 CAR+ T cells. Median CAR+ expression was 74.5% (min:max 61-87%) of total T cells. Of the evaluable subjects, median follow-up after cell infusion was 208 days (min:max 45 to 355+ days), 9/9 subjects were penta-refractory, 1 subject was also refractory to BCMA-directed ADC. 8/9 had high-risk cytogenetics (1 subject's sample not evaluable), and 6/9 subjects had extramedullary disease. No DLTs were reported. Per ASTCT Consensus Grading (Lee et al, 2019), 8 subjects developed G1/2 CRS, 1 subject in the higher dose cohort developed G3 CRS that rapidly resolved with tocilizumab. 1 subject developed G2 ICANS which rapidly resolved with intervention. 7 subjects received tocilizumab; 3 received dexamethasone. ORR was 100% (9/9) per IMWG criteria including 4 sCR, 1 VGPR, and 4 PR. 1 subject with PR relapsed and was retreated. All other subjects have ongoing responses; observations included sFLC normalization and elimination of detectable bone marrow disease by Month 1. Ongoing responses for subjects not yet achieving CR continue to deepen. 7 subjects were evaluable by MRD of which 5 are MRD-negative, and 2 are pending results. CAR-T cell expansion, as measured by vector transgene copies per microgram genomic DNA was observed in all patients. **Conclusions:** Early efficacy results are encouraging, with 9/9 (100%) ORR and manageable toxicities. 8/9 responses are ongoing and responses continue to deepen. These data are encouraging in high-risk subjects with penta-refractory myeloma. Subjects continue to be enrolled and treated. Clinical trial information: NCT04155749. Research Sponsor: Arcellx.

8016 **Poster Discussion Session**

Idecabtagene vicleucel (ide-cel, bb2121), a BCMA-directed CAR T cell therapy, in relapsed and refractory multiple myeloma: Updated KarMMa results. *First Author: Larry D. Anderson, Jr, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Patients (pts) with RRMM previously exposed to immunomodulatory agents, proteasome inhibitors (PIs), and CD38 antibodies (mAbs) have poor outcomes with subsequent treatments. Ide-cel, a BCMA-directed CAR T cell therapy, showed frequent, deep, and durable responses in heavily pretreated pts with RRMM in the pivotal KarMMa trial (Munshi NC, et al. *J Clin Oncol* 2020;38[suppl 15]. Abstract 8503). Here, we present updated data. **Methods:** Pts with ≥ 3 prior regimens (including immunomodulatory agent, PI, and CD38 mAb) and refractory to their last regimen per IMWG criteria were eligible (NCT03361748). Pts received 150450 $\times$ 10^6 CAR+ T cells (target dose range) after 3 days of lymphodepletion (cyclophosphamide 300 mg/m^2 + fludarabine 30 mg/m^2). Endpoints included overall response rate (ORR; primary) and complete response (CR) rate (key secondary). Additional secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. **Results:** KarMMa enrolled 140 pts, and 128 received ide-cel. Pts had a median age of 61 years and a median of 6 (range, 3-16) prior regimens; 84% were triple-class refractory, and 26% were penta-class refractory (lenalidomide, pomalidomide, bortezomib, carfilzomib, and daratumumab). Most pts (88%) had bridging therapy. Median follow-up was 15.4 mo (data cutoff, 7 Apr 2020). ORR was 73% and median PFS was 8.8 mo in all treated pts; both increased with higher dose (Table). At the highest target dose (450 $\times$ 10^6 CAR+ T cells), the ORR was 81%, the CR rate was 39%, and the median PFS increased to 12.2 months with longer follow-up. Responses were observed in all subgroups including difficult-to-treat subsets (eg, extramedullary disease [ORR, 70%], high tumor burden [71%], and R-ISS stage III disease [48%]). OS continues to mature and the median has not been reached; the 15-month event-free rate for OS was 71%. Cytopenias (97%) and cytokine release syndrome (CRS; 84%) were the most common any-grade toxicities. CRS was mostly grade 1/2; 5 pts (4%) had grade 3, 1 had grade 4 (at 300 $\times$ 10^6), and 1 had grade 5 (at 300 $\times$ 10^6). Investigator-identified neurotoxicity was reported in 23 pts (18%); 4 pts (3%) had grade 3 and 0 had grade ≥ 4. Tocilizumab was used in 67 and 3 pts with CRS and neurotoxicity, respectively. **Conclusions:** Updated results from the KarMMa trial continue to demonstrate deep, durable responses with ide-cel in heavily pretreated pts with RRMM. Efficacy and safety reflect prior reports and support a favorable clinical benefit-risk profile for ide-cel across the target dose range. Clinical trial information: NCT03361748. Research Sponsor: Celgene, a Bristol-Myers Squibb Company and bluebird bio.

Dose, $\times$ 10^6 CAR+ T cells	150 (n = 4)	300 (n = 70)	450 (n = 54)	Total (N = 128)

8017 **Poster Discussion Session**

Updates from ICARIA-MM, a phase 3 study of isatuximab (Isa) plus pomalidomide and low-dose dexamethasone (Pd) versus Pd in relapsed and refractory multiple myeloma (RRMM). *First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

Background: Isa is an approved monoclonal antibody that binds to a specific epitope on the CD38 receptor. The Phase 3 ICARIA-MM study (NCT02990338) demonstrated significantly improved progression-free survival (PFS) with Isa-Pd vs Pd (P= 0.001) and a manageable safety profile (Attal M, et al. *Lancet* 2019;394:2096-2107). Here we report updated ICARIA results. **Methods:** Pts with RRMM (N = 307) who have received ≥2 prior therapies, including lenalidomide (Len) and a proteasome inhibitor (PI), were randomized to Isa-Pd (n = 154) or Pd (n = 153). Isa was administered intravenously at 10 mg/kg weekly for 4 weeks, and every other week thereafter. This preplanned second interim analysis assessed longer term outcomes, including time to next treatment (TTNT), overall survival (OS), time from randomization to disease progression on first subsequent therapy or death (PFS2), and safety. **Results:** Pts had a median of 3 prior lines of therapy (IQR 2–4; table). As of Oct 1, 2020 (median follow-up, 35.3 months [mo]), 27 Isa-Pd pts (18%) vs 12 Pd pts (8%) were still on treatment; 60% vs 72% had proceeded to subsequent therapy. Median TTNT was 15.5 mo with Isa-Pd vs 8.9 mo with Pd (hazard ratio [HR] 0.56; 95% confidence interval [CI] 0.42–0.74; P< 0.0001); 24% vs 58% of pts with subsequent therapy received daratumumab (dara). Overall response rate (ORR) in subsequent treatment with dara monotherapy was higher after Pd (38%) than Isa-Pd (14%), but was similar (32% vs 31%) with dara combination therapy (table). Median PFS2 in the intent-to-treat population was 17.5 mo with Isa-Pd vs 12.9 mo with Pd (HR 0.76; 95% CI 0.58–0.99; P= 0.0202). Median OS was 24.6 mo with Isa-Pd vs 17.7 mo with Pd (HR 0.76; 95% CI 0.58–1.01; one-sided P= 0.0280). Median treatment duration was 47.6 weeks (range 1.3–171.6) with Isa-Pd vs 24.0 weeks (range 1.0–168.6) with Pd. Serious treatment-emergent adverse event (TEAEs) were seen in 73% of Isa-Pd pts vs 60% of Pd pts. Most frequent non-hematologic TEAEs (any grade) with Isa-Pd were infusion reaction (38%), upper respiratory tract infection (34%), and diarrhea (30%). Grade 3–4 neutropenia (85% vs 71%) and thrombocytopenia (34% vs 25%) were more frequent with Isa-Pd than with Pd. **Conclusions:** Isa-Pd demonstrates a significant improvement in TTNT and PFS2 compared with Pd. A strong trend in OS benefit was also seen in the Isa-Pd arm, with approximately 7 mo improvement in median OS. The overall safety profile remains unchanged from prior analyses. Funding: Sanofi. Clinical trial information: NCT02990338. Research Sponsor: Sanofi.

Prior treatments, n (%)	Isa-Pd (n = 154)	Pd (n = 153)
Len	154 (100)	153 (100)
PI	154 (100)	153 (100)
Len-refractory	144 (94)	140 (92)
PI-refractory	118 (77)	115 (75)
ORR on subsequent dara combination treatments, n/N* (%)		
ALL	4/13 (31)	7/22 (32)
+Immunomodulator	2/5 (40)	2/7 (29)
+Alkylator	0/4 (0)	1/5 (20)
+PI	2/5 (40)	4/12 (33)

8018 **Poster Discussion Session**

Oral selinexor, pomalidomide, and dexamethasone (XPd) at recommended phase 2 dose in relapsed refractory multiple myeloma (MM). *First Author: Darrell White, Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, NS, Canada*

Background: Exportin 1 (XPO1) mediates the nuclear export and functional inactivation of tumor suppressor proteins (TSPs), is associated with poor prognosis in MM, and contributes to proteasome inhibitor (PI) and immunomodulatory drug (IMiD) resistance. Selinexor (SEL) is a novel, oral, first-in-class selective inhibitor of nuclear export (SINE) compound that blocks XPO1, forcing the nuclear retention and activation of TSPs. SEL is approved with low-dose dexamethasone (dex) ± bortezomib (BOR) for patients (pts) with previously treated MM. In the Phase 3 BOSTON study, once weekly (QW) SEL, QW BOR, and dex (XVd) significantly increased progression-free survival (PFS) and overall response rate (ORR) with marked reduction of peripheral neuropathy as compared to standard twice weekly BOR/dex (Vd), despite XVd utilizing 40% less BOR and 25% less dex than Vd. Pomalidomide (POM) plus dex (Pd) has an ORR of 31% and median PFS (mPFS) of 4 months in MM pts refractory to BOR and lenalidomide (LEN). We hypothesized that the addition of once weekly SEL to Pd (XPd) would be an active, all-oral combination with an acceptable safety profile in pts with LEN refractory and BOR treated MM. **Methods:** In the SPd arm of the multi-arm Phase 1b/2 STOMP study, SEL was evaluated at 60, 80, or 100 mg QW or 60 or 80 mg twice weekly in combination with Pd. Study objectives were to determine the maximum tolerated dose and recommended Phase 2 dose (RP2D), and assess the safety and activity of the SPd regimen including in pts receiving the RP2D. **Results:** As of 4 Jan 2021, 65 pts (33 male) were enrolled with median age of 64 years (range 37-85 years) and median of 3 (range 1-10) prior lines of therapy. Previously treated/refractory rates were LEN 100%/85%, BOR 92%/49%, carfilzomib 43%/37%, POM 31%/29%, and daratumumab (dara) 26%/26%. RP2D was SEL 60 mg QW, POM 4 mg (days 1-21), dex 40 mg QW. Common hematologic, treatment-related adverse events (TRAEs) included (all grades, grades ≥3) neutropenia (63%, 55%), anemia (58%, 32%), and thrombocytopenia (54%, 31%). Non-hematologic TRAEs included nausea (62%, 2%), fatigue (55%, 11%), and decreased appetite (45%, 2%). Among POM naïve or nonrefractory MM pts (N = 44), ORR was 57% (1 sCR, 1 CR, 8 VGPR, 15 PR); mPFS was 12.2 months. In pts treated with RP2D (N = 20), ORR was 65% (1 sCR, 5 VGPR, 7 PR); mPFS was not reached with a median follow-up time of 3.9 months. In POM-refractory pts and those with prior dara, ORR was 44% (7/16) and 60% (9/15), respectively. **Conclusions:** SEL, once weekly, can be safely combined with Pd in pts with heavily pretreated MM. No new safety signals were identified. The all-oral combination of XPd is highly active with an ORR of 65% at RP2D (compared to expected ORR ≤30% for Pd) and produces durable responses with a mPFS of 12.2 months overall. These data support a planned Phase 3 study with an all-oral combination of XPd vs Pd in pts who have been previously treated with LEN, a PI, and an anti-CD38 mAb. Clinical trial information: NCT02343042. Research Sponsor: Karyopharm Therapeutics.

8019 **Poster Discussion Session**

Survival among older patients with previously treated multiple myeloma treated with selinexor, bortezomib, and dexamethasone (XVd) in the BOSTON study. *First Author: Thierry Facon, University of Lille, CHU Lille, Service des Maladies du Sang, Lille, France*

Background: Multiple myeloma (MM) typically affects older populations, which are more vulnerable to toxicity with anti-MM treatments. These patients (pts) have significant morbidity and mortality, resulting in a need for dose modifications or alternative suboptimal treatment options. Significant improvements were observed in the BOSTON study with XVd vs Vd in median progression-free survival (PFS), overall response rate (ORR), and rates of peripheral neuropathy (PN); median overall survival (OS) trended in favor of XVd. **Methods:** The phase 3 randomized BOSTON trial (NCT03110562) is a controlled, open-label study of once weekly XVd vs. twice weekly standard Vd in pts with MM and 1-3 prior treatment regimens. We performed post-hoc analyses to compare survival benefits in pts ≥65 vs < 65 years of age. **Results:** The BOSTON study enrolled a total of 402 pts between June 2017 and February 2019 that were randomized into XVd or Vd arms. The numbers of pts treated with XVd or Vd who were ≥65 were 109/132 and 86/75 who were < 65, respectively. Baseline characteristics were similar by age although pts ≥65 years were less likely to have received ASCT than those < 65 years (48.4% vs. 25.3%). Median PFS was prolonged with XVd compared with Vd, across both age groups: ≥65 (HR, 0.55 [95% CI, 0.37-0.83] P = 0.002) and < 65, (HR, 0. 74 [95% CI, 0.49-1.11], P = 0.07). Vd was associated with a lower ORR (64.4%) than treatment with XVd (76.1%) (OR, 1.77 [95% CI, 1.00-3.11], P = 0.024) in pts ≥65, while the ORR in those < 65 was 76.7% with XVd and 58.7% (OR, 2.33 [95% CI, 1.18-4.59], P = 0.007) with Vd. As of Jan 2021, the median OS for the overall population was not reached for both arms (HR = 0.86; p = 0.193), with 61 and 75 deaths in the XVd and Vd arms, respectively. Median OS was not reached in pts ≥65 with XVd and was 28.6 months with Vd (HR = 0.60; 95% CI, 0.38-0.94; p = 0.012), while there was no difference in the OS for pts < 65 (HR = 1.52; 95% CI, 0.86-2.68; p = 0.926). Pts ≥65 had a lower incidence of death with XVd as compared to Vd (29 vs 56) and there were 32 deaths with XVd and 19 with Vd in pts < 65. Grade ≥3 treatment-emergent adverse events were not observed more often in older compared to younger pts. Amongst pts ≥65, PN of any grade was lower with XVd (32.1%) compared to Vd (46.5%); (OR 0.57 [95% CI 0.34-0.97], p = 0.017), including a lower incidence of grade ≥3 PN (XVd 4.6% vs. Vd 11.6%). Pts < 65 followed a similar trend of PN AEs of any grade: XVd, 32.6%; Vd, 48.0% (OR 0.42 [95% CI 0.21-0.82], p = 0.006). **Conclusions:** In an older patient population with a poor prognosis, XVd was associated with a significant survival benefit, improved PFS and OR with reduced PN, and requires relatively short and infrequent clinic visits. XVd may be a simple, effective regimen for pts ≥65 years of age. Clinical trial information: NCT03110562. Research Sponsor: None.

8020 **Poster Discussion Session**

Oral ixazomib-dexamethasone versus oral pomalidomide-dexamethasone for lenalidomide-refractory, proteasome inhibitor-exposed multiple myeloma (MM) patients: A global, multicenter, randomized, open-label, phase 2 trial. *First Author: Meletios A. Dimopoulos, Therapeutic Clinic, General Hospital of Athens Alexandra, Athens, Greece*

Background: MM patients (pts) often receive several lines of therapy with multiple drug combinations and, as lenalidomide (R)-containing regimens are commonly used as first-line therapy, R-free options for subsequent lines are necessary. Additionally, as pts age and become less tolerant to treatment, more convenient regimens, such as all-oral options, with less toxicity are needed. Dexamethasone (dex)-based doublets are effective and tolerable in this setting. **Methods:** Proteasome inhibitor (PI)-exposed and/or intolerant and R-refractory pts who had ≥2 prior therapies (N = 122) were randomized 3:2 to receive: ixazomib (ixa) 4 mg (5.5 mg from cycle 2 if tolerated) on day (d) 1, 8, 15, and dex 20 mg (≥75 years [yrs], 10 mg) on d 1, 2, 8, 9, 15, 16, 22, 23; or pomalidomide (pom) 4 mg on d 1–21, and dex 40 mg (≥75 yrs, 20 mg) on d 1, 8, 15, 22, in 28-d cycles until progressive disease (PD) or unacceptable toxicity. Pts were stratified by age (< 65 vs ≥65 yrs), International Staging System (ISS) disease stage at study entry (I/II vs III), and prior lines of therapy (2 vs ≥3). The study was powered to test the primary endpoint of progression-free survival (PFS). **Results:** In the ixa-dex (n = 73) vs pom-dex (n = 49) arms, median age was 72 vs 68 yrs (36% vs 18% ≥75 yrs), 25% vs 22% of pts had ISS stage III MM, and 52% vs 53% had received ≥3 prior therapies (per stratification). At data cutoff (5/31/2020), 19% vs 20% of pts were ongoing on treatment with ixa-dex vs pom-dex; primary reasons for discontinuation were PD (47% vs 57%) and adverse events (AEs; 23% vs 12%). With median follow-up of 15.3 vs 17.3 months (mos), median PFS (mPFS) was 7.1 vs 4.8 mos with ixa-dex vs pom-dex (hazard ratio [HR] 0.847; 95% confidence interval [CI] 0.535–1.341; p = 0.477); the Table shows mPFS by prior lines, and secondary endpoints. Pts received a median of 6 cycles with both ixa-dex (range 1–25) and pom-dex (range 1–27); 64% of ixa-dex pts were able to escalate to a 5.5 mg dose of ixa. 69% vs 81% of ixa-dex vs pom-dex pts had grade (G) ≥3 AEs, 51% vs 53% had serious AEs, 39% vs 36% had an AE leading to drug discontinuation, 44% vs 32% had an AE leading to dose reduction, and 13% vs 13% died on study. Health-related quality of life (HRQoL; EORTC QLQ-C30/MY20, and EQ-5D-5L) was maintained, and similar between arms. **Conclusions:** Ixa-dex prolonged PFS vs pom-dex in these heavily pretreated, PI-exposed and/or intolerant, R-refractory pts, but the difference was not statistically significant. Ixa-dex was well tolerated, with lower G≥3 AE rates vs pom-dex, and comparable HRQoL. Clinical trial information: NCT03170882. High-dose lenalidomide and melphalan as conditioning for autologous stem cell transplantation in relapsed or refractory multiple myeloma. *First Author: Adriana C. Rossi, NYPH Weill Cornell, New York, NY*

Background: Autologous stem cell transplantation (ASCT) remains a standard of care of eligible patients with multiple myeloma, despite the many novel therapies introduced over the past decade. High dose melphalan (HDM) is the only approved regimen to date. Lenalidomide (LEN) is an oral immunomodulatory drug which has become the backbone of myeloma therapy from induction through salvage and maintenance. Early studies noted a dose response relationship, and found myelosuppression to be the dose limiting toxicity. We previously reported on our phase 1 study of high dose lenalidomide (HDLEN) with HDM in conditioning for ASCT, where no DLT was noted up to 350mg PO daily of LEN. Here we report the phase 2 data of patients undergoing ASCT with combination conditioning regimen. **Methods:** 50 patients with relapsed/refractory multiple myeloma (RRMM) underwent ASCT using HDLEN+HDM conditioning. HDLEN was dosed at 350mg PO daily from day -5 to day -1 and HDM was dosed 100mg/m2 on days -2 and -1. TPatients were heavily pre-treated: 32% had prior HDM-ASCT, 96% had received prior lenalidomide, and 42% prior pomalidomide; 40% prior anti-CD38 mAB. Of note, 68% entered the study with progressive disease at time of enrollment. **Results:** Overall response rate was 96%, with 80% being ≥VGPR. Median progression free survival (PFS) was noted at 14.3 months, while overall survival (OS) was 68.2 months. PFS was similar when patients were stratified by prior ASCT, depth of response at enrollment, or presence of high risk FISH. Toxicities were mostly hematologic (100% neutropenia and thrombocytopenia, 90% anemia) , GI (88% diarrhea, 72% nausea, 42% vomiting) and metabolic (30-96% derangement in electrolytes), and similar to historical controls receiving HDM alone. Second malignancies were noted in 2 patients. **Conclusions:** HDLEN/HDM is a well tolerated and effective conditioning regimen for ASCT in patients with RRMM. This regimen merits further investigation as ASCT is likely to remain an integral part of the treatment of RRMM patients, yet few advancements have been made to this modality. HDLEN may be particularly useful in patients with high risk disease and those progressing after multiple lines of therapy. HDLEN added little toxicity to HDM and SPMs were not more frequent than expected per SEER database for patients in this age range. Clinical trial information: NCT01054196. Research Sponsor: Celgene.

Improved outcomes with maintenance therapy after salvage autologous hematopoietic cell transplantation (AHCT) in multiple myeloma: A CIBMTR study. *First Author: Oren Pasvolsky, Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petah- Tikva, Israel*

Background: Maintenance therapy in multiple myeloma (MM) after first autologous hematopoietic cell transplantation (AHCT1) is considered standard of care. Data regarding maintenance therapy after a salvage AHCT (AHCT2) in the setting of relapsed MM are scarce. Therefore, we used data from the Center for International Blood and Marrow Transplant Research (CIBMTR) registry to examine the use of maintenance therapy after AHCT2 in MM patients and its effect on post-transplant patient outcomes. **Methods:** We included US adult MM patients who underwent AHCT2 after melphalan conditioning regimen from 2010-2018, and excluded patients who underwent tandem transplants. Outcomes of interest included non-relapse mortality (NRM), relapse/progression (REL), progression-free and overall survival (PFS, OS). Cox proportional hazards models were developed to study the main effect (maintenance use) with other covariates of interest including age, sex, race, performance status, HCT-comorbidity index, MM subtype, stage, creatinine, cytogenetic, conditioning melphalan dose, disease status at transplant, and time from AHCT1 to AHCT2. **Results:** Of 522 patients, 342 received maintenance therapy and 180 did not after AHCT2. Baseline characteristics were similar between the two groups. Median follow up was 58 months in the maintenance group and 61.5 months in the no-maintenance group. Common maintenance regimens included immunomodulatory drugs (IMID)-lenalidomide (N = 145, 42%) or pomalidomide (N = 46, 13%) and proteasome inhibitor, bortezomib (N = 45, 13%). Univariate analysis showed superior outcomes at 5 years in maintenance compared to the no-maintenance group: NRM 2 (0.7-3.9)% vs 9.9 (5.9-14.9)%, p < 0.001, REL 70.2 (64.4-75.8)% vs 80.3 (73.6-86.3)%, p 0.003, PFS 27.8% (22.4-33.5) vs. 9.8% (5.5-15.2) , p < 0.001, and OS 54% (47.5-60.5) vs 30.9% (23.2-39.2) p < 0.001, respectively. IMID-containing maintenance regimens were associated with an improved 5-year PFS and OS compared to other maintenance regimens. Use of maintenance therapy retained its association with improved outcomes in multivariate analysis, including NRM: hazard ratio (HR) 0.19 (0.08-0.44), p 0.0001, REL: HR 0.58 (0.47-0.72), p < 0.0001, PFS HR 0.52 (0.43-0.64), p < 0.0001, and OS HR 0.46 (0.36-0.60), p < 0.0001. We conducted additional analyses to investigate a possible selection bias in the maintenance group including landmark analysis at 100-days and 6-months post-AHCT2 as well as a subgroup analysis of patients who received melphalan 200mg/m^2 as conditioning for AHCT2 (as a surrogate for fitness)- all these analyses also showed improved outcomes in the maintenance group. Second cancers were reported in 17 (5%) patients in the maintenance group and 6 (3%) patients and no-maintenance group (p 0.39). **Conclusions:** Maintenance therapy after AHCT2 is associated with superior outcomes in MM patients. Research Sponsor: U.S. National Institutes of Health.

8023 **Poster Session**

Phase 2 study of MGTA-145 + plerixafor for rapid and reliable hematopoietic stem cell (HSC) mobilization for autologous transplant in multiple myeloma. *First Author: Surbhi Sidana, Stanford University, Stanford, CA*

Background: MGTA-145 (GroβT), a CXCR2 agonist, has shown promising activity for HSC mobilization with plerixafor in pre-clinical models and healthy volunteers. **Methods:** This phase 2 single center study evaluates HSC mobilization with MGTA-145 + plerixafor and same day apheresis in patients with multiple myeloma. Patients received plerixafor 0.24 mg/kg (0.16 mg/kg if renal dysfunction) SQ, followed 2 hours later by MGTA-145 (0.03 mg/kg) IV over 3-10 minutes and apheresis within 30 minutes. Mobilization was repeated for a second day if day 1 yield was < 6 x 10^6 CD34+ cells/kg. This interim analysis reports on mobilization in 10 patients (of 25 planned), including safety cohort of first 6 patients completing transplant. Primary endpoint is collection of 2 x 10^6 CD34+ cells/kg. **Results:** Median age was 63 years (range: 46-68), 50% were female, 22% had ISS stage 3 & 50% had high-risk FISH. Induction therapy was VRD in 7 and daratumumab + VRD in 3 patients; median induction duration: 4 months (3-6) & median lenalidomide exposure: 6 cycles (4-6), with > VGPR in 70%. Median total stem cell yield (CD34+ cells/kg x 10^6) was 7.1 (3-16.2), day 1 yield was 5.4 (1.1-16.2) & yield per apheresis session was 4 (1.1-16.2). 100% of patients met the primary endpoint of collecting sufficient HSCs in < 2 days of mobilization + apheresis to proceed to transplant (2 x 10^6 CD34+ cells/kg). Secondary endpoints of 4 and 6 x 10^6 CD34+ cells/kg in < 2 days were met in 90% & 80% patients. 30% patients underwent 1 apheresis, while 70% underwent 2 sessions. MGTA-145 was well tolerated. At least 1 adverse event (AE) was seen in 90% of patients, 20% had grade 2 AEs (anemia, hypokalemia) and 20% had grade 3 AEs (worsening of baseline grade 3 anemia; hypocalcemia); all resolved. Acute & transient bone pain was seen in 40% of patients (back-2, hip-1, sternum-1), all grade 1, all on day 1, & resolved without intervention after 6 minutes (3-10). All 6 patients in the safety cohort have completed transplant with melphalan 200 mg/m^2. Median of 4.1 (3.4-5.6) x 10^6 CD34+ cells/kg were infused. All patients have engrafted timely (DiPersio Blood 2009); median time to neutrophil engraftment: 12 days (11-13) & platelet engraftment: 17 days (16-19). Apheresis graft analysis is available in these 6 patients. Grafts with MGTA-145+plerixafor showed high enrichment for CD90+CD45RA- among CD34+ cells, a CD34 subset of long term engrafting HSCs (median: 31% of CD34+ cells, 27-52), higher than seen with G-CSF (6%, Goncalves TCT 2021). 67% of grafts were minimal residual disease negative with next generation flow cytometry. **Conclusions:** This is the first study to evaluate the novel regimen of MGTA-145 + plerixafor for same day stem cell mobilization & collection in myeloma/hematologic malignancies, with 100% efficacy in interim analysis and the first to demonstrate successful engraftment in patients with cells collected with this GCSF free regimen. Clinical trial information: NCT04552743. Research Sponsor: Magenta Therapeutics , U.S. National Institutes of Health, PI (Sidana) has a KL2 grant from NIH, although study per se was not sponsored via NIH funds.

8024 **Poster Session**

Effects of refractory status to lenalidomide on safety and efficacy of selinexor, bortezomib, and dexamethasone (XVd) versus bortezomib and dexamethasone (Vd) in patients with previously treated multiple myeloma. *First Author: Xavier Leleu, Department of Hematology, CHU la Miletrie and Inserm CIC 1402, Poitiers, France*

Background: Lenalidomide (LEN) is typically a frontline therapy for newly diagnosed MM. Patients (pts) with MM refractory to LEN are less likely to repond to other IMiDs and represent a signification area of unmet medical need. In the BOSTON study in the ITT population, XVd was associated with significant improvements in median progression-free survival (PFS), overall response rate (ORR), and rates of peripheral neuropathy, with trends in overall survival (OS) favoring XVd. **Methods:** The BOSTON trial (NCT03110562) is a Phase 3 randomized, controlled, open-label study of once weekly XVd vs twice weekly Vd in pts with MM and 1-3 prior therapies. We performed post-hoc analyses on two different subgroups to compare outcomes based on refractory status to LEN and immunomodulatory drug (IMiD) therapy. These post hoc analyses evaluated if PFS, overall response rate (ORR), time to next treatment (TTNT) and safety was influenced by prior treatment with LEN when comparing XVd with Vd. **Results:** Amongst the 402 pts in BOSTON, 160 had MM refractory to any IMiD (XVd = 74, Vd = 86). Of those, 106 were documented to be refractory to LEN (XVd = 53, Vd = 53) and 296 were not refractory to LEN (XVd = 142, Vd = 154). Baseline characteristics were generally well balanced between subgroups. In these subgroups based on refractory status to IMiD or LEN, median PFS was significantly longer in the XVd arm as compared to Vd (IMiD refractory, 13.9 vs. 8.4 months (mo), p = 0.005; LEN refractory, 10.2 vs. 7.1 mo, p = 0.012; not LEN refractory, 15.4 vs 9.6 mo, p = 0.014). Significant increases in TTNT were observed with XVd treatment in pts that were IMiD refractory (14.8 vs. 10.2 mo, p = 0.003), LEN refractory (13.0 vs. 7.6 mo, p = 0.015), and not refractory to LEN (19.1 vs 12.9 mo, p = 0.005). ORR was improved with XVd compared to Vd regardless of refractory status (IMiD refractory, 68.9% vs 55.8%, p = 0.045; LEN refractory, 67.9% vs. 47.2%, p = 0.016; and not refractory to LEN, 79.6% vs 67.5%, p = 0.010). The most common treatment-emergent AEs for the XVd/Vd arms for all subgroups were thrombocytopenia (66.2/30.6%; 71.7/40.4%; 55.6/22.4%), nausea (48.6/11.8%; 50.9/11.5%; 50.0/9.2%), and fatigue (40.5/20.0%; 45.3/21.2%; 40.8/17.1%) for IMiD, LEN, and not LEN refractory, respectively. Incidence of PN AEs of any grade were reduced compared to pts treated with Vd (IMiD refractory, 27% vs. 42.4%; LEN refractory, 30.2% vs 36.5%; not refractory, LEN 33.1% vs 50.7%). **Conclusions:** In pts with previously treated MM, PFS, ORR, and TTNT were significantly improved regardless of documented refractory status to any IMiD or to LEN-specifically. These analyses support the use of the XVd combination for pts with disease refractory to LEN and likely to any IMiD. Clinical trial information: NCT03110562. Research Sponsor: None.

8025 **Poster Session**

The clinical study of anti-BCMA CAR-T with single-domain antibody as antigen binding domain. *First Author: Lu Han, Department of Immunology, Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, China*

Background: Relapsed/refractory (RR) multiple myeloma (MM), RRMM, remains as an incurable disease and has a 5-year survival rate of nearly 50%. To address the unmet medical need, an autologous CAR-T cell therapy was developed previously with a humanized single-domain antibody (sdAb) targeting BCMA as the antigen binding domain, 4-1BB and CD3ζ as cytoplasmic domain. **Methods:** An investigator-initiated clinical trial (IIT) was conducted in China to assess the safety and efficacy of the sdAb-based CAR-T. The trail was started in June 2018 and the last patient infused in June 2019. As of 1 February 2021, 34 were treated and followed up. The patients had received multiple lines of prior treatment (including bortezomib, lenalidomide, and others). Following a lymphodepleting regimen of cyclophosphamide (300-600 mg/m^2, d-5, -4) and fludarabine (25-30 mg/m^2, d-5 to d-3), patients were infused with 2.5-10.0 $\times$ 10^6 CAR$^+$ cells/kg body weight. CAR-T was infused immediately after preparation and quality control performed in all patients except one, who was infused a 10.0 $\times$ 10^6 CAR$^+$ cells/kg dose of frozen cells. Efficacy was assessed based on the IMWG criteria, toxicity was graded by CTCAE 4.02, and CRS grading was based on the grading system by CARTOX working group. **Results:** All 34 patients had the tumor burden of plasma cells in bone marrow, or M protein or free light chains (FLCs) in serum, 7 patients were accompanied with extramedullary diseases. The efficacy shows the best ORR is 88.2% (30/34), sCR rate is 55.9% (19/34). The mPFS was 12.1 months, several patients shows continuous sCR after 2 years. No obvious correlation between efficacy and dosage were found in three dose groups of 2.5$\times$10^6 CAR$^+$ cells/kg (6 pts), 5.0$\times$10^6 CAR$^+$ cells/kg (23 pts) or 10.0$\times$10^6 CAR$^+$ cells/kg (5 pts). The observed adverse events include thrombocytopenia (≥grade 3, 38.2%), neutropenia (≥grade 3, 44.1%), leukopenia (≥grade 3, 32.4%), lymphopeniPa (≥grade 3, 26.5%), and anemia (≥grade 3, 20.6%). CRS was monitored occurring in 29 patients (any grade, 85.3%, ≥grade 3, 2.9%). **Conclusions:** Our result demonstrates that the CART employing one humanized sdAb targeting BCMA is safe and efficacious for clinical application. The phase I clinical trial has been initiated in China for searching the RP2D using the cryopreserved CAR-T cells. Clinical trial information: NCT03661554. Research Sponsor: Henan Medical Science and Technology Foundation (grant number 2018020484; SBGJ2018085); Henan Provincial Scientific and Technological Project (grant number 162300410095).

8026 **Poster Session**

Isatuximab plus carfilzomib and dexamethasone versus carfilzomib and dexamethasone in elderly patients with relapsed multiple myeloma: IKEMA subgroup analysis. *First Author: Thierry Facon, Department of Haematology, Lille University Hospital, Lille, France*

Background: A prespecified interim efficacy analysis of the Phase 3 IKEMA study (NCT03275285) demonstrated that isatuximab (Isa) plus carfilzomib (K) and dexamethasone (d) (Isa-Kd) significantly improved progression-free survival (PFS) compared with Kd in patients (pts) with relapsed multiple myeloma (RMM) (HR 0.531; 99% CI, 0.318–0.889; *P*=0.0007), with a clinically meaningful increase in minimal residual disease negativity (MRD-) (29.6% vs 13.0%) and complete response (CR) (39.7% vs 27.6%) rates, and a manageable safety profile. This subgroup analysis of IKEMA examined efficacy and safety in pts aged <70 and ≥70 years. **Methods:** Pts with 1–3 prior lines of therapy were randomized 3:2 to receive Isa-Kd (n=179) or Kd (n=123). The primary end point was PFS, as assessed by an independent response committee. We compared outcomes in pts <70 vs ≥70 years; division into different or additional age groups resulted in smaller sample sizes. **Results:** Of the 302 randomized pts, 71.5% were aged <70 years (Isa-Kd: 70.9%; Kd: 72.4%) and 28.5% were aged ≥70 years (Isa-Kd: 29.1%; Kd: 27.6%). Consistent with the significant improvement of PFS in the overall population, the addition of Isa to Kd resulted in improved PFS independently of age (Table). The CR, ≥very good partial response (VGPR), and MRD- rates were higher with Isa-Kd vs Kd. Within the Isa-Kd arm, CR rate and ≥VGPR rate were similar in elderly and younger pts. MRD- was observed in 32.3% of younger pts and 23.1% of elderly pts with Isa-Kd. In both arms, Grade ≥3 and serious treatment-emergent adverse events (TEAEs) were more frequently reported in elderly pts vs pts <70 years old (Table). For both age groups, the incidence of Grade ≥3 TEAEs was higher whereas the incidence of serious TEAEs was similar between Isa-Kd and Kd. In the elderly subgroup, 3 (5.9%) pts receiving Isa-Kd and 1 (2.9%) receiving Kd had fatal TEAEs (Isa-Kd, infection; Kd, general health deterioration due to progressive disease). The most common Grade ≥3 TEAEs in pts aged <70 and ≥70 years treated with Isa-Kd vs Kd were hypertension (18.3% vs 17.0% [<70 years] and 25.5% vs 26.5% [≥70 years]) and pneumonia (14.3% vs 9.1% [<70 years] and 21.6% vs 20.6% [≥70 years]). **Conclusions:** The addition of Isa to Kd improved PFS and quality of response in elderly pts, with a manageable safety profile, consistent with the benefit observed in the overall IKEMA study population. Isa-Kd provides a potential new treatment option for elderly pts with RMM. Funding: Sanofi. Clinical trial information: NCT03275285. Research Sponsor: Sanofi.

8027 **Poster Session**

Effects of weekly selinexor, bortezomib, dexamethasone (XVd) versus standard twice weekly bortezomib and dexamethasone (Vd) on *RAS*-mutated previously treated multiple myeloma (MM). *First Author: Christopher James Walker, Karyopharm Therapeutics Inc, Newton, MA*

Background: Activating mutations of the RAS genes *NRAS*, *KRAS*, and *HRAS* (*RAS*^{mut}) occur in up to 50% of MM and portend poor survival and high recurrence rates. MM cells with *RAS*^{mut} are susceptible to inhibition of germinal center kinase (GCK), resulting in IKAROS degradation independent of cereblon (CRBN). Selinexor is a selective inhibitor of nuclear export (SINE) compound that can induce IKAROS degradation through CRBN-independent pathways to overcome immunomodulatory drug resistance. We explored the benefit of selinexor treatment for pts with *RAS*^{mut} MM. **Methods:** In the randomized BOSTON study, pts with MM after 1-3 therapies received weekly XVd or twice weekly Vd. In the single-arm STORM study pts with penta-treated, triple class refractory MM were treated with twice weekly Xd. Both treatment regimens are now FDA approved. Mutations were assessed post-hoc by exome sequencing of 119 and 52 pts from BOSTON and STORM, respectively. Pts were considered *RAS*^{mut} if their MM had *NRAS*, *KRAS* or *HRAS* mutations in codons 12, 13 or 61. **Results:** There were 54 pts (45%) with *RAS*^{mut} in BOSTON (XVd = 26, Vd = 28), and 17 (33%) in STORM. In BOSTON, pts with *RAS*^{mut} MM treated with XVd had significantly longer progression-free survival (PFS) than those treated with Vd (median [med] = 12.9 vs 6.7 months [mo], hazard ratio [HR] = 0.48 [95% CI 0.24-0.97], p = 0.039). For pts treated with Vd, those with *RAS*^{mut} had significantly shorter overall survival (OS) compared to *RAS*$^{wild\text{-}type\ (WT)}$ (med = 16.8 mo vs not reached [NR], HR = 2.87 [95% CI 1.03-7.99], p = 0.035). PFS was not significantly different (med = 6.74 vs 9.82 mo, HR = 1.64 [95% CI 0.88-3.07], p = 0.122). Amongst pts on XVd, there was no difference in survival between *RAS*^{mut} and *RAS*^{WT} pts (PFS: med = 12.8 vs 12.9 mo, HR = 1.08 [95% CI 0.52-2.26], p = 0.83; OS: med = NR vs NR, HR = 0.94 [95% CI 0.36-2.45], p = 0.91). In STORM, pts with *RAS*^{mut} had shorter OS compared to *RAS*^{wt} pts (med = 6.1 vs NR, HR = 2.05 [95% CI 1.22-5.19], p = 0.010). Preliminary studies to explore the mechanisms of action related to *RAS*^{mut} MM sensitivity to XVd demonstrated that selinexor treatment in vitro leads to downregulation of GCK. **Conclusions:** Despite typically having the worst outcomes, pts with *RAS*^{mut} MM had a similar benefit from XVd as *RAS*^{WT} MM, showing that the XVd combination can overcome *RAS*^{mut}. Mechanistically, selinexor induced down regulation of GCK and enhanced killing of *RAS*^{mut} MM cells. With a manageable safety profile, the XVd regimen could provide a viable treatment option to improve survival of pts with MM with RAS mutations. Clinical trial information: NCT03110562. Research Sponsor: None.

Incidence, mitigation, and management of neurologic adverse events in patients with multiple myeloma (MM) treated with ciltacabtagene autoleucel (cilta-cel) in CARTITUDE-2. *First Author: Hermann Einsele, Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany*

Background: Cilta-cel (JNJ-68284528) is a chimeric antigen receptor T (CAR-T)-cell therapy with 2 BCMA-targeting, single-domain antibodies designed to confer high avidity binding. CARTITUDE-2 (NCT04133636) is a phase 2, multicohort, open-label study assessing the efficacy and safety of cilta-cel in patients (pts) with MM in various clinical settings. Here, we describe the mitigation and management strategies implemented to identify and reduce the risk for neurologic adverse events (AEs) in Cohort A pts (progressive MM after 1−3 prior lines of therapy). **Methods:** Eligible pts (≥18 years of age) had MM per IMWG criteria, measurable disease, ECOG ≤1, progressive disease after 1−3 prior lines of therapy (including a PI and IMiD) and were lenalidomide refractory (no prior BCMA-targeting agent). Cilta-cel (0.75×10^6 [range $0.5–1.0\times10^6$] CAR+ viable T cells/kg) was given as a single infusion 5–7 days after start of lymphodepletion (cyclophosphamide 300 mg/m^2 + fludarabine 30 mg/m^2 daily for 3 days). Monitoring and mitigation strategies for neurologic AEs include providing more effective bridging therapy to reduce tumor burden prior to lymphodepletion, frequent assessment of CAR-T-related ICANS using the ICE tool, regular handwriting assessments to detect micrographia, and neuroimaging (brain MRI) and EEG for pts with prior neurologic disease. Management strategies include evaluating infectious and paraneoplastic etiologies upon observation of ICANS ≥Grade (gr) 1, administration of tocilizumab (if concurrent CRS, all gr of ICANS) and/or dexamethasone (gr 2/3) or methylprednisolone (gr 4). ICANS and CRS were graded by ASTCT criteria; neurotoxicities not classified as ICANS were graded per CTCAE Version 5.0. **Results:** As of 15 Jan 2021 (median follow-up: 5.8 months [range: 2.5–9.8 months]), 20 pts in Cohort A received cilta-cel. Median age was 60 years (range: 38–75); 65% were male. Neurotoxicities occurred in 4 pts (20%). Three pts had ICANS (gr 1/2); median time to onset of symptoms was 8 days (range: 7–11) and median duration was 2 days (range: 1–2). Two of the 3 pts received supportive measures to treat ICANS, including levetiracetam and steroids; all 3 had concurrent CRS and all recovered. One pt developed isolated facial paralysis (gr 2) on Day 29 after cilta-cel infusion, and recovered 51 days after the onset of event following treatment with dexamethasone for 28 days. No movement or neurocognitive disorders were reported. **Conclusions:** Neurologic AEs were generally manageable in pts with MM following treatment with cilta-cel. With a median of 5.8 months of follow-up, there were no movement or neurocognitive disorders in pts from Cohort A. These results suggest that early detection and management of neurologic AEs can lead to better treatment outcomes. Clinical trial information: NCT04133636. Personalized, ctDNA analysis to detect minimal residual disease and identify patients at high risk of relapse with multiple myeloma. *First Author: Binod Dhakal, Medical College of Wisconsin, Milwaukee, WI*

Background: Despite treatment with high-dose chemotherapy followed by autologous stem cell transplantation (AHCT), MM patients invariably relapse. MRD-negativity post-AHCT has emerged as the most important prognostic marker. Currently, MRD in MM is monitored via bone marrow aspirate sampling. Marrow MRD assays are limited by the spatial heterogeneity of marrow MM localization; extramedullary disease and sampling variability of marrow aspiration. Sensitive, non-invasive blood-based MRD assay is an unmet need. ctDNA as a noninvasive biomarker can be utilized to predict relapse in MM. Here we attempt to evaluate MRD using ctDNA in AHCT recipients with MM. **Methods:** In this retrospective, single-center study, we analyzed ctDNA MRD in blood samples collected from 28 patients with MM after upfront AHCT. A total of 80 plasma timepoints were available pre and post AHCT with a median follow-up of 92.4 months. Multiparameter flow cytometry (MFC) at 10-4 level was used to assess the MRD from the BM biopsy. Individual bone marrow aspirates or FFPE slides from the time of MM diagnosis and matched normal blood were whole-exome sequenced, and somatic mutations were identified. MRD assessment at 3 months post-AHCT was performed by ctDNA analysis using a personalized, tumor-informed (Signatera^{TM}, bespoke mPCR NGS assay). The prognostic value of ctDNA was evaluated by correlating MRD status with clinical outcomes. **Results:** Table provides the baseline disease characteristics. Median age was 67 [41-75] years and 16 [57.1%] were males. ctDNA was detectable in 70.8% (17/24) of pre-AHCT, 53.6% (15/28) of ~3 months post-AHCT, and 39.2% (11/28) of patients during the surveillance phase post-AHCT. Of the 15 ctDNA MRD positive patients, 93.3% (n=14) experienced relapse on follow-up (hazard ratio: 5.64; 95% CI: 1.8-17; p=0.0003). Patients negative for ctDNA at 3 months post-AHCT had significantly superior progression-free survival (PFS) compared to positive (median PFS, 84 months vs. 31 months; p=0.003) The positive predictive value (PPV) for relapse among patients positive for ctDNA at 3 months post-AHCT was 93.3%, and significantly higher than marrow MFC of 68.4%. **Conclusions:** Our study shows the feasibility that a tumor-informed assay on archival blood samples is predictive of relapse post-AHCT. Future prospective studies with real-time marrow NGS and ctDNA samples are needed to define the role of ctDNA in MM and its prognostic significance. Research Sponsor: None.

Cilta-cel versus conventional treatment in patients with relapse/refractory multiple myeloma. *First Author: Luciano J. Costa, University of Alabama at Birmingham, Birmingham, AL*

Background: CARTITUDE-1 is a single arm study of Ciltacabtagene autoleucel (cilta-cel; JNJ-68284528) anti-BCMA CAR-T cell therapy in US patients (pts) with relapsed multiple myeloma (RRMM) refractory to both IMiD and proteasome inhibitor (PI) or with at least 3 prior lines of therapy and previously exposed to anti-CD38 monoclonal antibody (MoAb). While recently reported efficacy results of cilta-cel were encouraging, it is unknown how they compare with similar pts receiving conventional (non CAR-T) treatment. **Methods:** We utilized a contemporary US-based dataset of pts with MM refractory to anti-CD38 MoAb (MAMMOTH) to identify pts who would meet eligibility for CARTITUDE-1 and who received conventional therapy. We analyzed the intent-to-treat population (ITT) in CARTITUDE-1, defined as pts who underwent apheresis (N=113) and a modified ITT population (mITT) defined as subset of pts who received cilta-cel at the RP2D (N=97). From the MAMMOTH dataset, we identified a population corresponding to CARTITUDE-1 ITT (N=190) and a mITT population, pts without death or progression within 47 days (median time between apheresis and cilta-cel infusion) from onset of therapy (N=122). We calculated propensity scores (PS) with demographics, N of prior therapies, cytogenetics and refractoriness to MM agents as covariates. An analyst blinded to outcomes performed nearest neighbor 1:1 PS matching. We analyzed overall response rate (ORR), progression-free (PFS) and overall survival (OS) for ITT and mITT in CARTITUDE-1 vs matching MAMMOTH cohorts. **Results:** Ninety-five ITT (75 received bridging therapy, 82 received cilta-cel) and 69 mITT (54 received bridging) CARTITUDE-1 pts matched MAMMOTH pts (Table). Among the pts in the MAMMOTH ITT cohort 34% received pomalidomide, 24% anti-CD38 MoAb, 19% carfilzomib and 35% cytotoxic chemotherapy in next therapy. ORR in the ITT cohorts was higher in CARTITUDE-1 (84% vs. 28%). Compared to their MAMMOTH counterparts, pts in CARTITUDE-1 ITT cohort had improved PFS (12 mo. 73% vs. 12%) and OS (12 mo. 83% vs 39%). Between the mITT cohorts, CARTITUDE-1 pts had superior ORR (96% vs. 30%), PFS (12 mo 79% vs. 15%) and OS (12 mo. 88% vs. 41%). **Conclusions:** In pts with RRMM beyond therapy with IMID, PI, and anti-CD38 MoAb, treatment with cilta-cel is associated with higher response rate and superior PFS and OS when compared to conventional treatment. Assessing financial difficulty in patients with multiple myeloma: Preliminary results of ALLIANCE A231602CD. *First Author: Rena M. Conti, Boston University Questrom School of Business, Boston, MA*

Background: New orally administered anticancer treatments have launched in recent years, promising gains in survival and quality of life, but with high prices.Financial difficulties encountered over the course of cancer diagnosis and treatment is a growing concern. These difficulties include inability to pay for basic necessities, presence of medical debt, and high out of pocket burdens relative to income. The primary objective of this study was to estimate the proportion of patients with multiple myeloma (MM) who experience financial difficulties in the past 12 months.**Methods:** Data collection entailed a comprehensive, theoretically grounded telephone survey and companion medical chart abstraction. Subjects included individuals with a current diagnosis of MM whose current or recent treatment included pharmaceutical-based care and who were not enrolled in a treatment-based trial. Practices eligible to recruit respondents included 44 NCORP affiliates of the Alliance. 14 geographically diverse NCORP affiliates participated between 11/2019 and 6/2020. The primary endpoint of the study was the proportion of subjects who reported financial difficulty in the past 12 months, as measured by the EORTC QLQ-C30 item #28. This proportion and 95% Wilson score confidence interval were estimated for all MM patients who responded to the financial difficulty question ((# reported financial difficulty)/(total # in that category who answered the question)). NCI Central IRB approved this study. **Results:** 393 subjects were recruited. 304 subjects completed the survey (77.4% response rate). Mean age was 67.5 years (SD 9.8), 143 (46.4%) were female, 24 (7.8%) self-reported race as 'Black or African American', 82 (26.6%) reported insured by government insurance Medicare only, 116 (38.2%) reported highest education as high school or below, and 94 (30.5%) reported high income. Mean time from diagnosis to survey enrollment was 3.6 years (SD 4.5). 292 (95.1%) were currently receiving treatment and 192 (62.5%) reported currently receiving a pre-defined 'expensive' oral pharmaceutical-based cancer treatment. 20.2% (95% CI:16.1%, 25.0%) reported financial difficulties. **Conclusions:** This is the first national study to systematically assess the prevalence of financial difficulties and its correlates among MM patients. Approximately 1 in 5 surveyed patients reported financial difficulties. Results of this study aim to inform efforts to improve financial navigation and resources for cancer patients. Research Sponsor: U.S. National Institutes of Health, Leukemia and Lymphoma Society.

5-Hydroxymethylcytosines in circulating cell-free DNA and overall survival in patients with multiple myeloma. *First Author: Brian C Chiu, Department of Public Health Sciences, The University of Chicago, Chicago, IL*

Background: The epigenetic mark 5-methylcytosines (5mC) have been associated with poor prognosis and survival in multiple myeloma (MM), but the prognostic role of 5-hydroxymethylcytosines (5hmC) as marks of tissue-specific enhancers generated from 5mC through active demethylation is unknown. We showed that 5hmC can be profiled in circulating cell-free DNA (cfDNA) and is associated with relapse/death in another lymphoproliferative disorder diffuse large B-cell lymphoma. To date, no study has investigated genome-wide 5hmC profiles in cfDNA for its prognostic significance in MM. **Methods:** A total of 354 newly diagnosed MM patients at the University of Chicago Medical Center were prospectively enrolled between 2010-2017. Blood samples were collected at the time of diagnosis. Patients were followed through 31 December 2020 (avg. follow-up = 77.8 mths). We collected baseline clinical, laboratory, and cytogenetic data from electronic medical records. Vital status was ascertained in 351 of the 354 patients (deaths = 73) using the National Death Index. We profiled genome-wide 5hmC in cfDNA using the 5hmC-Seal and next-generation sequencing. The 5hmC-Seal data were mapped to the human genome reference (hg19) and annotated to gene bodies. Overall survival (OS) was defined as time from diagnosis until death from any cause. We used Cox proportional hazards model and the elastic net regularization to identify genes with modified 5hmC levels that are associated with OS. Patients were randomly divided into a training set (n = 264) and testing set (n = 87). **Results:** The median age at diagnosis was 61.8 years and 47% (n = 165) were males. We used the differential 5hmC enrichment levels of a preliminary four-gene marker panel (i.e., *YPEL1*, *VIPR2*, *PLAC8L1*, and *CYP2D6*) to compute a weighted prognostic score (wp-score). In the training set (deaths = 55), MM patients with high wp-score had worse OS (Hazard Ratio [HR] = 2.2, 95% Confidence Interval [CI]: 1.3-3.9; p = 0.004). The same trend was observed in the testing set (deaths = 18) (HR = 3.5, 95% CI: 1.1-10.6; p = 0.02). The 5hmC-based wp-score remained significantly associated with OS after controlling for standard prognostic factors, suggesting that 5hmC-based wp-score for this 4-gene panel is an independent prognostic factor for MM. We also explored population-specific 5hmC and wp-score. We found that 5hmC profiles in cfDNA differ between Blacks (n = 117) and Whites (n = 234). In addition, 5hmC marker genes associated with OS differ between Blacks (13 genes) and Whites (20 genes). **Conclusions:** Our results suggest that 5hmC in cfDNA at the time of diagnosis correlate with OS in MM and the 5hmC marker genes associated with OS differ between Blacks and Whites. These findings suggest that a plasma-derived cfDNA 5hmC-modified gene panel holds promise as a noninvasive approach for predicting prognosis in MM and may be integrated in clinical practice to improve precision care. Research Sponsor: U.S. National Institutes of Health.

Relationship between corneal exam findings, best-corrected visual acuity (BCVA), and ocular symptoms in patients with relapsed or refractory multiple myeloma (RRMM) receiving belantamab mafodotin (belamaf). *First Author: Evangelos Terpos, National and Kapodistrian University of Athens School of Medicine, Athens, Greece*

Background: Belantamab mafodotin (GSK2857916; belamaf; BLENREP) is a B-cell maturation antigen (BCMA)-targeting antibody–drug conjugate approved in the US and EU as a monotherapy for the treatment of adult patients with RRMM. Ocular events (OEs) during the pivotal DREAMM-2 trial (NCT03525678) included corneal exam findings (punctate keratopathy and microcyst-like epithelial changes), BCVA changes, and ocular symptoms. Dose reductions or delays based on corneal exam findings and BCVA were used to manage OEs. Here we performed a *post hoc* investigation of relationships between corneal exam findings, BCVA changes, and patient-reported ocular symptoms to explore if BCVA changes and symptoms could guide dosing, rather than corneal exams. **Methods:** Eye evaluations (including a corneal exam and BCVA assessment of Snellen visual acuity) were performed on all patients receiving single-agent belamaf (2.5 mg/kg) by ophthalmologists at baseline and prior to each belamaf dose. Changes in the corneal epithelium (Ker) and BCVA were both assessed as per protocol-defined criteria and assessment of grade (Gr) was based on the worse eye. BCVA grading was relative to baseline. Patient-reported ocular symptoms were reported as per the Common Terminology Criteria for Adverse Events. **Results:** In 12.5% of eye evaluations Gr 3–4 Ker was associated with minimal or no (Gr ≤1) BCVA changes. When patient-reported ocular symptoms were also considered, only 7.5% of evaluations found Gr 3–4 Ker with Gr ≤1 BCVA changes or ocular symptoms. Mild or no (Gr ≤2) Ker was associated with Gr ≤1 BCVA changes in 59.5% of evaluations, or in 38.8% of evaluations with no ocular symptoms reported. Overall, Gr 3–4 Ker were found in 24.9% of evaluations; by contrast, patients had Gr 2–4 BCVA changes or ocular symptoms in 53.7% of evaluations. Association of corneal epithelium changes (Ker) with BCVA changes and ocular symptoms. **Conclusions:** These findings highlight that BCVA changes and ocular symptoms should be further investigated to determine if they can be used as alternatives (eg, frequency of eye examinations based on symptoms) for the management of belamaf dosing to potentially reduce the burden on patients and healthcare professionals. Clinical trial information: NCT03525678. Research Sponsor: GlaxoSmithKline, Drug linker technology licensed from Seagen Inc.; mAb produced using POTELLIGENT Technology licensed from BioWa.

Isatuximab plus carfilzomib and dexamethasone in patients with relapsed multiple myeloma according to prior lines of treatment and refractory status: IKEMA subgroup analysis. *First Author: Roman Hajek, Department of Hemato-Oncology, University Hospital Ostrava and University of Ostrava, Ostrava, Czech Republic*

Background: Patients (pts) with multiple myeloma (MM) often relapse and become refractory to successive lines of therapy, warranting better treatment options. The Phase 3 IKEMA study (NCT03275285) demonstrated that isatuximab (Isa) plus carfilzomib and dexamethasone (Kd) significantly improved progression-free survival (PFS) compared with Kd in pts with relapsed MM (RMM) (HR 0.53; 99% CI 0.32–0.89; *P*= 0.0007). We evaluated the efficacy and/or safety of Isa-Kd by number of prior lines of therapy (1 vs > 1) and refractoriness to lenalidomide (Len) or bortezomib (Bor). **Methods:** Pts were randomized (3:2) to Isa-Kd (n = 179) or Kd (n = 123). Isa (10 mg/kg IV) was given weekly for 4 weeks, then every 2 weeks. K (20 mg/m^2 days 1-2, then 56 mg/m^2) was given twice-weekly 3 of 4 weeks, and d (20 mg) twice-weekly. The primary endpoint was PFS; key secondary endpoints were very good partial response or better (≥VGPR), minimal residual disease negativity (MRD-), and complete response (CR) rates. **Results:** Of the 302 randomized pts, 44.7% had 1 prior line, 55.3% had > 1 prior line, 32.8% were Len-refractory, and 30.1% were Bor-refractory. PFS was improved with Isa-Kd vs Kd in pts who received 1 prior line and > 1 prior line, as well as in pts refractory to Len, Len at last regimen, Bor, or Bor at last regimen (Table). The addition of Isa to Kd improved depth of response (≥VGPR, MRD-, and CR rates) in all subpopulations analyzed by prior treatment. Grade ≥3 treatment-emergent adverse events (TEAEs) were generally similar between the prior line subgroups (77.2% [Isa-Kd] vs 64.8% [Kd], 1 prior line; 76.5% [Isa-Kd] vs 69.1% [Kd], > 1 prior line) and the overall safety population (76.8% [Isa-Kd] vs 67.2% [Kd]). Serious AEs were 62.0% vs 48.1% in the 1 prior line subgroup, and 57.1% vs 64.7% in the > 1 prior line subgroup; TEAEs leading to discontinuations were 8.9% vs 11.1%, 1 prior line and 8.2% vs 16.2%, > 1 prior line. **Conclusions:** The addition of Isa to Kd improved PFS and depth of response, irrespective of prior lines of therapy or refractory status, consistent with the benefit observed in the overall IKEMA study population. Isa-Kd had a manageable safety profile regardless of number of prior lines. Isa-Kd is a potential new treatment option for pretreated pts with RMM. Clinical trial information: NCT03275285. Research Sponsor: Sanofi.

Daratumumab (DARA) maintenance therapy following DARA + cyclophosphamide, bortezomib, and dexamethasone (CyBorD) induction therapy in multiple myeloma (MM): End-of-study analysis of LYRA. *First Author: Robert M. Rifkin, US Oncology Research, Rocky Mountain Cancer Centers, Denver, CO*

Background: LYRA is a community practice-based, phase 2, single-arm study (NCT02951819) evaluating DARA + CyBorD as an immunomodulatory drug-sparing regimen in MM. The primary analysis demonstrated the safety and efficacy of DARA + CyBorD in newly diagnosed MM (NDMM) and relapsed MM (RMM), and an update showed that DARA maintenance therapy deepened responses. We present the final end-of-study analysis of LYRA. **Methods:** US pts aged ≥18 years with MM per IMWG criteria and ≤1 prior line of therapy received 4-8 induction cycles of DARA + CyBorD (cyclophosphamide 300 mg/m^2 PO weekly [QW]; bortezomib 1.5 mg/m^2 SC on Days [D] 1, 8, and 15; dexamethasone 40 mg PO or IV QW every 28 days; DARA IV 8 mg/kg on D1 and D2 of cycle [C]1, 16 mg/kg QW C1D8-C2, 16 mg/kg Q2W C3-6, and 16 mg/kg Q4W C7-8). After induction, eligible pts could receive autologous stem cell transplantation (ASCT). Pts received up to 12 maintenance cycles with DARA 16 mg/kg IV Q4W and were followed for up to 36 months after induction. **Results:** In total, 101 (NDMM, n = 87; RMM, n = 14) pts were enrolled; 36% of pts had high-risk cytogenetics. NDMM and RMM pts received a median of 6 and 8 induction cycles, respectively. Among NDMM pts, 44.8% (39/87) underwent ASCT and 72.4% (63/87) completed 12 months of maintenance. Rates of ≥VGPR and ≥CR were 82.1% and 48.7% in NDMM pts who underwent ASCT, and 70.2% and 29.8% in NDMM pts who did not (Table). With a median follow-up of 35.7 months, median progression-free survival (PFS) and overall survival (OS) were not reached for NDMM pts. Estimated 36-month PFS rates were 69.3% and 72.6% for NDMM pts who did and did not receive ASCT, respectively; estimated 36-month OS rates were 94.9% and 84.3% (Table). Among RMM pts, 7.1% (1/14) underwent ASCT and 50.0% (7/14) completed 12 months of maintenance; efficacy outcomes are shown in the Table. Grade 3/4 treatment-emergent adverse events (TEAEs) occurred in 62.0% of all pts, with the most common (≥10%) being neutropenia (14.0%). Serious TEAEs occurred in 33.0% of pts, the most common being pneumonia (4.0%) and pulmonary embolism (3.0%). TEAEs led to death in 2.0% of pts, all unrelated to study treatment. Infusion-related reactions occurred in 56.0% of pts; the majority were mild (4.0% of pts had grade 3/4 events). **Conclusions:** DARA used for induction with CyBorD and maintenance as monotherapy resulted in durable, deep responses in pts with NDMM or RMM, with a 3-year PFS rate of 70% in NDMM irrespective of ASCT status. With longer follow-up, no new safety concerns were identified. Clinical trial information: NCT02951819. Research Sponsor: Janssen Research & Development, LLC.

Characteristics of neurotoxicity associated with idecabtagene vicleucel (ide-cel, bb2121) in patients with relapsed and refractory multiple myeloma (RRMM) in the pivotal phase II KarMMa study. *First Author: Salomon Manier, Centre Hospitalier Regional Universitaire de Lille, Lille, France*

Background: Ide-cel, a BCMA-directed CAR T cell therapy, showed promising efficacy in patients (pts) with RRMM in the KarMMa study with an ORR of 73% and a CRR of 33% across target doses of 150–450 $\times$ 10^6 CAR+ T cells (Munshi NC, et al. *J Clin Oncol* 2020;38[suppl 15]. Abstract 8503). Associations of neurotoxicity (NT) with pt and disease characteristics, pt management, and impact on outcomes in the KarMMa study are reported here. **Methods:** Enrolled pts were triple-class exposed and refractory to their last regimen, with ide-cel given at target doses of 150, 300, or 450 $\times$ 10^6 CAR+ T cells after lymphodepletion (NCT03361748). Investigator-identified NT events were captured under the single preferred term of neurotoxicity and graded according to NCI CTCAE v4.03. Events were managed with corticosteroids (CS), anakinra (ANR), and tocilizumab (Toci) as needed. **Results:** Of 128 pts treated with ide-cel, NT was reported in 23 (18%); 12 pts (9%) had maximum grade (gr) 1 NT, 7 (5%) had gr 2, and 4 (3%) had gr 3. No gr 4 or 5 NT occurred. Most baseline characteristics were similar in pts with and without NT, including stage III disease (22% and 15%), high-risk cytogenetics (39% and 34%), and extramedullary disease (35% and 40%); exceptions were high tumor burden (65% and 48%) and sex (48% and 62% men). NT (any gr/gr 3) occurred in 0%/0%, 17%/1%, and 20%/6% of pts at doses of 150, 300, and 450 $\times$ 10^6 CAR+ T cells. Median time to onset was similar regardless of gr, and there were no late-onset events (Table). NT was managed with CS in 10 pts (43%), Toci in 3 (13%), and ANR in 1 (4%). Median (range) time to first use of CS was 2 d (1–6). ORR and DOR were similar in pts with and without NT (Table). All NT occurred in the proximity of cytokine release syndrome (CRS) events with the start date of NT events either overlapping with or occurring within 1 wk of the start of a CRS event. **Conclusions:** NT occurred early in the KarMMa study, was generally of short duration, and was mostly gr 1/2 with no gr ≥4 events. All NT was proximal to CRS. Pts with NT had a favorable ORR after ide-cel treatment. These results continue to demonstrate the durable efficacy and tolerability of ide-cel in pts with RRMM. Clinical trial information: NCT03361748. Research Sponsor: Celgene, a Bristol-Myers Squibb Company, and bluebird bio.

ANCHOR (OP-104): Melflufen plus dexamethasone (dex) and bortezomib (BTZ) in relapsed/refractory multiple myeloma (RRMM)—Optimal dose, updated efficacy and safety results. *First Author: Roman Hajek, Department of Hemato-oncology, University Hospital Ostrava, Ostrava, Czech Republic*

Background: Development of resistance to standard treatments for RRMM highlights the need for novel therapies. Melphalan flufenamide (melflufen) is a first-in-class peptide-drug conjugate (PDC) that leverages aminopeptidases and rapidly releases alkylating agents inside tumor cells. Melflufen + dex showed clinical activity and an acceptable safety profile in HORIZON (Richardson et al. *J Clin Oncol.* 2020 Dec 9 [Epub]). This is an update of the BTZ arm of the phase 1/2a ANCHOR study (NCT03481556). **Methods:** Patients (pts) with RRMM were intolerant or refractory to a prior IMiD, with 1-4 prior lines of therapy (LoTs). Prior treatment with a proteasome inhibitor (PI) was allowed, but pts could not be refractory to PIs in the last LoT. Melflufen (30, 40, or 20 mg intravenously; d 1 of each 28-d cycle) was administered with BTZ (1.3 mg/m^2 subcutaneous) + oral dex (20 mg on d 1, 4, 8, and 11 and 40 mg on d 15 and 22; dex dose reduced if aged ≥ 75 y). The primary objective in phase 1 was to determine the optimal phase 2 dose of melflufen for this combination. **Results:** As of the data cutoff date (October 19, 2020), 13 pts received melflufen (30 mg, n = 6; 40 mg, n = 7) + dex and BTZ. In the 30 mg and 40 mg cohorts, respectively, median age was 78.5 y (range, 70-82) and 70.0 y (range, 61-76); median prior LoTs was 3.5 (range, 2-4) and 2.0 (range, 1-4); 33% and 50% of evaluable pts had high-risk cytogenetics; 83% and 71% were refractory to last LoT; 100% and 86% received a prior PI; 33% and 14% were refractory to PIs. In the 30 mg and 40 mg cohorts, respectively, median treatment duration was 6.5 mo (range, 1.4-29.0) and 8.7 mo (range, 2.1-19.6); 4 (67%) and 4 pts (57%) were still on treatment; 2 and 3 pts discontinued (30 mg: progressive disease [PD] and other [1 pt each]; 40 mg: adverse event [AE], lack of efficacy, and PD [1 pt each]). Confirmed overall response rate in the 30 mg and 40 mg cohorts, respectively, was 50% (1 very good partial response [VGPR] and 2 partial response [PR]) and 71% (1 complete response, 3 VGPR, and 1 PR). Most common grade 3/4 treatment-related AEs (TRAEs) were thrombocytopenia (30 mg: 50%; 40 mg: 100%) and neutropenia (30 mg: 33%; 40 mg: 71%); grade 3/4 nonhematologic TRAEs were infrequent; 3 pts discontinued study treatment due to treatment-emergent AEs (30 mg: cardiac failure chronic and osteolysis [1 pt each]; 40 mg: thrombocytopenia [1 pt]). Serious TRAEs occurred in 2 pts (33%) in the 30 mg cohort (neutropenia and pneumonia [1 pt], syncope [1 pt]) and 1 pt (14%) in the 40 mg cohort (thrombocytopenia and neutropenia). No dose-limiting toxicities occurred at either dose level. Fatal AEs occurred in 1 pt in the 30 mg cohort (cardiac failure chronic; unrelated to study treatment). **Conclusions:** ANCHOR determined that the optimal dose of melflufen is 30 mg + dex and BTZ; results showed clinical activity in heavily pretreated pts. Recruitment is ongoing; updated data will be presented. Clinical trial information: NCT03481556. Research Sponsor: Oncopeptides AB.

Once weekly selinexor, carfilzomib, and dexamethasone (XKd) in carfilzomib nonrefractory multiple myeloma (MM) patients. *First Author: Cristina Gasparetto, Duke University Medical Center, Durham, NC*

Background: Exportin 1 (XPO1) mediates the nuclear export and functional inactivation of tumor suppressor proteins (TSPs), is associated with poor prognosis in MM, and contributes to proteasome inhibitor (PI) and immunomodulatory drug (IMiD) resistance. Selinexor (SEL) is a novel, oral, first-in-class selective inhibitor of nuclear export (SINE) compound that blocks XPO1, forcing the nuclear retention and activation of TSPs. SEL in combination with low dose dexamethasone (dex) ± bortezomib (BOR) is FDA approved for previously treated MM. The synergy of SEL with the PI BOR has been confirmed in the phase 3 BOSTON study in MM patients (pts) with 1-3 prior therapies; once weekly (QW) SEL, QW BOR, and dex (XVd) significantly increased progression-free survival (PFS), time to next therapy, and overall response rate (ORR) as compared to standard twice weekly BOR/dex (Vd), despite XVd using 40% less BOR and 25% less dex than standard Vd. We hypothesized that the addition of QW SEL to the PI carfilzomib (CAR)-dex (XKd) would be an active and tolerable regimen in pts with heavily pretreated MM. **Methods:** In the XKd arm of the multi-arm Phase 1b/2 STOMP study, SEL at 80 or 100 mg QW was evaluated in combination with CAR at 56 or 70 mg/m^2 QW plus dex at 40 mg QW in pts with heavily pretreated MM not refractory to CAR. Study objectives were to determine the maximum tolerated dose and recommended phase 2 dose (RP2D) and assess the safety and activity of the XKd regimen. **Results:** As of 4Jan2021, 27 pts were enrolled: 18 (67%) were male, median age 71 years (range 50-76), and median of 4 (range 1-8) prior lines of therapy. All 27 pts were previously treated with BOR, 26 (96%) lenalidomide (LEN), 19 (70%) pomalidomide (POM), 18 (67%) daratumumab (dara). The majority (67%) of pts were triple-class pretreated (PI, IMiD, and anti-CD38 mAb), and 44% had triple-class refractory MM. Nine pts (33%) had MM quad-refractory to BOR, LEN, POM, and dara. Common hematologic treatment-related adverse events (TRAEs) (total, grade ≥3) included thrombocytopenia (74%, 56%), anemia (59%, 19%), and neutropenia (30%, 7%). Non-hematologic TRAEs included nausea (67%, 4%), fatigue (52%, 7%), and anorexia (52%, 4%). RP2D was identified as SEL 80 mg QW, CAR 56 mg/m^2 QW, and dex 40 mg QW. As of 3Feb2021, ORR was 78% (21/27) with 5 pts reaching CR (19%), 8 VGPR (30%), and 8 PR (30%). Median PFS was 23.7 months. Among 18 pts pretreated with dara, ORR was 67% and median PFS 23.7 months. In 9 pts whose MM was refractory to BOR, LEN, POM, and dara, ORR was 67% with 4 VGPR (44%). **Conclusions:** In pts with heavily pretreated MM, weekly XKd is highly active with an ORR of 78% and deep responses (≥VGPR 48%) with an overall PFS of 23 months. All AEs including grade 3/4 thrombocytopenia can be managed with appropriate supportive care and dose modifications. These data support further investigation of XKd in pts with previously treated MM including those previously treated with dara. Research Sponsor: Karyopharm Therapeutics.

Phase Ib trial of vactosertib in combination with pomalidomide in relapsed multiple myeloma: A corticosteroid-free approach by targeting TGF-β signaling pathway. *First Author: Ehsan Malek, University Hospitals of Cleveland, Cleveland, OH*

Background: Immunosuppression and osteoclast activation are two hallmarks of the bone marrow environment in Multiple Myeloma (MM). Corticosteroids have been used historically as part of anti-myeloma regimens due to their anti-plasma cell activity, however they potentially could suppress immune system and activate osteoclast further; therefore there is an unmet need for corticosteroid-free approaches in the era of emerging anti-cancer immunotherapy modalities. There is an abundance of Transforming Growth Factor-beta (TGF-β), a crucial cytokine in suppression of immune system as well as catabolic bone remodeling, in the MM microenvironment. Vactosertib (Vacto) is a small molecule TGF-β type I receptor inhibitor that has shown single agent activity against myeloma in the syngeneic 5T33MM murine mouse model. Here, we report the phase Ib trial of Vacto in combination with pomalidomide (Pom) without any corticosteroids (NCT03143985). **Methods:** pts with relapsed MM with at least two lines of therapies enrolled on a 3 + 3 dose escalation design and received Vacto, 60 mg/d, 120 mg/d, 100 mg BID and 200 mg BID in combination with standard dose of Pom (4mg) without corticosteroids. The primary objectives of the study was to assess safety and recommended phase 2 dose. Vacto tablets, taken once or twice daily for 5 days followed by 2 days without treatment, is administered in 28-day cycles, until progression of disease or intolerable toxicity. **Results:** 15 pts were enrolled on the study (Table). The most common non-hematologic adverse event (AE) was grade II fatigue and pain in one pt, one episode of grade III renal failure that took less than 7 days to get back to baseline on another patient, sinus bradycardia that reversed to sinus rythem and an Afib that was rate controlled with beta blocerks. No grade IV non-hematologic AE was observed. Three pts had grade III hematologic AE, no grade IV hematologic AE. Three out of 15 pts experienced progression of disease (PFS-6: 80%). **Conclusions:** The phase Ib data shows safety of this agent in combination with Pom. The efficacy assessment (PFS-6: 80%) is higher than the historical control (PFS-6: 20% in randomized Phase II study by Richardson et al. Blood. 2014) with Pom only (PFS-6: 20%) or Pom with corticosteroids (PFS-6: 40%). Further advancement of this agent in clinical trial pipelines for MM is planned. Clinical trial information: NCT03143985. Research Sponsor: Medpacto Inc.

Using mobile wearables to establish sleep bioprofiles in newly diagnosed multiple myeloma (MM) patients. *First Author: Gil Hevroni, SUNY Downstate Medical Center, Brooklyn, NY*

Background: Passive monitoring using wearables can objectively measure sleep over extended time periods. MM patients (PTs) are susceptible to fluctuating sleep patterns due to pain and dexamethasone (dex) treatment. In this prospective study, we remotely monitored sleep patterns on 40 newly diagnosed MM (NDMM) PTs while administering electronic PT reported outcome (ePRO) surveys. The study aim was to establish sleep bioprofiles during therapy and correlate with ePROs. **Methods:** Eligible PTs for the study had untreated NDMM and assigned to either Cohort A – PTs < 65 years or Cohort B – PTs ≥ 65 years. PTs were remotely monitored for sleep 1-7 days at baseline [BL] and continuously up to 6 therapy cycles. PTs completed ePRO surveys (EORTC - QLQC30 and MY20) at BL and after each cycle. Sleep data and completed ePRO surveys were synced to Medidata Rave through Sensorlink technology. Associations between sleep measurement trends and QLQC30 scores were estimated using a linear mixed model with a random intercept. **Results:** Between Feb 2017 - Sep 2019, 40 PTs (21 M and 19 F) were enrolled with 20 in cohort A (mean 54 yrs, 41-64) and 20 in cohort B (mean 71 yrs, 65-82). Regimens included KRd 14(35%), RVd 12(30%), Dara-KRd 8(20%), VCd 5(12.5%), and Rd 1(2.5%). Sleep data was compiled among 23/40 (57.5%) PTs. BL mean sleep was 578.9 min/24 hr for Cohort A vs. 544.9 min/24 hr for Cohort B (p = 0.41, 95% CI -51.5, 119.5). Overall median sleep trends changed for cohort A by -6.3 min/24 hr per cycle (p = 0.09) and for cohort B by +0.8 min/24 hr per cycle (p = 0.88). EPRO data trends include global health +1.5 score/cycle (p = 0.01, 95% CI 0.31, 3.1), physical +2.16 score/cycle (p < 0.001, 95% CI 1.26, 3.07), insomnia -1.6 score/cycle (p = 0.09, 95% CI [-3.47, 0.26]), role functioning +2.8 score/cycle (p = 0.001, 95% CI 1.15, 4.46), emotional +0.3 score/cycle (p = 0.6, 95% CI -0.73, 1.32), cognitive -0.36 score/cycle (p = 0.44, 95% CI -1.29,0.56), and fatigue -0.36 score/cycle (p = 0.4, 95% CI -1.65, 0.93). No association between sleep measurements and ePRO were detected. Difference in sleep on dex days compared to all other days during the sample cycle period for cohort A was 81.4 min/24 hr (p = 0.004, 95% CI 26, 135) and for cohort B was 37.4 min/24 hr (p = 0.35, 95% CI -41, 115). **Conclusions:** Our study provides insight into wearable sleep monitoring in NDMM. Overall sleep trends in both cohorts do not demonstrate significant gains or losses, and these trends fit with HRQOL ePRO insomnia responses. Upon further examination, we demonstrate objective differences (younger PTs) in intra-cyclic sleep measurements on dex days compared to other cycle days (less sleep by > 1 hr). For older patients, less variation in sleep profiles was detected during dex days, possibly due to higher levels of fatigue or longer sleep duration. Sleep is an integral part of well-being in the cancer patient. Future studies should continue to characterize sleep patterns as it relates to HRQOL. Research Sponsor: None.

LocoMMotion: A prospective, non-interventional, multinational study of real-life current standards of care in patients with relapsed/refractory multiple myeloma (RRMM) receiving ≥3 prior lines of therapy. *First Author: Maria-Victoria Mateos, Hospital Clinico Universitario de Salamanca, Salamanca, Spain*

Background: Multiple myeloma (MM) remains incurable despite advances in medical treatment that have improved survival. Even with these improvements, most patients with MM eventually progress through standard drug classes of proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs), anti-CD38 monoclonal antibodies (mAbs), and others. There are currently no prospective data on real-world standard-of-care (SOC) in patients who progress after PIs, IMiDs, and anti-CD38 mAbs. Here, we present interim results from LocoMMotion (NCT04035226), the first prospective efficacy and safety study of real-life SOC in patients with RRMM. **Methods:** Eligible patients (aged ≥18 years [y]) with a diagnosis of MM were enrolled between August 2019 and October 2020 from 75 sites across 9 European countries and the US. Patients were included if they received ≥3 prior lines of therapy or were double-refractory to a PI and IMiD, had measurable disease at screening, received at least a PI, an IMiD, and anti-CD38 mAb with documented progressive disease since their last line of therapy, and had an ECOG PS score of 0 or 1. Responses were assessed per International Myeloma Working Group response criteria. A Response Review Committee assessed the overall response rate (ORR, primary objective) of real-life current SOC. Secondary objectives of the study included additional efficacy and safety evaluation of real-life SOC. **Results:** The data cut-off was November 4, 2020 for the first interim analysis of 225 patients with a median follow-up of 3.7 months (range: 0–12.7), 22 (9.8%) patients were from the US and 203 (90.2%) were from Europe. Median age was 68 y (range: 41–89), 124 (55.1%) were male, 162 (72.0%) had a baseline ECOG PS score of 1, and median time since initial MM diagnosis was 6.0 y (range: 0.3–22.8). Patients had received a median of 4.0 (range: 2–13) prior lines of therapy; all patients were triple-class exposed, 166 (73.8%) were triple-class refractory, and 208 (92.4%) were refractory to last line of therapy. The ORR with real-life SOC salvage therapy was 20.1% (95% CI: 15.0–26.0) in the response-evaluable population (n = 219). Treatment-emergent adverse events (TEAEs) were reported in 148 (65.8%) patients, 95 (42.2%) were grade ≥3. The most common grade ≥3 TEAEs were anemia, thrombocytopenia, and neutropenia. Fifteen deaths (6.7%) occurred due to TEAEs during the study. Treatment is ongoing in 121 (53.8%) patients. **Conclusions:** The interim results of this first, prospective study of real-life SOC treatment in heavily pretreated, triple-class exposed patients with RRMM demonstrate that patients continue to progress after multiple lines of therapy and have poor outcomes. Therefore, there is a need for new treatments with novel mechanisms of action for this patient population. Clinical trial information: NCT04035226. Research Sponsor: Janssen-Cilag International NV, Pharmaceutical/Biotech Company.

Isatuximab plus carfilzomib and dexamethasone in relapsed multiple myeloma patients with high-risk cytogenetics: IKEMA subgroup analysis. *First Author: Ivan Spicka, Clinical Department of Hematology, 1st Medical Department, Charles University, Prague, Czech Republic*

Background: A prespecified interim efficacy analysis of the Phase 3 IKEMA study (NCT03275285) demonstrated that isatuximab (Isa) + carfilzomib (K) and dexamethasone (d) (Isa-Kd) significantly improved progression-free survival (PFS) compared with Kd in patients (pts) with relapsed multiple myeloma (RMM) (HR 0.531; 99% CI, 0.318–0.889; *P*= 0.0007), with a clinically meaningful increase in minimal residual disease negativity (MRD-) (29.6% vs 13.0%) and complete response (CR) (39.7% vs 27.6%) rates, and a manageable safety profile. This subgroup analysis of IKEMA examined efficacy and safety in pts with high-risk cytogenetics [t(4;14), del(17p), and t(14;16)] and/or gain(1q21). **Methods:** Pts with 1–3 prior lines of therapy were randomized 3:2 to receive Isa-Kd (n = 179) or Kd (n = 123). High-risk cytogenetics was assessed by central laboratory analysis and defined as ≥1 of the following: del(17p): 50% cutoff; t(4;14) or t(14;16): 30% cutoff. Assessment of gain(1q21) was prespecified as ≥3 copies: 30% cutoff. **Results:** Of the randomized pts, 23.5% (Isa-Kd) and 25.2% (Kd) had ≥1 high-risk cytogenetic abnormality (CA); 26.3% (Isa-Kd) and 25.2% (Kd) had isolated gain(1q21). The addition of Isa to Kd improved PFS for pts with ≥1 high-risk CA and standard-risk pts (Table); pts with t(4;14) (HR 0.549; 95% CI, 0.232–1.301) had a more pronounced treatment effect than pts with del(17p) (HR 0.837; 95% CI, 0.281–2.496). A clear PFS benefit with Isa-Kd was also seen for pts with isolated gain(1q21) and gain(1q21) combined with other high-risk CA (Table). The trend toward improved CR, ≥very good partial response (VGPR), and MRD- rates with the addition of Isa was more pronounced in pts with gain(1q21) than in pts with high-risk CA alone. Grade ≥3 treatment-emergent adverse events (TEAEs) were more common with Isa-Kd vs Kd, but the incidence of serious and fatal TEAEs was similar with both arms for high-risk pts (Table). **Conclusions:** The addition of Isa to Kd improved PFS in pts with high-risk CA and disease response in pts with gain(1q21) isolated or combined with high-risk CA, with a manageable safety profile, consistent with the benefit observed in the overall IKEMA population. Isa-Kd is a potential new treatment option for the difficult-to-treat subgroup of pts with RMM and high-risk cytogenetics. Funding: Sanofi. Clinical trial information: NCT03275285. Research Sponsor: Sanofi.

Ixazomib (IXA), carfilzomib (CAR), elotuzumab (ELO) or daratumumab (DAR) with lenalidomide and dexamethasone (LEN+DEX) versus LEN+DEX only in relapsed/refractory multiple myeloma (R/R MM): A comparative cost-effectiveness analysis. *First Author: Mavis Obeng-Kusi, Center for Health Outcomes and Pharmacoeconomic Research, and Department of Pharmacy Practice and Science, Tucson, AZ*

Background: IXA, CAR, ELO and DARin combination with LEN+DEXhave been found superior in efficacy compared to LEN+DEX in the management of R/R MM. Applying indirect treatment comparisons from a network meta-analysis (NMA), this economic evaluation aimed to estimate the comparative cost-effectiveness and cost-utility of these four triplet regimens in terms of progression-free survival (PFS). **Methods:** In the absence of direct treatment comparison from a single clinical trial, NMA was used to indirectly estimate the comparative PFS benefit of each regimen. A 2-state Markov model simulating the health outcomes and costs was used to evaluate PFS life years (LY) and quality-adjusted life years (QALY) with the triplet regimens over LEN+DEX and expressed as the incremental cost-effectiveness (ICER) and cost-utility ratios (ICUR). Probability sensitivity analyses were conducted to assess the influence of parameter uncertainty on the model. **Results:** The NMA revealed that DAR+LEN+DEX was superior to the other triplet therapies, which did not differ statistically amongst them. As detailed in the Table, in our cost-effectiveness analysis, all 4 triplet regimens were associated with increased PFSLY and PFSQALY gained (g) over LEN+DEX at an additional cost. DAR+LEN+DEX emerged the most cost-effective with ICER and ICUR of $667,652/PFSLYg and $813,322/PFSQALYg, respectively. The highest probability of cost-effectiveness occurred at a willingness-to-pay threshold of $1,040,000/QALYg. **Conclusions:** Our economic analysis shows that all the triplet regimens were more expensive than LEN +DEX only but were also more effective with respect to PFSLY and PFSQALY gained. Relative to the other regimens, the daratumumab regimen was the most cost-effective. Research Sponsor: None.

Results of probabilistic sensitivity analysis: ICER (i$ / PFSLYg) / ICUR (i$/PFSQALYg).

ISB 1342: A first-in-class CD38 T cell engager for the treatment of relapsed refractory multiple myeloma. *First Author: Marie-Agnès Doucey, Ichnos Sciences, Epalinges, Switzerland*

Background: ISB 1342 is a bispecific antibody heterodimer based on the Ichnos proprietary Bispecific Engagement by Antibodies based on T cell receptor (BEAT) platform. ISB 1342 is a first-in-class CD38 T cell engager under investigation in subjects with relapsed multiple myeloma refractory to proteasome inhibitors (PIs), immunomodulators (IMiDs) and daratumumab (study ISB 1342-101). **Methods:** ISB 1342 was engineered with a single chain variable fragment (scFv) arm that specifically recognizes a cluster of differentiation (CD)3-epsilon (CD3ε) and a fragment antigen binding (Fab) arm which specifically recognizes CD38 and does not compete with daratumumab. By co-engaging CD3ε on T cells and CD38 on tumor cells, ISB 1342 redirects T cells to kill CD38-expressing tumor cells. This mechanism of action is differentiated from existing monospecific CD38 targeting therapies and was designed to overcome resistance to daratumumab in multiple myeloma. **Results:** *In vitro,* ISB 1342 killed a large range of CD38-expressing tumor cell lines (EC50:12 to 90 pM) with 8 to 239-fold superior efficacy than daratumumab. ISB 1342 was also able to efficiently kill CD38 low-intermediate-expressing tumor cells that were poorly killed by daratumumab. ISB 1342 retained the potency to kill CD38 low-intermediate-expressing tumor cells when used in sequential or concomitant combination with daratumumab. In addition, the presence of soluble CD38 or glucocorticoid did not impact ISB 1342 killing potency. ISB 1342 was constructed with a double LALA mutation that dampens the binding to Fcγ receptors and C1q. Consistently, ISB 1342 showed only residual Fc-mediated effector functions and its mechanism of tumor cell killing critically relies on the engagement and the activation of T lymphocytes. ISB 1342 showed a favorable on target specificity profile *in vitro* and was unable to activate T cells in the absence of CD38 positive target cells. Further, ISB 1342-induced tumor cell killing was not associated with a detectable T cell fratricide *in vitro*. Finally, the potency of ISB 1342 was assessed *in vivo* in a therapeutic model of a subcutaneously established Daudi tumor co-xenografted with human PBMCs. In marked contrast to daratumumab, which induced only a partial tumor control, ISB 1342 induced complete tumor eradication when injected intravenously weekly at 0.5 mg/kg. As anticipated, the ISB 1342 control molecule (ISB 1342_13DU) made of an irrelevant CD38 binder failed to control tumor growth. The release of the Granzyme A and B, TNF-alpha and CXCL-10 in the tumor micro-environment one week post-treatment was strongly and significantly increased by ISB 1342 but not by daratumumab and ISB 1342_13DU; this represents a correlate of anti-tumor immunity associated with ISB 1342 efficacy *in vivo*. **Conclusions:** Hence the higher potency of ISB 1342 relative to daratumumab supports the ongoing clinical development in multiple myeloma patients. Research Sponsor: Glenmark and Ichnos Sciences.

Comparison of outcomes with ciltacabtagene autoleucel (cilta-cel) in CARTITUDE-1 versus real-world standard of care (RW SOC) for patients (pts) with triple-class exposed relapsed/refractory multiple myeloma (RRMM). *First Author: Thomas G. Martin, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Pts with RRMM who are triple-class exposed (to immunomodulatory drugs [IMiDs], proteasome inhibitors [PIs] and an anti-CD38 antibody) cycle through multiple salvage regimens with progressively worse outcomes. CARTITUDE-1 (NCT03548207) is a single-arm phase 1b/2 study evaluating cilta-cel, a chimeric antigen receptor T-cell therapy with 2 B-cell maturation antigen–targeting single-domain antibodies, in pts with RRMM who received ≥3 prior lines of therapy (LOT) or were double refractory to an IMiD and PI, were triple-class exposed, had ECOG score of 0 or 1, and had disease progression ≤12 mo after the last LOT. Here, we compare efficacy outcomes for pts who received cilta-cel in CARTITUDE-1 (N = 97) with pts treated with SOC in a synthetic cohort from RW clinical practice. **Methods:** The Flatiron database, a primarily US community-based MM registry (Sep 2020 data cutoff), was used to identify a RW pt cohort who met CARTITUDE-1 (Sep 2020 data cutoff) eligibility criteria, including organ function. Progression-free/overall survival (PFS/OS) were compared between the cilta-cel–treated US pts and RW SOC cohort, using inverse probability of treatment (tx) weighting (IPTW) propensity scores adjusting for unbalanced baseline covariates of prognostic significance. Sensitivity analyses were conducted using multivariate Cox regression models and propensity score matching. **Results:** Baseline characteristics were similar between the 2 cohorts after propensity score weighting (Table). SOC tx regimens in the RW cohort primarily included pomalidomide (33%), carfilzomib (32%), daratumumab (13%), elotuzumab (16%), and ixazomib (8%). Pts had improved PFS and OS with cilta-cel (N = 97; median follow-up 12.4 mo) vs RW SOC (N = 196; median follow-up 9.2 mo) with a reduction in risk of progression/death and death by 84% and 78%, respectively (Table). Cilta-cel treatment benefit was robust across sensitivity analyses. **Conclusions:** Cilta-cel shows significantly better efficacy outcomes over RW SOC for PFS and OS, highlighting its potential as an effective tx option in pts with triple-class exposed RRMM. Clinical trial information: NCT03548207. Research Sponsor: Janssen Research & Development, LLC.

Health-related quality of life (HRQoL) in patients with relapsed/refractory multiple myeloma (RRMM) treated with pomalidamide and dexamethasone ± subcutaneous daratumumab: Patient-reported outcomes (PROs) in APOLLO. *First Author: Evangelos Terpos, National and Kapodistrian University of Athens, Athens, Greece*

Background: APOLLO (NCT03180736) is a phase 3 trial of pomalidomide and dexamethasone (Pd) ± subcutaneous daratumumab (1800 mg, co-formulated with recombinant human hyaluronidase PH20 in 15 mL) in patients with RRMM and ≥1 prior line of therapy including lenalidomide and a proteasome inhibitor. After 16.9 months (mo) median follow-up, D-Pd significantly reduced the rate of progression or death by 37% relative to Pd. Patients with RRMM have reduced HRQoL compared with age- and sex-matched populations. Here, we present PROs from the APOLLO trial. **Methods:** Patients were randomized 1:1 to D-Pd or Pd and treated in 28-day cycles until disease progression/unacceptable toxicity. PROs were assessed on Day 1 of each cycle using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30-item (EORTC QLQ-C30), EORTC QLQ Multiple Myeloma Module 20-item (MY20), and EuroQol 5-dimensional descriptive system. PRO analyses were performed on patients from the intent-to-treat population with a baseline (BL) and ≥1 post-BL assessment. Treatment effect was assessed by a mixed effects model with repeated measures. Time to worsening was estimated using the Kaplan-Meier method. **Results:** A total of 304 patients were included (151 D-Pd, 153 Pd). Median treatment duration was 11.5 mo with D-Pd vs 6.6 mo with Pd. At Cycle 16 (Cyc 16), 63 and 40 patients remained on treatment in the D-Pd and Pd groups, respectively. Compliance rates for PRO instruments were high and comparable between groups. Patients treated with D-Pd had a reduction in pain (maximum improvement: 6.8 points at Cyc 12) measured with the EORTC QLQ-C30 and no mean change in disease symptoms or the treatment side effects subscales of the EORTC QLQ-MY20. Group mean physical and emotional functioning were unchanged from BL with D-Pd but worsened in the Pd group (maximum worsening: 6.4 at Cyc 4 and 9.1 points at Cyc 14). The proportion of patients with a meaningful improvement from BL was 55.0% vs 49.0% for disease symptoms, 43.0% vs 35.3% for physical functioning, and 41.7% vs 31.4% for emotional functioning with D-Pd vs Pd, respectively. Median time to worsening was ~4 mo, except for the disease symptoms subscale (~10 mo); there were no differences between groups. **Conclusions:** When daratumumab was added to Pd, patients did not experience any decrements in HRQoL while on treatment, but some patients experienced reductions in pain as well as clinically meaningful improvements in symptoms and emotional/physical function. These findings complement the clinical benefits of D-Pd in RRMM patients and further support its use in this RRMM population. Clinical trial information: NCT03180736. Teclistamab and talquetamab modulate levels of soluble B-cell maturation antigen in patients with relapsed and/or refractory multiple myeloma. *First Author: Suzette Girgis, Janssen R&D, Spring House, PA*

Background: B-cell maturation antigen (BCMA, CD269) is a single transmembrane protein that is selectively expressed in the B-cell lineage and is a validated target for multiple myeloma. BCMA exists as both surface protein and as a free soluble form (sBCMA). γ-secretase activity at the transmembrane domain leads to a shed BCMA protein fragment of approximately 6 kilodalton that can exist as free circulating sBCMA in blood. Teclistamab and talquetamab are CD3 bispecific antibodies that have been developed to recruit CD3$^+$ T-cells to BCMA$^+$ or GPRC5D$^+$ multiple myeloma (MM) cells, respectively. The objective of this work was to evaluate sBCMA in relapsed and/or refractory MM patients in response to treatment with teclistamab or talquetamab. **Methods:** Serum samples from relapsed and/or refractory MM patients in teclistamab and talquetamab phase 1 studies (64007957MMY1001 and 64407564MMY1001) were collected (at various timepoints between baseline and cycle 4 or end of treatment) and analyzed for sBCMA by an electrochemiluminescence ligand binding assay. Soluble BCMA data were quantitatively analyzed in reference to patient's tumor burden and response, as well as pharmacokinetic data. **Results:** Teclistamab and talquetamab modulated levels of sBCMA in patients with high (≥ 50%) and low (< 50%) frequency of tumor plasma cells (TPCs), as well as in high and low risk cytogenetic groups. In cycle 3, majority of the responders had reduction in sBCMA [88% (50 out of 57) for teclistamab and 98% (49 out of 50) for talquetamab] compared to baseline. On the contrary, non-responders (progressive disease, stable disease, or minimal response) seemed to show an increase in sBCMA [80% (33 out of 41) for teclistamab and 49% (24 out of 49) for talquetamab] from baseline. Patients with deep responses tend to have higher magnitude of sBCMA reduction compared to others. Based on few patients who responded to teclistamab or talquetamab and then relapsed, sBCMA seemed to have an initial reduction followed by an increase in the levels. Soluble BCMA corelated with % bone marrow TPCs. Majority of patients with plasmacytoma (limited data) seemed to have high sBCMA; suggesting sBCMA could be a comprehensive marker for tumor burden. Teclistamab preliminary population pharmacokinetic analysis showed that sBCMA did not appear to impact teclistamab exposure, suggesting that sBCMA was not acting as a sink for teclistamab. **Conclusions:** Teclistamab and talquetamab induced changes in levels of sBCMA that correlated with clinical activity, further supporting clinical development of these bispecific antibodies. Lastly, the results support that sBCMA is a potential surrogate marker of myeloma tumor burden, and as a valuable marker for response in MM patients. Clinical trial information: NCT03145181 and NCT03399799. Research Sponsor: Janssen Research & Development, LLC.

Melflufen plus dexamethasone (dex) in patients (pts) with relapsed/refractory multiple myeloma (RRMM) exposed/refractory to prior alkylators: A pooled analysis of the O-12-M1 and HORIZON studies.

First Author: Paula Rodríguez-Otero, Clinica Universidad De Navarra, Pamplona, Spain

Background: Melphalan flufenamide (melflufen) is a first-in-class peptide-drug conjugate (PDC) that leverages aminopeptidases and rapidly releases alkylating agents inside tumor cells. Melflufen has a mechanism of action distinct from other alkylating agents (Slipicevic et al. AACR 2020. Abs. 1843). In the O-12-M1 (NCT01897714) and HORIZON (OP-106; NCT02963493) studies, melflufen plus dex showed meaningful efficacy and a clinically manageable safety profile in pts with RRMM (Richardson et al. *Lancet Haematol.* 2020;7:5; Richardson et al. *J Clin Oncol.* 2020;Dec 9 [Epub]). This pooled analysis examines pts from these studies exposed to prior alkylators. **Methods:** Both the O-12-M1 and HORIZON studies included pts with RRMM who received ≥ 2 prior lines of therapy (LoTs) and had a primary endpoint of overall response rate (ORR). Secondary endpoints included progression-free survival (PFS) and safety. Data from the 2 studies were pooled and analyzed according to previous exposure and refractoriness to alkylators before study entry. Refractoriness to prior alkylator therapy was defined as disease that failed to achieve a minimal response or progressed while on therapy, or within 60 d of last therapy. **Results:** Of 202 pts (HORIZON: n = 157, cutoff January 14, 2020; O-12-M1: n = 45, cutoff October 29, 2019), 178 (88%) had been exposed to alkylators in ≥ 1 prior LoT (see Table for subgroups). Pts exposed and refractory to alkylators in ≥ 2 LoTs had the highest number of pts refractory to an alkylator in the last LoT (61%), and 82% were refractory to an alkylator within 12 mo of study entry. Meaningful response rates were seen in all subgroups, except for pts who were exposed and refractory to alkylators in ≥ 2 prior LoTs (see Table). PFS trended toward being shorter with higher exposure and refractoriness to prior alkylators. Results should be interpreted with caution due to limited pt numbers. Grade 3/4 adverse events (AEs) were similar between pts exposed to prior alkylators (O-12-M1: 85%; HORIZON: 89%) and the overall population (O-12-M1: 84%; HORIZON: 89%). The most common AEs were hematologic, but were mostly reversible and clinically manageable. Nonhematologic AEs were infrequent and primarily grade 1/2. **Conclusions:** Melflufen in combination with dex showed meaningful efficacy and a clinically manageable safety profile in pts with RRMM exposed/refractory to prior alkylators. Clinical trial information: NCT02963493 and NCT01897714. Research Sponsor: Oncopeptides AB.

Prognostic impact of depth of response in Waldenström macroglobulinemia patients treated with fixed duration chemoimmunotherapy.

First Author: Nirosha D. Perera, Department of Internal Medicine, Mayo Clinic, Rochester, MN

Background: The treatment paradigm of Waldenström macroglobulinemia (WM) continues to evolve as new therapies expand our options for this indolent and incurable disease. While more profound responses are generally associated with longer treatment-free intervals, the impact of depth of response from fixed duration therapy in WM patients' survival needs further evaluation. In this international, multicenter cohort study, we report the prognostic impact of depth of response in WM. **Methods:** 319 WM patients treated with frontline fixed duration therapy [Dexamethasone/Rituximab/Cyclophosphamide (DRC), Bendamustine/Rituximab (BR), or Bortezomib/Dexamethasone/Rituximab (BDR)] were included. Response at the completion of therapy (6 months) was used in a landmark analysis for progression-free survival (PFS), time to next treatment (TTNT), and overall survival (OS) (defined as time from 6 months post treatment response to event or censor). Response was defined by modified IWWM-6 criteria. Associations between clinical variables and outcomes were evaluated using Cox proportional-hazard models. **Results:** The median age at the time of treatment initiation was 64 years (range: 29-94), 59% were men, and risk category by International Prognostic Scoring System (IPSS)-WM was low (n=67, 23%), intermediate (n=83, 29%), and high-risk (n=141, 48%). Evaluable responses at 6 months from frontline therapy [DRC (n=105; 41%), BR (n=83; 32%), BDR (n=68; 27%)] were available in 256 patients and included in the landmark analysis. Median follow-up was 63 months (95% CI: 59-70). The rate of major response (PR or better) at 6 months was 74% for the entire cohort. Five-year PFS rates from completion of therapy for patients who attained major response vs. those who did not were 71% and 43%, respectively ($p<0.001$). Five-year TTNT rates for patients who attained major response vs. not were 84% and 54%, respectively ($p<0.001$). Five-year OS rates for patients who attained major response vs. not were 92% and 77%, respectively ($p<0.001$). In multivariable analyses including other WM prognostic factors evaluated at initiation of frontline therapy, attaining a major response at 6 months was associated with superior PFS (HR 0.33, $p<0.001$), TTNT (HR 0.23, $p<0.001$), and OS (HR 0.31, p=0.001–Table). **Conclusions:** Achieving a major response at 6 months after frontline chemoimmunotherapy emerges as a significant prognostic factor for PFS, TTNT and OS in patients with WM. Research Sponsor: Mayo Clinic Division of Hematology for abstract submission fee and analysis software.

An animal model of MGUS/SMM to investigate the role of cellular senescence in progression to MM.

First Author: Hengwei Zhang, University of Rochester, Rochester, NY

Background: Multiple Myeloma (MM) is an incurable cancer of plasma cells that arises from precursor stages, monoclonal gammopathy of undetermined significance (MGUS) and/or smoldering MM (SMM). Mechanisms for the transformation of MGUS/SMM to MM are not fully known. There is no approved therapy for MGUS/SMM and research is limited by a lack of animal models. Here, we describe the use of a novel animal model of disease progression derived from patients with MGUS/SMM to study the impact of cellular senescence (CS) on the development of MM. **Methods:** CD 138+ plasma cells and CD138- stromal cells were isolated via magnetic beads from bone marrow aspirates of patients with MGUS/SMM and co-cultured CD138+/CD138- with different ratios. For the animal model CD138+/CD138- cells from MGUS/SMM patients were injected into the tibias of NSG mice (1:10). After 4 weeks, CD138+ cells were harvested and again co-transplanted into the tibia of a 2nd NSG mouse with the CD138- cells (1:10). Mice underwent serial imaging and tibias were histologically examined after 4 weeks in the 2nd mouse. CS gene expression was compared by RNAseq between patients with SMM and healthy older adults. The primary CD138- cells were stained for SA-β-gal. Human mesenchymal stem cells (hMSCs) induced by H_2O_2 for CS vs control were co-cultured with CD138+ cells. Patient derived CD138- cells were treated with anti-senolytic drugs, dasatinib (D) and quercetin (Q) and cell growth in co-culture with CD138+ plasma cells was measured. D+Q treated patient-derived CD138+/CD138- cells were co-transplanted into our NSG mouse model and followed with serial imaging. **Results:** CD138- stromal cells from patients with MGUS/SMM support the growth of CD138+ plasma cells (10:1). CD138- cells were found to gain CD138+ expression, suggesting another source for the plasma cell growth. Imaging of our mouse model showed the development of lytic lesions in the tibias of 5/5 mice versus no lytic lesions in mice transplanted with CD138+ cells alone. Staining of the lytic lesions revealed CD138+ plasma cells. Our RNA seq showed significantly increased expression of CS genes, CDKN2A, p16 and p19 (3 fold) in CD138- cells of SMM patients and confirmed by qPCR (8 fold) compared to healthy older adults. The primary stromal cell culture from MGUS/SMM patients showed the presence of SCs by SA-β-gal staining. H_2O_2 induced senescent hMSCs stimulate cell survival and growth of CD138+ cells. CD138- cells cultured with conditioned media from H_2O_2 induced hMSCs demonstrated more CD138+ cells than vehicle treated CD138- cells. Conversely, D + Q pre-treated CD138- cells lost the ability to promote CD138+ cells in co-culture. Our animal model treated with D+Q showed less bone erosion in tibias compared to untreated mice. **Conclusions:** Our work demonstrates a novel animal model for studying disease progression in patients with MGUS or SMM and demonstrates a role for CS in MM disease progression. Research Sponsor: University of Rochester.

TPS8051 **Poster Session**

LIGHTHOUSE (OP-108): A phase 3 study of melflufen in combination with dexamethasone (dex) and daratumumab (dara) versus dara in relapsed/refractory multiple myeloma (RRMM) patients (pts).

First Author: Maria-Victoria Mateos, Hospital Clínico Universitario de Salamanca/IBSAL/CIC, Salamanca, Spain

Background: Melphalan flufenamide (melflufen) is a first-in-class peptide-drug conjugate (PDC) that leverages aminopeptidases and rapidly releases alkylating agents inside tumor cells. Melflufen + dex showed clinical efficacy and was well tolerated in pts with heavily pretreated RRMM (HORIZON; Richardson et al. *J Clin Oncol.* 2020 Dec 9 [Epub]). The ongoing phase 1/2 ANCHOR study (OP-104) established the optimal dose for melflufen + dex and dara, showing meaningful clinical activity and manageable safety at both melflufen doses tested in pts with RRMM (Ocio et al. ASH 2020. Oral 417). The aim of this study (OP-108; NCT04649060) is to evaluate the efficacy and safety of melflufen + dex and dara vs dara in pts with RRMM previously treated with an IMiD and a proteasome inhibitor (PI), similar to the indication for dara monotherapy. **Methods:** Pt enrollment has begun (N = 240 planned). Pts must be ≥ 18 y, double refractory to (or intolerant of) an IMiD and a PI or had ≥ 3 prior lines of therapy (LoTs) including an IMiD and a PI, have measurable disease, and Eastern Cooperative Oncology Group performance status ≤ 2. Pts with primary refractory disease and refractoriness to an anti-CD38 antibody are excluded. Pts will be randomized 1:1 to open-label melflufen + dex and dara (Arm A) or single-agent dara (Arm B) until progressive disease [PD] or unacceptable toxicity, stratified by prior LoT number. Pts in Arm B with PD can opt to receive Arm A triplet therapy. Arm A: melflufen 30 mg intravenously on d 1 of each 28-d cycle; dex 40 mg/wk orally (20 mg if aged ≥ 75 y); dara 1800 mg subcutaneously on d 1, 8, 15, and 22 of cycle 1 and 2, d 1 and 15 of cycles 3-6, and d 1 of cycles 7+. Arm B: dara at the same dosage as Arm A. Primary objective: superiority (P value from the 2-sided statistical test < 0.05; upper limit of the 2-sided 95% CI for the hazard ratio < 1) of progression-free survival (PFS) in pts treated with triplet therapy vs dara. An estimated sample of 240 pts with 160 expected events (PD or death) and 15% assumed dropout rate would provide 90% power at a 2-sided log rank test at 5% significance level to detect a hazard ratio for death of 0.6. Key secondary endpoints: overall response rate (ORR; ≥ partial response [PR]), duration of response, and safety. Response will be assessed by a blinded independent review committee based on International Myeloma Working Group criteria. Other secondary endpoints: clinical benefit rate (≥ minimal response), time to response, time to progression, time to next treatment, and overall survival. Exploratory endpoints include: minimal residual disease in pts achieving ≥ very good PR, PFS following next line of treatment (PFS-2), pt-reported outcomes, pharmacokinetics, translational biomarkers, response rate in pts with extramedullary disease, and efficacy (including ORR) in Arm B pts who receive Arm A triplet therapy after PD. Clinical trial information: NCT04649060. Research Sponsor: Oncopeptides AB.

TPS8052 **Poster Session**

ECOG-ACRIN EAA181: Effective quadruplet utilization after treatment evaluation (EQUATE)—a randomized phase 3 trial for newly diagnosed multiple myeloma (NDMM) not intended for early autologous transplantation. *First Author: Shaji Kumar, Department of Hematology, Mayo Clinic Rochester, Rochester, MN*

Background: The monoclonal antibody (MoAb) daratumumab (dara) has been approved for treatment of newly diagnosed Multiple Myeloma (NDMM) in combination with lenalidomide (len) and dexamethasone (DRd) in patients who are not eligible to undergo stem cell transplantation (SCT). Ongoing trials are examining the role of adding bortezomib (Btz) to DRd, but it remains unclear if all patients benefit from a quadruplet regimen. Availability of sensitive assays to detect measurable/minimal residual disease (MRD) in MM and emerging data demonstrating significant prognostic value for attaining MRD negativity, offers an unprecedented opportunity to develop individualized treatment approaches. An important question is to identify who benefits from adding a fourth drug to the MoAb-IMiD triplet, thus individualizing therapy based on depth of response. We hypothesize that prolonged intensive therapy with the addition of Btz for consolidation and maintenance after DRd induction therapy for NDMM will improve survival outcomes with a more pronounced effect when used in MRD positive patients. **Methods:** Patients with NDMM, R-ISS Stage I or II, who are not eligible to undergo SCT or those willing to defer SCT to first relapse and have not received more than 1 cycle of any NDMM therapy will be enrolled, provided they have measurable disease, adequate organ and marrow function, have received no more than once cycle of therapy for MM and significant peripheral neuropathy or chronic obstructive pulmonary disease. Importantly, a dominant clone should be identified by lymphotrack assay for future MRD monitoring. Once enrolled, induction therapy will be in 28 day cycles consisting of daraSC (1800 mg) weekly for 2 cycles, every other week for cycles 3-6 and then every 4 weeks for 9 cycles, along with len 25 mg days 1-21 of each cycle and dex 40 mg (20 mg for those $>$ 75 years) weekly. At end of 9 cycles (induction), patients will undergo MRD testing by next generation sequencing and will be classified into MRD positive or negative subgroups. Using MRD as an integral biomarker, the trial employs a randomized biomarker-stratified design as proposed by Freidlin et al. to determine efficacy for each MRD subgroup. Patients will be stratified by MRD status and R-ISS stage and randomized to receive 9 cycles of consolidation with DRd, without (control arm) or with (experimental arm) Btz (1.3 mg/m2 weekly for 3 of 4 weeks), followed by DR maintenance until progression The primary endpoint is consolidation OS. Sample size considerations rest on estimates of MRD subgroup prevalence at the end of induction and operating characteristics establishing the treatment effect within the MRD positive subgroup as primary and MRD negative subgroup as key secondary. The total accrual goal is 1450 patients. Clinical trial information: NCT04566328. Research Sponsor: CTEP.

TPS8053 **Poster Session**

KarMMa-4: Idecabtagene vicleucel (ide-cel, bb2121), a BCMA-directed CAR T-cell therapy in high-risk newly diagnosed multiple myeloma. *First Author: Saad Z. Usmani, Levine Cancer Institute, Charlotte, NC*

Background: High-risk (R-ISS stage III) newly diagnosed multiple myeloma (NDMM) has a poor prognosis (median PFS, 29 mo), highlighting the need for novel disease-targeting approaches (Palumbo A, et al. *J Clin Oncol* 2015;33:2863-2869). Ide-cel, a BCMA-directed CAR T cell therapy, demonstrated deep, durable responses in heavily pretreated patients (pts) with relapsed and refractory MM (RRMM; Raje N, et al. *N Engl J Med* 2019;380:1726-1737; Munshi NC, et al. *J Clin Oncol* 2020;38[suppl 15]. Abstract 8503), including those with high-risk (R-ISS stage III) RRMM. In this population, earlier use of ide cel—when there may be more bone marrow reserve, more healthy peripheral blood mononuclear cells, a less compromised immune status, and less extensive disease to debulk before cell therapy—may result in improved outcomes vs standard therapies and offer an opportunity to replace transplant with CAR T cell therapy. **Methods:** KarMMa-4 (NCT04196491), a multicenter, open-label, phase 1, single-arm study, is currently evaluating ide-cel in pts with high-risk NDMM, defined as R-ISS stage III (ISS stage III [serum β_2 microglobulin $\geq$ 5.5 mg/L] and cytogenetic abnormalities t(4;14), del(17p), and/or t(14;16) by interphase FISH; or ISS stage III and serum LDH $>$ ULN). Pts must have received $\leq$ 3 cycles of the induction regimens listed below, be aged $\geq$ 18 years, and have ECOG PS 0-1. Nonsecretory MM and CNS involvement are exclusion criteria. Pts can enroll between induction cycles 1 and 3. Permitted cycle 1 regimens are carfilzomib + lenalidomide (LEN) + dexamethasone (DEX) ± daratumumab (DARA; KRd ± DARA), LEN + bortezomib (BOR) + DEX ± DARA (RVd ± DARA), or cyclophosphamide + BOR + DEX (CyBorD). Induction cycles 2-4 are limited to KRd or RVd, with DEX omitted during cycle 3. Pts will undergo T cell collection via leukapheresis after cycle 3, and ide-cel will be manufactured during cycle 4. Stem cell collection for future use may be conducted after cycle 3 (following leukapheresis) or 4 (before lymphodepletion). Ide-cel is infused after 2 days of rest following lymphodepletion with 3 days of fludarabine 30 mg/m^2 + cyclophosphamide 300 mg/m^2. LEN-based maintenance may be provided upon bone marrow recovery or 90 days after ide-cel infusion, whichever is later. Dose-limiting toxicity and safety are the primary endpoints. Secondary endpoints include complete response (CR) rate and overall response rate, duration of response, time to CR, time to start of maintenance, feasibility of initiating maintenance, PFS, overall survival, and pharmacokinetics. Exploratory endpoints include LEN maintenance safety, minimal residual disease, immunogenicity and biomarkers. The starting ide-cel target dose is 450 $\times$ 10^6 CAR+ T cells, with dose escalation/de-escalation (150, 300, and 800 $\times$ 10^6 CAR+ T cells). Upon determination of optimal target dose, 12 pts will be enrolled in the dose-expansion phase. Clinical trial information: NCT04196491. Research Sponsor: Celgene, a Bristol-Myers Squibb Company and bluebird bio.

TPS8054 **Poster Session**

Subcutaneous daratumumab (DARA SC) plus lenalidomide versus lenalidomide alone as maintenance therapy in patients (pts) with newly diagnosed multiple myeloma (NDMM) who are minimal residual disease (MRD) positive after frontline autologous stem cell transplant (ASCT): The phase 3 AURIGA study. *First Author: Nina Shah, Department of Medicine, University of California San Francisco, San Francisco, CA*

Background: DARA, a human anti-CD38 IgGκ monoclonal antibody, is approved in many countries as monotherapy in relapsed/refractory MM (RRMM) and in combination with standard of care (SoC) in RRMM and NDMM. However, no clinical studies have yet compared DARA maintenance versus SoC maintenance. The ongoing phase 3 AURIGA study will evaluate the addition of DARA to lenalidomide maintenance among pts with NDMM who are MRD positive after SoC induction and ASCT. The primary endpoint is the conversion rate to MRD negativity after 1 year of maintenance therapy. **Methods:** This open-label, multicenter, randomized phase 3 study will enroll approximately 214 pts in the United States aged 18-79 years with NDMM who receive $\geq$4 cycles of induction followed by ASCT. Pts must enroll within 6 months of ASCT, be naïve for anti-CD38 treatment, have a very good partial response or better per IMWG criteria, and be MRD positive at a threshold of 10^{-5} by next generation sequencing (NGS) within 30 days of screening. Pts will be stratified by cytogenetic risk (high vs standard/unknown) and randomized 1:1 to 28-day cycles of lenalidomide maintenance (10 mg PO; D1-28 [dose increasing to 15 mg if tolerated]) ± DARA SC (DARA 1,800 mg co-formulated with recombinant human hyaluronidase PH20 [rHuPH20; 2,000 U/mL; ENHANZE® drug delivery technology, Halozyme, Inc., San Diego, CA, USA; QW Cycle 1-2, Q2W Cycles 3-6, Q4W C7+). Treatment will continue for up to 36 cycles or until disease progression, unacceptable toxicity, or patient withdrawal. The primary endpoint is MRD conversion rate after 12 months of maintenance treatment, defined as the proportion of pts who achieve MRD negativity (10^{-5}) by NGS. Additional MRD assessments occur after 18, 24, and 36 months of maintenance. While MRD negativity is associated with improved long-term outcomes for pts with MM and is an emerging, validated prognostic factor, this study is among the first to use MRD negativity as a primary study endpoint. Importantly, MRD negativity allows for earlier efficacy assessment than traditional endpoints such as progression-free survival (PFS) and overall survival (OS). Secondary endpoints include overall MRD conversion rate at any time, sustained MRD negativity lasting $\geq$12 months, PFS, OS, response rates, duration of complete response, changes in health-related quality of life, and safety. Due to the COVID-19 pandemic, this study has been amended to improve enrollment access by allowing up to 12 months from start of induction therapy to ASCT to mitigate against ASCT delays and to allow greater flexibility for screening and laboratory assessments. Clinical trial information: NCT03901963. Research Sponsor: Janssen Research & Development, LLC.

TPS8055 **Poster Session**

A randomized, open-label, phase 3 study of low-dose selinexor and lenalidomide (Len) versus len maintenance post autologous stem cell transplant (ASCT) for newly diagnosed multiple myeloma (NDMM): ALLG MM23, Sealand. *First Author: HANG QUACH, St. Vincent's Hospital, University of Melbourne, Melbourne, VIC, Australia*

Background: Len maintenance post ASCT is standard of care for patients (pts) with NDMM. Deep responses (CR or better) post ASCT correlates with better progression free survival (PFS). In a meta-analysis of len maintenance post ASCT (McCarthy PL et al. J Clin Oncol. 2017), only 10.7% of pts achieve CR post ASCT, and 72% of pts who discontinued len maintenance did so because of progressive disease (PD). Selinexor is a selective inhibitor of nuclear export that blocks exportin 1, thus retaining tumour suppressor proteins within the nucleus while blocking proto-oncoprotein translation. It is approved in combination with bortezomib and dexamethasone (dex) for pts with MM who have had at least 1 prior line of treatment, or with dex for pts with penta-refractory MM by the FDA. The oral bioavailability and weekly schedule of selinexor makes it suitable in combination with len for maintenance therapy. Given the encouraging activity (ORR 92%) and tolerability of selinexor, len and dex from the phase 1b/2 STOMP study, we hypothesise that combination low-dose selinexor and len (XR) will be well tolerated and effective, increasing CR and MRD negativity rate post ASCT, thus prolonging PFS compared to len. **Methods:** ALLG MM23 SeaLAND, is an ongoing randomised, multi-centre, phase 3 trial. Eligible pts ($>$ 17 years of age) have measurable disease, have undergone 3-6 cycles (C) of induction containing a proteasome inhibitor (PI) and/or immunomodulatory drug and recovered post melphalan-conditioned ASCT with adequate haematopoiesis, renal and liver function, and with ECOG performance status . Registration occurs prior to ASCT with screening between 75 to 115 days post ASCT. The study includes a lead-in safety phase of 20 patients with XR: Len 10mg daily days 1 to 21 and Selinexor 40mg weekly in a 28-day cycle. If well tolerated, Selinexor escalates to 60mg po weekly from C2 and Len to 15mg po daily from C4. Two safety reviews will occur after the 10th and 20th patients completes C2, respectively. Upon meeting safety criteria, a sample size of 290 pts will be randomised 1:1 to XR or lenalidomide (R). Therapy will continue until PD. The primary endpoint is PFS at 3 years post randomisation. Secondary endpoints include ORR and MRD-negativity rate (International Myeloma Working Group Response Criteria), PFS on next treatment line (PFS2), OS, safety and tolerability, quality of life, and cost effectiveness. Main analysis occurs after 232 patients complete 3-years of follow-up. Exploratory objective is to correlate immunological and molecular profiles to treatment response and resistance. ALLG MM23 SeaLAND is a multisite bi-national investigator-initiated trial lead by Australia and New Zealand's national cooperative group, the Australasian Leukaemia & Lymphoma Group. Clinical trial registration: ACTRN12620000291987p. Clinical trial information: 12620000291987. Research Sponsor: Karyopharm Therapeutics Inc.

IMpower010: Primary results of a phase III global study of atezolizumab versus best supportive care after adjuvant chemotherapy in resected stage IB-IIIA non-small cell lung cancer (NSCLC). *First Author: Heather A. Wakelee, Stanford University Medical Center, Stanford, CA*

Background: Adjuvant platinum-based chemotherapy (chemo) provides only a modest 5-year survival benefit in fully resected, high-risk early-stage NSCLC. We report the primary disease-free survival (DFS) results from the pre-planned interim analysis of IMpower010, a randomized phase 3 open-label trial of adjuvant atezolizumab (atezo; anti–PD-L1) vs best supportive care (BSC) after adjuvant chemo in patients (pts) with early-stage resected NSCLC. **Methods:** Eligible pts had completely resected (4-12 weeks prior to enrollment) Stage IB (≥4 cm)-IIIA NSCLC (AJCC/UICC v7) and ECOG PS 0-1. A total of 1280 pts were enrolled, and 1269 pts received up to four 21-day cycles of cisplatin-based chemo (plus pemetrexed, docetaxel, gemcitabine or vinorelbine). Of these pts (n=1269), 1005 were subsequently randomized 1:1 to 16 cycles of atezo 1200 mg Q3W or BSC. The primary endpoint of investigator-assessed DFS and secondary endpoint of overall survival (OS) were tested hierarchically: first DFS in the PD-L1 TC ≥1% (SP263) subgroup with Stage II-IIIA disease, then DFS in all randomized pts with Stage II-IIIA disease, then DFS in the ITT population (Stage IB-IIIA) and finally OS in the ITT population. Efficacy assessments were based on randomized pts. Safety was assessed in the safety-evaluable population, defined as pts who received ≥1 dose of atezo or who had ≥1 post-baseline safety assessment if randomized to the BSC arm. **Results:** At data cutoff (January 21, 2021), median follow-up was 32.2 months in the ITT population. Baseline characteristics were generally balanced between arms. Atezo showed statistically significant DFS benefit vs BSC in the PD-L1 TC ≥1% Stage II-IIIA and all randomized Stage II-IIIA populations; the significance boundary was not crossed for DFS in the ITT population (Table). OS data were immature and not formally tested. Pts in the atezo arm received a median of 16 (range, 1-16) atezo doses. Any-grade AEs occurred in 92.7% (atezo) and 70.7% (BSC); events were Grade 3/4 in 21.8% and 11.5%, respectively. Grade 5 treatment-related AEs occurred in 0.8% of pts in the atezo arm. AEs leading to atezo discontinuation occurred in 18.2% of atezo-treated pts. **Conclusions:** IMpower010 met its primary endpoint, showing DFS benefit with adjuvant atezo vs BSC after adjuvant chemo in pts with resected Stage II-IIIA NSCLC, with pronounced benefit in the PD-L1 TC ≥1% subgroup. The safety profile of atezo was consistent with prior experience of atezo monotherapy across indications and lines of therapy. Funding: F. Hoffmann-La Roche Ltd. Clinical trial information: NCT02486718. Research Sponsor: F. Hoffmann-La Roche.

Adjuvant gefitinib versus cisplatin/vinorelbine in Japanese patients with completely resected, EGFR-mutated, stage II-III non-small cell lung cancer (IMPACT, WJOG6410L): A randomized phase 3 trial. *First Author: Hirohito Tada, Suita Tokushukai Hospital, Suita, Japan*

Background: Epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor is a standard of care for *EGFR* mutation-positive, untreated metastatic non-small cell lung cancer (NSCLC). However, the efficacy and safety of adjuvant gefitinib for patients with completely resected lung cancer harboring *EGFR* mutation over cisplatin-based adjuvant chemotherapy were not known in 2011 when this study was initiated. **Methods:** From September 2011 to December 2015, we randomly assigned 234 patients with completely resected, *EGFR* mutation-positive (exon 19 deletion or L858R), stage II–III NSCLC to receive either gefitinib (250 mg, once daily) for 24 months or cisplatin (80 mg/m^2 on day 1) plus vinorelbine (25 mg/m^2 on days 1 and 8) (cis/vin) every 3 weeks for four cycles. The primary endpoint was disease-free survival (DFS) according to a central review in the intent-to-treat (ITT) population. **Results:** Two patients in the gefitinib arm withdrew consent and were excluded from the ITT population. No treatment-related deaths were seen in the gefitinib arm, but three treatment-related deaths were reported in the cis/vin arm. Median duration of follow-up was 71 months. Median DFS was numerically longer in the gefitinib arm (36 months) than in the cis/vin arm (25.2 months). However, Kaplan-Meier curves began to overlap around 5 years after surgery, and no significant difference in DFS was seen, with a hazard ratio (HR) of 0.92 (95% confidence interval (CI), 0.67–1.28; P = 0.63). Overall survival was also not significantly different (median not reached in either arm). Five-year survival rates for gefitinib and cis/vin arms were 78.0% and 74.6%, respectively, with an HR for death of 1.03; 95%CI, 0.65–1.65; P = 0.89. Exploratory subset analysis revealed that patients ^{3}70 years old in the gefitinib arm (n = 19/27 with G to cis/vin) survived longer than those in the cis/vin arm (HR 0.31; 95%CI, 0.10–0.98; P = 0.046). **Conclusions:** Adjuvant gefitinib appeared to prevent early relapse, but did not significantly prolong DFS or OS in patients with completely resected stage II–III, *EGFR*-mutated NSCLC. The apparent non-inferiority of DFS/OS may justify the use of adjuvant gefitinib in selected subset of patients, especially those deemed unsuitable for cis/vin adjuvant therapy.Clinical trial information: UMIN000006252. Research Sponsor: Astra-Zeneca.

8502 **Oral Abstract Session**

CTONG1103: Final overall survival analysis of the randomized phase 2 trial of erlotinib versus gemcitabine plus cisplatin as neoadjuvant treatment of stage IIIA-N2 EGFR-mutant non–small cell lung cancer. *First Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong Provincial Peoples Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Median Overall survival (mOS) of stage IIIA resected NSCLC was 59.4 months (m) in CTONG 1104 adj gefitinib and 26.2m in SAKK neoadjuvant chemo trial. EMERGING-CTONG1103 showed neo-adjuvant/adjuvant erlotinib treatment significantly improved progression-free survival (PFS) vs standard doublet chemotherapy in patients (pts) with epidermal growth factor receptor (*EGFR*) mutation-positive resectable stage IIIA (N2) non-small-cell lung cancer (NSCLC). Here, we present the final overall survival (OS) results from the study. **Methods:** This was a multicenter (17 centers in China) phase II randomized controlled trial of erlotinib (E) versus gemcitabine plus cisplatin (GC) as neoadjuvant/adjuvant therapy in pts with stage IIIA-N2 NSCLC with EGFR mutations in exon 19 or 21. From Dec 2011 to Dec. 2017, 386 pts sites were screened and 72 pts were randomly assigned to neoadjuvant/adjuvant E arm (N = 37) or GC arm(N = 35). Patients received erlotinib 150 mg/d (neoadjuvant therapy, 42 days; adjuvant therapy, up to 12 months) or gemcitabine 1,250 mg/m^2 plus cisplatin 75 mg/m^2 (neoadjuvant therapy, two cycles; adjuvant therapy, up to two cycles). Assessments were performed at 6 weeks and every 3 months postoperative. The primary end point was objective response rate (ORR) by Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1; secondary end points were pathologic complete response, downstaging rates of pathological lymph nodes, PFS, OS, safety, and tolerability. Data cut-off date was January, 29 2021. **Results:** With a median follow-up of 62.5 months, the median OS was 42.2months based on 47 (65.3%) events in ITT whole population. The mOS was 42.2m in E and 36.9m in GC (HR 0.83, 95%CI 0.47-1.47, p = 0.513). The 3-,5-year OS rate were 58.6%, 40.8% in E and 55.9%, 27.6% in GC respectively (p3-y = 0.819, p5-y = 0.252). All predefined subgroups including age, gender, EGFR mutation type had no significant difference in statistics between two arms. Subsequent treatments (ST) especially targeted therapy contributed most to OS (HR = 0.35 ,95% CI 0.18- 0.70). Median OS of pts receiving ST was 45.8m (n = 38), 34.6m in other treatment (n = 12), 24.6m in without ST (n = 15). For E mOS were 46.4 (n = 15; target therapy), 42.2m (n = 8; other) and 24.6m (n = 9; without, p = 0.021), for GC 42.6 (n = 23; target therapy), 30.1m (n = 4;other) and 24.6m(n = 6; without, p = 0.130). The RR was 53.3%, DCR 93.3%, mPFS 10.9m and mPPS 21.9m for patients with rechallenged EGFR TKI in E arm (n = 15). No novel unexpected SAE was observed during follow up. **Conclusion:** Erlotinib as neoadjuvant/adjuvant therapy for resected N2 NSCLC was feasibility and had a promising OS. The PFS survival advantage of E did not translate to OS difference in EMERGING trial (NCT01407822). Clinical trial information: NCT01407822. Research Sponsor: Chinese Thoracic Oncology Group (CTONG).

8503 **Oral Abstract Session**

Surgical outcomes from the phase 3 CheckMate 816 trial: Nivolumab (NIVO) + platinum-doublet chemotherapy (chemo) vs chemo alone as neoadjuvant treatment for patients with resectable non-small cell lung cancer (NSCLC). *First Author: Jonathan Spicer, McGill University Health Center, Montréal, QC, Canada*

Background: CheckMate 816 (NCT02998528) is a randomized phase 3 study of neoadjuvant NIVO + chemo vs chemo in resectable NSCLC. The study met its first primary endpoint, demonstrating significantly improved pathological complete response (pCR) with neoadjuvant NIVO + chemo. Here we report key surgical outcomes from the study. **Methods:** Adults with stage IB (≥ 4 cm)–IIIA (per AJCC 7th ed) resectable NSCLC, ECOG PS ≤ 1, and no known *EGFR*/*ALK* alterations were randomized to NIVO 360 mg + platinum-doublet chemo Q3W or chemo Q3W for 3 cycles (n = 179 each). Definitive surgery was to be performed within 6 weeks of treatment. Primary endpoints are pCR (defined as 0% viable tumor cells in lung and lymph nodes) and event-free survival; both are evaluated by blinded independent review. Feasibility of surgery and surgery-related adverse events (AEs) are exploratory endpoints. **Results:** Baseline characteristics were comparable between arms; 64% of patients (pts) were stage IIIA. Definitive surgery rates were 83% with NIVO + chemo (n = 149) vs 75% with chemo (n = 135). Reasons for cancelled surgery were disease progression (12 and 17 pts, respectively), AEs (2 pts/arm), or other scenarios (14 and 19 pts, respectively; including pt refusal, unresectability, poor lung function). Minimally invasive surgery rates were 30% and 22%, and conversion from minimally invasive to open surgery rates were 11% and 16% for NIVO + chemo and chemo, respectively. Lobectomy was performed in 77% vs 61% of pts, and pneumonectomy in 17% and 25% for NIVO + chemo vs chemo, respectively. AEs were responsible for delays of surgery in 6 pts in the NIVO + chemo arm and 9 pts in the chemo arm. An R0 resection was achieved in 83% vs 78% of pts and median residual viable tumor (RVT) cells in the primary tumor bed were 10% vs 74% for NIVO + chemo vs chemo. There was no increase in median (Q1, Q3) duration of surgery and length of hospitalization between NIVO + chemo vs chemo (184 [130, 252] vs 217 [150, 283] min; and 10.0 [7, 14] vs 10.0 [7, 14] days, respectively). Any-grade and grade 3–4 surgery-related AEs were reported in 41% vs 47% and 11% vs 15% of the NIVO + chemo vs chemo arms, respectively. Grade 5 surgery-related AEs were reported in 2 vs 0 pts in the NIVO + chemo vs chemo arms; 0 vs 3 pts died due to treatment-related AEs, respectively. **Conclusions:** In CheckMate 816, neoadjuvant NIVO + chemo did not impede the feasibility and timing of surgery, nor the extent or completeness of resection vs chemo alone; treatment was tolerable and did not increase surgical complications. NIVO + chemo led to increased depth of pathological response. The surgical outcome data from CheckMate 816 along with significant improvement in pCR support NIVO + chemo as a potential neoadjuvant option for patients with stage IB to IIIA resectable NSCLC. Clinical trial information: NCT02998528. Research Sponsor: Bristol Myers Squibb.

Video-assisted thoracoscopic versus open lobectomy in patients with early-stage lung cancer: One-year results from a randomized controlled trial (VIOLET). *First Author: Eric Kian Saik Lim, Royal Brompton and Harefield Hospitals, London, United Kingdom*

Background: Video assisted thoracoscopic surgery (VATS) is a popular access for lung cancer resection. However, there is limited information from RCTs from in-hospital to one-year clinical efficacy, safety and oncologic outcomes of a minimal access approach. **Methods:** VIOLET is a parallel group multi-center RCT conducted in 9 centers in the United Kingdom that recruited participants with known or suspected (cT1-3, N0-1 and M0) lung cancer (ISRCTN13472721). Trial protocol: https://bmjopen.bmj.com/content/9/10/e029507.info. **Results:** From July 2015 to February 2019, 503 participants were randomized to VATS (n=247) or open (n=256) lobectomy. Patients allocated to VATS had less pain with a mean difference (MD) in visual analogue score of -0.54 (95%CI -0.99 to -0.10) despite less analgesic consumption (mean ratio 0.90, 95%CI 0.80 to 1.01). After discharge pain was consistent on multiple sub-scales including overall pain (MD -7.19, -10.59 to -3.80), chest pain (MD -4.66, -7.96 to -1.36) and an 18% relative risk (RR) reduction in incision pain (RR 0.82; 0.72 to 0.94) up to one-year. Better functional recovery continued in VATS arm after discharge with better physical function (primary outcome) with MD of 4.65 (1.69 to 7.61; P=0.002) at 5 weeks and overall improvement in global health status with a MD of 4.21 (1.62 to 6.79; P=0.001). In hospital, VATS arm had fewer complications (RR 0.74, 0.66 to 0.84; P<0.001) with no difference in serious adverse events (RR 0.98, 0.59 to 1.63; P=0.948). Median hospital stay was one day shorter in the VATS arm (4 vs 5 days) corresponding to hazard ratio (HR) for discharge of 1.34, 95%CI 1.09 to 1.65; P=0.006). After discharge VATS arm had 19% less serious adverse events (RR 0.81, 0.66 to 1.00; p=0.053) and lower readmission rates (29.0% vs. 35.9% respectively) to one-year. Of those with lymph node disease, 50.9% in the VATS and 45.9% in open arms received adjuvant treatment. There was no difference in the time to uptake of adjuvant chemotherapy (HR 1.12, 0.62 to 2.02; p=0.716). Recurrence with clinical follow up and CT at one-year was similar with 7.7% versus 8.1% in the VATS and open groups respectively. Progression-free survival (HR 0.74, 0.43 to 1.27; p=0.27) and overall survival HR 0.67, 0.32 to 1.40; p=0.282) was not significantly different. **Conclusions:** VATS lobectomy for lung cancer is associated with less pain, fewer in-hospital complications and shorter hospital stay, achieved without any compromise to early oncologic outcomes nor serious adverse events. Superior functional recovery continues in the post-operative period with improved physical function, lower re-admission rates and no difference in disease-free and overall survival up to one-year. Clinical trial information: ISRCTN13472721. Research Sponsor: UK National Institute of Healthcare Research.

8505 **Oral Abstract Session**

Phase 3 comparison of high-dose once-daily (QD) thoracic radiotherapy (TRT) with standard twice-daily (BID) TRT in limited stage small cell lung cancer (LSCLC): CALGB 30610 (Alliance)/RTOG 0538. *First Author: Jeffrey A Bogart, SUNY Upstate Medical University, Syracuse, NY*

Background: Although level 1 evidence is lacking, the majority of patients (pts) with LSCLC are treated with a high dose QD TRT regimen in clinical practice. CALGB 30610/RTOG 0538 was designed to determine if administering high dose TRT would improve overall survival (OS), compared with standard 45 Gy BID TRT, in LSCLC pts treated with chemoradiotherapy. **Methods:** Eligible pts had LSCLC, ECOG performance status (PS) 0-2 and regional lymph node involvement excluding contralateral hilar or supraclavicular nodes. This phase 3 trial was conducted in 2 stages. In the first stage, pts were randomized 1:1:1 to 45 Gy BID over 3 weeks, 70 Gy QD over 7 weeks, or 61.2 Gy concomitant boost (CB) over 5 weeks. For the second stage, the study planned discontinuation of one high dose arm based on interim toxicity analysis with patients then randomized 1:1 in the two remaining arms. TRT was given starting with either the 1st or 2nd (of 4 total) chemotherapy cycles. The primary endpoint was OS measured from date of randomization. **Results:** The trial opened 03/15/2008 and closed 12/01/2019 upon completing accrual, with the CB arm discontinued 3/11/2013 after interim analysis. This analysis includes 638 pts randomized to 45 Gy BID TRT (n = 313) or 70 Gy QD TRT (n = 325). Median age was 63 years (range 37-81), the majority of pts were Caucasian (86%), female (52%), and with ECOG PS 0-1 (95%). After median follow-up of 2.84 years (IQR:1.35 -5.61) for surviving pts, QD compared to BID did not result in a significant difference in OS (HR 0.94, 95% CI: 0.76-1.2 , p = 0.9). Median, 2- and 4-year OS for QD were 30.5 months (95% CI: 24.4-39.6), 56% (95% CI: 0.51-0.62), and 39% (95% CI: 0.33-0.45), and for BID 28.7 months (95% CI: 26.2-35.5), 59% (95% CI: 0.53-0.65), and 35% (95% CI: 0.29-0.42). QD also did not result in a significant difference in PFS (HR 0.96, 95% CI: 0.78-1.18, p = 0.94). Most grade 3+ hematologic and non-hematologic adverse events (AEs) were similar between cohorts. Rates of grade 3+ febrile neutropenia, dyspnea, esophageal pain and dysphagia for QD were 12.6% ,7%, 11.6% and 11.3% , and for BID 13.6%, 4%, 11.2 % and 9.5% . Grade 5 AEs were reported in 3.7% and 1.7% of the QD and BID cohorts, respectively. Results will be updated at presentation. **Conclusions:** High dose QD TRT to 70 Gy did not significantly improve OS compared with standard 45 Gy BID TRT. Nevertheless, favorable outcomes on the QD arm provide the most robust evidence available supporting high dose once-daily TRT as an acceptable option in LSCLC. Outcomes from this study, the largest conducted in LSCLC to date, will help guide TRT decisions for this patient population. Stereotactic ablative radiotherapy in operable stage I NSCLC patients: Long-term results of the expanded STARS clinical trial. *First Author: Joe Y. Chang, Department of Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We published a pooled analysis of 2 randomized trials (STARS/ROSEL) that compared lobectomy with mediastinal lymph node dissection (L-MLND) vs stereotactic ablative radiotherapy (SABR) in operable stage I NSCLC. There were no significant differences in disease progression but significantly higher 3-year overall survival (OS) in the SABR arm (95% vs 79%). Owing to concerns regarding the small sample size (n = 58), short follow-up (3 years), and non-uniform use of video-assisted thoracoscopic surgery (VATS), we expanded the STARS protocol to a single-arm SABR trial with a protocol-specified comparison to a published, longitudinally-followed institutional cohort of stage IA NSCLC status post VATS L-MLND (n = 229). **Methods:** Inclusion criteria were stage IA NSCLC (≤3 cm, N0M0 and staged by PET/CT with EBUS) with Zubrod performance status (PS) 0-2, baseline FEV1 > 40% and DLCO > 40% and deemed operable by a multidisciplinary team. SABR utilized 4-dimensional CT simulation and volumetric image guidance; 54 Gy in 3 fractions were delivered to planning target volumes (PTVs) located peripherally, or 50 Gy in 4 fractions to more central PTVs. All patients were followed by chest CT every three months for the first two years, every 6 months for another three years, and then annually. Non-inferiority of SABR could be claimed if the 3-year OS was not lower than the historical VATS L-MLND cohort by more than 12%. We conducted a risk-factor matched comparison study of the primary outcome between the SABR and the historical VATS L-MLND. **Results:** The median follow-up among the 80 SABR patients was 61 months (range, 34-79 months). The OS and progression-free survival (PFS) were 91% (95% CI: 85~98%) and 80% (95% CI: 72~89%) at 3 years, and 87% (95% CI: 79~95%) and 77% (95% CI: 68~87%) at 5 years, respectively. The 5-year cumulative incidence rate counting death as competing risk was 6.3% (95% CI: 2.3~13.2%) local, 12.5% (95% CI: 6.4~20.8%) regional, and 8.8% (95% CI: 3.8~16.2%) distant (any recurrence 17.6% (95% CI: 10.1~26.7%)). The 5 year cumulative incidence rate of second lung primary was 6.9% (95% CI: 2.5~14.6%). There were 1.3% grade 3 and no grade 4-5 toxicities. The propensity score matched (age, gender, tumor size, histology, PS) comparison of SABR vs VATS L-MLND revealed no significant differences in PFS (p = 0.063), lung cancer-specific survival (p = 0.075), or cumulative incidence rates of local (p = 0.54), regional (p = 0.97), or distant failures (p = 0.33). The SABR arm was associated with significantly higher OS (91% vs 82% at 3 years and 87% vs 72% at 5 years; p = 0.012 from log-rank test). The hazard ratio was 0.411 (95% CI: 0.193~0.875; p = 0.021). **Conclusions:** The long-term OS and PFS of SABR is not inferior to VATS L-MLND for operable stage IA NSCLC. SABR remains a promising approach for this population, but multidisciplinary management is strongly recommended. Clinical trial information: NCT02357992. Research Sponsor: Varian Medical Systems.

8507 **Oral Abstract Session**

A randomized phase II trial of oral vinorelbine as second-line therapy for patients with malignant pleural mesothelioma. *First Author: Dean Anthony Fennell, University of Leicester and University Hospitals of Leicester, Leicester, United Kingdom*

Background: All patients with malignant pleural mesothelioma (MPM) eventually relapse following standard chemotherapy. However, there is no standard treatment option in this setting. Vinorelbine, exhibits useful clinical activity but has not been formally evaluated in a randomised clinical trial, despite its widespread off-label use worldwide. BRCA1 regulates spindle assembly checkpoint in MPM and predicts vinorelbine sensitivity in preclinical models [1,2], suggesting that BRCA1 negative patients may be chemoresistant. **Methods:** VIM, a Cancer Research UK funded, investigator-initiated randomised controlled phase 2 multicentre UK trial, enrolled patients with MPM who had progressed after first-line chemotherapy. Pts were randomised 2:1 to either vinorelbine (60mg/m^2 weekly Q21d escalating to 80mg/m^2 from cycle 2) + active supportive care (ASC) versus ASC until disease progression, unacceptable toxicity or withdrawal of consent. The primary outcome was progression free survival (PFS) defined as the time from randomisation to any progression (based on Modified RECIST criteria for assessment of response in malignant pleural mesothelioma) or death. The trial had 90% power to detect a hazard ratio of 0.65 at the one-sided 20% significance level. Secondary endpoints were overall survival (OS), tolerability and safety. **Results:** Between May 2016 and Oct 2018, 154 patients were recruited from 10 UK sites and randomised to vinorelbine + ASC (n=98) or ASC alone (n=56). In the Intention-to-treat analysis, after 129 events, median PFS was 4.2 months (m) for vinorelbine + ASC compared to 2.8m for ASC alone (Hazard Ratio (HR) 0.59; 95% CI: 0.41 to 0.85; one-sided p = 0.0017). 108 deaths were reported. Median OS was 9.3m for vinorelbine + ASC compared to 9.1m for ASC alone (HR=0.79; 95% CI: 0.53 to 1.17; two-sided p = 0.24). Toxicity data and subgroup analyses including the impact of BRCA1 deficiency will be presented. **Conclusion:** The trial met its primary endpoint. Vinorelbine demonstrates useful clinical efficacy in relapsed MPM, supporting its off-label use, as a treatment option for patients with relapsed MPM.[1] Busacca et al, J Pathol 2012, 227(2), 200. [2] Busacca et al, Mol Cancer Res, 2021, 20(2) 379. Clinical trial information: NCT02139904. Research Sponsor: Clinical Trials Advisory and Awards Committee , Cancer Research UK Core funding.

8508 **Poster Discussion Session**

Real-world multiomic characterization of small cell lung cancer subtypes to reveal differential expression of clinically relevant biomarkers. *First Author: Sonam Puri, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: The dominant expression of four lineage-defining transcription factors (*ASCL1*, *NEUROD1*, *YAP1*, or *POU2F3*) has enabled the classification of small cell lung cancer (SCLC) into four subtypes (SCLC-A/N/Y/P, respectively). Emerging evidence suggests that *YAP1* expression is associated with a T-cell inflamed phenotype, and SCLC has significant intra-tumor heterogeneity mediated by MYC-driven activation of NOTCH signaling. We performed a large-scale analysis of real-world SCLC patient samples to examine the expression of clinically relevant biomarkers across SCLC subtypes. **Methods:** Comprehensive molecular profiling of 437 small cell lung neuroendocrine tumors (including 7.3% high-grade neuroendocrine lung carcinomas) was performed using next-generation DNA sequencing (592-gene panel), RNA sequencing (whole transcriptome), and immunohistochemistry at Caris Life Sciences (Phoenix, AZ). Tumors were stratified into 5 subgroups (SCLC-A/N/Y/P and -mixed) based on the relative expression of the four transcription factors. RNA expression of key genes and previously validated immune signatures (T-cell inflamed, NK cell, and STING pathway signatures) were evaluated across subgroups. Significance was tested by Chi-square, Fisher's exact test, or Mann-Whitney U test. **Results:** Median age of the study cohort was 66 years (IQR: 59-72) and 50.6% of patients were female. The majority (67.3%) of samples were derived from metastatic sites. Stratification of tumors by expression resulted in 35.7% SCLC-A, 17.6% SCLC-N, 21.1% SCLC-Y, 6.4% SCLC-P, and 19.2% SCLC-mixed samples. Compared to tumors from metastatic sites, *YAP1* expression was significantly increased ($p < 0.001$) in primary tumors. Amongst the 14 tumors obtained from the CNS, SCLC-N (36%, n = 5) was the most common subtype identified. dMMR/MSI-high (negative MMR protein expression/ ≥46 altered loci per tumor) was rare overall (0.5%, n = 2); TMB (median of 9-10 mut/Mb) was similar between the SCLC subtypes. SCLC-Y was associated with the highest expression of T-cell inflamed, NK cell and STING pathway signatures ($p < 0.0001$ each). *MYC* and *NOTCH* gene expression (*NOTCH1/2/3/4*) strongly correlated with *YAP1* expression. Analysis of co-mutations revealed that *EGFR*-sensitizing mutations (L858R and Exon 19 deletions) were recurrent (5.2%, n = 4) in SCLC-N tumors. The expression of *SNF11*, *SSTR2*, and *MYC* varied significantly among SCLC subtypes ($p < 0.001$ each), with the highest median expression of *SNF11* and *SSTR2* observed in SCLC-N, while *MYC* expression was highest in SCLC-P. **Conclusions:** Our analysis represents the largest real-world dataset of human SCLC tumors profiled by whole transcriptomic sequencing. The differential expression of immune genes and predictive biomarkers across SCLC subtypes may inform therapeutic vulnerabilities for rational and personalized treatment approaches in SCLC. Research Sponsor: None.

Signatures of plasticity and immunosuppression in a single-cell atlas of human small cell lung cancer. *First Author: Joseph Minhow Chan, MSKCC, New York, NY*

Background: Small cell lung cancer (SCLC) is an aggressive malignancy that includes subtypes defined by differential expression of *ASCL1*, *NEUROD1*, and *POU2F3* (SCLC-A, -N, and -P, respectively), which are associated with distinct therapeutic vulnerabilities. The emerging consensus on SCLC subtypes has led to new questions, such as whether subtypes are associated with different disease stages, metastatic potential, or immune microenvironments; whether there is plasticity between subtypes; and whether novel SCLC phenotypes exist. Single cell RNA sequencing (scRNA-seq) offers a unique opportunity to address these questions by dissecting intratumoral transcriptional heterogeneity and the surrounding tumor microenvironment (TME). However, efforts to apply this technology to human SCLC tumors have been limited, as these tumors are infrequently resected. **Methods:** We have optimized protocols to process both surgical resections and biopsies to construct the first single-cell atlas of SCLC patient tumors (N = 21), with comparative lung adenocarcinoma (LUAD) and normal lung data. We leverage computational methods including diffusion maps and non-negative matrix factorization to perform a deep annotation of SCLC phenotypes and the surrounding immune TME. We perform validation experiments using flow cytometry, Vectra, and immunohistochemistry in independent SCLC cohorts, as well as genetic manipulation in preclinical SCLC models. **Results:** Our data reveals substantial transcriptional heterogeneity in SCLC both within and across tumors and confirms a pro-metastatic gene program in SCLC-N subtype characterized by epithelial-mesenchymal transformation and axonogenesis. Beyond known subtypes, we discover a *PLCG2*-high tumor cell population with stem-like, pro-metastatic features that recurs across subtypes and predicts significantly worse overall survival. Manipulation of *PLCG2* expression in cells confirms correlation with key metastatic markers. Treatment and subtype are associated with substantial phenotypic changes in the SCLC immune microenvironment, with greater T-cell dysfunction in SCLC-N than SCLC-A. Moreover, the recurrent, *PLCG2*-high subclone is associated with exhausted CD8+ T-cells and a pro-fibrotic, immunosuppressive monocyte/macrophage population, suggesting possible tumor-immune coordination to promote metastasis. **Conclusions:** This atlas of SCLC illustrates how canonical subtypes and a novel *PLCG2*-high recurrent tumor subclone enlist diverse gene programs to create tumor heterogeneity and facilitate metastasis in a profoundly immunosuppressed TME. Our dataset provides further insight into tumor and immune biology in SCLC at single-cell resolution, with potential implications for design of novel targeted therapies and immunotherapeutic approaches. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

8510 **Poster Discussion Session**

Updated results from a phase 1 study of AMG 757, a half-life extended bispecific T-cell engager (BiTE) immuno-oncology therapy against delta-like ligand 3 (DLL3), in small cell lung cancer (SCLC). *First Author: Taofeek K. Owonikoko, Department of Hematology and Medical Oncology, Emory University School of Medicine, Atlanta, GA*

Background: DLL3, an inhibitory Notch ligand, is a promising target as it is highly expressed in SCLC compared to normal tissue. AMG 757, a half-life extended BiTE immuno-oncology therapy, binds DLL3 on tumor cells and CD3 on T cells, leading to T cell-dependent killing of tumors. Results from the first nine dosing cohorts showing preliminary efficacy of AMG 757 (confirmed partial response [PR], 14% of pts) were previously presented. Here, updated safety, efficacy, and pharmacokinetic data from 10 cohorts from the ongoing phase 1 study of AMG 757 in SCLC are reported (NCT03319940). **Methods:** AMG 757 (0.003100 mg) was administered IV every 2 weeks ± step dosing. Eligible patients (pts) had SCLC that progressed after ≥1 platinum-based regimen. Antitumor activity was assessed by modified RECIST 1.1. **Results:** As of 11 Jan 2021, 64 pts enrolled at 10 dose levels (DLs; 0.003100 mg) had received ≥1 AMG 757 dose and were available for analyses. Median age was 64 (range, 3280) y; 63 pts (98%) had ECOG PS 01 and median number of prior lines of therapy was 2 (range, 16), with 28 pts (44%) receiving prior PD-1/PD-L1 therapy. Median treatment duration was 6 (range, 0.171) wk. Treatment-related AEs occurred in 53 pts (83%): 16 (25%) ≥ grade (G) 3, 4 (6%) ≥G4, 1 (2%) G5 (pneumonitis; DL5 [0.3 mg]). AEs led to discontinuation in 1 pt (G3 encephalopathy, DL10 [100 mg]). Cytokine release syndrome (CRS; graded per Lee 2014 criteria) was reported in 27 pts (42%): G2 in 7 (11%), ≥G3 in 1 (2%). CRS presented mainly as fever (31%), tachycardia (17%), nausea (13%), fatigue (9%), and hypotension (9%). CRS was usually reversible and was managed with supportive care, corticosteroids, and/or anti-IL-6R. CRS did not lead to any treatment discontinuations. Sixty pts treated across 10 DLs, with a median follow-up of 4.2 (range, 0.218.6) mo, were evaluated for efficacy. Confirmed PR across all DLs was reported in 8/60 pts (13%), with 5/8 pts (63%) pts achieving unconfirmed PR at 100 mg (DL10). The median time to response was 1.7 (range, 1.23.7) mo. The estimated duration of response was >6 months in 71% pts (95% CI: 26, 92) with any PR. Disease control rate was 43%, with any tumor shrinkage in 23/60 pts (38%). AMG 757 serum exposures increased approximately dose proportionally within the evaluated dose range. **Conclusions:** AMG 757 has an acceptable safety profile at doses up to 100 mg. Responses were rapid and durable. Encouraging anti-tumor activity was seen across dose ranges, with ongoing unconfirmed PR in 5/8 pts (63%) at the highest DL. The study is ongoing; updated data, including response rates and duration of response, will be presented. Clinical trial information: NCT03319940. Research Sponsor: Amgen Inc.

8511 **Poster Discussion Session**

Five-year survival outcomes with durvalumab after chemoradiotherapy in unresectable stage III NSCLC: An update from the PACIFIC trial. *First Author: David R. Spigel, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: In the placebo-controlled Phase III PACIFIC trial of patients with unresectable Stage III NSCLC whose disease had not progressed after platinum-based concurrent chemoradiotherapy (cCRT), durvalumab improved overall survival (OS) (stratified hazard ratio [HR] 0.68; 95% confidence interval [CI] 0.53–0.87; p=0.0025; data cut-off [DCO] Mar 22, 2018) and progression-free survival (PFS) (stratified HR 0.52, 95% CI 0.42–0.65; p<0.0001; DCO Feb 13, 2017) based on the DCOs used for the primary analyses, and the degree of benefit remained consistent in subsequent updates. Durvalumab was associated with a manageable safety profile, and did not detrimentally affect patient-reported outcomes, compared with placebo. These findings established consolidation durvalumab after CRT (the 'PACIFIC regimen') as the standard of care in this setting. We report updated, exploratory analyses of OS and PFS, assessed approximately 5 years after the last patient was randomized. **Methods:** Patients with WHO PS 0/1 (and any tumor PD-L1 status) whose disease did not progress after cCRT (≥2 overlapping cycles) were randomized (2:1) 1–42 days following cCRT (total prescription radiotherapy dose typically 60–66 Gy in 30–33 fractions) to receive 12 months' durvalumab (10 mg/kg IV every 2 weeks) or placebo, stratified by age (<65 vs ≥65 years), sex, and smoking history (current/former smoker vs never smoked). The primary endpoints were OS and PFS (blinded independent central review; RECIST v1.1) in the intent-to-treat (ITT) population. HRs and 95% CIs were estimated using stratified log-rank tests in the ITT population. Medians and OS/PFS rates at 60 months were estimated with the Kaplan–Meier method. **Results:** Overall, 709/713 randomized patients received treatment in either the durvalumab (n/N=473/476) or placebo (n/N=236/237) arms. The last patient had completed study treatment in May 2017. As of Jan 11, 2021 (median follow-up duration of 34.2 months in all patients; range, 0.2–74.7 months), updated OS (stratified HR 0.72, 95% CI 0.59–0.89; median 47.5 vs 29.1 months) and PFS (stratified HR 0.55, 95% CI 0.45–0.68; median 16.9 vs 5.6 months) remained consistent with the results from the primary analyses. The 60-month OS rates were 42.9% and 33.4% with durvalumab and placebo, respectively, and 60-month PFS rates were 33.1% and 19.0%, respectively. Updated treatment effect estimates for patient subgroups will be presented. **Conclusions:** These updated survival analyses, based on 5-year data from PACIFIC, demonstrate robust and sustained OS plus durable PFS benefit with the PACIFIC regimen. An estimated 42.9% of patients randomized to durvalumab remain alive at 5 years and approximately a third remain both alive and free of disease progression. Clinical trial information: NCT02125461. Research Sponsor: AstraZeneca.

8512 **Poster Discussion Session**

KEYNOTE-799: Phase 2 trial of pembrolizumab plus platinum chemotherapy and radiotherapy for unresectable, locally advanced, stage 3 NSCLC. *First Author: Salma K. Jabbour, Department of Radiation Oncology, Rutgers Cancer Institute of New Jersey, Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ*

Background: KEYNOTE-799 (NCT03631784) is an ongoing study of the anti–PD-1 antibody pembrolizumab (pembro) plus concurrent chemoradiation therapy (cCRT) in patients (pts) with unresectable, locally advanced stage III NSCLC. Prior results from this study in a subset of pts (primary efficacy population) showed an ORR of 69.6% in cohort A (squamous and nonsquamous, n = 112) and 70.5% in cohort B (nonsquamous, n = 61), and grade ≥3 pneumonitis in 8.0% and 7.9% of pts, respectively. Here, we present results for all pts enrolled in KEYNOTE-799. **Methods:** This nonrandomized, multisite, open-label phase 2 trial enrolled pts aged ≥18 y with previously untreated, unresectable, pathologically confirmed, stage IIIA–C NSCLC with measurable disease per RECIST v1.1. Pts in cohort A (squamous and nonsquamous) received 1 cycle of carboplatin AUC 6 and paclitaxel 200 mg/m^2 and pembro 200 mg. After 3 wks, pts received carboplatin AUC 2 and paclitaxel 45 mg/m^2 QW for 6 wks and 2 cycles of pembro 200 mg Q3W plus standard thoracic radiotherapy (TRT). Pts in cohort B (nonsquamous only) received 3 cycles of cisplatin 75 mg/m^2, pemetrexed 500 mg/m^2,and pembro 200 mg Q3W, and TRT in cycles 2 and 3. All pts received an additional 14 cycles of pembro 200 mg Q3W. Primary endpoints were ORR per RECIST v1.1 by blinded independent central review (BICR) and the incidence of grade ≥3 pneumonitis (per NCI CTCAE v4.0). Efficacy and safety were assessed in all pts as-treated. **Results:** Of 216 pts enrolled in KEYNOTE-799 (cohort A, n = 112; cohort B, n = 104), 112 in cohort A and 102 in cohort B received treatment. As of October 28, 2020, the median (range) time from first dose to database cutoff was 18.5 (13.6–23.8) mo in cohort A and 13.7 (2.9–23.5) mo in cohort B. ORR (95% CI) was 70.5% (61.2%–78.8%) in cohort A and 70.6% (60.7%–79.2%) in cohort B. Median DOR was not reached in either cohort (Table). ORR was similar regardless of PD-L1 status ([TPS <1% and TPS ≥1%]; Cohort A, 66.7% and 75.8%; Cohort B, 71.4% and 72.5%) and tumor histology (Cohort A, squamous, 71.2% and nonsquamous, 69.2%). Grade ≥3 pneumonitis occurred in 9 pts (8.0%) in cohort A and 7 (6.9%) in cohort B. Grade 3–5 treatment-related AEs occurred in 72 pts (64.3%) in cohort A and 51 (50.0%) in cohort B. **Conclusions:** Pembro plus cCRT continues to demonstrate promising antitumor activity, regardless of PD-L1 TPS and tumor histology, and manageable safety in pts with previously untreated, locally advanced, stage III NSCLC with longer follow-up. Clinical trial information: NCT03631784. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

AFT-16: Phase II trial of neoadjuvant and adjuvant atezolizumab and chemoradiation (CRT) for stage III non-small cell lung cancer (NSCLC). *First Author: Helen J. Ross, Thoracic Oncology, Phoenix, AZ*

Background: A minority of the approximately 40,000 US patients diagnosed annually with stage III NSCLC can be cured by concurrent CRT. Standard adjuvant immune checkpoint inhibitors (ICI) improve outcome for those patients who complete CRT with good performance status (PS) and without disease progression, but most patients diagnosed with unresectable stage III NSCLC will not meet the criteria for adjuvant ICI. AFT-16 investigated safety and efficacy of neoadjuvant and adjuvant atezolizumab as a strategy that may allow more patients to benefit from ICI. **Methods:** Eligible patients received 4 cycles (cy) of atezolizumab 1200 mg IV q 21 days followed by CRT with 60 Gy + weekly carboplatin and paclitaxel (CP), CP consolidation and adjuvant atezolizumab to complete 1 year of therapy (17 cy). The primary endpoint of disease control rate at 12 weeks (wks) has been reported. Secondary endpoints reported here include overall response rate, safety, and progression-free and overall survival (PFS, OS) measured from the start of induction therapy. Correlative science data and quality of life endpoints will be reported elsewhere. **Results:** 64 patients with unresectable stage III NSCLC, PS 0-1 and no active autoimmune disease or significant organ dysfunction were enrolled at 13 Alliance for Clinical Trials in Oncology sites from 11/2017 to 7/2019. 62 patients who received at least one dose of atezolizumab are included in this analysis. Median age was 63.9 years (range 38.1-86.5). Patients were 51.6% female, 77.4% white, 88.7% current & former smokers and 56.5% PS 0. All patients are off study treatment. Mean cycles of treatment received was 9 (1-17). 46 patients were alive at median follow up 24.1 mo (range 3 – 34.1 mo). PFS at 12 and 18 mo from start of induction atezolizumab was 66% (95%CI 55-79) and 57% (95%CI 45-71) respectively. Median PFS was 23.7 mo (95%CI 13.2-NE). OS at 18 mo was 84% (95%CI 75-94). Median OS is not yet estimable. Atezolizumab was well tolerated. One grade (gr) 4 Guillain-Barre syndrome and 1 each gr 3 pneumonia, pneumonitis and colitis were attributable to neoadjuvant atezolizumab. The remaining 9 severe adverse events were unrelated to ICI. **Conclusions:** Atezolizumab prior to and following CRT for stage III unresectable NSCLC was well tolerated with encouraging PFS and OS without unexpected safety signals. Analysis of correlative endpoints and quality of life are ongoing. Further study of induction atezolizumab is warranted in patients with unresectable stage III NSCLC. Racial differences in incidence, outcomes, and genomic alterations in small cell lung cancer. *First Author: Leyla Bayat, University Hospital Case Western Medical Center, Cleveland, OH*

Background: While the incidence of small cell lung cancer (SCLC) has been decreasing in recent years, an increasing proportion of our patients are younger African American (AA) women. There have been no studies describing these changes as well its impact on outcome and potential genomic differences amongst white and AA populations. **Methods:** We maintain a clinical/genomic/pathological database of all patients with SCLC treated at our comprehensive cancer center starting from 1998. We compared the baseline characteristics and outcomes (Overall survival [OS] and progression-free survival [PFS]) between AA and white patients, and between females and males. In addition, we looked at genomic alterations in >350 cancer-related genes and compared the frequency and types of mutations in our study population. **Results:** A total of 917 patients with SCLC were included (median age 66 years, 486 female, 179 African American). Amongst the African American patients, 67.6% were female, a striking difference compared to the white population, where only 49.1% were women (P<0.001). In multivariable analysis, there was no association between gender or race with OS or PFS (P> 0.05). There was an increase in mutational frequency in AA women compared to both AA men and white patients. PIK3CA and KIT mutations were more frequent in females while APC mutations were more frequent in males (P=0.041 for all comparisons). There was a trend toward increased mutational frequencies in TP53, PTEN, and NOTCH1 in AA patients. The relative frequency of gene alterations is shown in the table. In univariable analysis, NOTCH1 mutation was associated with improved OS (HR 0.24 [0.06-0.96], P=0.04). **Conclusions:** In this large cohort of patients with SCLC followed over 2 decades, there was a striking 2-fold higher incidence of SCLC in AA females than in AA males, although there were no differences in OS or PFS by sex or race. Several genomic alterations occur in higher frequencies in AA patients and AA women, in particular, have higher mutational frequencies. Research Sponsor: None.

Impact of socioeconomic disparities on diagnosis and overall survival in small cell lung cancer: A National Cancer Database analysis. *First Author: Logan Roof, Cleveland Clinic, Cleveland, OH*

Background: Small cell lung cancer (SCLC) accounts for approximately 13% of all lung cancer diagnoses in the United States. The demographics of this disease have evolved over time; in the 1970s 28% of patients with SCLC were female, while in the early 2000s, 50% were female. Remarkable differences in incidence, mortality rates, and trends by race and geographic location have also been noted. There has been a paucity of data regarding changes in epidemiology and patient demographics in SCLC since the early 2000s. Given recent treatment advances, the impact these factors have on patient outcomes for SCLC requires further evaluation. **Methods:** We identified all patients with SCLC in the NCDB from 2004 to 2016. Differences in demographic, disease, and treatment characteristics were assessed by year of diagnosis using Chi-square test. The effect of age, race, insurance status, income, distance to treatment center, and education level on overall survival (OS) was assessed by log-rank test. **Results:** There were 137,253 cases of SCLC diagnosed in the NCDB between 2004-2010 and 124,796 cases between 2011-2016. Patients diagnosed after 2010 were significantly older, had more comorbidities, had more stage IV disease, were more frequently treated at academic centers, more commonly had government primary payer insurance, and lived significantly further away from their treatment center. There were significant differences in gender, race/ethnicity groups, education level, and residence area, with more females, more African Americans, more patients without a high school diploma, and more rural patients diagnosed after 2010. OS in general improved between the two time periods, with median OS of 8.41 months (95% CI: 8.34-8.48%) and 5-year OS rate of 6.8% (95% CI: 6.6-6.9%) in patients diagnosed between 2004-2010 and median OS of 8.61 months (95% CI: 8.54-8.67%) and 5-year OS rate of 8.7% (95% CI: 8.5-8.9%) in patients diagnosed after 2010, despite an increase in stage IV disease in the latter group. Some of the differences in demographics were associated with changes in OS. Older patients, male patients, Caucasian patients, patients with stage IV disease, patients with government primary payer insurance, and rural patients all had significantly worse OS. Patients without comorbidities and patients treated at an academic center had significantly better OS. OS was found to significantly increase as both income and education level increase. **Conclusions:** SCLC continues to be a frequent cancer diagnosis. Despite improvement in overall survival during the time frame studied, there were significant disparities noted in key demographics that negatively affect access to healthcare resources, including rural communities, distance to an academic center, income, insurer, and education level. Collective efforts to impact these disparities will likely lead to improved outcomes for patients with SCLC. Research Sponsor: None.

Racial disparities in lung adenocarcinoma: The contribution of African ancestry. *First Author: Michelle Jeung-Eun Lee, Morehouse School of Medicine, Atlanta, GA*

Background: Racial disparities in lung cancer are well-known with African Americans disproportionally affected by lung cancer in terms of incidence and survival. Previous comparative analyses of molecular features of lung cancer revealed racial differences in genomic profiles, which supports somatic differences arising from genetic ancestry. Using The Cancer Genome Atlas (TCGA), we investigated the genetic alterations in lung adenocarcinomas (LUAD) on individuals of African (AFR) ancestry. **Methods:** The genomic and clinical data of TCGA PanCancer Atlas LUAD were downloaded through the GDC Data Portal. Given that substantial proportion of the US population consist of genetically admixed populations, we utilized The Cancer Genome Ancestry Atlas (TCGAA) and LAMP for estimates of genetic ancestry and quantitative ancestral compositions. This dataset contains 518 samples, including 393 self-reported whites and 52 African Americans. For each case the proportion of European, AFR, East Asian, native American ancestry was estimated. The dominant ancestry was defined as ≥50% of admixture from one reference population. Differences in gene mutation frequency were analyzed based on AFR ancestry proportion. The Kaplan-Meier curves were generated, and Cox regression analyses were performed. **Results:** Global ancestry analysis identified 50 AFR ancestry cases with mean ancestry of 78.3%. The dominant AFR ancestry group matched the self-reported race with 96% accuracy. We identified 9 subjects with ≥90% AFR ancestry, 22 subjects with 80-90% AFR ancestry, 12 subjects with 70-80% AFR ancestry, and 7 subjects with 50-70% AFR ancestry. TP53 was the most frequently mutated gene, and ≥90% AFR ancestry had the highest rate of mutations (77.8%) compared with 80-90% AFR ancestry (68.2%), and 70-80% AFR ancestry (66.8%). We evaluated classic driver gene mutations (EGFR, KRAS, NRAS, PIK3CA, ALK) and found only 33% of ≥90% AFR ancestry subjects carry a known driver mutation, compared to 58-77% in lower proportion of AFR ancestry subjects. Higher AFR ancestry was associated with worse overall survival (OS) and progression free survival (PFS). Median OS was 14.5 months for ≥90% AFR ancestry compared to 71.47 months in 70-80% AFR ancestry (P = 0.048). ≥90% AFR ancestry had median PFS of 12.8 months compared to 33.5 months in 80-90% AFR ancestry, and 47.1 months in 70-80% AFR ancestry (P = 0.002). **Conclusions:** This study demonstrates the power of genomic study to investigate the etiology of health disparities by analyzing the effect of ancestry on genetic alterations in LUAD. Our results reveal different mutation loads even among AFR ancestry patients. We observed that AFR ancestry is associated with worse OS, suggesting possible influence of germline ancestry in subsequent somatic alterations. Further work is needed to explore how genetic ancestry impacts tumorigenesis and cancer progression to eliminate lung cancer disparities. Research Sponsor: None.

Residual ctDNA after treatment predicts early relapse in patients with early-stage NSCLC. *First Author: Davina Gale, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom*

Background: Liquid biopsies based on circulating tumor DNA (ctDNA) analysis are being investigated for detection of residual disease and recurrence. Conclusive evidence for utility of ctDNA in early-stage non-small cell lung cancer (NSCLC) is awaited. Due to low ctDNA levels in early-stage disease or post-treatment, effective methods require high analytical sensitivity to detect mutant allele fractions (MAF) below 0.01%. **Methods:** We analysed 363 plasma samples from 88 patients with NSCLC recruited to the LUng cancer CIrculating tumour DNA (LUCID) study, with disease stage I (49%), II (28%) and III (23%). 62% were adenocarcinomas. Plasma was collected before and after treatment, and at 3, 6 and 9 months after surgery (N = 69) or chemoradiotherapy (N = 19). Additional plasma was collected at disease relapse for 17 patients. Median follow-up was 3 years, and 40 patients progressed or died of any cause. We employed the RaDaR™ assay, a highly sensitive personalized assay using deep sequencing of up to 48 tumor-specific variants. Variants identified by tumor exome analysis were tested by deep sequencing of tumor tissue and buffy coat DNA to verify somatic mutations and exclude clonal hematopoiesis. The RaDaR assay demonstrated 90% sensitivity at 0.001% MAF in analytical validation studies. **Results:** ctDNA was detected in 26% of samples, at median MAF of 0.047% (range: 0.0007% to > 2%), and prior to treatment in 87%, 77% and 24% for disease stage III, II and I respectively. For 62 patients, plasma was collected at a landmark timepoint, between 2 weeks and 4 months after initial treatment. ctDNA detection at the landmark timepoint was strongly predictive of clinical disease relapse, with Hazard Ratio of 20.7 (CI: 7.7-55.5, p-value < 0.0001). All 11 cases with ctDNA detected at landmark had disease progression, a median of 121 days after detection, and these included all 8 patients that relapsed within 300 days of treatment. Across 27 patients whose disease progressed during the study, ctDNA was detected at any timepoint post-treatment in 17 cases, with a median lead time of 203 days, and up to 741 days prior to clinical progression. ctDNA was detected post-treatment, in 13 of the 15 patients that progressed and had ctDNA detected prior to treatment. **Conclusions:** Our results support an emerging paradigm shift, by demonstrating that liquid biopsies can reliably detect recurrence of NSCLC at a pre-clinical stage, many months before clinical progression, thereby offering the opportunity for earlier therapeutic intervention. Clinical trial information: NCT04153526. Research Sponsor: Cancer Research UK.

Leveraging phased variants for personalized minimal residual disease detection in localized non-small cell lung cancer. *First Author: David Matthew Kurtz, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Detection of circulating tumor DNA (ctDNA) has prognostic value in lung cancer and could facilitate minimal residual disease (MRD) driven approaches. However, the sensitivity of ctDNA detection is suboptimal due to the background error rates of existing assays. We developed a novel method leveraging multiple mutations on a single cell-free DNA molecule ("phased variants" or PVs) resulting in an ultra-low error profile. Here we develop and apply this approach to improve MRD in localized NSCLC. **Methods:** To identify the prevalence of PVs, we reanalyzed whole genome sequencing (WGS) from 2,538 tumors and 24 cancer types from the pan-cancer analysis of whole genomes (PCAWG). We applied Phased Variant Enrichment and Detection Sequencing (PhasED-Seq) to track personalized PVs in localized NSCLC. We compared PhasED-Seq to a single nucleotide variant (SNV)-based ctDNA method. **Results:** In the PCAWG dataset, we found that PVs were common in both lung squamous cell carcinomas (LUSC, median 1,268/tumor; rank 2nd) and adenocarcinomas (LUAD, median 655.5/tumor; rank 3rd). However, PVs did not occur in stereotyped genomic regions. Thus, to leverage PhasED-Seq, we performed tumor/normal WGS to identify PVs, followed by design of personalized panels targeting PVs to allow deep cfDNA sequencing. We performed personalized PhasED-Seq for 5 patients with localized NSCLC. PVs were identified from WGS of tumor FFPE and validated by targeted resequencing in all cases (median 248/case). The background rate of PVs was lower than that of SNVs, even when considering duplex molecules (background: SNVs, 3.8e-5; duplex SNVs, 1.0e-5; PVs, 1.2e-6; P < 0.0001). We next assessed PhasED-Seq for MRD detection in 14 patient plasma samples. Both SNVs and PhasED-Seq had high specificity in healthy control cfDNA (95% and 97% respectively). Using SNVs, ctDNA was detected in 5/14 samples; PhasED-Seq detected all of these with nearly identical tumor fractions (Spearman rho = 0.97). However, PhasED-Seq also detected MRD in an additional 5 samples containing tumor fractions as low as 0.000094% (median 0.0004%). We analyzed serial samples from a patient with stage III LUAD treated with chemoradiotherapy (CRT) and durvalumab. SNV-based ctDNA and PhasED-Seq detected similar MRD levels (0.8%) prior to therapy. However, 3 samples collected during CRT, as well as before and during immunotherapy, were undetectable by SNVs. SNV-based ctDNA then re-emerged at disease recurrence. PhasED-Seq detected MRD in all 3 samples not detected by SNVs with tumor fractions as low as 0.00016%, including prior to immunotherapy (8 months prior to progression). Similar improvements were seen in samples not detected by SNVs from 2 additional patients. **Conclusions:** Personalized ctDNA monitoring via PVs is feasible and improves MRD detection in localized NSCLC. PhasED-Seq allows clinical studies testing personalized treatment based on MRD. Early detection of lung cancer using cfDNA fragmentation. *First Author: Dimitrios Mathios, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Lung cancer incidence and mortality are increasing worldwide despite more effective treatments. This is primarily due to the late stage of diagnosis when treatments are less effective. Although large randomized trials have demonstrated a significant decrease in lung cancer mortality through screening of high-risk individuals with chest low dose computed tomography (LDCT), LDCT has made little impact in the community, mainly due to lack of accessibility. There is therefore an unmet clinical need for development of cost-effective and easily implemented tests for early lung cancer detection. **Methods:** We have previously shown that altered genome-wide fragmentation of cell free DNA (cfDNA) is a common characteristic of many cancers. In this study, we leverage this knowledge to increase the sensitivity of lung cancer detection by interrogating characteristics of the size distribution of cfDNA fragments across the genome using machine learning methods. The approach we present, called DELFI (DNA evaluation of fragments for early interception) generates a score that reflects the presence of tumor-derived DNA in plasma based on a multi-feature genomic analysis that assesses millions of cfDNA fragments for tumor-derived genomic and epigenomic changes in a small amount of blood (2-4 mls) via inexpensive low coverage (1-2x) whole genome sequencing. We applied this methodology in a prospectively collected cohort of 365 individuals under investigation for lung cancer and we prospectively validated it in a separate case-control cohort of patients with newly diagnosed early stage lung cancer as well as individuals without cancer (n=427). **Results:** These analyses revealed high performance for detection of early and late stage disease (Table). When DELFI was used as a prescreen for LDCT it increased specificity from 58% with CT imaging alone to 80% using the combined approach. The DELFI score was significantly associated with T and N stage in lung cancer cases (p<0.0001) as well as with overall survival (p=0.003). In a multivariable analysis including age, histology and stage, DELFI score was an independent prognostic factor of overall survival (HR=2.53; p=0.0003). Finally, we determined that genome-wide fragmentation profiles can be used to distinguish small cell lung cancer from non-small cell lung cancer with high accuracy (AUC 0.98). **Conclusions:** These findings provide key insights into cfDNA fragmentation in patients with cancer and a new and easily accessible avenue for non-invasive diagnosis and molecular profiling of lung cancer. Research Sponsor: Dr. Miriam and Sheldon G. Adelson Medical Research Foundation, SU2C in-Time Lung Cancer Interception Dream Team Grant, Other Foundation, Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

Sensitivity of DELFI followed by LDCT for lung cancer detection*.

	Sensitivity	
	DELFI	**DELFI, LDCT**
Stage		
Stage I (n=8)	88%	100%
Stage II (n=7)	86%	86%
Stage III (n=30)	93%	93%
Stage IV (n=49)	92%	98%
Histology		
Adenocarcinoma (n=46)	87%	94%
Squamous (n=25)	96%	100%
Small cell (n=8)	100%	100%
Other (n=15)	93%	93%

*Sensitivities refer to the fraction of cases detected at single or combined test specificities of 80%.

8520 **Poster Session**

Updated overall survival (OS) and exploratory analysis from the randomized, phase II EVAN study of erlotinib (E) versus vinorelbine plus cisplatin (NP) as adjuvant therapy in Chinese patients with stage IIIA EGFR+ NSCLC. *First Author: Dongsheng Yue, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: The EVAN study of E vs NP in stage III EGFR+ NSCLC has met its primary endpoint and been previously published: 2-year disease-free survival was 81.4% (95% CI, 69.6–93.1) in E group vs 44.6% (95% CI, 26.9-62.4) in NP group (HR, 1.823; 95% CI, 1.194–2.784; P=0.0054). We report 5-year OS and exploratory results from EVAN with a further 43 month follow up (cutoff date: Jan 6, 2021). **Methods:** Patients with stage IIIA EGFR+ NSCLC were randomized assigned (1:1) into either E arm (n=51, 150mg/day) or NP arm (n=51, vinorelbine 25mg/m^2 on day 1, 8 and cisplatin 75mg/m^2 on day 1 of a 21-day cycle). In order to explore the relationship between patient benefits and co-occurring variants, 47 patients received whole exome sequencing (WES) analysis (E, n=24; NP, n=23). **Results:** Median follow-up time was 54.8 months for E and 63.9 months for NP. E improved OS and 5-year survival rate compared with NP in ITT population. The median OS was 84.2m (95% CI, 78.1,-) with E vs 61.1m (95% CI, 39.6-82.1) with NP (HR, 0.318; 95% CI, 0.151-0.670). The 5-year survival rates were 84.8% (95%CI, 72.0-97.6) and 51.1% (95% CI, 34.7-67.5), respectively. In the WES analysis, we found that the most frequent genes with co-occurring variants at baseline were TP53, MUC16, FAM104B, KMT5A and DNAH9, and additional EGFR variants, each with similar prevalence regardless of EGFR-activating mutation subgroup. Moreover, in the erlotinib-treated patients, the SNP mutation of UBXN11 was associated with significantly worse DFS (P=0.0111). **Conclusions:** This is the first randomized study of EGFR-TKI to demonstrate a clinically meaningful improvement in OS vs chemotherapy in stage III EGFR+ NSCLC (5-year survival rate 84.8% in E vs 51.1% in NP). The co-occurring variants at baseline may be associated with reduced DFS. Further studies are required to confirm our results (EVAN, NCT01683175). Clinical trial information: NCT01683175. Research Sponsor: None.

8521 **Poster Session**

Different exposure duration of adjuvant icotinib in stage II-IIIA non-small cell lung cancer patients with positive EGFR mutation (ICOMPARE study): A randomized, open-label phase 2 study. *First Author: Chao Lyu, Thoracic Surgery II, Peking University Cancer Hospital, Beijing, China*

Background: EGFR-TKI has been widely used in the treatment for advanced non-small cell lung cancer (NSCLC). Previous studies, such as the EVIDENCE study and the ADAURA study, have confirmed that patients with EGFR-mutated NSCLC could benefit from adjuvant EGFR-TKI treatment. However, the optimal duration time of adjuvant EGFR-TKIs has not been clearly defined. **Methods:** In this multicenter, randomized, phase 2 trial, eligible patients with II-IIIA stage EGFR mutation-positive NSCLC after R0 resection were randomized in 1:1 to receive adjuvant icotinib for 1 year (group A) or 2 years (group B). The primary endpoint was disease-free survival (DFS). **Results:** Between September 2013, and September 2018, 109 patients from 8 centers were enrolled in this study, among whom 55 were randomized to group A and 54 to B. As of August 24, 2020 (data cutoff), the median follow-up was 44.1 months (95%CI 37.1-49.9), 31 (56%) of 55 patients in the 1-year group and 25 (46%) of 54 patients in the 2-year group had DFS events. The median DFS was 48.92 months (95%CI 33.15, 70.11) in 2-year group and 32.89 month (95%CI 26.61, 44.78) in 1-year group, respectively. 2-year icotinib significantly prolonged DFS (HR 0.521, 95%CI 0.278, 0.976; p = 0.039). OS events were observed in 20 patients, the OS was not mature yet. Icotinib was re-given for 32 patients with disease recurrence or metastasis as first-line treatment, objective response occurred in 66.7% of 30 patients with measurable disease. Treatment-related adverse events were recorded in 41 of 55 (75%) patients in 1-year group and 36 of 54 (67%) patients in 2-year group, and grade 3 or 4 treatment-related adverse events occurred in 4 (7%) of 55 patients in the 1-year group versus 3 (6%) of 54 in the 2-year group, respectively. No treatment-related deaths or interstitial lung disease were reported. **Conclusions:** 2-year adjuvant treatment with icotinib resulted in a significantly lower risk of recurrence than 1-year adjuvant icotinib in patients with stage II-IIIA NSCLC positive EGFR mutations and was not associated with increased toxic effects. Clinical trial information: NCT01929200. Research Sponsor: Betta pharmaceuticals.

8522 **Poster Session**

Two-year follow-up of single PD-1 blockade in neoadjuvant resectable NSCLC. *First Author: Shugeng Gao, Thoracic Surgery Department, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Early stage non-small-cell lung cancer (NSCLC) could benefit from anti-programmed cell death-1 (PD-1) monotherapy; however, the survival profiles remain to be disclosed. Here, we presented the two-year follow-up outcomes from a phase 1b study of sintilimab, an anti-PD-1 inhibitor in the neoadjuvant setting of NSCLC. **Methods:** Treatment-naive pts with resectable NSCLC (stage IA–IIIB) received two cycles of sintilimab followed by surgical resection. Postoperative treatment of sintilimab was at the discretion of investigator. The primary endpoint was AE, and key secondary endpoints included major pathological response (MPR), disease free survival (DFS) rate of 1 year and 2 years, and overall survival (OS) rate of 2 years. **Results:** Among 40 enrolled pts, 36 (90%) underwent R0 resection and were included in the R0 resection population. By data cutoff (January 20, 2021), the median follow-up for DFS and OS for all the enrolled pts was 23.9 (IQR 20.5–24.4) months and 26.4 (IQR 24.2–29.0) months. A total of 12 (33.3%) pts experienced relapse, and 6 pts died. The 1-yr and 2-yr DFS rate was 91.7%/73.3%. The 2-yr OS rate for overall population and R0 population was 87.5%/91.7%, respectively. In the R0 resection population, the median DFS and OS were both not reached. Superior 2-year DFS rates were observed in pts who achieved MPR (MPR vs. Non-MPR: 86.7% vs. 63.8%). DFS of pts with non-squamous cell carcinoma tended to be shorter than that of pts with squamous cell carcinoma (HR 2.71 [95%CI 0.67–11.0], p=0.1479). Pts with tumor mutation burden (TMB) ≥10 mutations/Mb and PD-L1 tumor proportion score (TPS)≥50% tended to have a better 2-yr DFS rate compared to those with TMB<10 and TPS<50. [table] For the post-hoc event free survival (EFS) analysis, the same trend was observed with DFS among different subgroups, and patients with TMB ≥10 mutations/Mb had a significant improved EFS (HR 0.125[95% CI 0.02,1.03], P=0.0222). **Conclusions:** Anti-PD-1 monotherapy emerged to be a promising neoadjuvant therapeutic strategy for resectable NSCLC with improved clinical outcomes. MPR could serve as a surrogate efficacy biomarker in this setting. Clinical trial information: ChiCTR-OIC-17013726. Research Sponsor: None.

Statewide rates of adjuvant checkpoint inhibitor use after definitive chemoradiation for stage III non-small cell lung cancer. *First Author: Alex K. Bryant, Department of Radiation Oncology, Rogel Cancer Center, University of Michigan, Ann Arbor, MI*

Background: In the landmark PACIFIC trial, adjuvant durvalumab after definitive chemoradiation for unresectable stage III non-small-cell lung cancer (NSCLC) produced a 11% absolute overall survival benefit at two years compared to placebo, and the US Food and Drug Administration approved durvalumab for this indication in February 2018. We investigated the real-world use of adjuvant durvalumab and other immune checkpoint inhibitors (ICI) in a contemporary cohort of patients. **Methods:** We identified patients with unresectable stage III (AJCC 8th edition) NSCLC treated with definitive chemoradiation from February 2018 to March 2020 from a statewide radiation oncology quality consortium, representing a mix of community (n=22 centers, 336 patients) and academic practice settings (n=5 centers, 64 patients) across the state of Michigan. Use of adjuvant durvalumab or other ICI (atezolizumab, nivolumab, or pembrolizumab) was ascertained at the time of routine three- or six-month follow-up after completion of chemoradiation. Baseline characteristics of patients treated with or without adjuvant ICI were compared with the Chi-squared test for categorical variables and a two-sided t-test for continuous variables. **Results:** Of 400 patients with unresectable stage III NSCLC treated with definitive chemoradiation, 268 (67%) received adjuvant ICI. Of these, the majority received durvalumab (86%) followed by pembrolizumab (7.5%) and nivolumab (6.0%). The proportion of patients receiving ICI remained stable throughout the study period with no discernable time trends. Eight-five percent of white patients received ICI compared with 77% of black patients (p=0.04), but there were no differences in gender (54.5% male in ICI vs 52.3% no ICI), current smoking (42.2% ICI vs 37.9% no ICI, p=0.68), number of comorbidities (29.5% with 3 or more comorbidities in ICI vs. 26.5% in no ICI, p=0.86), baseline oxygen use (8.9% ICI vs 10.6% no ICI, p=0.59), age (median 66.4 years [IQR 60.3-73.4] for ICI vs. 66.9 years [IQR 61.1-72.2] no ICI, p=0.89), treatment at an academic center (16.0% ICI vs 15.9% no ICI, p=0.97), or ECOG performance status (59.3% ECOG 0 in ICI vs 62.8% no ICI). **Conclusions:** In a broad range of academic and community-based practices across a state including 27 sites, only two-thirds of potentially eligible stage III NSCLC patients received adjuvant durvalumab or other ICI agents despite a proven overall survival benefit. Receipt of ICI was not strongly associated with baseline demographic or comorbidity variables. Further work will seek to clarify the patient-level reasons behind non-initiation of adjuvant ICI. Research Sponsor: None.

Osimertinib as neoadjuvant treatment for resectable stage II-IIIB EGFR mutant lung adenocarcinoma (NEOS). *First Author: Chao Lyu, Thoracic Surgery II, Peking University Cancer Hospital, Beijing, China*

Background: Neoadjuvant treatment has demonstrated efficacy in several types of cancer and is increasingly used for the treatment of early-stage cancers with the potential of cancer downstaging to enhance complete surgical resection and to improve clinical outcomes. Recent evidences have demonstrated that the neoadjuvant use of first/second-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) may provide clinically meaningful improvement in EGFRm non-small cell lung cancer (NSCLC) patients, however, limited data were reported on osimertinib, the third-generation EGFR-TKI, in the neoadjuvant setting. Here we present an interim analysis of osimertinib as neoadjuvant treatment for resectable EGFRm NSCLC. **Methods:** NEOS is a prospective, multi-center, single-arm study to evaluate the efficacy and safety of osimertinib as neoadjuvant treatment in resectable EGFRm (19del/L858R) lung adenocarcinoma. Eligible patients were treated with osimertinib 80 mg orally per day for six weeks followed by surgery. Assessment of response to neoadjuvant therapy was performed according to RECIST 1.1. The primary endpoint was response rate. Secondary endpoints included safety, R0 surgical resection rate, quality of life, major pathologic response (MPR) rate, pathological complete response (pCR) rate, and N2 downstaging rate. **Results:** As of Dec. 17, 2020, 18 eligible patients (median age 61 [range 46-73], 27.8% male, 22.2% ECOG PS 1) have been enrolled. Patients with clinical stages IIa, IIb, and IIIa (8th AJCC) accounted for 16.7%, 22.2% and 61.1%, respectively. Half (9/18) of the patients had EGFR exon 21 L858R mutations and the other half (9/18) had EGFR exon 19del mutations. Amongst all 15 patients who completed efficacy assessment after neoadjuvant osimertinib, the response rate (RR) was 73.3% (11/15) and the disease control rate (DCR) was 100% (15/15). R0 surgical resection was performed in 93.3% (14/15) patients. Pathological downstaging occurred in 53.3% (8/15) patients. 42.9% (3/7) of the patients with confirmed N2 lymph nodes experienced downstaging to N0 disease after receiving neoadjuvant osimertinib. One patient was identified with a pCR. Adverse events (AEs) were reported in 66.7% (12/18) of patients, with the most common AE being rash (8/18, 44.4%), oral ulceration (8/18, 44.4%), and diarrhea (5/18, 27.8%). No grade 3-5 AEs or serious AEs were reported. **Conclusions:** Interim analysis from this study indicated neoadjuvant osimertinib as an effective and feasible treatment in patients with resectable stage II-IIIB EGFRm NSCLC. The trial is ongoing and the final results will be provided in the future. Clinical trial information: ChiCTR1800016948. Research Sponsor: astrazeneca.

8525 **Poster Session**

Cost evaluation of adjunctive osimertinib use in resected epidermal growth factor receptor-positive non-small cell lung cancer. *First Author: Briana Choi, University of Arizona College of Pharmacy, Tucson, AZ*

Background: About 30% of patients with epidermal growth factor receptor positive (EGFR+) non small cell lung cancer (NSCLC) are eligible for surgical resection. Osimertinib, a first line therapy for advanced EGFR+ NSCLC (stages 1B, 2, 3A), has shown clinical efficacy compared to placebo as an adjunctive therapy post resection. We evaluated the cost effectiveness/utility of this regimen. **Methods:** A two health state Markov model was built (disease free vs. disease recurrence or death). Disease free survival (DFS) curves were digitized and fitted to exponential function. 3 year timeline as patients received osimertinib for 3 years in published data. US payer perspective and 3% discount rate were applied. Drug costs were per Redbook whole acquisition cost and monitoring costs were from published data (US$ 2020). No adverse events $> 5\%$ were reported hence none were included. Life years (LY) and quality adjusted life years (QALY) were estimated for each stage. Incremental cost-effectiveness and utility ratios (ICER/ICUR) for LY and QALY gained were estimated in base case (BCA) and probabilistic sensitivity analyses (PSA). **Results:** Shown in the table are BCA and (PSA) results. Using LY as outcome, for stage 1B, incremental DFSLY of 0.40 (0.39) and incremental cost of $500,782 ($501,034) yielded an ICER/DFSLYG of ~$1.3 million (M) (~$1.2 M). For stage 2, incremental DFSLY of 0.79 (0.79) and incremental cost of $503,144 ($503,092) resulted in an ICER/DFSLYG of $636,913 ($638,278). For stage 3A, incremental of DFSLY of 0.18 (0.07) and incremental cost of $322,356 ($293,377) yielded an ICER/DFSLYG of ~$1.2 M (~1.2 M). The incremental costs are the same for QALY outcomes. Using QALY as outcome, for stage 1B, incremental of DFSQALY of 0.26 (0.27) yielded an ICUR/DFSQALY of ~$1.9 M. In stage 2, incremental DFSQALY of 0.53 (0.53) resulted in an ICUR/DFSQALY of $950,616 ($952,654). For stage 1C, incremental DFSQALY of 0.18 (0.07) yielded an ICUR/DFSQALY of ~$1.8 M (~$3.7 M). **Conclusions:** The ICERs and ICURs indicate that cost effectiveness varies markedly across stages of disease. Stage 2 showed the lowest cost to outcome association. In general, the cost burden of adjunctive maintenance therapy with osimertinib in resected EGFR+ NSCLC is substantial relative to the observed clinical benefit. The incremental benefit of osimertinib in stage 2b is more evident than the ones in 1B and 3A. Research Sponsor: None.

Minimal residual disease (MRD) in patients with resected stage I NSCLC: Results of the prospective adjuvant IFCT-0703 trial. *First Author: Damien Vasseur, Gustave Roussy, Villejuif, France*

Background: MRD aims to detect circulating biomarkers of micrometastatic disease and ultimately predict recurrences. The IFCT-0703 randomized phase II trial failed to show a benefit of 6 months adjuvant pazopanib (P) vs. placebo after resection of stage I NSCLC (7th TNM edition). The outcome of pts based on their MRD status has been evaluated. **Methods:** Blood samples were collected in EDTA tubes (Becton Dickinson Company) after surgery (T0), after 3 months (T3) of P or placebo and at the end of treatment (T6). Plasmas were obtained after double centrifugation of total blood. Total nucleic acid was extracted using the Maxwell RSC LV plasma kit (Promega) according to the manufacturer's protocol. Samples were quantified using the QuBit dsDNA HS Assay kit on a QuBit 3.0 flurometer (Thermo Fisher Scientific). Molecular analysis was performed by next generation sequencing using the Oncomine Lung cfDNA Assay (ThermoFisher Scientific). Two MRD definitions were tested : 1) high level of DNA in the blood or 2) any mutation detected by the standard bioinformatic pipeline was considered present, whatever the allelic fraction. **Results:** 143 pts were randomized in 29 centers between March 2009 and August 2012, 71 and 72 in the placebo and P arms respectively. Among the 119 pts with evaluable T0 samples, 27 pts recurred and 14 died. Median DNA concentration ([DNA]) was 6.6 ng/ml and an increase of [DNA] of 10 ng/ml was found prognostic of poor DFS and OS, HR=1.4, 95%CI [1.14-1.72], p=0.0016 and HR=1.62, 95%CI [1.15-2.30], p=0.0057 respectively. In 81 pts with available T0-T6 samples, [DNA] variation had no different impact on DFS and OS, in the P arm and the placebo arm. ctDNA mutations (ctDNA+) were detected in 31/119 pts. ctDNA+ were more frequent in samples with high DNA quantity (p=0.0002). Genes mutated at T0 were *TP53* in 16, *NRAS* in 6, *MAP2K1* in 2, *KRAS* in 1, *EGFR* in 5, *BRAF* in 1, *ALK* in 2. 29 pts had 1 mutation, 2 had 2 mutations. DFS and OS were similar between pts with or without ctDNA+ : HR= 1.038 (95%CI 0.438-2.456, p=0.93) and 1.193 (95% CI 0.367-3.882, p=0.77) respectively. Among 27 pts with ctDNA+ at T0 and available sample at T6, 23 had no more mutations at T6. Two pts had a ctDNA+ only at T6 (not at T3), one of them had a recurrence at 7 months. **Conclusions:** Post-operative ctDNA mutations are found in 26.0% of the pts but their positivity had no impact on DFS or OS. In contrast, DFS and OS were poorer in pts with increased plasma DNA concentration. ctDNA mutations status do not recapitulate the complexity of MRD characterization. NGS will be performed on matched tissues in order to refine MRD definition. Clinical trial information: NCT00775307. Research Sponsor: Fondation ARC.

Modeling the cost-effectiveness of adjuvant osimertinib in resected EGFR-mutant non-small cell lung cancer patients. *First Author: Christopher Lemmon, Cleveland Clinic, Cleveland, OH*

Background: Adjuvant Osimertinib (Osi) was recently approved for resected EGFR-mutant non-small cell lung cancer (NSCLC) based on disease free survival (DFS) benefits from the ADAURA trial. Prior studies of adjuvant EGFR inhibitors yielding DFS benefits have lacked an overall survival (OS) benefit, leading to debate over early clinical implementation given the associated drug costs. This study aims to evaluate the cost-effectiveness (CE) of Osi in this setting. **Methods:** We constructed Markov models using post-resection health state transitions with digitized DFS data from the ADAURA trial to compare cost and quality-adjusted life years (QALYs) of the use of 3 years of adjuvant Osi versus placebo in the ADAURA patient population of stage IB to IIIA NSCLC patients over a 10-year time horizon. All patients entering the progressive disease (PD) state were assigned for re-treatment with Osi. Cost and utility values were derived from Medicare reimbursement data and literature (Table). A CE threshold of 3 times the GDP per capita was used. Deterministic sensitivity analyses were performed to assess the impact of a range of OS benefit, as the impact of adjuvant Osi on OS has not yet been reported. **Results:** The incremental cost-effectiveness ratio (ICER) for adjuvant Osi was $317,119.90 per QALY gained. Initial costs of Osi are higher in the first 3 years, but become lower than the placebo group in year 4 onward, with similar costs after year 7. Costs due to PD are higher in the placebo group through the first 6.5 years. Average pre-PD, post-PD, and total costs were $2,388, $379,047, and $502,937, respectively in the placebo group, compared to $505,775, $255,638, and $800,697, respectively in the Osi group. QALYs were higher in the Osi arm throughout. Sensitivity analysis using incremental OS gains reaches the CE threshold of $195,000 between 25-30% OS benefit of Osi over placebo. A 50% discount to the Osi annual cost yielded an ICER of $115,419. **Conclusions:** 3 years of adjuvant Osi is more cost-effective than placebo if one is willing to pay $317,119 more per QALY gained, with most costs accruing in the first 3 years as drug cost. This strategy became cost-effective with an OS benefit between 25-30% over placebo. Discount to Osi annual costs improves the ICER significantly. True cost-effectiveness of adjuvant Osi will require further study due to immaturity of ADAURA OS data and model limitations. Research Sponsor: None.

Model QALY utility an cost inputs.

QALY Utilities	NED state (osi/placebo)	0.81/0.83
	PD state (CNS+/CNS-)	0.55/0.71
Annual Costs	EGFR testing	$324.58
	Osimertinib cost	$222,196
	NED state healthcare costs	1914.83
	PD diagnostic costs	$7,202.88
	PD state healthcare costs	$1,186.76
	Average CNS+ PD lifetime costs	$45,081.39
	Palliative/end of life cancer costs	$78,571.06
	Adverse event costs and disutilities also incorporated

Driver mutations to predict for poorer outcomes in non-small cell lung cancer patients treated with concurrent chemoradiation and consolidation durvalumab. *First Author: Yufei Liu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The use of durvalumab after chemoradiation in locally advanced non-small cell lung cancer (NSCLC) patients significantly improves overall survival. However, it is unclear whether this benefit applies to all genetic subtypes of lung cancer. We hypothesize that patients with driver mutation NSCLC may derive less benefit from consolidation durvalumab. **Methods:** Using the Genomic Marker-Guided Therapy Initiative (GEMINI) database at MD Anderson, we identified 134 patients who were treated with chemoradiation followed by durvalumab for NSCLC. We segregated patients with driver mutations to targetable (EGFR, ALK translocation, ROS1 fusion, MET exon 14 skipping, RET fusion, and/or BRAF) (N = 24) and those driven by canonical KRAS mutations (N = 26). The rest (N = 84) had none of these mutations. We gathered demographic, treatment, and outcome data and compared progression-free survival (PFS) and overall survival (OS) using the Kaplan-Meier method. We used multivariate regression analysis to account for demographic and treatment variables. **Results:** For our cohort, median age at diagnosis was 64.8, 52% were female (n = 70), and median follow up was 1.5 years. 86% of patients have a history of smoking (n = 115). 21% had squamous cell histology (n = 28). 2 patients had stage IIA disease, 6 had stage IIB, 48 had stage IIIA, 56 had stage IIIB, 13 had stage IIIC, and 9 had stage IV. 73 patients had progression after durvalumab and 37 patients died. Patients with driver mutations had significantly worse median PFS compared to those without driver mutations (8.9 mo vs 26.6 mo; HR 2.62 $p < 0.001$). Patients with KRAS mutations had particularly poor PFS (Median 7.9 mo, HR 3.34, $p < 0.001$), while patients with targetable driver mutations trended to worse PFS (Median 14.5 mo, HR 1.96, p = 0.056). The median OS for the cohort was 4.8 yrs with no significant differences based on driver mutation status. On multivariate analysis, only driver mutation status was associated with PFS, but not OS. For patients with first progression, we found the targetable driver group to have significantly improved time to second objective progression (PFS2) compared to the KRAS (HR 0.28, p = 0.011) or non-mutated group (HR 0.38, p = 0.025). All patients in the targetable driver group received targeted therapy after first progression. **Conclusions:** Our results suggest that patients with driver mutations have worse PFS compared to patients without these mutations after chemoradiation. However, patients with targetable oncogene driver mutations have significantly improved prognosis after initial progression compared to the other groups, likely due to targeted therapy, suggesting that these therapies, including novel approaches towards KRAS mutants, should be further explored in this setting. Research Sponsor: None.

8529 **Poster Session**

Natural history of curatively resected stage IB-IIIA EGFR mutation (+) NSCLC: Clinicopathologic and molecular prognostic factors (ROOT-EGFR-ADJ). *First Author: Hyun Ae Jung, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Surgery is the primary therapy for patients with early-stage NSCLC. However, five-year recurrence rates were 45%, 62%, and 76% for pathologic stage (pStage) IB, II, and III respectively. In the ADARUA study, adjuvant osimertinib significantly improved DFS in patients with completely resected EGFR mutation (+) NSCLC. Though marked improvement of DFS is encouraging, OS is not mature yet and several questions remain unanswered; Does this DFS benefit translate to cure? Do all patients need to receive adjuvant Osiemrtinib? In order to address these questions we reviewed the clinical records of pStage IB-IIIA EGFR mutant NSCLC. **Methods:** From January 2008 and August 2020, total 2,340 patients with pStage IB-IIIA, non-SQ NSCLC underwent curative surgery at Samsung Medical Center. Using innovative in-house algorithm to retrieve medical big data-based cohort called ROOT (Realtime autOmetically updated data warehOuse in healTh care) detailed clinical data were analyzed to investigate any prognostic factors of recurrence. In order to identify any molecular prognostic factors, we did a comprehensive genomic analysis (WTS/WES)in a subset of patients with matched case-control. **Results:** Total 1,811 patients with pStage IB-IIIA, non-SQ EGFR mutation (+) NSCLC were included (367 patients : no EGFR mutation test) . Median follow-up duration was 38.8 (range: 0.5 -156.2). Patient demographics; Deletion 19 was 52.7%, L858R was 47.3%. Female was 64.7% and never smoker was 72%. Stage IB, IIA, IIIA was 50.4%, 26.5%, and 23.2%. Among them, 6.7% of pStage IB, 72.8% of pStage II, and 88.7% of pStage IIIA received adjuvant chemotherapy. Median DFS were 74.0 months (95% CI 63.2-84.8), 48.6 months (95% CI: 40.2-57.0), and 22.4 months (95%: 19.5-25.3) for pStage IB, II, and IIIA, respectively. The median OS were 132.1 months (95% CI: 101.3-162.8), 124.3 months (95% CI: 61.8-186.9), and 82.1 months (95% CI: 71.2-93.1) for pStage IB, II, and IIIA, respectively. In univariate analysis, pStage, poorly differentiation, histologic subtype (micropapillary, solid), lymphatic invasion, vascular invasion, and pleural invasion were related with high recurrence rate statistically. In multivariate analysis, pStage, vascular invasion, and pleural invasion were related with recurrence statistically. To detect molecular factors, 76 patients performed the matched case -control (included pStage, type of EGFR mutation, and sex) analysis (WES/WTS). **Conclusions:** This study showed that the median DFS of pStage II-IIIA EGFR mutation (+) NSCLC was 31.9 months. With approximately 55% of patients with pStage II-IIIA EGFR mutation (+) NSCLC experienced recurrence at the 3rd year, we need to find the appropriate subset who need 3-year adjuvant osimertinib by comprehensive predictive marker for cure. Updated and detail exploratory biomarker outcome will be presented at the annual meeting. Research Sponsor: None.

Molecular characteristics of EGFR exon 19 deletion subtypes in NSCLC patients. *First Author: Weiquan Gu, The Thoracic Surgery Department, Foshan First People's Hospital, Foshan , China*

Background: EGFR exon 19 deletion mutations are well characterized, known to be activating, and are associated with responses to EGFR tyrosine kinase inhibitors (TKIs). A variety of methods have been developed to identify EGFR mutations. Deletions of EGFR exon 19 are more complex compare to the other because they consist of different subtypes. **Methods:** In this study, we retrospectively analyzed the different subtypes of EGFR exon 19 deletions using next-generation sequencing(NGS). From May 2019 to December 2020, 3275 patients who were diagnosed with Non-small cell lung cancer (NSCLC)were detected. **Results:** In this analyzed cohort, the average age of patients was 62 years (range, 24-92 years). Most of the patients were female (61.07%) and were diagnosed with lung adenocarcinoma (82.60%). It is worth noting that the deletions in exon 19 of EGFR were also detected in 35 patients (1.07%) with squamous cell carcinoma and 1 patient (0.03%) with sarcomatoid. The most frequent EGFR exon 19 deletions were delE746-A750 (63.4%), followed by delL747-P753insS (9.7%) and L747-T751 (6.9%). The characteristics of the patients in this study are presented. Significantly, three samples with compound EGFR exon 19 deletions were detected: 1) S1:E746_A750delinsFP+E746_A750del; 2) S2: E746_S752delinsV+L747_P753delinsS; 3) S3:E746_P753delinsVS + L747_P753delinsS. **Conclusions:** EGFR exon 19 starting at codon 729 to 761, our data showed the deletions occur throughout almost the entire exon 19 amino acid. As our integrated data results, EGFR exon 19 has many different deletions and insertion subtypes could be defined as 79 subtypes. Among those subtypes,70 were complex with an accompanying insertion. The most frequent deletions were starting at E746 and L747. Based on several clinical researches, different deletion subtypes may have significantly different clinical responses after TKI treatment. However, more clinical research is needed to support this finding. Research Sponsor: None.

Seroprevalence and immunological memory against SARS-CoV-2 in lung cancer patients (p): SOLID study. *First Author: Mariano Provencio, Puerta de Hierro Majadahonda University Hospital, Madrid, Spain*

Background: Coronavirus disease 2019 (COVID-19) is diagnosed by detecting the virus by reverse transcription polymerase chain reaction (RT-PCR). The majority of p go on to develop antibodies (Ab) against viral proteins. However, it is not known how long these antibodies last nor whether cancer treatments could affect the duration of immune response. The prognosis and greater or lesser vulnerability of the oncological population are also unknown. **Methods:** This prospective, longitudinal, multicenter serological study in the setting of SARS-CoV-2 was carried out in 50 Spanish hospitals. Eligibility criteria was a diagnosis of any thoracic cancer. The first determinations were performed between April 21, 2020 and June 3, 2020, either for p in follow up or in active treatment. Between September 10, 2020, and November 20, 2020, the second antibody (Ab) determination was performed in all previously seropositive p. Clinical and treatment data were collected, as was their clinical situation at study end. Study objectives were to prospectively determine seroprevalence in unselected lung cancer p during the first wave of the pandemic; the natural history of these p; the persistence of immunity more than 4 months after first determination; protection or lack thereof against reinfection after this period, and the nature of such protection; and the influence of treatments on maintenance or loss of immunity. **Results:** Of 1,500 p studied, 128 were seropositive, representing an overall prevalence of 8.5% seropositivity [95% confidence interval [CI], 7.2%, 10.1%]. Seventy-five percent were in active cancer treatment. COVID-19 infection was suspected in 47.7% [95% CI, 38.8%, 56.6%]. A second determination was performed on average 4.5 months later [IQR: 4; 5] and obtained for 104 of the initially seropositive p (81%). A second determination could not be obtained in 24 p, the majority due to death caused by disease progression (73%). In the second determination, IgG was not detected in 30.8% (32/104) of p. The severity of the infection, the need for hospitalization *(p: 0.032)* and the presence of symptoms at diagnosis *(p: 0.02)*, including fever *(p: 0.005)* and nasal congestion *(p: 0.005),* were associated with persistence of immunity in the second determination. No variables or treatments received were associated with Ab loss. At time of last follow-up among those p for whom a second determination was performed, 89% (93 p) had completely recovered from the virus, with no lasting after effects. Only 1 of the 128 (0.78%) seropositive p had died from COVID-19. **Conclusions:** The prevalence of infection in lung cancer p is similar to that of the general population. Immunity against SARS-CoV-2 does not appear to be compromised by treatment, persisting beyond 4 months. Neither do mortality rates appear to be particularly high in this unselected population. Association of high level of plasma tissue factor activity with venous thromboembolism and early death in lung cancers. *First Author: Helene Doubre, Pneumology, Hopital Foch, Suresnes, France*

Background: Venous thromboembolism (VTE) is associated with tumor aggressiveness and mortality in cancers. Tissue Factor is the main activator of the coagulation but its variations in lung cancers (LC) have been less studied than D-dimers (DDi). We assessed plasma Tissue Factor Activity (TFa) and DDi and VTE events and mortality in patients with LC. **Methods:** This prospective study included patients, from 5 hospitals, recently diagnosed LC, without prior VTE or anticoagulant therapy within the last 2 months. Clinical and tumor data, Khorana score (KS), VTE events and overall survival (OS) were assessed (follow up 2 years). Blood samples were collected before any cancer treatment (V1): DDi (HemosIL) and TFa (chromogenic assay, Diagnostica Stago) were analyzed in a central lab. Independent nonparametric tests were used for group comparisons. A relevant clinical threshold of both markers was determined :1500 μg/ml for DDi and 1.2 ng/ml for TFa. Early death was compared using Cox model and Kaplan Meier curves and logrank tests. All tests were two-tailed tests and 0.05 was considered as significant. **Results:** Between 12/2014 and 01/2017, 302 consecutive patients (pts) were included (mean age 64 years, 61% males, 89% smokers, 85% NSCLC, 67% stage IV). At V1, TFa levels increased with cancer stage (p = 0.004) but not DDi. VTE incidence was 13,9%: 39 events (62% incidental and 51% pulmonary embolism) with 33 events within 6 months. KS failed to predict VTE (KS $>$ 3 in 23% of the pts in VTE group vs 21% of the 302 pts, p = 0.42). DDi and TFa levels were not significantly different in VTE pts than in no VTE pts. But, a TFa $>$ 1.2 ng/ml was significantly predictive in occurrence of VTE within the first 6 months (57.6% of the VTE pts vs 38.8% of no VTE pts, p = 0.04), and also within the first year (p = 0.03). Median OS was 17,6 months (m) in VTE pts and 19.5 m in no VTE pts (p = 0,97). Compared to survivors, higher levels of DDi and TFa were observed for the 38 pts who died within 6 months : 1.82 vs 0.67 μg/ml ($p < 0.001$) and 1.95 vs 0.33 ng/ml ($p < 0.001$) respectively. These differences were observed for the 97 pts who died during the first year, too. With thresholds of TFa $>$ 1.2 ng/ml and DDi $>$ 1500 μg/ml, median OS was significantly shorter: 14.4 m vs $>$ 29.8 m (p $<$ 0,001) and 13.8 m vs 22.6 m ($p < 0.001$), respectively. **Conclusions:** High TFa level discriminates a population with high risk to VTE and early death in LC. This biomarker could take place in a predictive score. Clinical trial information: NCT02853188. Research Sponsor: None.

Noninvasive identification of emergent mutations following cytotoxic therapy for lung cancer. *First Author: Everett James Moding, Stanford University, Stanford, CA*

Background: Lung cancer is the leading cause of cancer death world-wide, and chemotherapy and radiation remain backbones of therapy for patients with locoregionally advanced and metastatic disease. However, the genetic mechanisms that mediate resistance to chemotherapy and radiation are largely unclear due to a lack of available tissue at the time of relapse. We hypothesized that circulating tumor DNA (ctDNA) analysis could identify emergent mutations after chemotherapy and radiation that may lead to treatment resistance. **Methods:** To identify emergent mutations at the time of progression following an initial response to chemotherapy and/or radiation therapy for lung cancer, we utilized CAncer Personalized Profiling by deep Sequencing (CAPP-Seq) to analyze plasma samples and matched leukocytes collected pre-treatment and at the time of relapse. We analyzed a targeted panel enriched for lung cancer drivers and recurrently mutated genes for 27 patients treated with chemoradiation therapy for locoregionally advanced lung cancer. In addition, we performed ultra-deep whole exome sequencing ($>$ 2000X deduped depth) of pre-treatment and relapse cell-free DNA for 5 patients treated with combination chemotherapy for metastatic lung cancer. Functional enrichment analysis was performed on emergent mutation gene lists to identify significantly enriched pathways. **Results:** We identified emergent variants in 6 out of 27 patients using targeted sequencing after chemoradiation therapy. Emergent mutations after chemoradiation were enriched for plasma membrane adhesion molecules such as *PCDH17*, *PCDH10,* and *FAT3* (adjusted P = 0.03). Using ultra-deep whole exome sequencing, we observed emergent mutations in 3 out of 5 patients treated with combination chemotherapy. After combination chemotherapy, there was a trend towards enrichment in mutations in ATP-binding cassette transporters, including *ABCA13* and *ABCB4* (adjusted P = 0.057). Notably, there were no recurrent emergent mutations within our cohort. **Conclusions:** Our results suggest that ultra-deep whole exome sequencing can non-invasively identify emergent mutations at the time of progression. Resistance to cytotoxic therapy is likely multi-factorial and analysis in expanded cohorts will be helpful to identify recurrently mutated pathways that may contribute to disease progression after an initial response to therapy. Sequential monitoring of PD-L1 on circulating stromal cells in blood predicts PFS in NSCLC patients undergoing immunotherapy after definitive chemoradiation. *First Author: Daniel L Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Cancer Associated Macrophage-Like cells (CAMLs) are circulating stromal cells in the blood of patients (pts) with solid tumors that are phagocytic macrophages that may represent the inflammatory state of the tumor microenvironment. Previously, we demonstrated CAMLs ≥50μm after chemo-radiation therapy (CRT) in NSCLC is associated with worse progression free survival (PFS) and overall survival (OS). We also showed that PDL1 expression in CAMLs is dynamic & can change with CRT, difficult to assess with repeat biopsies, but possible with liquid biopsy. For this study we evaluated whether CAML properties can predict response to CRT with/without immunotherapy (IMT) agents in unresectable NSCLC. **Methods:** A single blind multi-year prospective study was undertaken to test the relationship of PDL1 expression and ≥50μm CAML size to PFS/OS in NSCLC, pre and post CRT with (n = 96) and without (n = 72) anti-PDL1/PD1 IMT. This included atezolizumab (prospective single arm NCT02525757) n = 39, durvalumab n = 52 or pembrolizumab n = 5 both after 2018 FDA approval. We recruited 168 pts with pathologically confirmed unresectable NSCLC prior to CRT. Blood samples 15 mL were taken at baseline (BL), CRT completion (T1), and ~1 month after CRT (T2) (with n = 96 or without n = 72 IMT). Blood was filtered by CellSieve filtration and CAMLs quantified for size ($<$ 49 μm or ≥50 μm) and PDL1 expression to evaluate PFS and OS hazard ratios (HRs) by censored univariate and multivariate analysis at 24 months. **Results:** CAMLs were found in 90% of all samples, average 5.8 CAMLs/15mL. At BL, ≥50μm CAMLs did not predict PFS in CRT/IMT pts (HR 1.6, p = 0.220) nor CRT alone (HR 1.3, p = 0.593). However, after completion of CRT (T1) ≥50μm CAMLs predicted PFS in CRT/IMT pts (HR 2.7, p = 0.003) and CRT alone (HR 2.5, p = 0.015). In primary tumor biopsies, PDL1 expression $>$ 1% did not predict CRT/IMT response (PFS HR 1.8, p = 0.262 & OS HR 2.3, p = 0.158). At BL, high CAML PDL1 did not predict PFS in CRT/IMT pts (HR 1.4, p = 0.427) nor CRT alone (HR 1.1, p = 0.982). Further, at CRT completion (T1), high CAML PDL1 only trended for better PFS in CRT/IMT pts (HR 1.7, p = 0.137), but not CRT alone (HR 1.1, p = 0.972). At T2, however, pts with continuously high CAML PDL1 had significantly better PFS with IMT (HR 3.2, p = 0.002) vs CRT alone (HR 1.4, p = 0.616). While ≥50μm CAMLs at BL did not predict 24 month progression, ≥50 μm CAMLs after CRT (with or without 1 cycle of anti-PDL1 IMT) was 84% accurate at predicting progression. Further subtyping and analysis is ongoing to evaluate OS and PDL1 in the CAML populations. **Conclusions:** Our data suggests that in unresectable NSCLC, ≥50 μm CAMLs after completion of CRT is prognostic regardless of IMT use. PDL1 expression in CAMLs also appears to predict for response to consolidated IMT after CRT. Additional studies are needed to validate these findings. Genomic and immunologic characterization of large-cell neuroendocrine carcinoma of the lung. *First Author: Chul Kim, Georgetown University, Department of Hematology and Oncology, School of Medicine, Washington, DC*

Background: Large-cell neuroendocrine carcinoma (LCNEC) is a rare type of lung cancer with a poor prognosis. Due to its rarity, molecular characterization of LCNEC is not well elucidated. We aim to understand the genomic and immunologic landscape of LCNEC to identify molecular alterations and relevant biological pathways with potential therapeutic value. **Methods:** Comprehensive profiling including whole exome sequencing (WES), next-generation sequencing (NGS), whole transcriptome sequencing (WTS), and immunohistochemistry (IHC) for PD-L1 was performed (Caris Life Sciences, Phoenix, AZ). Tumor mutational burden (TMB) was calculated based on somatic nonsynonymous mutations. LCNEC was categorized as small cell lung cancer (SCLC)-like LCNEC (*TP53*/*RB1* co-mutated) and non-small-cell lung cancer (NSCLC)-like LCNEC (wild type for one or both of *TP53*/*RB1*). Molecular features of LCNEC were compared among the subgroups and with those of SCLC using the χ^2 test with Benjamini & Hochberg correction. **Results:** A total of 467 cases of LCNEC were included. Commonly altered genes (≥ 5%) included *TP53* (79.1%), *RB1* (36.8%), *SMARCA4* (10.4%), *ARID1A* (10.3%), *KRAS* (9.7%), *KEAP1* (9.2%), *KMT2D* (8.7%), *STK11* (8.4%), *NF1* (7.1%), *PTEN* (6.1%), and *CDKN2A* (5.9%). The prevalence of potentially actionable mutations was as follows: *EGFR* exon 19 deletion (0.48%), *EGFR* L858R (0.48%), *ALK* fusion (1.7%), *KRAS* G12C (2.9%). *EGFR* exon 19 deletion, *EGFR* L858R, and *ALK* fusion were exclusive to NSCLC-like LCNEC tumors. *RET* fusion, *NTRK* fusion and $BRAF^{V600E}$ were not detected. Copy number alterations (CNAs) were found in *MYC* (8.8%), *ZNF703* (4.1%), *FOXA1* (4.0%), *FGFR1* (4.0%), *ATK2* (3.9%), *CCNE1* (3.7%), *FGF19* (3.4%), *TNFRSF14* (3.4%), and *CCND1* (2.7%). Over-expression of cMET was noted in 10% and PD-L1 expression (by 22C3 pharmDx) of $>$ 1% was noted in 21.5% of samples. WTS detected cMET exon 14 skipping mutations in 2.4% of samples. High tumor mutation burden (TMB; ≥ 10 Mut/MB) was seen in 40.6%. Among the 467 cases of LCNEC, 112 (24%) were SCLC-like LCNEC and 335 (76%) NSCLC-like LCNEC. Mutations in *KRAS* (12%), *STK11* (11%), *CDKN2A* (9%), and *SMARCA4* (14%) were more common in NSCLC-like LCNEC, compared with SCLC-like LCNEC (p value $<$ 0.05). 442 cases of SCLC were compared with LCNEC tumors. *SLFN11:SLFN12* fusion events, detected by WTS, were exclusively seen in SCLC and were not seen in any of the LCNEC cases. Gene expression profiles revealed that 1) B cell infiltration was higher in SCLC-like LCNEC, compared with SCLC, and 2) NK and T cell infiltration was lower, but B-cell infiltration was higher in NSCLC-like LCNEC, compared with SCLC. **Conclusions:** LCNEC displays a broad pattern of genomic alterations that overlap in the SCLC-like subset with the classic alterations in SCLC. The distinct genomic alterations and transcriptomic profiles present opportunities for therapeutic targeting and inform a future framework for development of therapeutics for LCNEC. Deep learning to predict subtypes of poorly differentiated lung cancer from biopsy whole slide images. *First Author: Gouji Toyokawa, Department of Thoracic Surgery, Clinical Research Institute, National Hospital Organization, Kyushu Medical Center, Fukuoka, Japan*

Background: Lung cancer is the leading cause of cancer-related death in many countries, and its prognosis remains unsatisfactory. Since treatment approaches differ substantially based on the subtype, such as adenocarcinoma (ADC), squamous cell carcinoma (SCC) and small cell lung cancer (SCLC), an accurate histopathological diagnosis is of great importance. However, if the specimen is solely composed of poorly differentiated cancer cells, distinguishing between histological subtypes can be difficult. The present study developed a deep learning model to classify lung cancer subtypes from whole slide images (WSIs) of transbronchial lung biopsy (TBLB) specimens, in particular with the aim of using this model to evaluate a challenging test set of indeterminate cases. **Methods:** Our deep learning model consisted of two separately trained components: a convolutional neural network tile classifier and a recurrent neural network tile aggregator for the WSI diagnosis. We used a training set consisting of 638 WSIs of TBLB specimens to train a deep learning model to classify lung cancer subtypes (ADC, SCC and SCLC) and non-neoplastic lesions. The training set consisted of 593 WSIs for which the diagnosis had been determined by pathologists based on the visual inspection of Hematoxylin-Eosin (HE) slides and of 45 WSIs of indeterminate cases (64 ADCs and 19 SCCs). We then evaluated the models using five independent test sets. For each test set, we computed the receiver operator curve (ROC) area under the curve (AUC). **Results:** We applied the model to an indeterminate test set of WSIs obtained from TBLB specimens that pathologists had not been able to conclusively diagnose by examining the HE-stained specimens alone. Overall, the model achieved ROC AUCs of 0.993 (confidence interval [CI] 0.971-1.0) and 0.996 (0.981-1.0) for ADC and SCC, respectively. We further evaluated the model using five independent test sets consisting of both TBLB and surgically resected lung specimens (combined total of 2490 WSIs) and obtained highly promising results with ROC AUCs ranging from 0.94 to 0.99. **Conclusions:** In this study, we demonstrated that a deep learning model could be trained to predict lung cancer subtypes in indeterminate TBLB specimens. The extremely promising results obtained show that if deployed in clinical practice, a deep learning model that is capable of aiding pathologists in diagnosing indeterminate cases would be extremely beneficial as it would allow a diagnosis to be obtained sooner and reduce costs that would result from further investigations. A new model using artificial intelligence to predict recurrence after surgical resection of stage I-II non-small cell lung cancer. *First Author: Natalie Lui, Stanford University, Stanford, CA*

Background: Five-year survival for stage I-II lung cancer is quite low even after complete surgical resection. Current guidelines recommend adjuvant treatment only for selected patients with stage II or higher disease. A prediction model that identifies patients at high risk of recurrence who may benefit from adjuvant treatment is greatly needed. Many existing prediction models include a small number of genes that were found to be significant in previous studies. We propose using artificial intelligence to analyze a microarray of $>$ 20,000 well-annotated genes to create a model that predicts recurrence after surgical resection of stage I-II lung cancer. **Methods:** We identified 275 patients who underwent surgical resection for pathologic stage I-II lung adenocarcinoma or squamous cell carcinoma from 2009 to 2019 in our institution's prospective surgical database. We excluded patients who had follow up time less than 3 years or received adjuvant therapy and had not had a recurrence, as well as patients with missing specimen blocks. Patient characteristics and recurrence information were obtained from chart review. The patients were divided into training (192 patients) and validation (83 patients) cohorts, and the recurrence status for the validation cohort was initially blinded. Gene expression levels were generated using Clariom S human array (ThermoFisher) from 10um sections cut from the formalin-fixed, paraffin-embedded surgical specimen blocks. The artificial intelligence algorithm Support Vector Machine (SVM) was used to create a prediction model for recurrence using the gene expression and recurrence status of the patients in the training cohort. The model was then tested on the validation cohort using Kaplan-Meier analysis and the area under the receiver operator curve (AUROC). **Results:** The recurrence prediction model separated the validation cohort into 15 (18.1%) patients in the high-risk group and 68 (81.9%) patients in the low-risk group. Kaplan-Meier analysis showed the five-year disease-free survival was significantly higher in the low-risk group compared to the high-risk group (86 vs. 50%, HR = 4.41, p = 0.0025). The AUROC for predicting recurrence was 0.744. **Conclusions:** Our model uses artificial intelligence to successfully predict recurrence after surgical resection for stage I-II non-small cell lung cancer. With an AUROC of 0.744, our model outperforms previously described models with AUROC up to 0.6. Our model separates patients into high-risk and low-risk groups, which will make management decisions clearer compared to other models that also include an intermediate-risk group. Patients in the low-risk group had 86% five-year disease-free survival; patients in the high-risk group had 50% five-year disease-free survival and may benefit from increased postoperative surveillance or adjuvant therapy. Surgical outcomes for early-stage non-small cell lung cancer at facilities with stereotactic body radiation therapy programs. *First Author: Yusef Syed, Emory University, Atlanta, GA*

Background: Patients undergoing surgery for early-stage non-small cell lung cancer (NSCLC) may be at high-risk for post-operative mortality. Access to stereotactic body radiation therapy (SBRT) offers a less invasive alternative for this population that may facilitate more appropriate patient selection for surgery. **Methods:** An analysis of all patients with early-stage NSCLC reported to the National Cancer Database between 2004-2015 was performed. Post-operative mortality rates were derived using vital status data. Utilization of SBRT was defined by each facility's SBRT Experience in years and SBRT-to-Surgery volume ratios, defined by quartiles. Multivariable logistic regression with backward elimination was used to test for independence of associations between exposures of interest and post-operative mortality. Interaction testing was performed to assess the statistical relationship of covariates found to have independent associations. **Results:** The study cohort consisted of 202,542 patients who underwent surgical resection of clinical stage T1-T2 NSCLC (AJCC 7th edition). The 90-day post-operative mortality rate declined significantly during the study period from 4.6% to 2.6% ($p < 0.001$). During this period, the proportion of facilities that utilized SBRT increased from 3.3% to 77.5% ($p < 0.001$) and the proportion of patients treated with SBRT increased significantly from 0.7% to 15.4% ($p < 0.001$). Lower 90-day post-operative mortality rates were observed at facilities with greater than six years of SBRT experience (OR 0.84, CI 0.76-0.94, p = 0.003) and SBRT-to-Surgery volume ratios above 17% (OR 0.85, CI 0.79-0.92, $p < 0.001$). Additional covariates associated with 90-day mortality included higher surgical volume, geographic region, year of diagnosis, age, sex, race, insurance status, facility type, Charlson-Deyo score, clinical T stage, histology, anatomic location, surgery type, and prior malignancy. Interaction testing between these covariates was negative, demonstrating that higher SBRT Experience and SBRT-to-Surgery volume ratios were independently associated with lower 90-day surgical mortality. **Conclusions:** Patients who underwent surgery for early-stage NSCLC at facilities with higher SBRT Experience and SBRT-to-Surgery volume ratios had lower rates of post-operative mortality. These findings suggest that the availability of SBRT may be a surrogate for a more comprehensive and safer approach to matching patients to surgery or SBRT. The observation of higher post-operative mortality rates at facilities without an SBRT program deserves further study. Research Sponsor: None.

Prognostic value of SUVmax on FDG-PET/CT before and after stereotactic body radiotherapy (SBRT) on recurrence and survival in early-stage non-small cell lung cancer (NSCLC). *First Author: Saarang Deshpande, Case Western Reserve University School of Medicine, Cleveland, OH*

Background: Stereotactic body radiotherapy (SBRT) is the standard of care in medically inoperable early-stage non-small cell lung cancer (NSCLC). Assessment of FDG-PET/CT before and after SBRT may stratify risk of disease recurrence and survival outcomes. **Methods:** Patients with T1-2N0M0 NSCLC who underwent PET/CT prior to SBRT (50-60 Gy over 3-5 fractions) between 2012 and 2019 were retrospectively identified. Pre-SBRT SUVmax and change in SUVmax at 3 and 6 months after SBRT were assessed as predictors of local control (LC), progression-free survival (PFS), and overall survival (OS). Optimal cutoff points for comparison were determined by receiver operator characteristic (ROC) analysis. Survival analyses were performed with Kaplan-Meier estimates with log rank testing, and Cox proportional hazards models including age, sex, T stage, histology, and performance status. **Results:** Out of 163 patients identified, 71 (43.6%) underwent repeat PET/CT within 6 months of SBRT completion. Median follow-up was 19 months (range 1 – 94 months). For the whole cohort, 1-year and 2-year LC, PFS, and OS were 95.0% and 80.3%, 75.9% and 47.7%, and 87.1% and 67.0%, respectively. Pre-SBRT SUVmax greater than 12.3 had an aHR of 2.80 (95% CI 1.3 – 6.2, p = 0.011) for PFS. A cutpoint of 12.6 for pre-SBRT SUVmax had an aHR of 3.00 (95% CI 1.6 – 5.8, p = 0.003) for OS. Pre-SBRT SUVmax did not significantly predict LC. A 3-month SUVmax decrease of at least 45% was associated with improved LC (aHR = 0.15, 95% CI 0.02 – 0.91, p = 0.018). At 6 months following SBRT, a cutoff point of a 53% decrease in SUVmax was associated with better LC (p = 0.038). Change in SUVmax was not significantly associated with PFS or OS at either time point. Performance status significantly predicted PFS and OS in all models. No other factors were significant. **Conclusions:** Pre-treatment SUVmax cutoffs can predict PFS and OS in early-stage NSCLC. At both the 3- and 6-month time points following SBRT, cutoff values for change in SUVmax can stratify risk of local recurrence. Research Sponsor: None.

	Outcome	Cutoff value	p-value
Pre-SBRT SUVmax	LC	14.8	0.097
Pre-SBRT SUVmax	PFS	12.3	0.011
Pre-SBRT SUVmax	OS	12.6	0.003
3-mo SUVmax change	LC	-45%	0.018
3-mo SUVmax change	PFS	-50%	0.936
3-mo SUVmax change	OS	-72%	0.245
6-mo SUVmax change	LC	-53%	0.038
6-mo SUVmax change	PFS	-78%	0.317
6-mo SUVmax change	OS	-40%	0.089

Multiomics analysis reveals high-immune infiltration in tumor-adjacent lung tissues affects the prognosis of stage I NSCLC. *First Author: Lisa Ying, Department of Pathology, Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital);Institute of Basic and CancerMedicine (IBMC), Chinese Academy of Sciences, Hangzhou, China*

Background: Along with the wide application of low-dose spiral CT in lung cancer screening, a large number of resectable patients with lung cancer are identified, especially stage I Non-Small Cell Lung Cancer (NSCLC). However, their prognosis varies greatly and 5-year recurrence rate of stage I NSCLC is around 30%. Therefore, it is crucial to explore the potential mechanism of recurrence of early NSCLC. **Methods:** Eighty-seven patients with stage I NSCLC were enrolled from April 2008 to July 2015, including 79 squamous carcinoma and 28 adenocarcinoma. Frozen tumor tissues and paired tumor-adjacent lung tissues were collected to employ targeted panel sequencing, RNA sequencing and TCR repertoire sequencing. **Results:** Ninety-five non-silent mutations were detected in tumor-adjacent lung tissues with a median tumor mutation burden of 1.5/Mb, significantly lower than that in tumor tissues (11/Mb), $p < 0.05$. 42 mutations were specifically detected in the adjacent normal tissues, enriching in the immune response pathways. Comparing with paired tumors, tumor-adjacent lung tissues were found more favorable immune infiltration including higher immune cell activity like CD8+ T cell (0.50 vs 0.43, $p < 0.0001$), up-regulated immune-associated pathways, higher TCR clonality (0.19 vs 0.18, $p < 0.05$), less loss of heterozygosity (LOH) of human leukocyte antigen (HLA) (6.25% vs 50%, $p < 0.0001$) and observed predicted neoantigens expression (1 vs 128, $p < 0.01$). However, more shared viral-associated TCRs in tumor and tumor-adjacent tissues were found using the GLIPH algorithm. Prognostic analysis showed patients with higher overlap of TCR in tumors and tumor-adjacent lung tissues were prone to recur in five years. Furthermore, patients with higher immune infiltration in tumor-adjacent lung tissues had favorable outcomes than those with lower immune infiltration (HR: 0.37 for DFS, $p < 0.05$, HR: 0.31 for OS, $p < 0.05$), irrelevant of the infiltration level in tumor tissues. **Conclusions:** Immune microenvironment in tumor-adjacent lung tissues plays important roles in progress of stage I NSCLC. Phase II trial of toripalimab plus chemotherapy as neoadjuvant treatment in resectable stage III non-small cell lung cancer (NeoTPD01 Study). *First Author: Zerui Zhao, Department of Thoracic Surgery, Sun Yat-Sen University Cancer Center, Guangzhou, VA, China*

Background: Multi-modality treatment provides modest survival benefits for locally advanced non-small-cell lung cancer (NSCLC) patients. Preoperative immunotherapy has continuously been shown to be promising in treating resectable NSCLC. The current study aimed to investigate the activity and safety of the PD-1 inhibitor, toripalimab, with chemotherapy given as neoadjuvant treatment for resectable stage III NSCLC in Asian population. **Methods:** Eligible patients recruited were aged 18 years or older with histologically confirmed AJCC-defined stage IIIA or T3-4N2 IIIB NSCLC who deemed surgically resectable. Patients received 3 cycles of neoadjuvant treatment with intravenous toripalimab (240 mg), carboplatin (area under curve 5), and pemetrexed (500 mg/m^2 for adenocarcinoma) or nab-paclitaxel (260 mg/m^2 for others) on day 1 of each 21-day cycle. Surgical resection was performed 4-5 weeks following the first day of the last cycle of treatment. The primary endpoint was major pathological response (MPR; ≤10% viable tumor cells). Secondary endpoints included pathological complete response (pCR), R0 resection rate, disease-free survival and safety. Paired primary tumor +/- lymph node and blood samples at baseline and surgery were obtained for exploratory study. This study is registered with ClinicalTrials.gov, NCT04304248. **Results:** Between August 2019 and July 2020, 33 patients (median age: 61, IQR: 56-66; female: 6, 18.2%) were enrolled and received neoadjuvant treatment. 18 (54.5%) patients had squamous cell lung cancer, and 13 (39.4%) had T3-4N2 stage IIIB disease. Two patients refused surgery and one had progressive disease after treatment. 30 (91.9%) patients underwent resection (median interval between neoadjuvant treatment and surgery: 36.5 days, IQR 30-42.5) and all except one achieved R0 resection (29/30, 96.7%). 20 patients (20/30, 66.7%) had an MPR, including 15 patients (15/30, 50.0%) had a pCR in the per-protocol population. Surgical complications included three arrhythmias, one prolonged air leak, and one chylothorax. 24 patients (80.0%) had pathological downstaging following treatment, and complete lymph node clearances (ypN0) were seen in 70.0% (21/30) of patients. The most common grade 3-4 treatment-related adverse events in the intention-to-treat population were anemia (2, [6.0%]). Severe treatment-related adverse event included one (3.0%) patient with grade 3 peripheral neuropathy (Guillain-Barré syndrome) and resulted in surgery cancellation. At the time of data cutoff (Feb 7, 2021), the median duration of follow-up was 4.13 months, and there were no treatment-related deaths. **Conclusions:** Toripalimab plus platinum-based doublet yields a high MPR rate, manageable treatment-related toxicity, and feasible surgical resection in resectable stage III NSCLC. Ongoing analysis of biomarker will be available at the meeting. Clinical trial information: NCT04304248. Research Sponsor: None.

Impact of genomic aberrations and additional therapies on survival outcomes of patients with operable non-small cell lung cancer (NSCLC) from the NEOSTAR study. *First Author: Nicolas Zhou, Thoracic and Cardiovascular Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The NEOSTAR study compared nivolumab (N) vs. nivolumab plus ipilimumab (NI) with major pathological response (MPR; ≤10% viable tumor) as primary outcome. We report updated rates of treatment failure (TF), including in patients whose tumors harbored genomic aberrations, and outcomes of additional treatments. **Methods:** Patients (pts) with stage I-IIIA resectable NSCLC (AJCC 7th) were randomized to either neoadjuvant N or NI followed by surgery (n = 44). TF was defined as radiographic and/or biopsy-proven recurrence from primary lung cancer and/or death (treatment or cancer-related). Additional systemic therapy at recurrence included immuno-oncology (IO)-based therapy (IO or chemo-IO), targeted therapy (TT), or chemotherapy. Disease control rate (DCR) was defined as the proportion of pts with radiographic objective responses and stable disease at first restaging. Cox proportional hazards model was used to associate baseline characteristics and time to TF. **Results:** A total of 44 randomized pts were evaluated, the median follow-up was 35 months (mts) as of February 4, 2021. Among the 12 TF pts (12/44, 27%), 42% (5/12) did not undergo surgery on trial, 9 (9/44, 20%) experienced recurrence and 6 (6/44, 14%) died (1 non-cancer-related, 5 cancer-related). TF was less likely in smokers vs. never smokers (hazard ratio = 0.20, 95% confidence interval = 0.06-0.65, p = 0.007). Among pts with pathological specimen resected on trial, MPR was achieved in 40% (12/30) of non-TF pts. Only 1 (1/7, 14%) TF pt achieved MPR, but died of a non-cancer related cause. TF-free survival rate at 2 years was 92% in MPR and 78% in non-MPR pts. Eight (8/9, 89%) pts had tumors with canonical oncodriver aberrations (5 *EGFR mutations*, 1 with *STK11+ KRAS Q61H* mutations, 1 *ALK* translocation and 1 *RET* fusions). Of the 9 recurrences, 44% (4/9) were treated with IO therapy, and all 7 pts with targetable aberrations were treated with TT (3 after retreatment with IO therapies). Of the 4 pts retreated with IO therapy, duration between end of neoadjuvant and retreatment were 20, 17, 23, and 19 mts. Duration from retreatment until progression (PD) were 1, 1, and 2 mts, respectively. Last pt was treated without PD for 2 mts but switched to TT due to discovery of genomic aberration. IO retreatment achieved 25% DCR (1/4). In comparison, the DCR for TT treated pts was 71% (5/7, p = 0.242). Median time to treatment was 21 mts, and median time to PD was not reached. Among 32 non-TF pts, 12 had genomic analysis and 7 aberrations were found in 6 pts (2 *STK11*, 2 *ERBB2*, 1 *STK11* + 1 *KRAS G12C*, and 1 *KRAS G12C* mutation). **Conclusions:** A 27% TF rate was observed after neoadjuvant IO. TF was less likely to occur in smokers and MPR pts, and 42% of TF pts did not undergo curative-intent surgery on trial. Genomic aberrations were common in pts with recurrence (89%), and treatment with TT achieved 71% DCR vs. 25% DCR with IO-based retreatment. Clinical trial information: NCT: 03158129. PIT-2: A multicenter phase II trail of S-1 plus cisplatin with concurrent radiotherapy followed by surgery in stage IIIA (N2) lung squamous cell carcinoma. *First Author: Kazuya Takamochi, Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo, Japan*

Background: A multicenter phase II study, PIT-2 (Personized Induction Therapy-2), was performed to investigate the efficacy and safety of S-1 plus cisplatin and concurrent thoracic radiation therapy (TRT) followed by surgery in patients with stage IIIA (N2) lung squamous cell carcinoma (LSCC). To date, no clinical trials on the use of induction therapy prior to surgery have focused solely on the treatment of N2 LSCC. **Methods:** Eligible patients were 20 to 75 years old and had stage IIIA (pathologically proven N2) LSCC, performance status of 0-1, and no prior treatment. The patients received induction therapy consisting of three cycles of S-1 and cisplatin plus concurrent TRT (45 Gy in 25 fractions) followed by surgery. S-1 was administered orally at 40 mg/m^2 twice per day, on days 1 through 14 along with an intravenous infusion of cisplatin (60 mg/m^2) on day 1. The treatment cycles were repeated every four weeks. The primary endpoint was 2-year progression-free survival (PFS) rate and key secondary endpoints included overall survival (OS), the objective response rate (ORR) as defined by the Response Evaluation Criteria in Solid Tumors version 1.1, pathological complete remission (pCR) rate, feasibility, and toxicity. **Results:** Of the 45 patients registered between December 2013 and September 2018, 43 received induction therapy. Of the 43 patients, 39 (91%) underwent surgery (25 lobectomies, 10 bilobectomies, three pneumonectomies, and one wedge resection). The complete resection rate was 95% (37/39). Median follow-up time was 35.7 months. The 2-year PFS and OS rates were 67% (90% CI: 54-78%) and 70% (95% CI: 53-81%), respectively. The ORR and pCR rates were 86% (37/43, 95% CI: 76-96%) and 39% (15/39, 95% CI: 23-54%), respectively. Grade (G) 3 or 4 toxicities during the induction therapy in 43 patients included neutropenia (40%), anemia (9%), thrombocytopenia (7%), and hyponatremia (7%). Severe surgical complications in 39 patients included G3/4 pneumonia (5%), G3 bronchopleural fistula (5%), and G3 pleural effusion (5%). No G3/4 intraoperative adverse events occurred. There was no 30-day postoperative mortality and one 90-day postoperative mortality in a patient who underwent right pneumonectomy and developed pneumonia after discharge. **Conclusions:** Induction therapy using S-1 plus cisplatin and concurrent TRT followed by surgery is a promising treatment for patients with stage IIIA (N2) LSCC. Clinical trial information: 000012413. Research Sponsor: None.

Impact of society and national guidelines on patient selection for lung cancer surgery in the United Kingdom. *First Author: Aina Pons, Royal Brompton and Harefield Hospitals, London, United Kingdom*

Background: In 2010 the British Thoracic Society (BTS) guidelines introduced clinical decision based on patient perception of risk to make surgery more permissive and revised recommendations for broader oncologic criteria such as surgery for N2 disease to improve surgical resection rates. In 2011 the National Institute for Health and Care Excellence (NICE) guidelines were updated with similar recommendations, but notable disagreement on surgery for N2 disease. We sought to conduct one of the largest cross-sectional studies to ascertain the impact of national clinical guidelines (with conflicting recommendations) on clinician behaviour. **Methods:** We analysed data from the UK national registry (National Lung Cancer Audit) comprising all patients diagnosed with lung cancer between 2008 to 2013 within England and Wales. Categorical data was summarised as frequency (%) and continuous data was summarised as mean (SD). Linear and logistic regression analyses were used with each year as an independent categorical outcome to determine global and year specific changes in FEV1 and proportions with N2 undergoing surgery respectively. **Results:** From January 2008 to December 2013, data from 167,192 patients with primary lung cancers were submitted to the NLCA. In 2008, 23,293 new lung cancers were diagnosed in England and Wales increasing annually by 2013 to 29,224. The most common presentation was advanced disease stage IV (49.7%), IIIB (13.2%) and IIIA (12.0%) and early-stage disease was less frequent with presentations IA (7.0%), IB (6.7%), IIA (2.9%) and IIB (4.27%). Lung function tests were undertaken in a subset of 53,905 of all diagnosed patients from 2008 to 2013. The mean FEV_1 (SD) increased annually from 67 (22)% in 2008 to 71 (24)% in 2013 ($p < 0.001$). Overall, 28% (n = 46,742) of the patients were preoperatively staged as N2 disease at diagnosis. The proportion of patients with N2 disease increased from 24 to 29% in this timeframe (P = 0.003). The proportion of patients undergoing surgery for lung cancer increased from 9.5% in 2008 to 20.5% in 2013 ($p < 0.001$). Mean FEV_1 of surgical patients were higher at 79 (22)% than the population average of 69 (23)%, an accepted reflection of surgical selection. Over time, mean FEV_1 of surgical patients increased from 76 (22)% in 2008 to 81 (22)% in 2013 ($p < 0.001$). Of the patients undergoing surgery, the proportion of patients across the 6-year interval were broadly consistent between 8 to 11% without any evidence of trend (P = 0.125). **Conclusions:** Within 3 years of new clinical guidelines, we did not observe any overall change in selection based on lower levels of lung function and when presented with conflicting recommendation no observable change in attitudes of clinicians on surgery for N2 disease. The observed increase in surgical resection rates is more likely due to (greater access to surgery by) increasing number of surgeons rather than any impact of guideline recommendations. The efficacy of PD-1 antibody sintilimab on ground glass opacity lesions in patients with early-stage multiple primary lung cancer (CCTC-1901, NCT04026841). *First Author: Bo Cheng, Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou, China*

Background: Immune checkpoint inhibitors (ICIs) targeting programmed cell death protein 1 (PD-1) have been proven its significant efficacy on advanced non-small cell lung cancer (NSCLC). However, it remains unknown and is of great interest whether the PD-1 antibody affects early-stage lung cancer. Here, we reported the preliminary efficacy and safety outcomes of sintilimab on these early-stage GGO lesions in patients (pts) with multiple primary lung cancer in the CCTC-1901 study, the first trial evaluating PD-1 antibody in preinvasive or low invasive lung cancer worldwide. **Methods:** This single-center, phase II, Simon's two-stage design trial included pts who had a pathological diagnosis of resected lung cancer and at least one unresectable GGO lesion suspicious malignant which evaluated by a multidisciplinary team's consensus. The enrolled pts received 4 cycles of intravenous sintilimab 200 mg every 3 weeks. The primary endpoint is the objective response rate (ORR) of unresectable GGO lesions. For persistent GGO lesions that did not respond to treatment, either observation or second operation was taken. Also, immune biomarkers (T/B/NK subpopulation etc.) were monitored during treatment to validate the immune activity. **Results:** A total of 36 pts were included, with median age 59.5 (53.5-69), 66.7% females, 80.6% never smokers. All resected lesions were adenocarcinomas, of which 52.8% were EGFR mutated. 49 unresected GGOs (pure 11[22.4%], mixed 38[77.6%]) were defined as target lesions from 36 enrolled pts, with a mean size of 13.20±5.06 mm. The ORR (RECIST v1.1) was 5.6% (2/36, 1 PR and 1 CR); none of the pts had PD. Additionally, 3 non-target lesions (unresected solid lesions) from 3 included pts showed PR after the treatment of sintilimab, and the rest lesions (target or non-target) of 31 pts performed SD. Grade 1-2 fatigue (13, 36%), rash (13, 36%) and arthralgia (8, 22%) were the most common treatment-related adverse events (TrAEs), and no grade 3-5 TrAEs occurred. The proportion of $CD8^+$ T-cell and the ratio of $CD8^+/CD4^+$ in 5 patients who showed PR of unresected lesions were significantly higher compared to those with SD lesions at baseline ($CD8^+$ 36.6% vs 24.6%, $p < 0.01$; $CD8^+/CD4^+$ 1.09±0.18 vs 0.64±0.22, $p < 0.01$). **Conclusions:** This study is the first to confirm that PD-1 antibody sintilimab has immune-related antitumor activity on GGO-featured lung cancer and could be well tolerated among pts with early-stage lung cancer. Clinical trial information: NCT04026841. Research Sponsor: China National Science Foundation (Grant No. 81871893).

Doubling of median overall survival in a nationwide cohort of veterans with stage III non-small cell lung cancer in the durvalumab era. *First Author: Kamya Sankar, Division of Hematology and Oncology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI*

Background: The standard of care for patients with unresectable stage III non-small cell lung cancer (NSCLC) is concurrent chemoradiotherapy followed by durvalumab maintenance based on outcomes from the PACIFIC trial. However, PACIFIC did not include Veterans, a unique population with significant co-morbidities; thus, the impact of durvalumab on survival of Veterans with stage III NSCLC is unknown. **Methods:** Using the U.S. Department of Veterans Affairs Corporate Data Warehouse, patients with stage III non-small cell lung cancer who received chemoradiotherapy and at least one dose of durvalumab were selected. Kaplan-Meier survival analysis and univariate Cox proportional hazards modeling were used to determine progression-free survival (PFS), overall survival (OS) and independent predictors of PFS and OS. PFS was manually extracted by review of serial surveillance scans. All statistical computations were performed using SAS 9.4 software. **Results:** 1106 Veterans met our inclusion criteria. The median age was 69. 95.1% (n = 1052) were male. The median Charlson Comorbidity Index was 1. 86.4% (n = 956) reported current or former tobacco use. 48.1% (n = 532) had adenocarcinoma histology, 48.4% (n = 535) squamous cell, 0.5% (n = 5) large cell, 0.3% (n = 3) neuroendocrine, and 0.1% (n = 1) sarcomatoid. 60% (n = 619) had AJCC 8^{th} edition stage IIIA disease, 34.5% (n = 382) stage IIIB, and 3.3% (n = 36) stage IIIC. Median PFS was 19.9 months (95% CI: 16.9 – 23.6) and median OS was 34.9 months (95% CI: 29.7 – not reached). In univariate survival analyses, adenocarcinoma histology (HR 1.14, $p = 0.03$) predicted progression. Older age (HR 1.03, $p < 0.0001$) and stage IIIB/IIIC disease (HR 1.05, $p = 0.008$) predicted inferior OS. 18.4% (n = 204) of patients completed all planned cycles of adjuvant durvalumab. The median number of durvalumab infusions received was 6 (range: 1 – 38). Among evaluable patients, 175 (19.4%) discontinued durvalumab for progression, 211 (23.4%) discontinued for suspected immune-related toxicity and 17 (1.9%) died during treatment. **Conclusions:** While several factors have led to the improvement of OS in patients with stage III NSCLC over time, we report a doubling of median OS in Veterans with stage III NSCLC who received chemoradiotherapy plus durvalumab as compared to historical cohorts who received chemoradiotherapy alone (1). Veterans in our study received a lower median number of durvalumab infusions as compared to patients in the PACIFIC trial (6 vs. 14), and a significant proportion discontinued durvalumab due to suspected immune-mediated toxicity (23.4%). If further analyses confirm our findings, investigation of alternative dosing regimens and/or dosing intervals of durvalumab in order to balance safety and efficacy of durvalumab therapy in Veterans is warranted. Elderly patients with unresectable stage 3 NSCLC treated with definitive chemoradiation with or without durvalumab: Safety and outcomes. *First Author: Malcolm Isaiah Ryan, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Recently, it has been demonstrated that the addition of durvalumab after chemoradiation (CRT) in unresectable stage 3 non-small cell lung cancer (NSCLC) significantly improves overall survival (OS). The benefit of CRT in elderly patients is considered controversial given its increased toxicity. As such, CRT followed by durvalumab in elderly patients may be underutilized despite its demonstrated superiority. The practice pattern at our center is to offer curative treatment unless clearly contraindicated. We sought to investigate the outcomes of elderly patients treated with CRT +/- durvalumab at our center. **Methods:** We conducted a review of all stage 3 NSCLC patients treated with CRT between 2018 and 2020. Patients were analyzed based on age: < 70 years, ≥ 70 years. Endpoints evaluated were treatment patterns, toxicity, progression free survival (PFS) and overall survival (OS). **Results:** We identified 115 stage 3 patients: 44 patients ≥ 70 years (70-89) and 71 patients < 70 years (34-69). Patients were fit: ECOG 0-1 (98%/97%), mean Charlson comorbidity index (CCI) (1.1/0.9) in elderly vs young patients; $p > 0.05$. All other baseline characteristics including PD-L1 expression were similar. The chemotherapy regimens (platinum in combination with etoposide, paclitaxel or pemetrexed), dose intensity (97% vs 97%) and percentage of planned cycles received (91% vs 96%) were similar. There were 2 treatment related deaths from CRT among the younger cohort and none in the elderly patients. At the completion of CRT, 75% of elderly and 72% of young patients received durvalumab. Clinician/patient preference was the most common reason for not receiving consolidation durvalumab in older patients (55% vs 25%). The median time to starting durvalumab was 43 days in the elderly and 37 days in young patients (p = 0.19). Durvalumab was well tolerated in the elderly and incidence of grade ≥ 3 immune-related adverse events was 9% compared to 6% in young patients; p = 0.68. The durvalumab completion rates were 30% in elderly and 24% in young patients; p = 0.22. Median PFS was similar between elderly and young patients (17.9 vs 10.6 months respectively; p = 0.07), even after adjusting for the CCI (HR 0.60; p = 0.07). The 24- and OS rates are also similar (p = 0.93): 77% in elderly and 77% in young patients. **Conclusions:** Definitive CRT followed by durvalumab can be safely delivered in elderly patients ≥ 70 years with comparable outcomes. The non-significant trend towards better PFS in elderly patients suggests that only select fit patients are being referred for treatment. In conclusion, all patients should undergo comprehensive oncologic assessment to determine if curative intent treatment can be delivered to avoid undertreatment of elderly patients. Research Sponsor: None.

NRG-RTOG 1106/ACRIN 6697: A phase IIR trial of standard versus adaptive (mid-treatment PET-based) chemoradiotherapy for stage III NSCLC—Results and comparison to NRG-RTOG 0617 (non-personalized RT dose escalation). *First Author: Feng-Ming Spring Kong, Clinical Oncology Department, The University of Hongkong-Shenzhen Hospital, Shenzhen, China*

Background: NRG-RTOG 0617 (R0617) found that non-personalized dose escalation of radiotherapy (RT) with concurrent chemotherapy was deleterious. NRG-RTOG 1106/ACRIN 6697 (R1106) studied adaptive chemoradiotherapy, using tumor and patient individualized RT dose intensification simultaneously with field reduction, based upon mid-treatment FDG-PET. **Methods:** The control arms of both studies used 60 Gy (+ weekly carboplatin/paclitaxel). The investigational arm of R0617 used 74 Gy in 37 fractions, with no field/dose adaptation, while R1106 used mid-treatment FDG-PET (after ~40 Gy) to design an individualized dose adaptive RT plan with daily-fraction size 2.2 to 3.8 Gy (up to 80.4 Gy/30 fractions), based upon a model of isotoxic lung risk. Nearly all (93%) patients had IMRT. No patients had consolidation immunotherapy. The primary endpoint for R1106 was local-regional-progression freedom (LRPF) assessed by central review. Other endpoints reported here were survival, toxicity, and institution-defined local/regional control. **Results:** From 2012-2017, 127 patients were enrolled to R1106 (43 in the standard and 84 in the adaptive arms), with a median follow-up of 3.6 years. The median actual RT dose in the adaptive arm was 71 Gy (Q1-Q3 68-76 Gy). The 2-year LRPF was 59.5% versus 54.6% (p=0.66) for standard versus adaptive RT; the 3-year survival rates were 49.1% versus 47.5% (p=0.80). An exploratory analysis of 2-year in-field local primary tumor control and local-regional tumor control (institution-assessed) were 58.5% and 55.6% for standard RT, and 75.6% and 66.3% for adaptive RT, respectively. As shown in the table, there were no significant differences in cardiac or esophageal adverse events between the two arms; the adaptive RT arm had more Grade 3+ respiratory events (23.8% versus 14.3%). **Conclusions:** NRG-RTOG1106 did not meet its primary endpoint of demonstrating improved LRPF. Unlike R0617, there was no suggestion of a detrimental effect of adaptive dose-intensified RT on survival and cardiac events. Studies to refine personalized RT, especially in the immunotherapy era, should be considered. Outcome comparison between R0617 and R1106. Clinical trial information: NCT01507428. Research Sponsor: This project was supported by grants UG1CA189867 (NCORP), U10CA180822 (NRG Oncology SDMC), U10CA180868 (NRG Oncology Operations), and U24CA180803 (IROC) from the National Cancer Institute (NCI).

	R0617 Control Arm	R0617 High-dose Arm	R1106 Control Arm	R1106 Adaptive Arm
3-yr OS	44.5%	31.1%	49.1%	47.5%
3-yr Local-regional failure (institution reported)	47.1%	50.9%	30.0%	30.2%
2-yr In-field primary tumor local control (institution reported)	NS	NS	58.5%	75.6%
2-yr In-field local-regional control (institution reported)	NS	NS	55.6%	66.3%

The impact of a genomic sequencing classifier (GSC) on clinical decision making in patients with a high-risk lung nodule. *First Author: Sonali Sethi, Cleveland Clinic, Cleveland, OH*

Background: Current guidelines recommend that patients who have lung nodules with high risk of malignancy (ROM) ($>$ 65%) should undergo surgical and other ablative therapies. However, prior studies have shown that clinicians may opt for more conservative management in these high-risk patients. Percepta Genomic Sequencing Classifier (GSC), a RNA-seq based classifier derived from bronchial epithelial cells to assess risk of lung cancer, was designed to risk stratify lung nodules by both down classifying ROM as a "rule -out" test with high sensitivity as well as up-classifying ROM as a "rule- in" test with high specificity for malignancy. This study assesses the impact of up-classification of high ROM to very high- risk (ROM $>$ 90%) by Percepta GSC in increasing the number of ablative therapies recommended for high-risk lung nodules. **Methods:** This prospective randomized decision impact survey included 37 patients from the AEGIS I/ II cohorts and the Percepta Registry who were undergoing work up of a lung nodule and had a high ROM that was up-classified to very high ROM by Percepta GSC. 97 physicians assessed 10 randomly assigned patient cases. They then responded to a survey designed to test the hypothesis that including a Percepta GSC result will increase the recommendation for surgical or other ablative therapy in very high- risk patients as well as their level of confidence of this recommendation. Physicians were first presented with the patient's clinical information without Percepta GSC and then with Percepta GSC. **Results:** 97 physicians provided a total of 682 evaluations of 37 patients. In this study, the recommendation for surgical or other ablative therapy increased from 19/341 (5.6%) prior to the Percepta GSC result to 157/341 (46%) after the Percepta GSC result (odds ratio of 4.76, p-value $<$ 0.001). The number of extremely confident recommendations increased from 72/341 (21%) without Percepta GSC to 106/341 (31%) with Percepta GSC. Significantly more physicians had increased confidence in their recommended next step post-Percepta GSC when collapsing the confidence level responses into increased confidence (n = 93) and decreased confidence (n = 44) (p-value = 0.002). **Conclusions:** Percepta GSC had a quantifiable impact on clinical decision making. It increased the number of surgical and other ablative therapies recommended when patients were re-classified from high to very high- risk of lung cancer with a higher confidence in the recommended next step. By up-classifying nodules from high to very high ROM, Percepta GSC will improve the likelihood and timeliness of appropriate therapies and assist clinicians more effectively manage patients to improve patient outcomes. Research Sponsor: Veracyte, Inc.

Patients with early-stage (T1-2N0) adenosquamous lung cancer have worse long-term survival compared to patients with early-stage lung adenocarcinoma or squamous cell histology. *First Author: Larisa Shagabayeva, Harvard Medical School, Boston, MA*

Background: Survival outcomes for patients with adenosquamous carcinoma of the lung are not well understood by virtue of reduced prevalence. The objective of this study is to compare the long-term survival among patients with adenocarcinoma, squamous cell carcinoma and adenosquamous carcinoma of the lung. **Methods:** Overall survival of all patients with adenosquamous carcinoma, squamous cell carcinoma, and adenocarcinoma who received guideline-concordant treatment for T1-2N0M0 from 2004-2017 in the National Cancer Data Base was assessed using Kaplan-Meier analysis, multivariable Cox proportional hazard analysis, and propensity score-matched analysis. **Results:** Among patients who met study criteria (N = 88,983), there were 2,469 (2.77%) patients with adenosquamous, 60,148 (67.59%) with adenocarcinoma and 26,366 (29.63%) with squamous cell carcinoma histology. In patients who had T1-T2 N0 M0 disease, adenosquamous carcinoma was associated with significantly worse 5-year overall survival (58.9% [95%CI:56.6%-61.1%]) when compared with adenocarcinoma (72.4% [95% CI:72.0%-72.8%]) and squamous cell carcinoma (62.6% [95% CI:61.9%-63.3%]). In multivariable Cox proportional hazards analysis, adenocarcinoma (HR 0.81 [95% CI:0.76-0.87], p $<$ 0.001) and squamous cell carcinoma (HR 0.86 [95% CI:0.80-0.92], p $<$ 0.001) continued to be associated with significantly better survival when compared to adenosquamous carcinoma histology. A propensity score-matched analysis of 1,854 adenocarcinoma and 1,854 adenosquamous patients who were well matched by 17 common prognostic covariates (including tumor size and comorbidities) found that adenosquamous histology (57.2% [95% CI:54.7%-59.6%]) was associated with worse survival when compared to adenocarcinoma (63.0% [95% CI:60.6%-65.4%]). An additional propensity score-matched analysis of 1,852 squamous cell carcinoma and 1,852 adenosquamous patients matched by the same covariates demonstrated that adenosquamous carcinoma (57.1% [95%CI:54.6%-59.6%]) was associated with worse survival when compared with squamous cell carcinoma (64.0% [95% CI:61.5%-66.4%]). **Conclusions:** Early stage adenosquamous carcinoma of the lung is associated with worse overall survival compared to its individual histologic components of adenocarcinoma or squamous cell carcinoma. These observations in both the unmatched and propensity matched patient cohorts invoke consideration of multimodality therapy for these early tumors. Research Sponsor: Departmental Funding.

Early candidate nasal swab classifiers developed using machine learning and whole transcriptome sequencing may improve early lung cancer detection. *First Author: Peter J. Mazzone, Cleveland Clinic, Cleveland, OH*

Background: The goal of lung nodule management is to make an early diagnosis in patients with lung cancer while avoiding unnecessary, costly and potentially harmful procedures in patients with benign lesions. Increased implementation of low dose CT screening will lead to increased numbers of both benign and malignant nodules that will require effective management. We have previously described the feasibility of detecting gene expression changes associated with lung cancer ("field of injury") in nasal epithelium utilizing whole transcriptome RNA sequencing from non-invasive nasal brush samples. Using this approach, we now report the performance of candidate nasal classifiers that combine both genomic and clinical features to risk stratify lung nodules from ever-smokers to aid in the diagnosis of lung cancer. **Methods:** Patients from several clinical cohorts who were ever-smokers with a lung nodule $<$ 30 mm and without a history of prior cancer underwent nasal epithelium sampling. All patients had at least one year of follow up or until a final diagnosis of benign or malignant nodule was made. Candidate classifiers were developed using whole-transcriptome RNA sequencing and machine learning. Training of these classifiers included genomic and clinical information (age, sex, pack-years, years-since-quit, nodule size and nodule spiculation). Two decision boundaries were chosen to maximize sensitivity and specificity for low and high-risk nodules, respectively. The performance of these classifiers was evaluated using cross-validation (CV). **Results:** All candidate nasal classifiers underwent CV assessment on over 700 patients with lung nodules. All candidate classifiers achieved CV performance of $>$ 40% specificity at 95% sensitivity in low- risk nodules and all candidate classifiers achieved CV performance of $>$ 60% sensitivity at 90% specificity in high-risk nodules. The classifiers stratified benign nodules as low- risk with $>$ 95% negative predictive value (NPV), intermediate risk nodules were stratified as 5-65% risk and malignant nodules were stratified as high- risk with $>$ 65% positive predictive value (PPV) in a population with estimated 25% prevalence. This performance was robust across subgroups of age ($<$ 65 year vs. $>$65 year), sex, and current versus former smokers. **Conclusions:** The nasal genomic-clinical candidate classifiers have a high NPV effectively identifying benign nodules when calling them low- risk, thereby, informing decisions to more safely avoid a diagnostic workup. Additionally, the high PPV of these classifiers identifies malignant nodules when calling them high- risk and informs decisions regarding the urgency of a further diagnostic work-up. A nasal genomic-clinical classifier has the potential to serve as a non-invasive tool for lung cancer risk-stratification to help inform decision making in patients with lung nodules. A comparative analysis of mortality between black and white stage III non–small cell lung cancer patients in the United States. *First Author: Elizabeth Blessing Elimimian, Cleveland Clinic Fl, Weston, FL*

Background: Lung cancer remains the leading cause of cancer death in the United States (U.S.). For stage III non-small cell lung cancer (NSCLC), concurrent chemotherapy (CT) plus radiotherapy (RT) within 30 days (CCRT) confers a survival benefit. The proportion of Black and White NSCLC patients not receiving CCRT and their outcomes have not been explored. **Methods:** Stage III NSCLC in Black and White patients diagnosed between 2004 and 2015 from the U.S. NCDB were included. Those with multiple tumors and who received surgery were excluded. Six groups were analyzed: CCRT (0-30 days between CT and RT), SCRT (31-120 days between CT and RT), RT (only RT), CT (only CT), No-RT-nor-CT (didn't receive RT nor CT), and other (uncategorized). Univariate, multivariate, and Kaplan-Meier analyses were utilized ($p<0.05$). **Results:** A total of 22,459 Black (CCRT 42.3%, SCRT 7.6%, RT 13.8%, CT 15.1%, and No-RT-nor-CT 21.2%) and 138,477 White (CCRT 43.9%, SCRT 7.0%, RT 12.7%, CT 14.9%, and No-RT-nor-CT 21.5%) stage III NSCLCs were analyzed. Male gender and White race were positive predictive factors for receiving CCRT (Table). In Black patients SCRT (HR 1.1; 95% CI 1.04-1.17), RT only (HR 1.2; 95% CI 1.81-1.99), CT only (HR 1.4; 95% CI 1.36-1.49), and No RT or CT (HR 2.6; 95% CI 2.49-2.69) was associated with decreased overall survival (OS) compared to CCRT. In White patients, SCRT (HR, 1.0; 95% CI, 0.99-1.03) did not decrease OS compared to CCRT, whereas RT only (HR 1.8; 95% CI, 1.74-1.80), CT only (HR 1.3; 95% CI, 1.29-1.34), and No RT or CT (HR 2.6; 95% CI, 2.59-2.67) were associated with decreased OS. Median OS with CCRT was 18 months for Black patients, versus 16 months for White patients ($p<0.0001$). **Conclusions:** OS was highest when CCRT was given. A lower proportion of Black cases were managed with CCRT, but Black patients benefit more from CCRT and had improved OS than White patients. Despite the known benefits of CT and RT in stage III NSCLC, the second largest management cohort received neither RT nor CT. Research Sponsor: None.

Factors associated with receiving CCRT versus other treatments [a] in NSCLC.

Early detection of lung cancer with an incidental lung nodule program (ILNP). *First Author: Matthew Smeltzer, University of Memphis, School of Public Health, Memphis, TN*

Background: Lung cancer early detection improves survival, but risk-based low-dose CT screening (LDCT) only identifies a minority of patients. We implemented an ILNP in a community healthcare system, and evaluated its risks and benefits. **Methods:** Patients with lung lesions on routinely-performed radiologic studies were flagged by radiologists and triaged using evidence-based guidelines. We tracked demographics, clinical characteristics, procedures, complications, and health outcomes. We analyzed ILNP subjects' eligibility for LDCT by National Lung Screening Trial (NLST), Center for Medicaid Services (CMS), NEderlands Leuvens Screening ONderzoek (NELSON), National Comprehensive Cancer Network (NCCN) Risk Groups 1 and 2 (screening recommended), NCCN Risk Group 3 (screening not currently recommended), and US Preventive Services Task Force (USPSTF) criteria from 2013 and 2020. Statistical analysis used the chi-square test and Kaplan Meier method. **Results:** From 2015-2020, 13,710 patients were evaluated in the ILNP program: median age, 64 years; 42% male; 65% White, 29% Black; 667 (4.9%) were diagnosed with lung cancer. Lung cancers diagnosed from ILNP were 39% adenocarcinoma / 20% Squamous Cell with clinical stage distribution 49% I, 8% II, 17% III, and 16% IV. 832 (6.1%) had invasive diagnostic testing- CT-guided biopsy (50%), bronchoscopy (30%), and/or EBUS (26%); 11% of the 832 had >1 invasive diagnostic test. The most common complications from invasive testing were pneumothorax and chest tube placement. Only 11%-20% of all ILNP patients would have been eligible for LDCT. In ILNP patients diagnosed with lung cancer, only 33% were eligible for screening by NLST criteria; the proportion increased substantially when USPSTF 2020 or NCCN Group 2 criteria were applied (Table). Compared to NLST, NCCN Group 2 criteria increased screening eligibility among cancer patients by 22% (from 33% to 55%), while only increasing screening eligibility by 6% (from 8% to 14%) in non-cancer patients. Aggregate 1-year and 3-year survival rates for lung cancer patient diagnosed through ILNP were 76% (95% CI: 73, 80) and 64% (95% CI: 59, 69). **Conclusions:** The ILNP identified early-stage lung cancer more frequently than most LDCT programs, with promising survival rates. The majority of subjects with lung cancer were not eligible for LDCT, we still need to optimize risk-based screening criteria. Even with new, expanded criteria for LDCT, structured ILNP is necessary to expand early detection of lung cancer. Research Sponsor: None.

Screening Criteria	**%ILNP Lung Cancer Patients Eligible for LDCT Screening**
NLST Criteria	33%
CMS Criteria	39%
NELSON Criteria	41%
USPSTF 2013	41%
USPSTF 2020	47%
NCCN Group 1	39%

Radical surgery in malignant pleural mesothelioma (MPM): An analysis of SEER database. *First Author: Qian Wang, Department of Medicine, Icahn School of Medicine at Mount Sinai St Luke's and West, New York, NY*

Background: MPM is an aggressive malignancy with poor overall prognosis. A combined treatment approach involving radical surgery (RS), radiation (RT) and chemotherapy (CT) provide improved survival compared to systemic treatment alone. Selecting patients who may benefit from RS is challenging. The NCCN guidelines recommend that up to T3N1M0 (Stage IIIA) epithelioid or biphasic MPM should be considered for multimodality therapy incorporating RS. However, the impact of clinical and pathologic features within each histologic subtype of MPM on RS outcomes is unknown. **Methods:** MPM patients from the SEER 18 program from 2004-2015 were identified. Cox proportional hazard regression models were used to examine the independent contribution of several clinical and pathologic features on overall survival (OS) in patients who received RS vs those that did not. **Results:** A total of 5,498 MPM patients were identified, of which 531 underwent RS. Overall, RS was associated with improved OS in the multivariate model adjusting for important clinical and pathological characteristics (Table). When stratifying according to histology, epithelioid subtype was linked to improved OS with RS despite of the presence male gender, age > 60 years old, T3, T4 or N2 or above disease; and the OS improved among those who also underwent CT ± RT with RS. Patients with sarcomatoid histology also had OS benefit from RS (HR=0.59, 95%CI: 0.37-0.93), even those that were > 60 years old, but not among those with more advanced disease (T3/4, N2/3). Sarcomatoid patients who received CT ± RT (HR = 0.52, 95%CI: 0.30-0.90) also experienced OS benefit. Among biphasic histology, no OS benefit was found overall (P = 0.11) or within other high-risk clinical features except for those who were treated CT ± RT (HR = 0.64, 95%CI: 0.45-0.90). **Conclusions:** Our findings demonstrate that the presence of high-risk clinical and pathologic features does not impact OS benefit of RS in epithelioid MPM, however should be considered when deciding on RS in sarcomatoid and biphasic histologies. Poor prognostic histology especially sarcomatoid subtype may experience improved survival with RS if in conjunction with other treatment modalities. Research Sponsor: None.

Comprehensive molecular profiling of pleural mesothelioma according to histologic subtype. *First Author: Ibiayi Dagogo-Jack, Massachusetts General Hospital, Boston, MA*

Background: Malignant pleural mesothelioma (MPM) is an aggressive malignancy with limited therapeutic options. Immunotherapy has emerged as an effective therapeutic strategy, particularly in the non-epithelioid MPM subgroup. An improved understanding of the molecular profile of MPM may inform targeted therapeutic approaches and provide insights into factors underlying differential sensitivity to therapies. **Methods:** We performed comprehensive genomic profiling of MPMs from 980 patients, with histologic subtyping on a subset (n = 340; n = 235 epithelioid, n = 48 sarcomatoid, n = 57 biphasic). Analyses included quantifying tumor mutational burden (TMB), assessing microsatellite instability (MSI), and evaluating PD-L1 expression (Dako 22C3). **Results:** Median TMB of MPM was 1.74 (0.87-2.61) mutations per megabase (mut/mb). Median TMB was comparable for non-epithelioid (biphasic, sarcomatoid) vs epithelioid MPM (1.25 mut/mb vs 1.25 mut/mb, p = 0.43). In the overall cohort, inactivating alterations in the following genes were most prevalent: *CDKN2A* (49%), *BAP1* (44%), *CDKN2B* (42%), *MTAP* (35%), and *NF2* (33%). *MTAP* loss co-occurred with *CDKN2A* and *CDKN2B* loss in > 99% and 94% of cases, respectively. *MTAP* loss was observed in 28% of epithelioid vs 46% of non-epithelioid MPMs (p = 0.03). *BAP1* alterations were detected in 51% of epithelioid vs 36% of non-epithelioid MPMs (p = 0.81). PD-L1 expression was assessed in 308 MPMs, among which 153 (49%) had PD-L1 ≥1%, including 35 (11%) with PD-L1 ≥50%. Among 164 specimens that underwent histologic subtyping and PD-L1 evaluation, PD-L1 was expressed in 46 (71%) non-epithelioid MPMs compared to 49 (51%) epithelioid MPMs (p = 0.03). Given the high prevalence of alterations involving the two genes, we evaluated impact of *BAP1* and *MTAP* status on PD-L1 and TMB. TMB (1.74 mut/mb vs 1.74 mut/mb) and PD-L1 expression (50% vs 54%) were comparable in *BAP1*-altered vs wildtype specimens. Although TMB was comparable in *MTAP*-deficient and *MTAP*-intact tumors (1.25 mut/mb vs 1.74 mut/mb), more tumors with *MTAP* loss expressed PD-L1 (68% vs 44%, p = 0.0004). **Conclusions:** Compared to epithelioid MPM, non-epithelioid tumors demonstrate comparable TMB, higher PD-L1 expression, and enrichment for *MTAP* loss. As *MTAP* is frequently altered in MPM, further study is indicated to explore the relationship between *MTAP* status and MPM biology, including sensitivity to therapeutics such as immunotherapy and synthetic lethal approaches. Research Sponsor: Foundation Medicine.

Improved survival among patients with malignant pleural mesotheliomas who develop immune-related adverse events on immunotherapy. *First Author: Michael Offin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: While immune checkpoint inhibitors (ICI) are a standard option for patients with malignant pleural mesotheliomas (MPM), there is limited data on the rate of immune related adverse events (irAEs) and effects on clinical outcomes. **Methods:** 61 patients with MPM who received ICI between January 2016 and October 2020 were assessed and followed through November 2020. irAEs (CTCAE v5.0) were noted along with the time from ICI start to irAE onset. Patients were grouped into irAE ever versus never. Clinicopathologic characteristics, prior treatments, and investigator assessed clinical benefit rate (CBR; partial response [PR] + stable disease [SD]) were compared by Fisher's Exact and Mann-Whitney Tests. Overall survival (OS) and investigator assessed progression free survival (PFS) from ICI start were compared using Kaplan Meier. In consented patients (n = 56), next generation sequencing (MSK-IMPACT) was performed with HLA genotyping analysis by POLYSOLVER software and alleles for the three major MHC class I (HLA-A, -B, -C) genes were obtained from whole exome recapture. **Results:** Most patients were male (72%), smokers (55%), > 70 years old (median 72, range 34-90), and had epithelioid histology (67%). No patients had baseline autoimmune disease. The median line of prior systemic therapies to ICI start was 2 (range 1-5). 17 patients (28%) developed an irAE on therapy including 7 (11%) with grade 3 to 5 events (pneumonitis, myositis, pancreatitis, nephritis, encephalitis and adrenal insufficiency). The median time from ICI start to irAE was 2.5 months (range 2 days – 5.8 months). There was no association with dual ICI (n = 6) vs single agent (n = 11) and sooner onset (2.1 vs 4.0 months; p = 0.10) nor higher grade (median grade 2 vs 3; p = 0.31) of irAEs. 1 patient developed grade 5 pneumonitis with onset 2 days after initial dose of dual-ICI. Comparing patients with irAEs to those without, there was no difference in distribution of epithelioid histology (n = 10 vs 31; p = 0.54), median age (71 vs 72 years old; p = 0.43), nor prior thoracic radiation (n = 5 vs 11; p = 0.75).There was no difference in HLA type nor the fraction of HLA alleles of individual genes amongst the groups. Patients who had an irAE were on ICI longer than those that did not (median time on ICI 5.4 vs 0.9 months, respectively; p = 0.02). OS was higher in patients with irAEs compared to those without (21.1 vs 4.7 months; p = 0.003) as was PFS (6.8 vs 1.7 months; p = 0.01). There was a significant increase in the CBR between those that had an irAE (65%; 5 PR, 6 SD) and those that did not (27%; 2 PR, 10 SD; p = 0.006). **Conclusions:** 28% of patients with MPM who received ICIs developed an irAE and onset tended to be early in the course of treatment. There was no clear predictive clinicopathologic feature that correlated with the occurrence of irAE. There was a significant increase in OS, PFS, and CBR in patients that had an irAE compared to those that did not. Comprehensive genomic profiling of malignant peritoneal mesothelioma (MPeM) reveals key genomic alterations (GAs) distinct from malignant pleural mesothelioma (MPM). *First Author: Lynne O. Chapman, Baylor College of Medicine, Houston, TX*

Background: MPeM is a rare and aggressive cancer with very limited treatment options. Lack of dedicated research has impeded improvements in outcomes. Defining prevalent GAs is a critical unmet need for use of targeted therapies in these patients. Although MPeM is notably distinct from MPM vis-à-vis epidemiologic and clinical attributes, the genomic underpinings of these differences have yet to be established. We aimed at describing a comprehensive genomic profile (CGP) of MPeM in comparison to MPM. **Methods:** We performed a retrospective comparative analysis between 89 patients with MPeM and 241 patients with MPM (N = 330) who underwent CGP using CLIA certified next-generation sequencing assays. The cohort was generated using mesothelioma patients at MD Anderson Cancer Center (N = 223) and supplemented by additional mesothelioma patients (N = 107) from a publicly available database from Memorial Sloan Kettering Cancer Center, the MSK-IMPACT database. Essential clinicopathological variables were collected. Descriptive statistics, Fisher's exact and Mann-Whitney tests were used for comparison. Kaplan-meier method and log rank tests were used for overall survival (OS) estimates. **Results:** MPeM cohort (vs. MPM) had more women (54% vs. 31%, $P < 0.001$) and younger age at diagnosis (56 vs. 69 years, $P < 0.001$). Histology was epithelioid, biphasic and sarcomatoid in 86%, 7% and 7% cases, a distribution similar to MPM cohort. At least 1 GA was found in 64 (72% vs. 82% in MPM, P = 0.044) of MPeM patients with a median of 1 (range 1 – 12) (vs. a median of 2, range 1 – 24, $P < 0.001$) GA per patient. A significantly lower proportion of MPeM patients had ≥ 3 mutations (14% vs. 26%, OR 2.1, P = 0.028) per patient. The most frequent mutations were present in the following genes: *TP53* (24%), *BAP1* (16%), *NF2* (15%), *MET* (9%) and *TRAF7*, *KIT* and *PIK3CA* (each 6%). MPeM patients harbored more mutations in *MET* (9% vs. < 1%, $P < 0.001$) and *TRAF7* (6% vs. < 1%, P = 0.02) but fewer mutations in *BAP1* (16% vs. 32%, P = 0.003) and *CDKN2B* (0% vs. 5%, P = 0.041). The most common copy number variations (CNVs: amplifications or deletions) were seen in *BAP1*, *MCL1*, *SETD2*, *WT1* (each 2%) and *AURKA* (1%) genes. Among genes with CNVs, MPeM had a lower rate of deletions in *CDKN2A* (1% vs. 6%, P = 0.040). Among more common GAs, only *BAP1* mutations appeared to be associated with poor OS (45.7 vs. 127.1 months, HR 2.5, 95%CI: 0.6 – 10.1, P = 0.050) in patients with MPeM. **Conclusions:** In this large cohort with CGP, we identified potential molecular drivers in MPeM and demonstrated key genomic differences between MPeM and MPM. MPeM is frequently driven by GAs involved in cell cycle control, a potentially targetable pathway. Despite this insight from CGP, a large subset of patients do not have actionable GAs and for these patients, further collaborative trans-"omic" research efforts are needed to advance potential therapeutic options. A phase II trial of abemaciclib in patients with p16ink4a negative, relapsed mesothelioma. *First Author: Dean Anthony Fennell, University of Leicester and University Hospitals of Leicester, Leicester, United Kingdom*

Background: Genetically stratified therapy for malignant mesothelioma (MM) is lacking. MMs frequently harbour loss of chromosome 9p21.3 locus (CDKN2A) associated with shorter survival. CDKN2A encodes the tumour suppressor p16ink4a, an endogenous suppressor of CDK4 and CDK6. Genetic reconstitution of p16ink4a into CDKN2A suppresses MM in preclinical models, underpinning the rationale for targeting of CDK4/6 in p16ink4a negative MM. We therefore developed a multi-centre molecularly stratified phase IIa trial to test this hypothesis as arm 2 of the Mesothelioma Stratified Therapy umbrella trial (NCT03654833, MiST2). **Methods:** Patients with histologically confirmed MM (pleural or peritoneal) were molecularly screened by immunohistochemistry for p16ink4a, BAP1, BRCA1, and PDL1 (Dako 22C3). Patients with p16ink4a negative MM were eligible. Key inclusion factors: histological confirmation of MM with an available archival tissue block, ECOG performance status 0-1, prior platinum-based 1st line chemotherapy (any line allowed), evidence of disease progression with measurable disease by CT (RECIST 1.1), and adequate haematological/organ function. Patients received Abemaciclib (Ab) 200mg bd po daily in q21 day cycles. Primary endpoint was disease control rate at 12 weeks (DCR12w). The null hypothesis was rejected if ≥ 11 patients had disease control (A'Hern design). Secondary endpoints: DCR at 24 weeks (DCR24w), best objective response rate and toxicity (NCI CTCAE 4.03). Patients could undergo an optional re-biopsy upon disease progression. **Results:** Between November 2019 and March 2020, 26 patients with p16ink4a negative MM received at least one dose of Ab. The median age of pts was 67 (range, 64-74) years, 89% were male, 80.8% epithelioid, 84.6% ECOG PS1, > 1 prior systemic therapy 62%. All patients received at least one cycle with 27% completing 6 cycles. No dose reductions occurred in 53.9% of pts. DCR12w: 54% (95% confidence limit (CI), 36% – 71%), DCR24w: 23% (95%CI, 9% – 44%). Best responses (within 24w): partial - 15% (95%CI, 4-35%), one occurring after 18 weeks; stable disease - 53.8% (33.4 – 73.4%); progression - 7.7% (0.9 – 25.1%). Adverse events (any cause): ≥ grade 3 toxicities affected 5.7% of pts. **Conclusions:** MiST2 met its primary endpoint, warranting further clinical evaluation of Ab. Whole exome sequencing of the cohort is ongoing to explore genomic correlates of *de novo* and acquired resistance. Clinical trial information: NCT03654833. Research Sponsor: Mesothelioma Stratified Therapy 2.

Genomic landscape of malignant mesothelioma by site and histology. *First Author: Elio Adib, The Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: Malignant mesothelioma (MM) is a highly lethal tumor that can develop in the pleura, the peritoneum, the pericardium or the testes. While the genomic features of pleural MM have been well-described overall, less is known about the distribution of genetic alterations (GAs) according to histology. In addition, few reports comparing genetic features according to disease site are available. **Methods:** We identified patients with pleural or peritoneal mesothelioma with mutational analysis through the GENIE registry. Patient tumor genetic data were provided by Memorial Sloan-Kettering Cancer Center (MSK)-IMPACT and Dana-Farber Cancer Institute (DFCI)-Oncopanel NGS initiatives. Patients with more than one sequenced sample were excluded. We limited our analysis to genes common to all versions of both panels and that were significantly mutated in the TCGA mesothelioma cohort. Mutation and copy number variant (CNV), collectively called GAs, were determined, and were compared using the Fisher's Exact test and Kruskal-Wallis Test. Comparisons were made both by disease site (pleural vs. peritoneal) and histology for the pleural samples (epithelioid vs. biphasic vs. sarcomatoid). Nominal *p*-values were obtained, and FDR correction was employed ($q<0.1$). **Results:** We identified 439 patients with MM in the GENIE registry who fit the inclusion criteria. The median age was 70.5 years for pleural MM and 60 years for peritoneal MM (Wilcoxon-rank sum test *p*-value = 3e-9). 72% of patients were male. *CDKN2A/CDKN2B* GAs (97% and 100% being deletions in *CDKN2A* and *CDKN2B* respectively), a described prognostic marker in MM, were more common in pleural than in peritoneal MM. Among pleural MMs, tumors of epithelioid histology had less *NF2* GAs than biphasic or sarcomatoid tumors, whereas sarcomatoid tumors had the lowest frequency of *BAP1* GAs (Table). **Conclusions:** Malignant mesotheliomas of different disease sites and/or histologies display distinct patterns of GAs. These findings may contribute in part to differences in response to treatment and survival among these subsets of MM. Research Sponsor: None.

Efficacy and safety analysis of anlotinib combined with etoposide plus cisplatin/carboplatin as first-line therapy for extensive-stage small cell lung cancer (SCLC): The final results from a phase II single-arm trial. *First Author: Tiandong Kong, Cancer Hospital of Henan University/the Third People's Hospital of Zhengzhou City, Zhengzhou, China*

Background: In recent years, the therapeutic regimens of extensive-stage small cell lung cancer (ES-SCLC) have progressed a lot. The most significant clinical studies include IMpower133 and CASPIAN**.** However, the relevant results showed that the combination of PD-L1 monoclonal antibody and EC regimen chemotherapy as first-line treatment of small cell lung cancer have a median PFS (progession-free survival) of about 5 months, which is comparable to that of simple chemotherapy. Therefore, the EP/EC is still the standard treatment for extensive-stage small cell lung cancer. Meanwhile, we noticed that anlotinib (multi-target small molecule oral VEGF inhibitor) has a curative effect on patients with extensive-stage SCLC as a third-line or above treatment in the ALTER 1202 study in China. Therefore, we tried to add anlotinib to the first-line treatment with EP/EC regimen in patients with ES-SCLC to observe the efficacy and safety. **Methods:** Eligible ES-SCLC pts (18~75 years old, initial treatment, no obvious heart, liver and kidney dysfunction) were received anlotinib (12mg QD from day 1 to 14 of a 21-day cycle) + etoposide(100mg/m^2, d1~3 of a 21-day cycle)+CBP (AUC = 4~5 ,d1,Q3W) or DDP (70~75mg/m^2, d1,Q3W) for 4~6 cycles, then anlotinib maintenance (12mg QD from day 1 to 14 of a 21-day cycle) until the disease progresses or intolerable adverse reactions occur. During the treatment, dose reduction of anlotinib was permitted, which could be reduced to 10mg or 8mg if it was intolerable. The main observation endpoints were ORR, PFS and adverse events. **Results:** Between January 2019 and August 2020, a total of 20 patients with extensive-stage SCLC were enrolled in the study, with an average age of 66.2 ± 8.1(45-75) years old, 17 males (85%) and 3 females (15%). The median PFS was 10 months (95% CI: 7.809-12.191), median OS was 15 months (95%CI:10.639-19.361), ORR (objective remission rate) was 90% and DCR (disease control rate) was 100%. The most common grade 3 or 4 adverse events related to the trial regimen included: neutropenia was 10/20 (50.0%), thrombocytopenia was 5/20 (25.0%), anemia, nausea and fatigue were all 2/20 (10%), hypertension, transaminase elevation and hoarseness were all 1/20 (5%). **Conclusions:** Anlotinib combined with EP/EC regimen has better PFS, OS, ORR and DCR for the initial treatment of extensive-stage SCLC, and a manageable safety profile. A randomized, controlled phase III clinical study will be conducted to confirm this conclusion. Clinical trial information: ChiCTR2000035043. Research Sponsor: Tianqing Pharmaceutical Group Co. Ltd.

Real-world evidence of cancer immunotherapy (CIT) combination treatment in first-line (1L) extensive-stage small cell lung cancer (ES-SCLC). *First Author: Eric S. Nadler, Texas Oncology-Baylor Charles A. Sammons Cancer Center, Dallas, TX*

Background: Atezolizumab plus chemotherapy was the first CIT combination regimen approved for 1L treatment of ES-SCLC in 2019. This study investigated patient characteristics and treatment patterns for patients with ES-SCLC receiving this regimen in the real-world community oncology setting. **Methods:** This was a retrospective study including adult patients diagnosed with ES-SCLC between 01-Oct-2018 (after IMpower 133 publication in NEJM Sep-2018) and 31-Dec-2019, with follow-up through 31-March-2020 using The US Oncology Network electronic health records data. Descriptive analyses of patient characteristics and treatment patterns were conducted, with Kaplan-Meier (K-M) methods used to assess time to treatment discontinuation (TTD) and time to next treatment/death (TTNT). **Results:** Of the 408 patients included in this study, 267 (71.4%) received atezo+carboplatin+etoposide (Atezo+Chemo), 80 (21.4%) received carboplatin+etoposide (Chemo only) and the rest received other regimens. The Atezo+-Chemo patients in the real-world cohort compared with the IMpower 133 trial (n = 201) were older (median age 68 vs. 64 years) and included fewer males (45% vs. 64%), fewer white race (73% vs. 81%), more patients with brain metastases at baseline (23% vs. 9%), and more patients with worse ECOG (2/3) performance-status score (24% vs. 0%). The median follow-up, TTD, and TTNT in months (mo) for the real-world cohort are presented in the table alongside the best comparable measures reported for the trial. **Conclusions:** Most patients in this real-world ES-SCLC cohort received the Atezo+Chemo regimen in the 1L setting. While the follow-up was much shorter and patients had worse baseline characteristics (age, brain metastases, ECOG) in the real-world setting compared to the IMpower 133 trial, the real-world median TTD in this descriptive analysis was found to be in line with the median duration of treatment in the trial. Further research with longer follow-up comparing the real-world effectiveness of the CIT and chemo regimens is needed. Research Sponsor: Genentech.

Real-world Cohort: Atezo+Chemo (n = 267)	IMpower 133: Atezo+Chemo (Reference) (n = 201)
Median follow-up (FU): 5.45mo (range 0.72, 14.36)	Median FU 13.9mo (Data cut-off April 24, 2018)
K-M median TTD*: 4.9mo (95% CI 4.2, 5.3)	Median duration of treatment: 4.7mo (range:0, 21)†
% still on treatment at 6mo (K-M): 35.1% (95% CI 28.4, 41.9)	% still on treatment 6mo: 31.3%†
K-M median TTNT: 6.9m0 (95% CI 6.4, 8.2)	K-M Median progression-free survival (PFS): 5.2mo (95%CI 4.4, 5.6)
% not initiated on 2L at 6mo: 64.5% (95% CI 56.7, 71.3)	PFS (RECIST criteria) at 6mo: 30.9% (95% CI 24.3, 37.5)

*From 1L treatment initiation to discontinuation for any cause (including death). Patients who did not discontinue treatment during the study period were censored on the study end date or the last visit date available in the dataset, whichever occurred first.
†Not based on K-M.

The clinical efficacy of olaparib monotherapy or combination with ceralasertib (AZD6738) in relapsed small cell lung cancer. *First Author: Sehhoon Park, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: The molecular profiling of small cell lung cancer (SCLC) has demonstrated a high incidence of genomic alterations in cell cycle-related genes and DNA damage and response (DDR) pathways, which correlates with devastating clinical outcomes of SCLC. Using two small molecules targeting the DNA repair pathway, olaparib (PARP inhibitor) and ceralasertib (ATR inhibitor), we evaluated their clinical efficacy in monotherapy or in combination, in relapsed SCLC. **Methods:** As part of the phase II biomarker-driven umbrella study in SCLC (SUKSES), patients who failed prior platinum-based regimen were enrolled and allocated based on their genomic alterations. Patients with mutations harboring HR pathway gene mutation not limited to BRCA 1 or 2, ATM deficiency or MRE11A mutations were allocated to the olaparib monotherapy (SUKSES-B, NCT03009682). As an biomarker non-matched arm, biomarker unselected patients were also allowed to receive olaparib and ceralasertib arm (SUKSES-N2, NCT0328607). The primary endpoint was objective response rate (ORR), and two-stage Simon's design was used. **Results:** Based on pre-defined protocol criteria, both arms terminated at stage 1. In the olaparib monotherapy arm (SUKSES-B, n = 15), ORR was 6.7%, and disease control rate (DCR) was 26.7%, 1 partial response (PR), and 3 stable diseases (SD). Median progression-free survival (PFS) was 1.25 months (95% confidential interval [CI] 1.18–NA), and median overall survival (OS) was 8.56 months (95% CI, 6.62–NA). Adverse events that led to treatment discontinuation (n = 2 total, 13.3%) were drug related grade 3 renal impairment, thrombocytopenia, and grade 2 anemia. A patient with confirmed PR showed a tumor volume decrease of 37% compared to the baseline, and a splicing site mutation in BRCA2 was identified from deep target sequencing. In the olaparib and ceralasertib treatment arm (SUKSES-N2, n = 26), ORR was 3.8% (n = 1) and DCR was 42.3% (n = 11). Median PFS was 2.75 months (95% CI 1.77–5.44), and OS was 7.18 months (95% CI 5.97-10.79). Three patients discontinued treatment due to drug related grade 5 pneumonia, grade 3 drug-induced pneumonitis and grade 2 anemia. The most common adverse events for the combination were anemia (n = 11, 42.3%), followed by thrombocytopenia (n = 6, 23.1%). A patient with confirmed PR with a 43% decreases in tumor volume compared with baseline had a mutation in TP53. **Conclusions:** Targeting the DDR pathways with olaparib as single agent or in combination with ceralasertib demonstrated early signal of efficacy in relapsed SCLC patients with a tolerable safety profile. Clinical trial information: NCT03009682, NCT0328607. Research Sponsor: AstraZeneca.

Analysis of homologous recombination DNA repair gene mutation status in patients with metastatic small cell lung cancer treated with cediranib and olaparib on NCI 9881 study. *First Author: Joseph W. Kim, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Cediranib, a pan-vascular endothelial growth factor receptor tyrosine kinase inhibitor, suppresses expression of homologous recombination DNA repair (HRR) genes and increases sensitivity of tumors to a poly-(ADP-ribose) polymerase (PARP) inhibitor *in vitro* and *in vivo* models of breast and ovarian cancer. Olaparib, a PARP inhibitor, demonstrated clinical efficacy in patients with advanced solid tumor with a deleterious mutation in HRR genes. We hypothesized that cediranib induces HRR deficient phenotype by suppressing expression of HRR genes and cediranib and olaparib combination (C+O) results in an objectives response in patients with HRR proficient (HRP) advanced solid tumors. Herein, we report the biomarker data from analyses of targeted sequencing of 84 DNA repair (DR) genes with BROCA-HR assay in patients with metastatic small cell lung cancer (mSCLC). **Methods:** This multi-institutional phase 2 trial enrolled patients with mSCLC previously treated with a platinum-based chemotherapy. Patients received cediranib 30mg orally (po) daily plus olaparib 200mg po twice daily until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) by RECIST v1.1. A tumor biopsy was obtained from the patients with safely accessible metastatic tumor. HRR deficiency (HRD) was defined as presence of a deleterious mutation in any of the 10 key HRR-related genes per BROCA-HR assay including: ATM, BARD1, BRCA1, BRCA2, BRIP1, CDK12 (somatic mutations only), NBN, PALB2, RAD51C, or RAD51D. Otherwise, the tumors were defined as HRR proficiency (HRP). **Results:** A total of 25 patients with SCLC received the study treatment. Fourteen patients had available tumor biopsy samples and/or germline available for BROCA-HR. One patient (7%) was determined to have a HRD tumor by a presence of PALB2 mutation. This patient had stable disease as a best overall response but came off study due to unequivocal clinical progression. Thirteen patients (93%) had a HRP tumor. Six of these (46%) patients had PR. Median PFS in patients with HPR tumors was 122 days. The most common gene alterations detected by BROCA-HR assay was TP53 (93%) and RB1 (79%). Other DR gene alterations noted from our study samples were MRE11, CKD12 PALB2, ERCC4, FANCB, and BAP1. **Conclusions:** HRD was infrequent in our mSCLC samples. C+O resulted in objective responses in 46% of mSCLC patients with HRP tumors. Mutations in *TP53* and *RB1* were the most common gene alterations. Further investigation in warranted to confirm this observation. Clinical trial information: NCT02498613. Research Sponsor: U.S. National Institutes of Health.

Circulating tumor DNA (ctDNA) mutations may predict treatment response in extensive-stage small cell lung cancer (ES-SCLC) treated with talazoparib and temozolomide (TMZ). *First Author: Matthew Mulroy, UCLA Medical Center, Los Angeles, CA*

Background: Poly (ADP-ribose) polymerase (PARP) inhibition in combination with TMZ is a promising treatment strategy for ES-SCLC. In SCLC models, talazoparib, a potent PARP inhibitor, exhibits cytotoxic effects by inhibiting PARP proteins 1/2 and trapping PARP on DNA while TMZ potentiates antitumor response by contributing to genomic instability (Wainberg 2016). Prior ctDNA studies in SCLC have suggested that treatment precipitates the appearance of DNA repair alterations (Nong 2018), but it is unknown whether homologous recombination deficiency (HRD) predicts for treatment response with this combination. **Methods:** Patients (pts) with relapsed or refractory ES-SCLC were treated with oral talazoparib 0.75 mg daily on 28-day cycles and oral TMZ 37.5 mg/m2 on days 1-5 in a phase 2 clinical trial (UCLA/TRIO-US L-07, NCT03672773). ctDNA was collected and assessed based on allele frequency and plasma copy number at baseline and every 8 weeks during treatment with the Guardant360 assay (Redwood City, CA). HRD was defined as a deletion or missense mutation known or likely to result in aberrant expression of *ATM* or *BRCA1/2* (other HRD genes not detected by assay). Response to treatment was defined by RECIST 1.1 criteria. Fisher's exact tests were used to compare proportions of patients with P-values < 0.05 considered statistically significant (www.r-project.org, Vienna, AU). **Results:** For 15 evaluable pts in the first Simon stage of this trial, 45 ctDNA samples were collected. The most common baseline genetic alterations were mutations in *TP53* (14 pts), *BRCA2* (5 pts), *ATM* (4 pts), and *RB1* (3 pts). Of those with > 1 ctDNA timepoint collected, 10/11 (90.9%) pts had $\geq$1 new mutation (range 1-19) detected after receiving treatment (range 8-35 weeks), most commonly in *ATM* (5 pts). Overall, 5 pts had confirmed partial responses (PR), 7 had stable disease, and 3 had progressive disease. Disease control (DC) was associated with the presence of new mutations ($P = 0.022$) and was more common in those with HRD, with DC in 9/10 (90.0%) HRD pts vs 3/5 (60.0%) pts without HRD. All those with PRs experienced a ctDNA nadir at 8 weeks of treatment with nearly all (4/5, 80.0%) exhibiting HRD, 2 at baseline and 2 at 8 weeks of treatment. **Conclusions:** Mutations in DNA repair genes occur on treatment with talazoparib and TMZ and may associate with disease control. With a response rate of 33% in the first Simon stage of this trial, the TRIO-US L-07 trial exploring the combination of talazoparib and TMZ will be assessed in 13 additional patients, after which additional ctDNA analyses will be performed on the cohort as a whole. Clinical trial information: NCT03672773. Research Sponsor: Pfizer, U.S. National Institutes of Health.

Cisplatin versus carboplatin for the treatment of limited-stage small cell lung cancer (LS-SCLC). *First Author: Ibrahim Azar, Albany Medical College, Albany, NY*

Background: Standard of care therapy for LS- SCLC is concurrent chemo-radiation (CRT) with a platinum-etoposide backbone. Cisplatin is traditionally the preferred platinum agent in the curative intent setting. Data comparing the efficacy of the less toxic carboplatin to cisplatin in LS-SCLC are lacking. **Methods:** Data from the National VA Cancer Cube were collected. Pathologically confirmed cases of LS-SCLC that received concurrent CRT with platinum-based multiagent chemotherapy were included. Interval-censored Weibull and Cox proportional hazard regression models were used to estimate median overall survival (OS) and hazard ratio (HR), respectively. Survival curves were compared by a Wald test. **Results:** 801 LS-SCLC patients who received carboplatin-based therapy (Carbo-SCLC) and 1018 who cisplatin-based therapy (Cis-SCLC) were included in the analysis. Median OS with Carbo-SCLC and Cis-SCLC were 2.13 years (95% CI 1.97-2.31) and 2.24 years (95% CI 2.09-2.4), respectively (HR=1.04;95% CI, 0.94-1.16; p=0.46). Subset analysis showed similar median OS for Carbo-SCLC and Cis-SCLC in patients with ECOG-PS of 0, 1 and 2, as well as patients in their 50s, 60s and >70. Multivariable regression analysis accounting for age and ECOG-PS shows a HR of 0.99 (95% CI 0.86-1.14; p=0.91). **Conclusions:** Concurrent CRT with carboplatin-etoposide was associated with similar OS compared to cisplatin-etoposide in LS-SCLC, irrespective of PS and age. Carboplatin's advantageous toxicity profile and comparable OS indicate that it is an acceptable choice of platinum for LS- SCLC. Research Sponsor: None.

	Median OS in years (95% CI)	
	Carboplatin	Cisplatin
Total population	2.13 (1.97-2.31)	2.24 (2.09-2.40)
ECOG-PS 0	2.60 (2.18-3.11)	2.74 (2.35-3.16)
ECOG-PS 1	2.15 (1.86-2.48)	2.15 (1.88-2.43)
ECOG-PS 2	1.62 (1.28-2.05)	1.95 (1.51-2.47)
Age 50-59	2.75 (2.15-3.52)	2.89 (2.44-3.39)
Age 60-69	2.32 (2.07-2.59)	2.22 (2.02-2.42)
Age>70	1.78 (1.57-2.01)	1.82 (1.56-2.10)
Stage I	2.35 (1.88-2.93)	2.85 (2.28-3.49)
Stage II	2.48 (2.05-3.01)	2.70 (2.25-3.17)
Stage III	2.04 (1.85-2.24)	2.09 (1.92-2.27)

Application value of plasma exosomal long RNA in SCLC diagnosis and prognosis. *First Author: Chang Liu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Little research has focused on blood exosomal transcription profile in small cell lung cancer (SCLC). The aim of this study is to identify plasma exosomal specific transcriptional profile in SCLC and explore the application value of plasma exosomal long RNA (exLR) in SCLC diagnosis and prognosis. **Methods:** This study included 81 healthy people and 40 SCLC patients receiving standard first-line chemotherapy with etoposide and carboplatin/cisplatin. The efficacy was evaluated by progression-free survival (PFS), objective response rate (ORR) and disease control rate (DCR). 19 Patients who achieved complete response (CR) or partial response (PR) as best response during the first-line therapy and had not progressed within the following 90 days after the end of first-line therapy were defined as chemosensitive. 21 Patients who achieved stable disease (SD) as best response or received progressive disease during the first-line therapy or within the following 90 days after the end of first-line therapy were defined as chemoresistant. Baseline plasma samples were collected from 40 SCLC patients (17 patients' samples after 2 courses were collected) and 81 healthy people. Plasma exosomes were isolated and purified; exosomal RNA were extracted for high-throughout sequencing analysis. **Results:** We obtained plasma exLRs profiles from 81 healthy control samples and 57 SCLC samples (baseline samples from 40 patients plus samples collected by 17 patients after 2 courses). Bioinformatics analysis found that exLRs were significantly different between the SCLC and the healthy control group; between the chemosensitive and the chemoresistant group; between the baseline samples and the paired samples after 2 courses. For 40 SCLC patients receiving first-line chemotherapy, ORR was 65.0%, DCR was 90.0% and mPFS was 6.0 months (95% CI, 4.3-7.7 months). Multivariate analysis showed that baseline brain metastases and baseline bone metastases were independent predictors of poor PFS; and 223 genes were independent predictors of PFS. There were 10 genes (AC107954.1, H2AFZP2, CALB2, IFITM9P, GFPT2, PLA1A, CHST10, AC021231.2, SETP20, HILPDA) intersected in differentially expressed genes between the SCLC and the healthy control group, differentially expressed genes between the chemosensitive and the chemoresistant group and independent predictors of PFS. These 10 genes were highly expressed in both the SCLC group and the chemoresistant group, and their high expression was an independent risk factor for poor PFS. **Conclusions:** This study firstly identified the plasma exLRs profiles in SCLC patients, verified the feasibility and value of identifying biomarkers based on exLRs profiles in SCLC diagnosis and prognosis. Research Sponsor: None.

Imfirst: A phase IIIb, safety, single arm study of carboplatin (CB) or cisplatin (CP) plus etoposide (ET) with atezolizumab (ATZ) in patients with untreated extensive-stage small cell lung cancer (ES-SCLC) in Spain—Primary safety results of the induction phase. *First Author: Maria Rosario García Campelo, Complejo Hospitalario Universitario A Coruna Hospital Teresa Herrera-Materno Infantil, A Coruna, Spain*

Background: Clinical trial (CT) IMpower133 met both primary endpoints and is the first CT to show significant clinical improvement over standard chemotherapy (C) with a good safety profile in first line (1L) ES-SCLC. The addition of ATZ to CB + ET resulted in an OS landmark of 34% and 22% compared to 21% and 16.8% of patients alive at 18 and 24 months respectively versus C. IMfirst evaluates ATZ + CB or CP + ET in a broader patient population than the pivotal study. ECOG Performance status (PS) 2, asymptomatic untreated brain metastases, underlying stable autoimmune diseases and HIV+ pts are eligible. IMfirst also includes the possibility of 6 C induction cycles according to investigator's choice and consolidation radiotherapy. **Methods:** To evaluate the safety and efficacy of ATZ added to CB or CP + ET as 1L treatment in an interventional real world setting of ES-SCLC. Exploratory endpoints include tumor biomarker analysis related to ATZ. **Results:** As of Oct 2020, 117 pts had been enrolled, 105 treated with ATZ + CB + ET and 12 with ATZ + CP + ET. The median age was 65 years (Y) (range 35-89); 84 males; 14 pts (12%) had CNS metastases and 66 pts were current smokers and 50 former smokers, one had never smoked. The PS was 0 in 28 pts (24%), 1 in 75 (64%) and 2 in 14 (12%). The median of cycles of ATZ received was 4 for all the pts (range 1-12) and 2 for the pts (40) in maintenance phase (range 1-8). Number of pts with adverse events (AEs) was 109, 36 with Serious Adverse Events (SAEs) and 63 with AEs. 8 pts had SAEs related to treatment, 4 had adverse events of special interest and 13 pts discontinued the treatment due to AEs: 6 to ATZ, 12 to CB or CP and 10 to ET, 1 patient discontinued ATZ due to a related AE. Table shows the treatment related AEs (TRAEs). No grade 5 TRAEs were reported. **Conclusions:** IMfirst induction phase analysis confirms the safety profile of ATZ plus C in a broader population of patients. Efficacy, biomarker and further safety analyses will be presented in the future with longer follow up. Research Sponsor: Roche Farma S.A.

Treatment related AEs	Grade 1-2	Grade 3-4
Neutropenia	5 (4.3%)	6 (5.1%)
Thrombocytopenia	3 (2.6%)	4 (3.4%)
Platelet Count Decreased	3 (2.6%)	3 (2.6%)
Anaemia	11 (9.4%)	2 (1.7%)
Febrile Neutropenia	0 (0%)	2 (1.7%)
Alanine Aminotransferase Increased	7 (6.0%)	2 (1.7%)
Gamma-Glutamyltransferase Increased	4 (3.4%)	2 (1.7%)

Regarding the immune-mediated AEs (IMAEs), there were two pts (2.6%) with grade 1 and 2 hyperthyroidism. One patient had a grade 2 increase in Alanine Aminotransferase. One patient presented grade 4 hepatotoxicity and another one had grade 3 pneumonitis. All patients with IMAEs were treated accordingly.

Penpulimab plus anlotinib as second-line treatment for the small cell lung cancer after failure of platinum-based systemic chemotherapy. *First Author: Changgong Zhang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: Combined therapy of an immune checkpoint inhibitor with a targeted anti-angiogenic agent had been proved to be effective for lung cancer. Penpulimab (AK105) was engineered to eliminate FcγR binding and antibody-dependent cell-mediated cytotoxicity (ADCC)/ antibody-dependent celluar phagocytosis (ADCP) completely, where ADCC/ADCP effects could induce T-cell apoptosis and clearance and therefore compromise anti-tumor activity. Penpulimab demonstrated a slower programmed death-1(PD-1) antigen binding off-rate, which resulted in better cellular activity and higher receptor occupancy. Penpulimab also showed numerous contacts with N58 glycosylation on the BC loop of PD-1. These structural differentiations enhance the anti-tumor activity of penpulimab and improve its safety. Anlotinib is a multi-targeted tyrosine kinase inhibitor selective for VEGF receptors 1/2/3, FGF receptors 1-4, PDGF receptors α and β, and c-kit. Anlotinib has been approved by National Medical Products Administration as the treatment for small cell lung cancer (SCLC) patients, who had progressed/relapsed on or after at least two regimens of chemotherapy. Here we report the results of one cohort which received penpulimab plus anlotinib in a Phase II study. **Methods:** In Cohort 4 of an open-label, multi-center, multi-cohort Phase II study evaluating the efficacy and safety of penpulimab plus anlotinib in pts with advanced head, neck or chest tumors(NCT04203719), the SCLC patients, who failed to platinum-based systemic chemotherapy treatment, received penpulimab (200 mg IV Q3W) and anlotinib (12/10 mg PO 2 weeks on/1 week off). Primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints were disease control rate (DCR), duration of response, progression-free survival (PFS) and overall survival. **Results:** 20 patients (median age was 61 [range:37–75] years old, Eastern Cooperative Oncology Group performance status 0/1 [5%/95%], male/female [65%/35%]) were enrolled and received combination therapy (17 received 12 mg anlotinib, 3 received 10 mg anlotinib; and all received 200 mg penpulimab). At data cut-off (Jan 25, 2021), the confirmed ORR was 50.0% (10/20, 1 complete response and 9 partial response) and DCR was 75.0% (15/20). 9 PFS events (45%) had occurred, and the median PFS was 4.7 months (95% CI: 3.6-not reached). Grade 3 treatment-related adverse events (TRAEs) occurred in 30% (6/20, 2 hypertension, 1 hypertriglyceridaemia, 1 gamma-glutamyltransferase increased, 1 palmar-plantar erythrodysaesthesia syndrome and 1 hyponatraemia) of patients, No Grade 4 or 5 TRAEs had occurred. **Conclusions:** Penpulimab plus anlotinib showed favorable antitumor activity and an acceptable safety profile in SCLC patients who failed to platinum-based systemic chemotherapy. This new combination therapy warrants further evaluation for the treatment of SCLC. Clinical trial information: NCT04203719. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

Chemoimmunotherapy for the treatment of extensive-stage small cell lung cancer (ES-SCLC) in patients with an Eastern Cooperative Group (ECOG) performance status (PS) of two or greater. *First Author: Daniel Almquist, Mayo Clinic, Phoenix, AZ*

Background: Immune checkpoint inhibitor (atezolizumab or durvalumab) combined with platinum-etoposide is the standard first-line therapy for patients with extensive-stage small cell lung cancer (ES-SCLC). The phase III clinical trials that led to the approval of chemoimmunotherapy in ES-SCLC, excluded patients with an Eastern Cooperative Group (ECOG) Performance Status (PS) of Two or Greater. Therefore, data on efficacy of this combination in this subgroup of ES-SCLC patients whose performance status two or greater is limited. **Methods:** A retrospective analysis was performed of patients diagnosed with ES-SCLC who received chemoimmunotherapy (atezolizumab or durvalumab) within the Mayo Clinic Health System between January 2016 and January 2021. Cases were identified from clinical databases at Mayo Clinic. Data on demographics, ECOG-PS, date of diagnosis, date of progression, whole brain radiation, CNS involvement, liver involvement, stereotactic body radiation, chest consolidation, platinum sensitivity, lines of therapy and last follow up date were extracted. Overall Survival (OS) and progression free survival (PFS) for ECOG-PS 2-3 were compared to patients with an ECOG-PS 0-1. **Results:** A total of 84 patients were identified with a median age of 68.2 (48-88) years old. Of these, 54 patients were identified with an ECOG-PS 0-1 and 30 patients with an ECOG-PS 2-3. The median PFS for the ECOG PS 0-1 cohort was 5.2 months (95% CI 4.6-6.1) while the median PFS for the ECOG-PS 2-3 cohort was 6.0 months (95% CI 4.2-7.7; logrank p = 0.93). The median OS for the ECOG-PS 0-1 cohort was 10.8 months (95% CI 8.5-12.9) while the median OS for the ECOG-PS 2-3 cohort was 10.3 months (95% CI 6.0-14.1; logrank p = 0.39). Hazard ratios of ECOG-PS 0-1 versus 2-3 showed no tendency of increased PFS or OS for either group within cox proportional hazards models. Forty-three percent of ECOG-PS 0-1 achieved a partial response (PR) and 57% of patients who had ECOG-PS 2-3 also achieved a PR (Fisher's exact p = 0.23). A complete response was found in 4% of ECOG-PS 0-1 compared to 3% in the ECOG-PS 2-3 cohort. For patients who responded to initial therapy, 46% of ECOG-PS 2-3 patients had a platinum sensitive relapse while only 33% of ECOG-PS 0-1 were still platinum sensitive at the time of relapse. Five ECOG-PS 2-3 patients were able to receive a second-line therapy. **Conclusions:** To our knowledge, this is the first study to evaluate chemoimmunotherapy in the subgroup of ES-SCLC patients with an ECOG-PS 2 or greater. This retrospective study demonstrated no significant difference in PFS, OS, and ability to achieve a least a PR in ECOG-PS 2-3 cohort when compared to ECOG-PS 0-1. Therefore, chemoimmunotherapy should not be reserved for only an ECOG-PS of 0-1 but should be considered for all treatment eligible patients. Research Sponsor: None.

A phase I trial of plinabulin in combination with nivolumab and ipilimumab in patients with relapsed small cell lung cancer (SCLC): Big Ten Cancer Research Consortium (BTCRC-LUN17-127) study. *First Author: Jyoti Malhotra, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Plinabulin (BPI-2358) is a vascular disrupting agent with immune-enhancing function by inducing dendritic cell maturation and decreasing regulatory T cells. Preclinical studies report that plinabulin potentiates the cytotoxicity of dual checkpoint inhibition (CPI) with nivolumab and ipilimumab. Plinabulin may also reduce immune-related AEs from CPI through its phosphodiesterase-4 (PDE4) inhibitory activity which is associated with anti-inflammatory effects. We report initial results from a Phase I study assessing plinabulin in combination with nivolumab and ipilimumab. **Methods:** In this dose-escalation phase I study, patients with extensive-stage SCLC who had progressed on or after prior platinum-based chemotherapy (±CPI) were enrolled using a 3+3 design. The primary objective was to determine dose-limiting toxicities (DLT's) and recommended Phase 2 dose (RP2D). Patients received nivolumab (1 mg/kg), ipilimumab (3 mg/kg) and plinabulin (as per dose escalation schema) IV on day 1 of each 21 day cycles. After completion of 4 cycles, patients continued therapy with nivolumab (240 mg) and plinabulin every 2 weeks till progression or intolerable toxicity. Patients were evaluable for DLT if they received at least 2 cycles of therapy; DLT period was defined as the first 6 weeks from C1D1. Secondary endpoints were ORR, PFS and frequency of irAEs. Correlative analysis included inflammatory biomarkers: hsCRP, ESR, SAA and haptoglobin. **Results:** Between 9/2018 and 11/2020, 17 patients were enrolled (1 patient withdrew consent before treatment, 16 were evaluable for safety). Median age was 59 years (range 43 to 78); 9 patients were male and 10 had received prior CPI. Eight patients were treated at dose-level 1 of plinabulin (20 mg/m2) and 8 patients at 30 mg/m2 of plinabulin (level 2); dose-level 2 was determined to be RP2D. There were 2 DLTs; 1 at dose-level 1 (grade 3 altered mental status lasting $<$ 24 hours) and 1 at dose-level 2 (grade 3 infusion reaction). The most common treatment-related AEs (all grades) were nausea (10; 63%), infusion reaction (8; 50%), vomiting (7; 44%), diarrhea (7; 44%) and fatigue (6, 32%). Seven patients (44%) had at least one grade 3 or higher treatment-related AE; there were no treatment-related deaths. Two patients (13%) had grade 3 or higher irAE requiring steroids (1 colitis, 1 transaminitis); both at dose-level 1. At data cutoff (12/30/20), there were 3 PRs in CPI naïve patients (3/6; 50%) and 2 PRs in evaluable CPI-resistant patients (2/7; 29%). In the two CPI-resistant patients with confirmed response, the tumor reduction was 68% and 52%. **Conclusions:** Plinabulin in combination with nivolumab and ipilimumab was safe and well tolerated. A phase 2 study in CPI-experienced patients with relapsed SCLC is planned to confirm the preliminary signals of clinical activity and reduced immune toxicity. Clinical trial information: NCT03575793. Research Sponsor: BeyondSpring Pharmaceuticals, Bristol Myers Squibb.

A randomized phase II/III study comparing carboplatin and irinotecan with carboplatin and etoposide for the treatment of elderly patients with extensive-disease small cell lung cancer (JCOG1201/TORG1528). *First Author: Tsuneo Shimokawa, Department of Respiratory Medicine, Yokohama Municipal Citizen's Hospital, Yokohama-Shi, Japan*

Background: Carboplatin and etoposide is the current standard treatment for elderly extensive-disease small-cell lung cancer (ED-SCLC). The purpose of this study is to evaluate the efficacy and safety of carboplatin and irinotecan compared with carboplatin and etoposide in elderly Japanese patients with ED-SCLC in a randomized phase II/III design. **Methods:** Eligibility included histologically or cytologically proven SCLC, no previous systemic chemotherapy, performance status of 0 to 2, and aged 71 years or older. Patients received carboplatin (AUC 5 mg/ml/min on day 1) and etoposide (80 mg/m^2 on day 1 to 3) (CE) every 3 weeks for 4 cycles or carboplatin (AUC 4 mg/ml/min on day 1) and irinotecan (50 mg/m^2 on day 1 and 8) (CI) every 3 weeks for 4 cycles. In the phase II part, the primary endpoint was the objective response rate of the CI arm and the secondary endpoint was adverse events. In the phase III part, the primary endpoint was overall survival, and the secondary endpoints were progression-free survival, objective response rate, adverse events, and symptom score. This study was designed to confirm the superiority of CI arm in terms of overall survival over CE arm. The median survival time with CI arm was expected to be increased by 3.5 months with hazard ratio (HR) of 0.750 (10.5 vs. 14.0 months). The sample size was set at 250 to observe the required number of events of 227 with one-sided alpha level of 0.05, a power of 70%, an accrual period of 6.5 years, and a follow-up period of 1.5 years. **Results:** Between December 2013 and June 2019, 258 patients were randomized (CE arm, 129 patients; CI arm, 129 patients). The median age was 75 (range, 71-90). The characteristics of the patients were well balanced between CE arm and CI arm. Overall survival, progression-free survival, and objective response rate of CE arm vs. CI arm were 12.0 (95% CI, 9.3-13.7) vs. 13.2 (95% CI, 11.1-14.6) months (HR, 0.848 (95% CI, 0.650-1.105)) (one-sided P=0.11), 4.4 (95% CI, 4.0-4.7) vs. 4.9 months (95% CI, 4.5-5.2) (HR, 0.851 (95% CI, 0.664-1.090)) (two-sided P=0.21), and 59.7% (77 of 129) vs. 64.3% (83 of 129), respectively. Symptom score showed no significant difference between the arms. Higher incidences of myelosuppression of grade 3 or worse occurred with CE arm, whereas higher incidences of gastrointestinal toxicity of grade 3 or worse occurred with CI arm. Three treatment-related deaths including lung infection in CE arm and lung infection and sepsis in CI arm were observed. **Conclusions:** Efficacy tended to be favorable in carboplatin and irinotecan arm, but there was no statistically significant difference. These results indicate that carboplatin and etoposide is a still standard treatment in elderly Japanese patients with ED-SCLC. Clinical trial information: 000012605. Research Sponsor: None.

Combination of quantitative features from H&E biopsies and CT scans predicts response to chemotherapy and overall survival in small cell lung cancer (SCLC). *First Author: Cristian Barrera, Case Western Reserve University, Cleveland, OH*

Background: Small Cell Lung Cancer (SCLC) is an aggressive malignancy with a rapid growth, and Chemotherapy remains mainstay of treatment. Identifying therapeutic targets in SCLC presents a challenge, partially due to a lack of accurate and consistently predictive biomarkers. In this study we sought to evaluate the utility of a combination of computer-extracted radiographic and pathology features from pretreatment baseline CT and H&E biopsy images to predict sensitivity to platinum-based chemotherapy and overall survival (OS) in SCLC. **Methods:** Seventy-eight patients with extensive and limited-stage SCLC who received platinum-doublet chemotherapy were selected. Objective response to chemotherapy (RECIST criteria) and overall survival (OS) as clinical endpoints were available for 51 and 78 patients respectively. The patients were divided randomly into two sets (Training (Sd), Validation (Sv)) with a constraint (equal number of responders and nonresponders in Sd)—Sd comprised twenty-one patients with SCLC. Sv included thirty patients. CT scans and digitized Hematoxylin Eosin-stained (H&E) biopsy images were acquired for each patient. A set of CT derived (46%) and tissue derived (53%) image features were captured. These included shape and textural patterns of the tumoral and peritumoral regions from CT scans and of tumor regions on H&E images. A random forest feature selection and linear regression model were used to identify the most predictive CT and H&E derived image features associated with chemotherapy response from Sd. A Cox proportional hazard regression model was used with these features to compute a risk score for each patients in Sd. Patients in Sv were stratified into high and low-risk groups based on the median risk score. Kaplan-Meier survival analysis was used to assess the prognostic ability of the risk score on Sv. **Results:** The risk score comprised nine CT (intra and peri-tumoral texture) and six H&E derived (cancer cell texture and shape) features. A linear regression model in conjunction with these 15 features was significantly associated with chemo-sensitivity in Sv (AUC = 0.76, PRC = 0.81). A multivariable model with these 15 features was significantly associated with OS in Sv (HR = 2.5, 95% CI: 1.3-4.9, P = 0.0043). Kaplan-Meier survival analysis revealed a significantly reduced OS in the high-risk group compared to the low-risk group. **Conclusions:** A combined CT and H&E tissue derived image signature model predicted response to chemotherapy and improved OS in SCLC patients. Image features from baseline CT scans and H&E tissue slide images may help in better risk stratification of SCLC patients. Additional independent validation of these quantitative image-based biomarkers is warranted. Research Sponsor: U.S. National Institutes of Health.

Myasthenia gravis-associated thymoma and myasthenia gravis-free thymoma have distinct somatic mutation and gene expression profiles. *First Author: Yi Zhang, Thoracic Surgery Department, Xuanwu Hospital, Capital Medical University, Beijing, China*

Background: A significant proportion of thymoma patients have concurring autoimmune diseases such as myasthenia gravis (MG). However, the molecular signature of myasthenia gravis-associated thymoma (MGT) is largely unknown. Genomic and transcriptomic profiling of MGT may provide valuable insight to the etiology of MGT and facilitate the development of effective therapeutic approaches. **Methods:** To study the molecular signature of MGT, 26 thymoma patients were divided into two subgroups according to their clinical presentations. One group included 16 thymoma patients associated with MG (MGT) and the other group had 10 patients without MG (MGF). We profiled the genomic and transcriptomic changes of tumor samples from both subgroups with whole exome sequencing (WES) and RNA sequencing (RNA-seq). **Results:** The WES results indicated that more genes were mutated in the MGF subgroup than the MGT group, although the difference between two subgroups was not statistically significant. There were only five mutated genes (*NBPF1*, *HRAS*, *ATAD3B*, *IFITM3* and *MUC4*) appeared total mutation frequency exceeded 10%. *NBPF1* is the most frequently mutated gene, seen in 25% of the MGTs (4/16) and 10% (1/10) of the MGFs. Neuroblastoma breakpoint family member 1 encoded by *NBPF1* was involved in several cancer types including gastric cancer and neuroblastoma, but there is no report on the link of *NBPF1* with thymoma or MG. Recent studies showed that NBPF1 is a negative regulator of Akt-p53-Cyclin D and PI3K/mTOR signal pathways. Recurrent mutations in *HRAS* was only observed in MGFs but not MGTs. Genes mutated in more than one patient were *NBPF1*, *ATAD3B*, *RPDM9*, *LOC642131*, *ADAM21*, *CGNL1*, *MUC4* and *MUC2* in the MGT subgroup, while only three genes *HRAS*, *CSPG4* and *IFITM3* were mutated in more than one patient in the MGF subgroup. Moreover, RNA-seq data identified 106 significantly differentially expressed genes, including 54 upregulated and 52 downregulated genes in the MGT subgroup, further pathway enrichment analysis revealed that the Hippo, Wnt, TGF-β and focal adhesion signaling pathways were significantly downregulated in the MGT subgroup compared with the MGF subgroup. **Conclusions:** Our findings provide new insights for the etiology of thymoma with and without MG. mTOR signaling pathway is a key regulator of immune response. Importantly, the protein level of some components in the mTOR pathway was reduced in MG caused-atrophic muscle. Further investigation is warranted to examine the functional roles of *NBPF1* in mTOR signaling regulation and the etiology of MG-associated thymoma. Research Sponsor: None.

First long-term results on efficacy and safety of long-acting pasireotide in combination with everolimus in patients with advanced carcinoids (NET) of the lung/thymus: Phase II LUNA trial. *First Author: Eric Baudin, Department of Nuclear Medicine and Endocrine Oncology, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Everolimus (EVE) improves progression-free survival (PFS) in patients (pts) with progressive non-functioning thoracic and digestive advanced neuroendocrine tumors (NET). The LUNA trial aimed to assess the efficacy and safety of long-acting pasireotide (PAS) and EVE alone or in combination in pts with progressive bronchial or thymic carcinoids. Core phase results for primary endpoint (PFS) and secondary endpoints at 9 and 12 months (mo) were previously published. Cumulative data results at the end of the extension phase are presented here. **Methods:** LUNA was a prospective, multicenter, randomized, open-label, 3-arm, phase II trial. Adult pts with carcinoids of lung/thymus were randomized (1:1:1) to receive either PAS (60 mg/mo i.m.) or EVE (10 mg/day orally) or PAS + EVE. The key secondary endpoints assessed in this extension phase, including all the patients who were still not progressing at 12 months, were PFS, duration of biochemical response (DBR), and biochemical PFS (BPFS). **Results:** Of the total 124 pts included in the core phase, 41 pts with a median age of 61 years entered the extension phase including PAS (12), EVE (14) and PAS + EVE (15). Lung was the primary site of cancer in 95.1% and 82.9% had non-functioning tumors. Surgery/local or regional therapy was the preferred prior treatment in 63.4% pts. Disease progression was the primary reason for discontinuation among 3 arms with 65.9% in overall extension phase; no pts in PAS arm discontinued due to adverse events (AEs). Mean relative dose intensity (RDI) was higher for PAS (95.6% alone and 90.4% in combination) when compared to EVE (76.6% alone and 72.4% in combination); 38.1% pts in the EVE arm and 43.9% pts in the combination arm with EVE had RDI <70%. PAS +EVE combination showed clinical benefit in terms of PFS and BPFS compared to PAS and EVE alone as shown in Table. At least one dose reduction of PAS or EVE was reported in >50% pts. Most common AEs of any grade regardless of the study drug in PAS +EVE arm were hyperglycemia (87.8%), diarrhea (80.5%), and weight loss (58.5%), while stomatitis was reported in 34.1%. Twelve deaths were reported during the study and up to 56 days from last study treatment dose. Duration of exposure and efficacy. **Conclusions:** Mature median PFS and BPFS data suggest a benefit of PAS+EVE combination. The safety and tolerability profile of PAS and EVE alone or in combination were consistent with prior experience of these treatments in the oncology setting, with no new safety signals being reported during the study. Post-hoc prognostic studies are ongoing. Clinical trial information: NCT01563354. Research Sponsor: None.

	PAS N=41	EVE N=42	PAS + EVE N=41
Duration of exposure, weeks (range)	38.9 (4.0-295.6)	26.9 (1.0-224.1)	49.0 (4.0-307.9)
Median PFS, mo, (95% CI)	8.51 (5.68-14.03)	12.48 (5.55-20.21)	16.53 (11.10-23.26)
Median BPFS, mo, (95% CI)	2.89 (2.79-5.49)	2.86 (2.79-3.52)	5.62 (3.19-8.31)

Cancer activation pathways of thymic epithelial tumors (TETs) by targeted gene expression analysis. *First Author: Jose Carlos Benitez, Gustave Roussy, Villejuif, Paris, YT, France*

Background: TETs are rare malignancies of the anterior mediastinum. Clinical behavior varies from mild thymoma (T) A to aggressive thymic carcinoma (TC). The biology of TETs is poorly understood and knowledge of the transcriptomic fingerprint of T and TC is limited. Additionally, up to 30% of patients (pts) will develop associated autoimmune disorders (AIDs). We aimed to characterize the main cancer activation pathways of the TET subgroups. **Methods:** We selected a representative balanced set of Ts and TCs to analyze 24 main cancer activation pathways using HTG Oncology biomarkers panel (2562 genes) by RNA sequencing. Tumor representative paraffin-embedded blocks were macrodissected for gene expression analysis. We analyzed epidemiologic, clinical and pathological characteristics of pts with TET's and correlated with genes expression based on cancer Hallmarks. **Results:** From January 2010 to December 2019, 219 pts were included in the cohort. Molecular results of 194 pts were available. Median age at diagnosis was 56 (9-83) years. 54.1% were women. 65/194 (33.5%) reported AIDs. T B2 was the most frequent (n=41, 21.1%), followed by B1, AB, B3, TC and A. RNA expression analysis identified 2 main clusters, corresponding mainly to T (cluster 2) and TC (cluster 1) respectively ($p<0.0001$) (Table). Tumors of cluster 1 (TCs predominant) shown activated pathways (MYC [gene ratio= 0.5]; $p<0.0001$). In cluster 2 (T predominant), activated pathways differed among subgroups: B1 (E2F[0.5], G2M checkpoint [0.45]; $p<0.001$), B2 (E2F [>0.4]; $p<0.0001$). Routes were mostly suppressed: A (MYC [>0.5], E2F[>0.4], G2M checkpoint[>0.45], mitotic spindle[>0.35], MTOR [<0.35]; $p<0.001$), AB (INFα [>0.5], inflammatory response [>0.45], INTγ [0.45], NFkb [>0.4], MTOR[>0.4]; $p<0.001$), B1 (EMT [0.6], angiogenesis [>0.5], INFα [0.5], homeostasis [0.5], NFkb [0.5], INTγ [>0.45], myogenesis [<0.4]; $p<0.0001$), B2 (INFα [>0.65], INTγ [>0.5], NFkb [0.5], EMT [0.45], inflammatory response [<0.4]; $p< 0.0001$), B3 (EMT [0.6], MYC [0.45]; $p<0.001$). Among pts reporting AIDs 61 and 4 were associated to cluster 2 and 1, respectively ($p=0.017$). **Conclusions:** We describe differential molecular characteristics among histological subgroups in 2 clusters. The analysis suggests new therapeutic venues. Additional analysis will be presented on outliers and response to treatment. Research Sponsor: None.

Correlation between histological subgroups and molecular clusters (K means used for all subgroups).

Histological subtype	Cluster (n)	
Thymoma A	1	2
Thymoma AB	1	16
Thymoma B1	1	34
Thymoma B2	2	34
Thymoma B3	1	40

A phase II study of palbociclib for recurrent or refractory advanced thymic epithelial tumor (KCSG LU17-21). *First Author: Myung-Ju Ahn, Samsung Medical Center, Seoul, South Korea*

Background: Thymic epithelial tumors (TETs) are rare but the most common tumor of the anterior mediastinum. Platinum-based combination chemotherapy is standard of care which is associated with a 50%-90% overall response rate (ORR) in metastatic disease. However, there is no standard chemotherapeutic option after failure of platinum-based combination chemotherapy. Genetic alterations associated with cell cycle including pRB, $p16^{INK4A}$, and cyclin D1 are commonly observed in TETs. Based on these results, we conducted a phase II trial to evaluate the efficacy and safety of palbociclib in patients with recurrent or refractory advanced TETs. **Methods:** This is a phase II multicenter, open-label, single arm study of palbociclib monotherapy in patients with recurrent or metastatic advanced TETs who failed one or more cytotoxic chemotherapy. Patients receive oral palbociclib 125mg daily for 21 days followed by a 7-day break. The primary endpoint was the progression-free survival (PFS) rate at 6 months (H0 = 30% vs H1 = 48%). **Results:** Between August 2017 and October 2019, 48 patients were enrolled. The median number of previous chemotherapy was 1 (range: 1-4) and 21 (43.7%) of 48 patients received thymectomy. By WHO classification, Type A (n = 1), Type B1 (n = 2), Type B2 (n = 8), Type B3 (n = 13), Type C (n = 23), and unknown (n = 1). With medial follow-up of 14.5 months (range 0.8-38.2), the median cycle of palbociclib was 10 (range 1-40). The PFS at 6 months was 60% and the median PFS was 11.0 months (95% CI: 4.6-17.4). Six of 48 patients (12.5%) achieved partial response. The median overall survival was 26.4 months (95% CI: 17.4-35.4). The most common adverse events of any grade included neutropenia (62.5%), anemia (37.5%) and thrombocytopenia (29.1%). **Conclusions:** Palbociblib monotherapy is well tolerable and encouraging efficacy in patients with TETs who failed platinum-based combination chemotherapy. Updated results will be presented. Clinical trial information: NCT03219554. Research Sponsor: None.

Cell-free circulating tumor DNA (cfDNA) analysis of advanced thymic epithelial tumors (TETs). *First Author: Hiba I. Dada, Guardant Health, Inc., Redwood City, CA*

Background: Thymic epithelial tumors (TETs) are rare tumors originating from the epithelial cells of the thymus. Thymomas tend to be slowly growing, whereas thymic carcinomas are more aggressive and often metastasize wildly. TETs have a very low tumor mutational burden (TMB). cfDNA has been used in several tumor types to describe the molecular characteristics and select treatment options, especially in absence of tissue availability. There is no information on the cfDNA detected in TETs. The purpose of this study was to identify common genomic alterations occurring in circulating tumor DNA (ctDNA) in patients with advanced TETs, detected using a cfDNA assay. **Methods:** We retrospectively evaluated 157 TET samples from the Guardant Health database between November 2017 – November 2020. The cfDNA analysis interrogated single nucleotide variants (SNV), fusions, indels and copy number variations (CNV) of up to 83 genes using a commercially available liquid biopsy assay (Guardant360; Guardant Health, Redwood City, CA). We evaluated the frequency of genomic alterations based on diagnosis, age, and sex. **Results:** In this cohort, 66% of the patients had thymic carcinoma and 34% had thymoma. The median age was 60 years, and 59% of patients were male. 126 patients (80%) of this cohort had ≥1 somatic alteration detected. The most prevalent mutations detected are TP53 (55%), KIT (13%), EGFR (12%), BRCA2 (11%), PIK3CA (10%), ARID1A (10%), ATM (10%), KRAS (9%), APC (9%), and BRAF (9%). Mutations were more commonly observed in thymic carcinomas than thymomas, but statistical significance was not reached due to the small sample size. Frequencies of the observed genomic alterations are shown in the table below. **Conclusions:** This study confirms that advanced stage TETs shed tumor DNA into the circulation that can be picked up in the majority of patients, using a solid tumor platform, despite the low TMB typically observed in these tumors. This assay can potentially be used to monitor response to therapy. A more targeted gene panel, enriched for genes commonly mutated in TETs (e.g. GTF2I, BAP1, CYLD) might provide further insights in the future in the management of TETs. Research Sponsor: None.

	Thymic Carcinoma	Thymoma
Amp	12.7%	10.7%
Fusion	0.4%	0.0%
Indel	9.2%	5.3%
Missense	59.4%	58.7%
Nonsense	2.8%	6.7%

Outcomes of thymic epithelial tumors (TETs) with pleural metastases: Real-world insight from RYTHMIC. *First Author: Jean-Michel Maury, Department of Thoracic Surgery Lung and Heart Lung Transplantation, Lyon, France*

Background: TETs are rare and potentially aggressive malignancies with high associated prevalence of autoimmune disorders (AIDs). The pleura is the main metastatic site at relapse, referred as Masaoka-Koga stage (MK) IVa. The benefit of surgical management is unknown, so we have collected outcomes of patients with MK IVa TETs in a large prospective database. **Methods:** RYTHMIC (Réseau tumeurs THYMiques et Cancer) is a French nationwide network mandated to systematically discuss every case of TETs. The database, hosted by IFCT (Intergroupe Francophone de Cancérologie Thoracique), prospectively includes all consecutive pts with a diagnosis of TET discussed in RYTHMIC national or regional tumor boards. We analyzed epidemiologic, clinical and pathological characteristics of patients (pts) with MK IVa TETs. **Results:** From January 2012 to December 2019, 2909 pts were included in the database, including 182 MK IVa (6.2%). The median age at diagnosis was 63.5 (range 9 to 91). 58/182 (32%) pts reported AIDs, 76% myasthenia gravis. 129/182 pts had synchronous pleural metastasis. 118/182 (65%) tumors were resected, of them 10 (8.4%) had only pericardial metastases. Thymoma (T) B2 rate was 35.6%, B3 17.8% and thymic carcinoma (TC) 13.5%. Induction chemotherapy (CT) was given in 46 (39%) T and 10 (8%) TC with response rate of 50% and 70% respectively. Thymectomy was performed in addition to pleurectomy in 44 pts (37.2%), pericardiectomy in 68 (57.6%), lung resection in 80 (67.8%) or pneumonectomy in 15 (12.7%). Node resection was performed in 57.6% (n = 67), 12 (18%) were positive. The complete resection rate assessed by surgeons was 57% with a median of 15 (0 to 28) resected pleural metastasis. Intrapleural chemotherapy was added for 19 (16%) pts. No mortality was reported 90 days after surgery procedure. Median follow-up was 36 months. Pleural recurrence was seen in 47 (72%) pts. Median disease-free survival (DFS) was 39 vs 16 months in resected vs not resected tumors ($p < 0.0001$), 5-years overall survival (OS) was 88 vs 66% ($p = 0.28$), respectively. Risk of relapse decreased by 60% with surgery (HR = 0.4, 95CI (0.25-0.62); $p < 0.0001$). **Conclusions:** The prevalence of MK IVa in our cohort was 6.2%. Surgery appears to be a safe and valid option for pts with MK IVa TET at diagnosis. Research Sponsor: None.

Clinicogenomic characterization of metastatic thymic epithelial tumors. *First Author: Fatemeh Ardeshir-Larijani, Indiana University, Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Thymic epithelial tumors (TET) are one of the rarest adult malignancies. Overall, patients have favorable survival outcomes, however a small subset develop metastatic disease. Genomic characterization of this very rare, clinically aggressive TET subset is lacking. Herein, we evaluated the clinical and genomic characteristics of metastatic TET (mTET) compared to a large cohort (n = 117) of primary TET (pTET) from The Cancer Genome Atlas (TCGA). **Methods:** From 2015 to 2020, 52 pts with mTET underwent clinical CLIA-based sequencing using either whole-exome (n = 35), panel-based testing (n = 13) and/or liquid biopsy (n = 22). The specimen was taken from a metastatic organ (n = 34) or relapsed primary mediastinal mass (n = 14); 4 pts had liquid bx only. Data on pTET was derived from the TCGA. Kaplan-Meier and log-rank test was used for assessment of PFS, OS. **Results:** The median age was 56 yrs in mTET (range 32-74) vs. 60 yrs (range 17-84) in TCGA data. The M/F (%) was 40/60 in mTET and 48/52 in TCGA, respectively. Of note, 13 mTET pts had other types of cancer prior or concurrent with TET diagnosis (4-breast, 2-bladder, 5-other) in which radiotherapy (n = 4) and/or chemotherapy (n = 3) was administered prior to TET diagnosis. In our cohort, 19 pts had stage IVA and 33 pts had stage IVB (most common metastatic site was liver in 17 pts). WHO histologic classification was: A = 1, A/B = 3, B1 = 4, B2 = 10, B3 = 12, TC = 18, TC with neuroendocrine feature = 3, and lymphoepithelial carcinoma = 1. WHO B3 and TC histologies were more common in our cohort of mTET than in the TCGA cohort (63% (33/52) vs. 17% (20/117), respectively). Pts with TC had worse mOS compare to thymoma (109m vs. 163m, HR = 2.78, P = 0.04). The most common genomic alteration in mTET was TP53 (n = 17, 33%) compared to 3% in TCGA. This was followed by CDKN2A (n = 5, 10%), PIK3CA (n = 4, 8%), CDKN2B (n = 3, 6%) and NF1 (n = 3, 6%). All TP53 missense mut functionality was analyzed with polyphen-2 software and 91.6% (22/24) had 98-100% damaging probability. 70% of pts that harbored TP53 muts were TC (41%) or B3 (29%) histology. Clinically actionable genomic alterations targetable with available or investigational agents (e.g. high TMB; gain-of-function mutations in PIK3CA, CDK4, and mTOR; loss-of-function mutations in NF1) were seen in 23% (12/52) of pts. **Conclusions:** Patients with mTET are associated with more aggressive WHO histology (B3 and TC). Greater frequency of TP53 mutations are observed in mTET compared to pTET. Clinically actionable genomic alterations are frequently seen in mTET suggesting value in the routine sequencing of these patients. Research Sponsor: None.

TPS8580 **Poster Session**

Phase 3 study of pembrolizumab with concurrent chemoradiation therapy followed by pembrolizumab with or without olaparib versus concurrent chemoradiation therapy followed by durvalumab in unresectable, locally advanced, stage III non-small cell lung cancer: KEYLYNK-012. *First Author: Salma K. Jabbour, Rutgers Cancer Institute of New Jersey, Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ*

Background: Pembrolizumab, an anti–PD-1 antibody is standard of care therapy for metastatic non–small-cell lung cancer (NSCLC) as monotherapy and in combination with chemotherapy. Durvalumab, an anti–PD-L1 antibody, is approved for unresectable, stage III NSCLC without disease progression following concurrent chemoradiation therapy (CCRT). Early trials of pembrolizumab in combination with chemoradiotherapy, either concurrently or as consolidation, showed acceptable tolerability and promising PFS in patients with unresectable stage III NSCLC. Early data suggest the combination of poly(ADP-ribose) polymerase (PARP) plus anti–PD-(L)1 inhibition can enhance treatment effects. KEYLYNK-012 (NCT04380636) is evaluating pembrolizumab plus CCRT followed by pembrolizumab with/without the PARP inhibitor olaparib vs CCRT followed by durvalumab in patients with unresectable, locally advanced, stage III NSCLC. **Methods:** This global phase 3, randomized, placebo- and active-controlled, double-blind study is enrolling patients aged ≥18 y with previously untreated, pathologically confirmed, stage IIIA–C NSCLC, an ECOG PS of 0 or 1, and a tumor sample available for PD-L1 evaluation. Patients are randomized 1:1:1 to CCRT (platinum-doublet chemotherapy [cisplatin plus pemetrexed or etoposide; or carboplatin plus paclitaxel] plus radiotherapy 60 Gy over 6 wks [cycles 2–3]) with pembrolizumab 200 mg Q3W (groups A and B) or CCRT alone (group C) for 3 cycles. This is followed by pembrolizumab 200 mg Q3W for 17 cycles plus placebo (group A) or olaparib 300 mg BID (group B); or durvalumab 10 mg/kg Q2W for 26 cycles (group C). Randomization is stratified by disease stage (IIIA vs IIIB/IIIC), tumor histology (squamous vs nonsquamous), PD-L1 tumor proportion score (≥50% vs < 50%) and region (East Asia vs North America/Western Europe/UK vs other). PFS (RECIST v1.1 by blinded independent central review [BICR]) and OS are dual primary endpoints. Secondary endpoints include ORR, duration of response, safety and tolerability, and quality-of-life outcomes. Tumor response will be evaluated per RECIST v1.1 by BICR after CCRT and at regular intervals throughout the study until disease progression, new cancer therapy, study withdrawal, or death. AEs will be graded by National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE) v5.0. Enrollment began July 6, 2020 and is ongoing at 204 sites in 24 countries. Clinical trial information: NCT04380636. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

A phase III clinical trial of adjuvant chemotherapy versus chemoimmunotherapy for stage IB-IIIA completely resected non-small cell lung cancer (NSCLC) patients nadim-adjuvant: New adjuvant trial of chemotherapy versus chemoimmunotherapy. *First Author: Virginia Calvo, Instituto Investigacion Sanitaria Puerta de Hierro-Segovia de Arana, Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain*

Background: The results of current studies are considered acceptable evidence to support the hypothesis of efficacy of the proposed combination of immunotherapy with chemotherapy (CT-IO) in patients with NSCLC stages Ib-IIIA candidates for adjuvant treatment. **Methods:** This is an open-label, randomised, two-arm, phase III, multi-centre clinical trial. Primary objective and endpoint: The primary objective is disease free survival (DFS) defined time from randomization to the earliest event defined as disease recurrence, any new lung cancer (even in the opposite lung), or death from any cause at any known point in time Sample size: 210 patients NSCLC stages Ib-IIIA (Experimental Arm (Adjuvant Chemotherapy-Inmunotherapy + maintenance adjuvant Inmunotherapy): 105 patients, Control Arm (Adjuvant Chemotherapy): 105 patients Treatment Patients randomised to the experimental arm will receive Nivolumab 360mg + Paclitaxel 200mg/m2 + Carboplatin AUC5 for 4 cycles every 21 days (+/- 3 days) as adjuvant treatment followed by maintenance adjuvant treatment for 6 cycles with Nivolumab 480 mg Q4W (+/- 3 days). Patients randomized to the control arm will receive Paclitaxel 200mg/m2 + Carboplatin AUC5 for 4 cycles every 21 days (+/- 3 days) followed by 2 observation visits. Total trial duration: 6.5 years, 3.5 years of recruitment, 1 year of adjuvant treatment or observation and 2 years of follow up. The start date was January 2021. The estimated primary completion date is June 2027. Clinical trial information: NCT04564157. Research Sponsor: BMS.

TPS8583 **Poster Session**

A randomized phase II trial of adjuvant pembrolizumab versus observation following curative resection for stage I non-small cell lung cancer (NSCLC) with primary tumors between 1-4 cm: Big Ten Cancer Research Consortium BTCRC-LUN18-153. *First Author: Greg Andrew Durm, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: There are approximately 35,000 cases of stage I lung cancer in the United States each year. While these patients have better 5-year overall survival (OS) rates than their counterparts with locally advanced and metastatic disease, there is still considerable room for improvement. Based on a recent publication validating the 8th edition of the TNM classification, the 5-year OS for node-negative pathologically-staged NSCLC between 1-4cm ranges from 73-86%, and recurrence rates for resected stage I NSCLC can range from 18-38%. Previous studies looking at adjuvant chemotherapy in this setting have shown no benefit for stage IA tumors, and the current standard of care is observation alone. Checkpoint blockade with PD-1/PD-L1 inhibitors has shown considerable activity in NSCLC including in metastatic disease, as consolidation in stage III disease after chemoradiation, and in studies evaluating neoadjuvant immunotherapy. Given this activity and their favorable safety profile, we designed a study of adjuvant PD-1 inhibition following resection in stage I NSCLC. **Methods:** This study is a randomized phase II multicenter trial of adjuvant Pembrolizumab versus observation alone following complete resection of stage I NSCLC with tumors between 1-4cm. The trial will enroll 368 patients randomized 1:1 to either Pembrolizumab 400mg IV every 6 weeks for up to 9 cycles or observation alone with scheduled CT scans and routine clinical follow-up. Stratification factors include PD-L1 ≥50% vs. < 50% and tumor size of 1-2cm vs. > 2-4cm. The lead site is Indiana University, and the trial will be conducted through the Big Ten Cancer Research Consortium. The primary endpoint is disease free survival (DFS), and secondary endpoints include OS, DFS at 1-, 2-, and 3-year time points, and toxicity. The trial opened to accrual at the lead site in May 2020, and there are currently 6 patients enrolled. Clinical trial information: NCT04317534. Research Sponsor: Merck.

TPS8584 **Poster Session**

Randomized phase III Trial of MEDI4736 (durvalumab) as concurrent and consolidative therapy or consolidative therapy alone for unresectable stage 3 NSCLC: A trial of the ECOG-ACRIN Cancer Research Group (EA5181). *First Author: John M. Varlotto, Edwards Comprehensive Cancer Center, Huntington, WV*

Background: Platinum-based concurrent chemoradiation(CRT) followed by one year of the human immunoglobulin G1 kappa (IgG1κ) monoclonal antibody, durvalumab, which blocks the interaction of PD-L1 with its receptors PD-1 and CD80, is the standard of care for locally advanced, unresectable non-small cell lung cancer (NSCLC). Early studies have noted the feasibility of concomitant administration of radiotherapy and immune checkpoint inhibition in NSCLC. EA5181 will evaluate the use of concomitant durvalumab with chemo-radiotherapy for locally advanced NSCLC. **Methods:** EA5181 is a randomized, multi-center, phase III study for patients with unresectable Stage III NSCLC comparing the efficacy of CRT with concomitant durvalumab to CRT, followed by one year of durvalumab. Eligibility criteria include: an ECOG PS of 0-1, adequate pulmonary function (FEV1 and DLCO both > 40%), no history of auto-immune disease and no past chemotherapy or RT for this lung cancer. Stratification factors include age, sex, stage, and planned concurrent chemotherapy type. Eligible patients with be randomized 1:1 to receive 60Gy RT (2Gy fractions) CRT and durvalumab (Arm A) or 60Gy CRT (Arm B). Investigators will be allowed to choose from three different chemotherapy options: cisplatin/etoposide q 28 days, Pemetrexed/cisplatin q 21 days, and weekly paclitaxel/Carboplatin. Arm A will use 750mg fixed of durvalumab (considered equivalent to 10mg/kg) on days 1, 11, and 21 of RT. Assuming no disease progression, patients in both arms will be followed by monthly (q28 days) fixed dose of 1500mg durvalumab for one year which will be given optimally within 14 days of radiation or when (non)hematologic toxicity is < Grade 2. The primary endpoint is overall survival. Secondary endpoints include progression-free survival, incidence of local/distant progression and toxicity. The target sample size is 660 patients, anticipated to recruit over 55 months, with follow up for an additional 42 months. This provides approximately 82% power if the true hazard ratio for overall survival was 0.75 or less, with 2-sided alpha of 0.05, and assuming a median survival of 42.5 months in the control arm. The study was activated on 04/09/20 and has currently accrued 90 patients on 02/03/21. Clinical trial information: NCT04092283. Research Sponsor: Astra Zeneca.

TPS8585 **Poster Session**

Thoracic radiotherapy PLUS durvalumab in elderly and/or frail NSCLC stage III patients unfit for chemotherapy: Employing optimized (hypofractionated) radiotherapy to foster durvalumab efficacy—The TRADE-hypo trial. *First Author: Farastuk Bozorgmehr, Thoraxklinik at University Hospital Heidelberg, Heidelberg, Germany*

Background: Non-small cell lung cancer (NSCLC) is the most common cause of cancer death worldwide highlighting the importance of improving current therapeutic options. In particular, elderly and frail patients are not only underrepresented in clinical trials, but also frequently do not receive standard treatment regimens due to comorbidities. For example, patients with unresectable stage III NSCLC who are unfit for chemotherapy (CHT) do not benefit from the recent seminal therapy algorithm change for this disease, i.e. consolidation therapy with the immune checkpoint inhibitor (ICI) durvalumab after combined radiochemotherapy (RChT). Instead, these patients are treated with radiotherapy only, raising the serious concern of undertreatment. This issue is addressed by the TRADE-hypo clinical trial that investigates a novel therapy option for NSCLC stage III patients not capable of receiving CHT. To this end, thoracic radiotherapy (TRT) is administered together with durvalumab, employing the synergism created by the combination of restoring anti-tumor immune response by the ICI with the induction of immunogenicity by irradiation. The latter effect has been suggested to be further boosted by hypofractionated radiotherapy, which could also be more practicable for the patient. Taken these considerations into account, the TRADE-hypo trial addresses safety and efficacy of durvalumab therapy combined with either conventional or hypofractionated TRT. **Methods:** The TRADE-hypo trial is a prospective, randomized, open-label, multicentric phase II trial. Eligible patients are diagnosed with unresectable stage III NSCLC and not capable of receiving sequential RChT due to high vulnerability as reflected by a poor performance status (ECOG 2 or ECOG1 and CCI$\geq$ 1) and/or high age ($\geq$ 70)]. Two treatment groups are evaluated: Both receive durvalumab (1,5000 mg, Q4W) for up to 12 months. In the CON-group this is combined with conventionally fractionated TRT (30 x 2 Gy), while in the HYPO-group patients are treated with hypofractionated TRT (20 x 2.75 Gy). In the HYPO-arm, a safety stop-and-go lead-in phase precedes full enrollment. Here, patients are closely monitored with regard to toxicity (i.e., pneumonitis grade $\geq$ 3 within 8 weeks after TRT) in small cohorts of 6. The primary objective of the trial is safety and tolerability. As a primary efficacy endpoint, the objective response rate after 3 months will be evaluated. Further endpoints are additional parameters of safety and efficacy, as well as the comprehensive collection of biomaterials to be analyzed regarding treatment-induced changes and potential novel biomarkers. As of February 10, 2021, 9 patients of planned 88 patients have been enrolled in the TRADE-hypo trial. Clinical trial information: NCT04351256. Research Sponsor: AstraZeneca.

TPS8586 **Poster Session**

DREAM3R: Durvalumab with chemotherapy as first-line treatment in advanced pleural mesothelioma—A phase 3 randomized trial. *First Author: Patrick M. Forde, Johns Hopkins University School of Medicine, Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Standard first line treatment for unresectable malignant pleural mesothelioma (MPM) is platinum-based chemotherapy with pemetrexed. Two recent, single-arm, phase 2 trials (DREAM1 and PrE05052) combining the PD-L1 inhibitor durvalumab and standard first line cisplatin and pemetrexed (CP) exceeded pre-specified criteria for proceeding to phase 3. DREAM3R aims to determine the effectiveness of adding durvalumab to first line CP chemotherapy in advanced MPM. **Methods:** Treatment-naïve patients with advanced MPM will be randomised (2:1) to EITHER durvalumab 1500 mg every 3 weeks plus doublet chemotherapy (cisplatin 75 mg/m2 and pemetrexed 500 mg/m2) every 3 weeks for 4-6 cycles, followed by durvalumab 1500 mg every 4 weeks until disease progression, unacceptable toxicity or patient withdrawal; OR doublet chemotherapy alone for 4-6 cycles, followed by observation. The target sample size is 480 patients (320 durvalumab, 160 control) recruited over 27 months, with follow up for an additional 24 months. This provides over 85% power if the true hazard ratio for overall survival is 0.70, with 2-sided alpha of 0.05, assuming a median survival of 15 months in the control group. Key inclusion criteria: MPM of any histological subtype; measurable disease as per RECIST 1.1 modified for mesothelioma (mRECIST 1.1) without prior radiotherapy to these sites; ECOG PS 0-1; and, adequate hematologic, renal, and liver function tests. Key exclusion criteria: prior systemic anticancer treatment for MPM; diagnosis based only on cytology or fine needle aspiration biopsy; contraindication to immunotherapy; and conditions requiring immunosuppressives or corticosteroids. Stratification: Age (18-70 years vs. $>$ 70), sex, histology (epithelioid vs. non-epithelioid), and region (USA vs. ANZ). The primary endpoint is overall survival. Secondary endpoints include progression-free survival; objective tumour response (by mRECIST 1.1 and iRECIST); adverse events; health-related quality of life; and healthcare resource use. Tertiary correlative objectives are to explore and validate potential prognostic and/or predictive biomarkers (including features identified in the DREAM and PrE0505 studies, PD-L1 expression, tumour mutation burden, nuanced genomic characteristics, and HLA subtypes) in tissue and serial blood samples. An imaging databank will be assembled for validation of radiological measures of response, and studies of possible radiomic biomarkers in mesothelioma. Clinical trial information: NCT04334759. and ACTRN 12620001199909. Research Sponsor: AstraZeneca.

TPS8587 **Poster Session**

KEYLYNK-013: A phase 3 study of pembrolizumab in combination with concurrent chemoradiation therapy followed by pembrolizumab with or without olaparib versus concurrent chemoradiation therapy in patients with newly diagnosed limited-stage SCLC. *First Author: Andreas Rimner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Concurrent chemoradiotherapy with etoposide and platinum (carboplatin/cisplatin) plus the anti–PD-1 antibody pembrolizumab (pembro) has shown antitumor activity and acceptable safety in patients with limited-stage small-cell lung cancer (LS-SCLC). The poly (ADP-ribose) polymerase (PARP) inhibitor, olaparib, has shown clinical activity in combination with checkpoint inhibitors in patients with SCLC. KEYLYNK-013 (NCT04624204) is a randomized, placebo-controlled, double-blind phase 3 trial of pembro plus concurrent chemoradiation therapy followed by pembro with or without olaparib in patients with newly diagnosed LS-SCLC. **Methods:** Eligible patients are those aged $\geq$18 years with previously untreated LS-SCLC, ECOG PS 0/1, and adequate pulmonary function. Patients are randomized 1:1:1 to receive pembro 200 mg Q3W (groups A and B) or pembro placebo (saline) Q3W (group C) during the chemoradiation phase. All patients also receive 4 cycles of chemotherapy (etoposide 100 mg/m^2 on days 1, 2, and 3 of each cycle and investigator's choice of carboplatin AUC 5 mg/mL/min or cisplatin 75 mg/m^2 on day 1 of each cycle) with definitive thoracic radiotherapy (total dose of 45 Gy in 30 fractions twice daily over 3 weeks or 66 Gy in 33 fractions once daily over 6.5 weeks starting on day 1 of cycle 2). After chemoradiation, prophylactic cranial irradiation is strongly recommended for patients with CR/PR or at investigator's discretion for patients with SD. Postchemoradiation patients receive pembro 400 mg Q6W plus olaparib placebo (group A), or pembro 400 mg Q6W plus olaparib 300 mg BID (group B), or pembro placebo plus olaparib placebo (group C) for 9 cycles/12 months. Randomization is stratified by ECOG PS (0 vs 1), SCLC stage (I/II vs III), radiation fractionation (twice vs once daily), and region (east Asia vs North America/western Europe/UK/Australia vs rest of world). Tumor imaging occurs at baseline, within 12 weeks of cycle 1 day 1, followed by Q9W to the end of year 2, Q12W in year 3, Q16W in year 4, every 6 months in year 5, and annually thereafter. Imaging is assessed per RECIST v1.1 by blinded independent central review. AEs are monitored from randomization to 30 days after cessation of study treatment (90 days for serious AEs) and graded per NCI-CTCAE v5.0. Health-related quality of life is assessed using EORTC-QLQ-C30 and QLQ-LC13. Primary endpoints are OS and PFS per RECIST v1.1 by blinded independent central review. OS and PFS are estimated by the Kaplan-Meier method. Between-group differences will be evaluated with stratified log-rank tests and Cox proportional hazard models with Efron's method of tie handling. Secondary endpoints include ORR, duration of response, safety, and patient-reported outcomes. The study began enrollment in December 2020. Clinical trial information: NCT04624204. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS8588 **Poster Session**

A phase I, open-label, dose-escalation trial of BI 764532, a DLL3/CD3 bispecific antibody, in patients (pts) with small cell lung carcinoma (SCLC) or other neuroendocrine neoplasms expressing DLL3. *First Author: Martin Wermke, Department of Thoracic Oncology, Carl-Gustav-Carus Dresden University Hospital, Dresden, Germany*

Background: First-line standard of care for pts with metastatic SCLC and neuroendocrine carcinoma (NEC) is platinum-based chemotherapy ± immunotherapy. While the addition of anti-PD1 antibodies has improved outcomes, nearly all pts relapse and prognosis is poor. There is a major unmet need for additional treatment (tx) options. BI 764532 is a delta-like ligand 3 (DLL3)/CD3 T cell engaging bispecific antibody. DLL3 is expressed on the cell surface of many SCLC and NEC tumors, but not on normal cells. In preclinical studies, BI 764532 induced cytotoxicity of DLL3-positive cells and showed anti-tumor activity in animal models. **Methods:** NCT04429087 is a first-in-human, open-label, dose-escalation trial of BI 764532 in adults with locally advanced/metastatic SCLC, large cell neuroendocrine lung carcinoma, NEC or small cell carcinoma of any other origin. Pts must have failed on or be ineligible for available standard therapies (including $\geq$1 line of platinum-based chemotherapy). Tumors must be positive for DLL3 expression (archived tissue/in-study fresh biopsy) according to central review. Pts must have $\geq$1 evaluable lesion (modified RECIST 1.1) outside of CNS and adequate liver, bone marrow and renal organ function. Main exclusion criteria: previous tx with T cell engagers or DLL3-targeted therapies; persistent toxicity from previous tx that has not resolved to $\leq$ CTCAE grade 1; immunodeficiency or receiving immunosuppressive therapy $\leq$7 days, prior anti-cancer therapy $\leq$3 wks/5 half-life periods or extensive field radiotherapy $\leq$2 wks of first dose of BI 764532. The main objective of phase Ia is to determine the maximum tolerated dose (MTD) or recommended dose for expansion of BI 764532, based on dose-limiting toxicities during the MTD evaluation period. Further objectives are to evaluate safety, tolerability, PK/PD and preliminary efficacy. The phase Ib objectives, endpoints and design will be specified after availability of phase Ia results. The trial will assess $\leq$3 dosing regimens: Regimen A (fixed iv dose once every 3 wks); Regimen B1 (fixed iv dose once every wk); Regimen B2 (step-in dose[s] followed by fixed-dose weekly doses; optional). Tx will continue until confirmed progressive disease, unacceptable toxicity, other withdrawal criteria or a maximum tx duration of 36 mos, whichever occurs first. For Phase Ia, ~160 pts will be screened and 110 pts accrued. As of Feb 2021, pts are being recruited and treated in early dose escalation cohorts. Clinical trial information: NCT04429087. Research Sponsor: Boehringer Ingelheim.

TPS8589 **Poster Session**

Trial in progress: A multicenter phase Ib/II study of pelcitoclax (APG-1252) in combination with paclitaxel in patients with relapsed/refractory small-cell lung cancer (R/R SCLC). *First Author: Angel Qin, University of Michigan, Ann Arbor, MI*

Background: Increased expression of BCL-2, BCL-xL, and MCL-1 allows certain tumors to evade apoptosis. Pelcitoclax is a novel, dual BCL-2/BCL-xL inhibitor with strong single-agent antitumor activity against tumor cells addicted to BCL-2, BCL-xL, and BCL-w, and exhibits even broader antitumor activity when administered with chemotherapy. Pelcitoclax reduces tumor growth in SCLC and other human cancer xenograft models, with manageable effects on platelet counts. Preliminary findings from the first-in-human study suggested promising antitumor activity and a favorable safety profile. **Methods:** This open-label study is evaluating the safety and preliminary efficacy of pelcitoclax combined with paclitaxel in adults with R/R SCLC that has progressed on or after initial treatment. Prior treatments may include platinum-based therapy (± thoracic radiation), immunotherapy, or chemotherapeutic agents other than paclitaxel. Eligible patients have an ECOG performance status of 0-2; adequate organ function; no known bleeding diathesis, immune thrombocytopenic purpura, autoimmune hemolytic anemia, serious gastrointestinal bleeding, or concomitant use of most anticoagulants; and no residual grade ≥ 2 adverse events from previous treatment. In the phase Ib study, the pelcitoclax maximum tolerated dose is being determined using a time-to-event continual reassessment method. In this phase, pelcitoclax is administered by IV infusion over 30 minutes on Days 1, 8, and 15 at dose levels of 80, 160, and 240 mg per week, with fixed-dose paclitaxel 80 mg/m^2 on Days 1 and 8 of a 21-day cycle. In addition to a baseline scan within 4 weeks before study entry, computed tomography will be performed every two cycles to evaluate antitumor response. Treatment will continue until disease progression, unacceptable toxicity, consent withdrawal, or administrative discontinuation. The primary endpoint of this phase includes dose-limiting toxicity by NCI CTCAE v5.0 over 21 days. After determination of the recommended phase II dose of pelcitoclax in the phase Ib study, the efficacy of pelcitoclax with paclitaxel will be determined in the phase II study using a Simon two-stage design, with overall response rate as the primary endpoint. Other study endpoints in the phase II study include pharmacokinetics of pelcitoclax with paclitaxel, as well as progression-free and overall survival. As of February 8, 2021, 15 of 58 patients had been enrolled. Internal study identifier APG1252SU101. Clinical trial information: NCT04210037. Research Sponsor: Ascentage Pharma Group Corp Limited (Hong Kong).

9000 **Oral Abstract Session**

First-line nivolumab (NIVO) plus ipilimumab (IPI) plus two cycles of chemotherapy (chemo) versus chemo alone (4 cycles) in patients with advanced non-small cell lung cancer (NSCLC): Two-year update from CheckMate 9LA.

First Author: Martin Reck, Airway Research Center North, German Center for Lung Research, LungClinic, Grosshansdorf, Germany

Background: In the randomized phase 3 CheckMate 9LA trial (NCT03215706), first-line NIVO + IPI combined with 2 cycles of chemo significantly improved overall survival (OS), progression-free survival (PFS), and objective response rate (ORR) vs chemo alone (4 cycles). Clinical benefit was observed regardless of programmed death ligand 1 (PD-L1) expression level and histology. Here we report data with 2 years' minimum follow-up from this study. **Methods:** Adult patients (pts) with stage IV / recurrent NSCLC, ECOG performance status ≤ 1, and no known sensitizing *EGFR/ALK* alterations were stratified by PD-L1 (< 1% vs ≥ 1%), sex, and histology (squamous vs non-squamous) and were randomized 1:1 to NIVO 360 mg Q3W + IPI 1 mg/kg Q6W + chemo (2 cycles; n = 361) or chemo alone (4 cycles; n = 358). Pts with non-squamous NSCLC in the chemo-alone arm could receive pemetrexed maintenance. The primary endpoint was OS. Secondary endpoints included PFS and ORR by blinded independent central review, and efficacy by different PD-L1 levels. Safety was exploratory. **Results:** At a minimum follow-up of 24.4 months for OS (database lock: Feb 18, 2021), pts treated with NIVO + IPI + chemo continued to derive OS benefit vs chemo, with a median OS of 15.8 months vs 11.0 months, respectively (HR, 0.72 [95% CI, 0.61–0.86]); 2-year OS rates were 38% vs 26%. Median PFS with NIVO + IPI + chemo vs chemo was 6.7 months vs 5.3 months (HR, 0.67 [95% CI, 0.56–0.79]); 8% and 37% of pts who had disease progression received subsequent immunotherapy, respectively. ORR was 38% with NIVO + IPI + chemo vs 25% with chemo. Similar clinical benefit with NIVO + IPI + chemo vs chemo was observed in all randomized pts and across the majority of subgroups, including by PD-L1 expression level (Table) or histology. Any grade and grade 3–4 treatment-related adverse events were reported in 92% and 48% of pts in the NIVO + IPI + chemo arm vs 88% and 38% in the chemo arm, respectively. **Conclusion:** With 2 years' minimum follow-up, first-line NIVO + IPI + chemo demonstrated durable survival and benefit versus chemo in pts with advanced NSCLC; no new safety signals were identified. Clinical trial information: NCT03215706. Research Sponsor: Bristol Myers Squibb.

9001 **Oral Abstract Session**

Outcomes of anti-PD-(L1) therapy in combination with chemotherapy versus immunotherapy (IO) alone for first-line (1L) treatment of advanced non-small cell lung cancer (NSCLC) with PD-L1 score 1-49%: FDA pooled analysis.

First Author: Oladimeji Akinboro, U.S. Food and Drug Administration, Silver Spring, MD

Background: IO + chemotherapy ± anti-angiogenics comprise FDA-approved 1L regimens for metastatic NSCLC, with IO-only therapy approved only for PD-L1-positive NSCLC. Patients with PD-L1 scores 1-49% have many therapeutic options, and little is known about how subgroups of patients experience benefit across treatment regimens. **Methods:** Data was pooled from 8 randomized controlled trials investigating anti-PD-(L)1 therapy as IO-only or in chemo-IO regimens for the 1L treatment of patients with advanced NSCLC. PD-L1 score was defined as the proportion of tumor cells stained by the assay, and analysis was conducted for patients whose tumors had PD-L1 score 1-49%. Tumor-infiltrating immune cell staining was not considered. OS and PFS were compared between chemo-IO and IO alone via a pooled analysis. Median survival times were estimated using Kaplan-Meier methods. Hazard ratios were estimated using Cox proportional hazards models stratified by trial and adjusted for age, sex, race, ECOG, histology and smoking status. **Results:** A total of 2108 patients with NSCLC and PD-L1 score 1-49% were identified for this analysis. Baseline characteristics were: 37% aged 65-74 years and 12% aged ≥75; 67% male; 79% white; 65% ECOG ≥ 1; and 85% smokers. Median follow-up was 12.1 months. This pooled analysis showed that patients receiving chemo-IO (N=639) had longer PFS and OS compared to patients treated with IO alone (N=529), with median PFS 7.7 vs 4.2 months (HR 0.60; 95% CI 0.48, 0.76) and median OS 21.4 vs 14.5 months (HR 0.68; 95% CI 0.52, 0.90). All results presented are considered exploratory and hypothesis generating. **Conclusions:** This exploratory pooled analysis suggests that chemo-IO may improve efficacy outcomes over IO alone in most subgroups of patients with advanced NSCLC with PD-L1 score 1-49%. Patients 75 and over experienced similar outcomes across therapeutic options. Research Sponsor: None.

Efficacy outcomes of Chemo-IO vs. IO alone by subgroup.

	Subgroup	N[1]	Median OS in months	OS HR[2] (95% CI)	Median PFS in months	PFS HR[2] (95% CI)
Age	<65	580	23.7 vs 16.1	0.63 (0.43, 0.92)	7.1 vs 4.0	0.55 (0.40, 0.76)
	65-74	443	22.5 vs 14.8	0.61 (0.38, 0.97)	9.5 vs 4.5	0.60 (0.40, 0.88)
	≥75	132	13.9 vs 10.3	0.95 (0.42, 2.14)	6.4 vs 4.9	0.85 (0.42, 1.71)
ECOG	0	415	25.2 vs 20.0	0.65 (0.38, 1.10)	9.6 vs 5.8	0.57 (0.38, 0.86)
	1+	751	16.8 vs 11.0	0.68 (0.50, 0.94)	7.0 vs 4.0	0.65 (0.49, 0.86)
Smoking	Never	160	28.2 vs 18.0	0.57 (0.22, 1.46)	8.1 vs 4.1	0.44 (0.21, 0.92)
	Ever	1005	20.8 vs 13.5	0.68 (0.51, 0.91)	7.6 vs 4.2	0.62 (0.49, 0.80)

9002 **Oral Abstract Session**

Pooled analyses of immune-related adverse events (irAEs) and efficacy from the phase 3 trials IMpower130, IMpower132, and IMpower150.

First Author: Mark A. Socinski, AdventHealth Cancer Institute, Orlando, FL

Background: PD-L1/PD-1 inhibitors have transformed the treatment (tx) of advanced NSCLC. Evidence suggests that the occurrence of irAEs with these agents may predict improved outcomes in cancers such as NSCLC. Atezolizumab (atezo; anti–PD-L1) has shown efficacy and tolerability in NSCLC and is currently approved in the 1L and 2L+ settings. The Ph 3 IMpower130, IMpower132 and IMpower150 trials evaluated atezo + chemo ± bevacizumab (bev) as 1L tx of NSCLC. We explore the association between irAEs and efficacy in these trials. **Methods:** Each trial enrolled tx-naive patients (pts) with nonsquamous stage IV NSCLC. Pts were randomized to: carboplatin (carbo) + *nab*-paclitaxel alone or with atezo in IMpower130; carbo or cisplatin alone or with atezo in IMpower132; atezo (A) + bev (B) + carbo + paclitaxel (CP), ACP or BCP in IMpower150. Data were pooled (data cutoffs: Mar 15 2018 [IMpower130]; May 22 2018 [IMpower132]; Sep 13 2019 [IMpower150]) and analyzed by tx (atezo-containing vs control) and irAE status. A time-dependent Cox model and landmark analyses at 1, 3, 6 and 12 mo were used to control for immortal bias. Study protocols required atezo tx interruption/discontinuation for grade (Gr) ≥3 irAEs. **Results:** 2503 pts were included in the analysis (atezo, n = 1577; control, n = 926). In both arms, baseline characteristics were generally balanced between pts with irAEs (atezo, n = 753; control, n = 289) and without irAEs (atezo, n = 824; control, n = 637). Any-Gr irAEs occurred in 48% (atezo) and 32% (control) of pts; Gr 3-5 irAEs occurred in 11% (atezo) and 5% (control). The most common irAEs (atezo vs control) were rash (28% vs 18%), hepatitis (lab abnormalities; 15% vs 10%) and hypothyroidism (12% vs 4%). Median time to onset of first irAE was 1.7 (atezo) vs 1.4 mo (control). OS HRs (95% CI) from the time-dependent Cox model between pts with vs without irAEs were 0.69 (0.60, 0.78) in the atezo arm and 0.82 (0.68, 0.99) in the control arm; after excluding rash (perceived as the least specific irAE), OS HRs (95% CI) were 0.75 (0.65, 0.87) and 0.90 (0.71, 1.12), respectively. OS landmark data are in the Table. **Conclusions:** In this exploratory pooled analysis, pts with irAEs had longer OS vs pts without irAEs in the atezo-containing and control arms per the time-dependent Cox model and landmark analyses; this trend remained for the atezo arm after excluding rash. Landmark analyses suggest that in the atezo arm, pts with Gr 1/2 irAEs had the longest OS and pts with Gr ≥3 irAEs had the shortest OS, potentially due to tx interruption/discontinuation. Clinical trial information: NCT02367781; NCT02657434; NCT02366143. Research Sponsor: F. Hoffmann-La Roche, Ltd.

Overall survival and exploratory subgroup analyses from the phase 2 CodeBreaK 100 trial evaluating sotorasib in pretreated *KRAS* p.G12C mutated non-small cell lung cancer.

First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Cambridgeshire, United Kingdom

Background: In the registrational phase 2 CodeBreaK 100 trial, sotorasib demonstrated an objective response rate (ORR) of 37.1% (95% CI: 28.6, 46.2) and a median progression-free survival (PFS) of 6.8 months (95% CI: 5.1, 8.2) in patients with pretreated *KRAS* p.G12C mutated non-small cell lung cancer (NSCLC). Tumor response was observed in patients bearing co-mutations in *STK11*, a driver of poor clinical outcomes with standard of care. Here, we report efficacy across an extended set of patient subgroups by key baseline characteristics and biomarkers. **Methods:** Sotorasib was given orally at 960 mg once daily to eligible patients who had advanced NSCLC harboring *KRAS* p.G12C and received prior standard therapies. Primary endpoint was ORR assessed by central review. Key secondary endpoints included PFS, overall survival, and safety. *KRAS* p.G12C mutant allele frequency (MAF) and tumor mutational burden (TMB) were analyzed by next-generation sequencing (NGS) using tissue samples. Mutational status of individual genes was determined by NGS using tissue and/or plasma samples. Correlations between response and *KRAS* p.G12C MAF, TMB, or co-mutations were analyzed in subsets of patients who had available respective results. Association between MAF and response was reported by odds ratio (95% CI), from a logistic regression with dependent variable of log odds of being a responder and an independent variable of MAF in a unit of 10%. **Results:** ORR across subgroups is presented in the Table. Response was independent of *KRAS* p.G12C MAF in the study population (odds ratio [95% CI]: 1.11 [0.88, 1.39]). OS remained immature. **Conclusions:** In the exploratory analyses of the phase 2 CodeBreaK 100 trial, the clinical benefit of sotorasib was observed across patient subgroups. Overall survival and updated exploratory analyses will be presented. Clinical trial information: NCT03600883. Research Sponsor: Amgen Inc.

9004 **Oral Abstract Session**

Biomarker tissue journey among patients (pts) with untreated metastatic non-small cell lung cancer (mNSCLC) in the U.S. Oncology Network community practices. *First Author: Nicholas J. Robert, Ontada, Irving, TX*

Background: Given the importance of molecular testing and targeted therapy for mNSCLC, the MYLUNG (Molecularly Informed Lung Cancer Treatment in a Community Cancer Network) consortium pragmatic study assessed real-world biomarker testing rates and turnaround times (TAT) within The US Oncology Network of over 1,000 providers across the United States. **Methods:** This was a retrospective observational chart review study of pts with mNSCLC initiating first-line (1L) systemic therapy between 04/01/2018 and 03/31/2020. iKnowMed electronic health records were used to examine timing of biomarker testing: before 1L therapy (cohort 1), after 1L therapy (cohort 2) or no testing (cohort 3). We assessed testing rates for ALK, BRAF, EGFR, ROS1, and PD-L1; use of full next-generation sequencing panel (NGS); time from mNSCLC diagnosis (dx) to 1L therapy; TAT from biomarker orders to results; and time from mNSCLC dx to test results. **Results:** We identified 3474 adults. Median age was 69 years (range 23-90), 51% female, 74% with adenocarcinoma and 76% with a documented ECOG performance status of 0 or 1. Testing rates are shown in table: 90% of pts had at least one biomarker test and 46% received all 5 biomarker tests. Changes in testing rates from 2018 to 2020 were 51% to 59% for BRAF, 71% to 71% for EGFR, 71% to 70% for ALK, 69% to 67% for ROS1, 82% to 84% for PD-L1, and 42% to 49% for pts tested for all 5 biomarkers. NGS testing increased from 33% to 44% ($p<0.0001$). The median (interquartile range [IQR]) time from mNSCLC dx to 1L therapy for all pts was 35 (22, 55) days. Median (IQR) TAT from biomarker testing orders to results ranged from 10 (6, 17) to 15 (10, 22) days for the individual biomarkers; and time from mNSCLC dx to biomarker results ranged from 14 (7, 26) to 21 (12, 36) days by biomarker. **Conclusions:** This real-world study showed that most pts received at least one biomarker test prior to 1L, but <50% received all 5 tests. NGS testing occurred in <50% of pts but increased over the periods examined. Median time from dx to 1L therapy was about 5 weeks and TAT from orders to results about 2 weeks. Analyses by histology and other trends will be reported. These data will be compared to the next phase of the MYLUNG study, which will evaluate contemporary ordering practices and TATs prospectively Research Sponsor: Amgen Inc.; Mirati Therapeutics, Inc.; Eli Lilly and Company.

9005 **Oral Abstract Session**

Racial disparities in biomarker testing and clinical trial enrollment in non-small cell lung cancer (NSCLC). *First Author: Debora S. Bruno, The MetroHealth System, Cleveland, OH*

Background: Cancer racial disparities may exist at many levels in the health care system, from screening to timely diagnosis and treatments received, as well as clinical trial enrollment. This study investigated differences in black versus white race among patients with NSCLC undergoing biomarker testing and clinical trial enrollment in the US. **Methods:** This retrospective observational study utilized the Flatiron Health database, which includes longitudinal data of patients with advanced/metastatic NSCLC. Patients were eligible if they had evidence of systemic therapy in the database from 1/1/2017 through 10/30/2020. Descriptive analyses summarized differences by race in biomarker testing and trial enrollment. Multivariable regression examined the relationship between these factors. **Results:** A total of 14,768 patients were eligible: 9,793 (66.3%) were white and 1,288 (8.7%) were black. 76.4% of white patients and 73.6% of black patients underwent at least one single molecular test or comprehensive genomic analysis ($p = 0.03$). Next-generation sequencing (NGS) was performed among 50.1% of white patients and 39.8% of black patients ($p < 0.0001$. Trial participation was observed among 3.9% of white and 1.9% of black patients ($p = 0.0002$). There was a statistically significant association between race (white vs black) and both biomarker testing (ever vs never) and trial participation (yes vs no) (both $p < 0.001$, unadjusted chi square). Differences in NGS testing, baseline biomarker testing, and race were retained as statistically significant ($p < 0.01$) in adjusted regression analyses. The receipt of first-line targeted therapy was comparable between white and black patients (10.2% and 9.2%, respectively, $p = 0.24$); however, this summary did not consider biomarker test results. First line use of pembrolizumab+carboplatin+pemetrexed was observed among 19.8% of white and 22.6% of black patients; carboplatin+paclitaxel was observed among 16.5% and 18.6%, and single-agent pembrolizumab was observed among 14.8% and 11.5%, respectively. **Conclusions:** The use of NGS-based testing, which is recommended by the National Comprehensive Cancer Network Clinical Guidelines in Oncology for patients with advanced/metastatic NSCLC, is the most notable disparity among black patients, with more than a 10 percentage-point difference in receipt of this testing versus white counterparts. This may in part contribute to the more than double the rate of participation in clinical trials observed among white patients, as many second line and beyond trials utilize molecular targets as inclusion criteria. While multiple factors are known to impact health care disparities, access to and receipt of appropriate biomarker testing may be an attenable goal in order to ensure equal access to quality care. Research Sponsor: None.

9006 **Oral Abstract Session**

Amivantamab in combination with lazertinib for the treatment of osimertinib-relapsed, chemotherapy-naïve EGFR mutant (EGFRm) non-small cell lung cancer (NSCLC) and potential biomarkers for response. *First Author: Joshua Bauml, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: Preliminary efficacy was observed with the combination of amivantamab, an EGFR-MET bispecific antibody, and lazertinib, a 3rd-generation tyrosine kinase inhibitor, in both treatment-naïve and osimertinib (osi)-relapsed patients (pts) with EGFRm NSCLC (Cho *Ann Oncol* 2020;31:S813). We present updated results of the combination in osi-relapsed pts, including an analysis of potential biomarkers of response. **Methods:** Pts with EGFR exon 19 deletion or L858R mutation NSCLC, who had progressed on osi without intervening chemotherapy, were enrolled in the combination cohort of the ongoing CHRYSALIS study (NCT02609776). With pre-treatment tumor biopsies and ctDNA collected prospectively, pts received the combination dose of 1050/1400 mg amivantamab + 240 mg lazertinib to assess safety and efficacy in the osi-relapsed population. Response was assessed by investigator per RECIST v1.1. Osi-resistance mutations or amplifications in EGFR/MET identified by next-generation sequencing (NGS) in either ctDNA or tumor biopsy (biomarker-positive [pos]), were evaluated for enriching response. Immunohistochemistry (IHC) staining for EGFR and MET expression was also explored as a potential biomarker for response. **Results:** Of the 45 osi-relapsed pts, 36% (95% CI, 22–51) had a confirmed response (1 complete response and 15 partial responses [PR]). At a median follow-up of 8.2 mo (1.0–11.8), 20/45 pts (44%) remain on treatment. With 11/16 pts (69%) continuing in response (2.6–9.6+ mo), median duration of response has not been reached (NR). The median progression-free survival (mPFS) was 4.9 mo (95% CI, 3.7–8.3). In total, 44/45 pts were evaluable by ctDNA and 29/45 by tumor NGS. Genetic testing identified 17 biomarker-pos pts, of whom 8 (47%) responded. Of the remaining 28 pts, 8 (29%) responded. Among these 28 pts, 18 had unknown mechanisms of osi-resistance (8 PR) and 10 had non-EGFR/MET mechanisms of resistance identified (none responded). The mPFS (95% CI) for biomarker-pos and remaining pts was 6.7 mo (3.4–NR) and 4.1 mo (1.4–9.5), respectively. Adequate tissue was available for 20 pts to perform IHC testing for EGFR and MET–9/10 (90%) IHC high (combined EGFR+MET H score>400) pts responded to treatment, while 1/10 IHC low pts responded to treatment. **Conclusions:** Treatment with the combination of amivantamab and lazertinib yielded responses in 36% of chemotherapy-naïve pts who progressed on osi. Among these pts, genetic EGFR and MET-based biomarkers of resistance identified a subgroup of pts more likely to respond to amivantamab and lazertinib, although additional pts lacking identified resistance markers also responded. An IHC-based approach may identify pts most likely to benefit from the combination regimen, but further investigation is warranted. Clinical trial information: NCT02609776. Research Sponsor: Janssen R&D, LLC.

9007 **Oral Abstract Session**

Efficacy and safety of patritumab deruxtecan (HER3-DXd) in EGFR inhibitor-resistant, *EGFR*-mutated (*EGFR*m) non-small cell lung cancer (NSCLC). *First Author: Pasi A. Janne, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients (pts) with advanced *EGFR*m NSCLC have limited treatment options after failure of EGFR TKI and platinum-based chemotherapy (PBC). HER3-DXd is an antibody drug conjugate consisting of a fully human monoclonal antibody to HER3 attached to a topoisomerase I inhibitor payload via a tetrapeptide-based cleavable linker. We previously presented efficacy/safety data (median follow-up, 5.4 mo) from an ongoing study of HER3-DXd in *EGFR*m NSCLC after failure of EGFR TKI therapy. We now present extended follow-up of pts receiving the recommended dose for expansion (5.6 mg/kg IV Q3W). **Methods**: This Ph 1 dose-escalation/expansion study included pts with locally advanced or metastatic *EGFR*m NSCLC with prior EGFR TKI therapy (NCT03260491). Pts with stable brain metastases (BM) were allowed. The primary endpoint was confirmed ORR by blinded independent central review (BICR) per RECIST v1.1; secondary endpoints included DOR, PFS and safety. **Results**: At data cutoff (Sept 24, 2020), 57 pts were treated with HER3-DXd 5.6 mg/kg IV Q3W; median follow-up, 10.2 mo (range, 5.2-19.9 mo). Median number of prior anticancer regimens was 4 (range, 1-10). 100% had prior EGFR TKI (86% prior osimertinib [OSI]) and 91% had prior PBC. 47% had a history of BM. Median treatment duration was 5.5 mo (range, 0.7-18.6 mo); treatment was ongoing in 18 pts (32%). Confirmed ORR by BICR was 39% (22/57; 95% CI, 26.0%-52.4%; 1 CR, 21 PR, 19 SD) with 14/22 responses occurring within 3 mo of starting HER3-DXd. DCR was 72% (95% CI, 58.5%-83.0%). Median DOR was 6.9 mo (95% CI, 3.1 mo-NE), and median PFS was 8.2 mo (95% CI, 4.4-8.3 mo). Antitumor activity was observed across diverse mechanisms of EGFR TKI resistance, including those not directly related to HER3 (*EGFR* C797S, MET or HER2 amp, and BRAF fusion). Among pts with prior PBC, ORR was 37% (19/52; 95% CI, 23.6%-51.0%); in pts with prior OSI and PBC, ORR was 39% (17/44; 95% CI, 24.4%-54.5%). Among 43 pts evaluable for HER3 expression, nearly all expressed HER3; median membrane H-score by IHC was 180 (range, 2-280). Median H-score (range; N) was 195 (92-268; 15) in pts with CR/PR, 180 (4-280; 15) with SD, 126.5 (2-251; 6) with PD, and 180 (36-180; 7) in pts unevaluable for best overall response. The most common grade ≥3 adverse events (AEs) were thrombocytopenia (30%), neutropenia (19%), and fatigue (14%). Drug-related interstitial lung disease by central adjudication occurred in 4 pts (7%; 1 grade ≥3 [2%]; no grade 5). 6/57 pts (11%) had AEs associated with treatment discontinuation (none were due to thrombocytopenia). **Conclusions**: HER3-DXd 5.6 mg/kg IV Q3W demonstrated antitumor activity across various EGFR TKI resistance mechanisms in heavily pretreated metastatic/locally advanced *EGFR*m NSCLC. The safety profile was consistent with previous reports. A Ph 2 study of HER3-DXd in pts with *EGFR*m NSCLC after failure of EGFR TKI and PBC has been initiated (NCT04619004). Clinical trial information: NCT03260491. Research Sponsor: Daiichi Sankyo, Inc.

9008 **Oral Abstract Session**

Preliminary safety and efficacy results from phase 1 studies of DZD9008 in NSCLC patients with EGFR Exon20 insertion mutations. *First Author: James Chih-Hsin Yang, National Taiwan University Hospital and National Taiwan University Cancer Center, Taipei, Taiwan*

Background: There are no approved targeted therapies for EGFR exon20 insertion (exon20ins) mutant NSCLC. DZD9008 is a rationally designed selective, irreversible EGFR exon20ins inhibitor being studied in two ongoing phase 1/2 studies (NCT03974022 and CTR20192097). **Methods:** The objectives of the studies are to assess the safety, tolerability, pharmacokinetics, and preliminary anti-tumor efficacy of DZD9008 in NSCLC with EGFR or HER2 mutations. Both studies include dose escalation and expansion cohorts. Pooled analysis is applied to define recommended phase 2 dose (RP2D). **Results:** Between July 9, 2019 and February 5, 2021, 97 NSCLC patients with EGFR or HER2 mutations were dosed with DZD9008 (dose range: 50 mg to 400 mg, once daily). M/F: 44/53; 59 with EGFR exon 20. DZD9008 was well tolerated up to 400 mg (MTD) once daily. The DLTs were diarrhea and cardiac arrhythmia. The most common TEAEs were diarrhea (grade 3, 5.2%) and skin rash (grade 3, 1%). DZD9008 showed approximately dose-proportional PK, with a half-life of around 50 hours. Fifty-six patients with $>$ 16 different EGFR exon20ins mutations had $>$ 1 post-treatment efficacy assessment. Prior therapies: median 2 (range 1 - 10), prior chemotherapy 92.9% (52/); prior TKI 44.6% (25/56) including 1 patient had poziotinib treatment; 42.9% (24/56) with brain metastasis. Partial response was observed at $\geq$ 100 mg dose levels. At the RP2D dose of 300 mg once daily, the objective response rate was 48.4% (15/31), and disease control rate (DCR) was 90.3% (28/31). Responses were observed in 2 patients with prior JNJ-61186372 treatment. Anti-tumor activity was observed across different EGFR exon20ins mutation subtypes. By data cut-off, the median treatment duration was 100 days (range 1 – 422). The longest duration of response was over 6 months, and 18 out of 22 responders are still responding. **Conclusions:** DZD9008 showed a favorable safety profile and promising anti-tumor efficacy in pre-treated NSCLC with EGFR exon20ins mutations. The updated data will be presented at the meeting. DZD9008 is currently in phase II clinical development (NCT03974022). Clinical trial information: NCT03974022. Research Sponsor: Dizal pharma.

Overall survival with circulating tumor DNA-guided therapy in advanced non-small cell lung cancer. *First Author: Justin Jee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The effectiveness of circulating tumor DNA (ctDNA) at matching patients to life prolonging therapy has been studied mostly in small cohorts with limited follow up. The prognostic value of ctDNA alterations, particularly those absent on tissue, is also unclear. To address these questions, we studied survival outcomes in a prospective cohort of patients (N = 1002) with non-small cell lung cancer (NSCLC). **Methods:** Adults with metastatic or recurrent NSCLC were eligible if they had no known driver mutation or a known driver with progression following targeted therapy. Patients were enrolled at Memorial Sloan Kettering Cancer Center (New York, NY) starting October 21, 2016; analysis here is from a snapshot November 1, 2020. All patients had ctDNA sequenced via the Resolution ctDx Lung platform. To reduce inclusion of incidental germline mutations, we excluded non-functionally significant mutations with an allele frequency 35-65% that were present in gnomAD. Patients could also receive, at their provider's discretion, tissue sequencing with MSK-IMPACT, which filters germline and clonal hematopoietic (CH) mutations with matched white blood cell sequencing. We performed survival analyses using Cox proportional hazards models from time of diagnosis of advanced disease to death, left truncating at time of study entry. **Results:** Of 1002 patients, 348 (35%) were treated with targeted therapy; in 181 of these (52%) the targetable alteration was detected in ctDNA. Patients treated with targeted therapy had prolonged survival whether matched by tissue-based methods (HR 0.39, 95%CI 0.30-0.51) or ctDNA (HR 0.47, 95%CI 0.37-0.61). These benefits persisted across multiple subgroups. ctDNA alterations themselves were associated with worse survival (HR 2.2, 95%CI 1.8-2.8), in a manner that scaled with allele fraction and burden. Of 401 patients with time-matched tissue sampling, 62 (15%) had ctDNA alterations that were absent on IMPACT ("unique" ctDNA alterations). Three such patients had unique ctDNA EGFR T790M mutations leading to changes in therapy. However, unique ctDNA alterations were generally associated with worse survival than no ctDNA alterations (HR 2.5, 95%CI 1.7-3.7) and even tissue-matched ctDNA alterations (HR 1.7, 95%CI 1.1-2.4). Of 98 unique ctDNA mutations, 48 (49%) were detectable in tissue at subthreshold levels, 12 (12%) were filtered by IMPACT as CH or germline, and 38 mutations (39%) were absent even at subthreshold levels. ctDNA alteration burden correlated with radiographic disease extent. In multivariate models with radiographic disease extent and other clinical variables, ctDNA alterations were the strongest independent predictor of worse survival. **Conclusions:** Our results show that ctDNA may match patients to life-prolonging targeted therapy and have prognostic importance. ctDNA may provide data about a patient's cancer missed by spatially restricted tissue sequencing. Clinical trial information: NCT01775072. Research Sponsor: U.S. National Institutes of Health.

Concordance of tissue- and plasma-derived genomic profiling in CheckMate 9LA, using the FoundationOne CDx and GuardantOMNI assays. *First Author: Jonathan F. Baden, Bristol Myers Squibb, Princeton, NJ*

Background: Blood-based profiling of genomic features including tumor mutational burden (TMB) has generally demonstrated positive correlations with tissue-derived assessments from paired tumor samples. However, both technical and biological factors contributing to discordance between these measurements and underlying sequence alterations need further investigation for the successful adoption of noninvasive tumor profiling. We explored the genomic landscape, including the association between tissue TMB (tTMB) and blood TMB (bTMB), in samples from patients with stage IV non-small cell lung cancer (NSCLC) enrolled in CheckMate 9LA (NCT03215706), a phase 3, randomized clinical trial of nivolumab + ipilimumab in combination with 2 cycles of chemotherapy (chemo) vs 4 cycles of chemo as first-line treatment for NSCLC. **Methods:** Tissue- (FoundationOne CDx [F1CDx]) and blood-based (GuardantOMNI [OMNI]) genomic data obtained from both treatment arms were utilized for our retrospective analysis of genomic variants and complex biomarkers, including tTMB and bTMB. In total, 692 tissue and 646 plasma samples were analyzed. **Results:** Following the established criteria for the validated F1CDx and OMNI platforms, 464 tissue and 537 plasma samples passed quality control, resulting in ascertainment levels of 67% for tTMB and 83% for bTMB. Across 344 paired tissue and plasma samples, tTMB and bTMB scores were found to be moderately correlated (Spearman's $r = 0.56$; $P < 0.001$); median tTMB score was 7.7 mutations per megabase (mut/Mb) and median bTMB score was 13.5 mut/Mb. For the prespecified cutoffs of 10 mut/Mb for tTMB and 16 mut/Mb for bTMB, the positive, negative, and overall percentage agreements between assays were 65%, 79%, and 73%, respectively. Interestingly, 2 discordant sample pairs had considerably higher bTMB than tTMB (76.1 vs 3.8 and 172.6 vs 5.0 mut/Mb for bTMB and tTMB, respectively) and both had high microsatellite instability from blood-based assessments. OMNI and F1CDx data from 477 patients were evaluable for the analysis of short sequence variants (single nucleotide variations and indels). OMNI detected 4557 variants, F1CDx detected 4620, and 2903 (46% of total reported variants) were detected by both assays. **Conclusions:** In CheckMate 9LA, data from paired samples revealed the complementary nature of TMB assessments from tissue and blood and suggest that both approaches may have the potential to identify genomic alterations that may be useful in the management of patients with NSCLC. Further interrogation of the biological and analytical factors affecting tumor- and blood-derived genomic profiling is warranted to support their implementation in clinical settings. Clinical trial information: NCT03215706. Research Sponsor: Bristol Myers Squibb.

9011 **Clinical Science Symposium**

Early circulating tumor (ct) DNA dynamics and efficacy of lorlatinib: Analysis from the CROWN study. *First Author: Ross A. Soo, National University Cancer Institute, Singapore, Singapore*

Background: Lorlatinib, a third-generation ALK tyrosine kinase inhibitor, significantly improved progression-free survival (PFS) and overall/intracranial responses vs crizotinib in patients (pts) with previously untreated *ALK*-positive advanced non-small cell lung cancer (NSCLC) in the ongoing randomized Phase 3 CROWN study (NCT03052608). To identify whether additional molecular biomarker analysis correlated with efficacy, we evaluated early ctDNA dynamics compared with clinical outcomes. **Methods:** Plasma samples were prospectively collected at screening (SC), week 4 (cycle 2, day 1 [C2D1]), week 24 (C7D1), and end of treatment for ctDNA analysis. ctDNA was analyzed using Guardant360CDx (Guardant Health, Inc., Redwood City, CA, USA). Mean variant allele fraction (VAF) of *ALK* alterations (fusions and/or mutations) and overall detected alterations at each time point and longitudinal mean change (dVAF) as (VAF_{C2D1}) – (VAF_{SC}) were calculated; dVAF $<$0 indicated decreased ctDNA at week 4. Objective tumor response and PFS were evaluated according to dVAF. These analyses were repeated vs ctDNA results at week 24. Additional correlation analyses between depth of molecular response and/or ctDNA clearance and clinical outcomes are ongoing. **Results:** Paired samples were available at SC and week 4 from 232 of 255 pts included in the ctDNA analysis: 118/130 (90.8%) in the lorlatinib arm and 114/125 (91.2%) in the crizotinib arm. *ALK* alterations were detected in 122/232 (52.6%) pts at SC (62/118 [52.5%] from the lorlatinib arm) but only 19/232 (8.2%) at week 4 (8/118 [6.8%] from the lorlatinib arm). Mean VAF of *ALK* alterations at week 4 was significantly decreased compared with SC in both treatment arms (lorlatinib -1.54, crizotinib -1.25; both $P<0.0001$; $P=0.4239$ between arms). In the lorlatinib arm, mean VAF at week 4 was significantly decreased compared with SC in pts with a complete or partial response (dVAF -1.53; n=47; $P<0.0001$), or stable disease (dVAF -1.37; n=12; $P=0.0304$). Similar results were observed in the crizotinib arm. In pts with dVAF $<$0 for *ALK* alterations, mean percent change from screening in tumor size was -40.8% with lorlatinib (n=59) and -38.7% with crizotinib (n=58). Only 2 pts had dVAF $\geq$0, both from the crizotinib arm. Median PFS for pts with dVAF $<$0 for *ALK* alterations was not reached in the lorlatinib arm (n=62), and was 7.4 months (95% CI, 7.2–9.3) in the crizotinib arm (n=58). Similar response and PFS data were observed in the analysis of dVAF for *ALK* alterations at week 24. **Conclusions:** Early ctDNA dynamics may predict lorlatinib efficacy in pts with previously untreated *ALK*-positive NSCLC. The magnitude of reduction in ctDNA at 4 weeks may be associated with better responses and potentially longer PFS. These findings further support the utility of dynamic ctDNA monitoring in *ALK*-positive NSCLC. Reference: Shaw AT, et al. N Engl J Med. 2020;383:2018-2029. Clinical trial information: NCT03052608. 9012 **Clinical Science Symposium**

*MET*ex14 ctDNA dynamics & resistance mechanisms detected in liquid biopsy (LBx) from patients (pts) with *MET*ex14 skipping NSCLC treated with tepotinib. *First Author: Paul K. Paik, Memorial Sloan-Kettering Cancer Center, New York, NY*

Background: In the VISION study, tepotinib in *MET*ex14 skipping NSCLC pts (Cohort A) had robust and durable clinical activity. Serial LBx samples were collected for biomarker analyses, presented herein. **Methods:** LBx samples taken at baseline (BL), Week 6, 12, & end of treatment (EOT) were analyzed using Guardant360® CDx (73 genes). Investigator (INV)-assessed clinical outcome was evaluated per BL biomarker profiles and by molecular response (MR; defined as > 75% depletion from BL in *MET*ex14 variant allele frequency [VAF] ctDNA confirmed in 2 consecutive samples) or molecular progression (MP; defined as VAF increase > 0 from BL). Acquired resistance was investigated in EOT samples, following progression per INV. **Results:** LBx pts (n = 99) had a median age of 72 yrs (range 49–88), 53% were male, 44% never smokers, 85% had adenocarcinoma. INV ORR was 53% (95% CI 42, 63); ORR in 1L (n = 44) was 59% (43, 74) & ≥2L (n = 55) was 47% (33, 61). 94 pts had BL biomarker profiles; these were similar in 1L and ≥2L pts, except *EGFR* amp: 1/43 1L [2%] vs 8/51 ≥2L [16%]. Outcomes were not impacted by location/type of *MET*ex14 alteration. 1 pt with concomitant *MET* M1250T mutation had a PFS of 17.3 months. A trend towards better efficacy was seen in pts with concomitant *MET* amp (6 responses in 8 pts). Response to tepotinib occurred both in pts with wt or mutant *TP53*; however, there was a trend for longer mDOR in pts with wt *TP53* (18.3 [95% CI 9.7, ne] vs 7.1 [4.7, 10.9] months) and mPFS (9.5 [6.7, 19.7] vs 5.1 [2.8, 6.9] months). Concomitant oncogenic mutations were rare, with no responses in 3 pts with *KRAS*, *NRAS* alterations and 3 responses in 5 pts with *PI3K/AKT* alterations. 65 pts had 2 consecutive on-treatment samples: 46 (71%) had confirmed MR, 5 (8%) had confirmed MP, 14 (22%) had no change in VAF or lacked confirmation. MR was associated with clinical response and MP was associated with no response/short PFS (Table). 52 pts with progression had EOT LBx samples. Emerging *MET* resistance mutations (Y1230H/C & D1228H/N) occurred in 7 (13%) pts, all responders and 5/7 had PFS > 10 months. Analyses on non-MET-driven resistance mechanisms will be presented. **Conclusions:** LBx biomarker analysis from the largest on-treatment data set for a MET inhibitor in *MET*ex14 skipping NSCLC, showed that ctDNA depletion in *MET*ex14 VAF is associated with improved clinical response in pts treated with tepotinib. This suggests serial LBx could help us to monitor response/non-response, understand resistance, and guide trials that test escalation/de-escalation strategies to improve outcomes and maximize QOL. Clinical trial information: NCT02864992. Research Sponsor: Merck KGaA, Darmstadt, Germany.

Randomized phase III trial of aumolertinib (HS-10296, Au) versus gefitinib (G) as first-line treatment of patients with locally advanced or metastatic non-small cell lung cancer (NSCLC) and EGFR exon 19 del or L858R mutations (EGFRm). *First Author: Shun Lu, Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai JiaoTong University, Shanghai, China*

Background: Au is a novel, irreversible epidermal growth factor receptor tyrosine kinase inhibitor (EGFR TKI) with favorable pharmacologic properties that selectively inhibits both EGFR sensitizing and resistance mutations. Au has been approved in China for treatment of patients (pts) with EGFR mutant NSCLC with EGFR T790M upon progression of disease on previous EGFR TKIs (Proc. AACR 2020, Abstract CT190). This Phase III trial assessed the efficacy and safety of Au versus G as initial treatment of patients with advanced NSCLC with EGFRm. **Methods:** Pts with previously untreated metastatic or locally advanced NSCLC and EGFR exon 19 deletion or L858R were randomly assigned in a 1:1 ratio to receive either Au (110 mg once daily) or G (250 mg once daily). The primary endpoint was progression-free survival (PFS) by RECIST v1.1 per investigator assessment. At 262 PFS events, the study had 90% power to detect a PFS HR = 0.67. Secondary endpoints included overall survival (OS), objective response rate (ORR), duration of response (DoR) and safety. **Results:** Between Nov 30, 2018 and Sept 6, 2019, 429 patients across 53 sites in China were enrolled and randomized. Pt. characteristics were well-balanced. At the planned final event-driven PFS analysis, Au significantly prolonged PFS (median 19.3 vs 9.9 months, HR 0.46, p-value <0.0001). DoR was also significantly prolonged with Au. Median OS has not been reached. Efficacy and relevant safety results are summarized in Table. Despite a significantly longer duration of treatment (median 463 vs 254 days), Au was associated with a lower incidence of rash, diarrhea, AST/ALT increase, and treatment related serious adverse events (SAEs) (4.2% vs 11.2%). Au was associated with more frequent events of CPK increased, platelet count decreased, and neutrophil count decreased, which were predominantly low grade. **Conclusions:** Au significantly prolonged PFS and DoR compared to G as first-line therapy in pts with advanced NSCLC with EGFRm. Au demonstrated a favorable safety profile, especially regarding toxicities mediated by wild-type EGFR. These results establish Au as a promising option for advanced NSCLC with EGFRm. Clinical trial information: NCT03849768. Research Sponsor: Hansoh Pharma.

Mobocertinib (TAK-788) in *EGFR* exon 20 insertion (ex20ins)+ metastatic NSCLC (mNSCLC): Additional results from platinum-pretreated patients (pts) and EXCLAIM cohort of phase 1/2 study. *First Author: Suresh S. Ramalingam, Emory University, Atlanta, GA*

Background: No approved targeted therapies are available for *EGFR* ex20ins+ mNSCLC. Mobocertinib, a first-in-class, potent, oral TKI targeting *EGFR* ex20ins mutations, has Breakthrough Therapy Designation in the US and China for post-platinum-based chemotherapy pts with *EGFR* ex20ins+ mNSCLC. **Methods:** This 3-part, open-label, multicenter study (NCT02716116) has dose-escalation/expansion and extension (EXCLAIM) cohorts. Pts with *EGFR* ex20ins+ mNSCLC, ECOG status 0–1, and ≥1 prior line of therapy for locally advanced/metastatic disease received mobocertinib 160 mg QD. Primary endpoint was confirmed objective response rate (ORR; RECIST v1.1) assessed by independent review committee (IRC). We present additional efficacy and safety data for 114 platinum-pretreated pts (PPP) and 96 pts from EXCLAIM safety cohort. **Results:** Results are from Nov 1, 2020, data cutoff. Among PPP pts (n=114; median age 60 y [27–84 y]), 66% were female, 60% were Asian, and 59% had ≥2 prior systemic anticancer lines. Confirmed ORR per IRC was 28%, including 1 complete response (CR); disease control rate (DCR) was 78% [95% CI: 69–85]; median duration of response (DOR) was 17.5 mo (Table). In EXCLAIM (n=96; median age 59 y [27–80 y]), 65% were female, 69% were Asian, and 49% had ≥2 prior lines. Confirmed ORR per IRC was 25%, with 1 CR; DCR was 76% [95% CI: 66–84]; median DOR was not reached (Table). In EXCLAIM, baseline brain metastases were present in 33/96 pts (34%); the first site of disease progression by IRC was the brain in 40% of all pts and 73% of pts with baseline brain metastases. Confirmed responses were seen in all prespecified subgroups in PPP and EXCLAIM. Efficacy by *EGFR* ex20ins mutation variant will be presented. Treatment-related adverse events (TRAEs; >20%) in PPP were diarrhea (91%), rash (45%), paronychia (38%), decreased appetite (35%), nausea (34%), dry skin (31%), vomiting (30%), increased blood creatinine (25%), stomatitis (24%), and pruritus (21%); the only grade ≥3 TRAE in ≥5% was diarrhea (22%). AEs leading to discontinuation in >2% were diarrhea (4%) and nausea (4%). A similar safety profile was observed in EXCLAIM. **Conclusions:** Mobocertinib demonstrated clinically meaningful benefit for pts with *EGFR* ex20ins+ mNSCLC in PPP and EXCLAIM cohorts, with a manageable safety profile.Clinical trial information: NCT02716116. Research Sponsor: Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

9015 **Poster Discussion Session**

Combination of trastuzumab, pertuzumab and docetaxel in patients with advanced non-small cell lung cancer (NSCLC) harboring HER2 mutation: Final results from the IFCT-1703 R2D2 trial. *First Author: Julien Mazieres, Thoracic Oncology Department, CHU Toulouse–Hôpital Larrey, Toulouse, France*

Background: Human epidermal growth factor receptor 2 (*HER2)* exon 20 insertions and mutations are oncogenic drivers found in 1-2% of NSCLC. However, there are no approved therapies for these patients. Many studies suggest that the use of HER2 inhibitors developed for breast cancer patients might be of interest in this setting. The aim of this trial was to prospectively evaluate the interest of a combination of two antibodies against HER2 (trastuzumab and pertuzumab) with docetaxel. **Methods:** IFCT-1703 R2D2 trial is a multicenter, non-randomized phase 2 study with a two-stage design, a power of 90% and an alpha risk at 5% (one-sided). *HER2* mutational status was assessed locally in certified molecular genetic centers. Main other inclusion criteria were advanced NSCLC, progression after ≥ 1 platinum-based chemotherapy, asymptomatic brain metastases, left ventricular ejection fraction (LVEF) ≥ 50%, and PS 0-2. Patients were treated every 3 weeks with pertuzumab at a loading dose of 840 mg, and 420 mg thereafter; plus trastuzumab at a loading dose of 8 mg/kg and 6 mg/kg thereafter; and docetaxel at 75 mg/m^2. Treatment was given until toxicity or disease progression. The primary outcome was overall response rate (ORR). Other endpoints included duration of response, progression-free survival and safety. NCT number: NCT03845270. **Results:** From May 2019 to October 2020, 45 patients were enrolled in 17 centers and received study treatment. Median age was 64.5 years (range 31–84), 72% females, 35% smokers, 100% non-squamous histology and 15% with ECOG PS 2. 31.1% patients had brain metastases. PD-L1 was expressed ≥ 1% and ≥ 50% in 36% and 7% of the patients, respectively. No other oncogene driver was found associated with HER2 exon 20 mutation. With a median follow-up of 12 months, 44 (98%) patients were evaluable for the primary endpoint. Overall response rate was 29% (n = 13), stable disease 56% (n = 26). Median PFS was 6.8 months (95% CI[4.0-8.5]). Median duration of treatment in patients with confirmed response (n = 13) was 10 months (95% CI[2.7-14.9]). At the time of data cut-off, 15 patients (33%) were still under treatment. Grade 3/4 treatment-related adverse events (AEs) were observed in 64% of patients. No patient experienced treatment discontinuation because of toxicity. One sudden death was possibly related to treatment. Most frequent grade ≥ 3 AEs were neutropenia (33%), diarrhea (13%) and anaemia (9%). Grade 1/2 dyspnea was observed in 3 (6.7%) patients. No ILD were reported. Variation LVEF was -1.72% on average (min: -18 %; max: 10 %). **Conclusions:** The triplet trastuzumab, pertuzumab and docetaxel is feasible and active in *HER2* pretreated advanced NSCLC. These results confirm the activity of *HER2* antibodies-based strategy which should be considered in these patients. Clinical trial information: NCT03845270. Research Sponsor: Intergroupe Francophone de Cancerologie Thoracique, Pharmaceutical/Biotech Company.

9016 **Poster Discussion Session**

Nivolumab (NIVO) plus ipilimumab (IPI) versus chemotherapy (chemo) as first-line (1L) treatment for advanced non-small cell lung cancer (NSCLC): 4-year update from CheckMate 227. *First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, CNIO-H12o Lung Cancer Clinical Research Unit, Universidad Complutense & CiberOnc, Madrid, Spain*

Background: 1L NIVO + IPI was shown to provide durable long-term overall survival (OS) benefit vs chemo regardless of tumor programmed death ligand 1 (PD-L1) expression in patients (pts) with advanced NSCLC in CheckMate 227 Part 1 (NCT02477826); 3-year OS rates were 33% vs 22% in pts with PD-L1 ≥ 1% (HR, 0.79 [95% CI, 0.67–0.93]) and 34% vs 15% in pts with PD-L1 < 1% (HR, 0.64 [95% CI, 0.51–0.81]). Here we report updated results from the study with 4 years' minimum follow-up. **Methods:** Adults with previously untreated stage IV / recurrent NSCLC, no known *EGFR*/*ALK* alterations, and ECOG performance status ≤ 1 were enrolled; pts were stratified by squamous (SQ) and non-squamous (NSQ) histology. Pts with PD-L1 ≥ 1% (n = 1189) were randomized 1:1:1 to receive NIVO (3 mg/kg Q2W) + IPI (1 mg/kg Q6W), NIVO alone (240 mg Q2W), or chemo. Pts with PD-L1 < 1% (n = 550) were randomized 1:1:1 to receive NIVO + IPI, NIVO (360 mg Q3W) + chemo, or chemo. OS with NIVO + IPI vs chemo in pts with PD-L1 ≥ 1% was the primary endpoint. **Results:** With minimum follow-up of 49.4 months (database lock, Feb 18, 2021), pts were at least 2 years beyond the protocol-specified end of immunotherapy treatment. Pts with PD-L1 ≥ 1% continued to show durable benefit with NIVO + IPI vs chemo (HR, 0.76 [95% CI, 0.65–0.90]); 4-year OS rates were 29% (NIVO + IPI), 21% (NIVO), and 18% (chemo). At 4 years, 14% (NIVO + IPI), 10% (NIVO), and 4% (chemo) remained progression free. Among responders, 34%, 30%, and 7% remained in response, respectively. In an exploratory analysis in pts with PD-L1 ≥ 50%, 4-year OS rates were 37% (NIVO + IPI), 26% (NIVO), and 20% (chemo). In pts with PD-L1 < 1%, OS HR for NIVO + IPI vs chemo was 0.64 (95% CI, 0.51–0.81); 4-year OS rates were 24% (NIVO + IPI), 13% (NIVO + chemo) and 10% (chemo). At 4 years, 12% (NIVO + IPI), 7% (NIVO + chemo), and 0% (chemo) remained progression free. Among responders, 31%, 13%, and 0% remained in response, respectively. Among pts who progressed on NIVO + IPI vs chemo, 7% vs 40% (PD-L1 ≥ 1%), and 9% vs 33% (PD-L1 < 1%), received subsequent immunotherapy. Benefit with NIVO + IPI vs chemo was observed for both SQ and NSQ histology (Table). With long-term follow-up, no new safety signals were identified. **Conclusions:** With 4 years' minimum follow-up, 1L NIVO + IPI continued to provide durable, long-term OS benefit vs chemo in pts with advanced NSCLC regardless of PD-L1 expression or histology. Clinical trial information: NCT02477826. Research Sponsor: Bristol Myers Squibb and Ono Pharmaceutical.

Effect of antibiotic therapy on immunotherapy outcomes for non-small cell lung cancer: Analysis from the Veterans Health Administration Database. *First Author: William A. Stokes, Emory University School of Medicine, Atlanta, GA*

Background: Dysregulation of the gut microbiota induced by antibiotic therapy (Abx) may alter the anticancer immune response. Multiple small studies have associated Abx use with inferior immune checkpoint inhibitor (ICI) efficacy in patients with non-small cell lung cancer (NSCLC). We aimed to study the impact of Abx in a larger population of NSCLC patients treated with ICI within the Veterans Health Administration. **Methods:** We conducted a nested cohort study of Veterans who were diagnosed with NSCLC between 2010 & 2018 and treated with ICI. Two exposures to Abx were specified and separately analyzed: prior Abx (pAbx) was defined as receipt of an Abx prescription within 30 days prior to initiation of ICI, and concurrent Abx (cAbx) was defined as receipt of an Abx prescription within 60 days following ICI initiation. A landmark analysis of 2 months from ICI start was applied to the cAbx analysis to exclude any Veterans with an OS event before that time point. OS was measured from start of ICI using Cox proportional hazard multivariate analyses (MVA). **Results:** 3,634 Veterans received ICI, mostly nivolumab (59.3%) or pembrolizumab (35.1%). Their median age was 69, and a plurality had male gender (97.0%), white race (73.0%), comorbidity count ≥1 (60.4%), adenocarcinoma (47.8%), and stage IV disease at diagnosis (40.9%). Of the 762 (21.0%) Veterans prescribed pAbx, beta-lactams, quinolones, and macrolides were the most common classes. These patients had shorter OS than those without pAbx (median 7 versus 10 months). Receipt of pAbx was also associated with lower OS on MVA (HR 1.31, $p<0.01$). In the propensity-matched cohort analysis, Veterans receiving pAbx had lower OS (HR 1.27, $p<0.01$) (Table top). For the cAbx analysis, 3,223 Veterans survived to the 2-month landmark, of whom 970 (30.1%) received cAbx. These Veterans had shorter OS than those without cAbx (median 7 versus 10 months). Lower OS with cAbx was also observed both on Cox MVA (HR 1.33, $p<0.01$) and in the matched cohort (HR 1.32, $p<0.01$) (Table bottom). **Conclusions:** In the largest analysis to date of Abx use in NSCLC patients receiving ICI, receipt of Abx within either 30 days before or 60 days after start of ICI was associated with lower OS. These findings suggest Abx therapy may have a detrimental effect on immunotherapy outcomes. Research Sponsor: Morningside Center for Innovative and Affordable Medicine, Emory Woodruff Health Sciences Center, Other Government Agency.

9018 **Poster Discussion Session**

Association of a very high tumor mutational load with increased CD8+ and PD-1+ T-cell infiltration and improved clinical outcomes to PD-(L)1 blockade across different PD-L1 expression levels in non-small cell lung cancer. *First Author: Biagio Ricciuti, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Although high TMB correlates with improved outcomes to immune checkpoint inhibitors (ICI) in patients (pts) with non-small cell lung cancer (NSCLC), an optimal TMB cutoff to discriminate cancers most likely to respond to ICI has not been identified. Whether TMB impacts outcomes to ICI in different PD-L1 levels subgroups is also unclear. **Methods:** Unbiased recursive partitioning (URP) was used to identify an optimal TMB cutoff for objective response rate (ORR) in two independent cohorts of pts with NSCLC treated with ICI at DFCI and MSKCC. TCGA was interrogated to find differences in tumor immune cell subsets according to the TMB cutoff identified. Multiplexed immunofluorescence (IF) for CD8, PD-1, PD-L1, Foxp3, and CK7 was also performed on NSCLC samples at the DFCI. **Results:** In the DFCI (N=686) and MSKCC (N=672) cohorts, URP found an optimal TMB cutoff for ORR at 19 mutations/megabase (mut/Mb), corresponding to the ~90th percentile in each cohort. Median progression-free (PFS) and overall survival (OS) were significantly longer in NSCLCs with TMB ≥19 mut/Mb vs <19 mut/Mb, in both cohorts (Table). After harmonizing TMB between DFCI OncoPanel and MSK-IMPACT NGS platforms, URP confirmed an optimal TMB cutoff for ORR at the 90th percentile in the combined cohort, which also associated with longer PFS/OS to ICI (Table). A TMB ≥90th percentile correlated with longer PFS/OS to ICI among NSCLCs with PD-L1 levels ≥50% and 1-49%, and longer PFS among those with PD-L1 <1% (Table). Cell subset transcriptome analysis from the TCGA showed higher proportions of CD8+ T cells (P=0.02) and M1 macrophages (P<0.01) among NSCLCs with a TMB ≥ vs <90th percentile. IF confirmed increased CD8+, CD8+ PD1+ T-cell infiltration (P<0.01), and increased CD8+/Foxp3+ ratio in NSCLC with very high TMB **Conclusions:** A very high TMB is associated with better outcomes to ICI and a distinct immunophenotype in NSCLC. Rational integration of TMB and PD-L1 expression may identify NSCLCs most likely to respond to ICI. Research Sponsor: None.

Intestinal *Akkermansia muciniphila* predicts overall survival in advanced non-small cell lung cancer patients treated with anti-PD-1 antibodies: Results a phase II study. *First Author: Lisa Derosa, Department of Cancer Medicine, Gustave Roussy Cancer Campus, Paris-Sud University, Francepartment of Cancer Medicine, Gustave Roussy Cancer Campus, Paris-Sud University, Villejuif, France*

Background: The gut microbiome, most specifically centered on one of the most prevalent anaerobic bacterium *Akkermansia muciniphila (Akk),* has emerged as a potential hallmark of clinical benefit to ICI. The goal of this study was to validate the prognostic significance of *Akk* in advanced NSCLC patients amenable to ICI. **Methods:** The multicentric prospective observational study enrolled patients with advanced NSCLC amenable to single agent ICI in first and second line. Stool sample was collected at study entry. Primary end-point was investigator-assessed objective response rate (ORR). We considered that a meaningful clinical difference would correlate to a 10% ORR increase in the Akk-Pos group compared to the Akk-Neg group. At least 292 patients equally divided each in each group would be required for a power at 80% and a two-sided alpha level of 5%. **Results:** From Dec 2015 to Nov 2019, a total of 409 patients were screened and 311 patients enrolled across 12 academic centers in France and Canada. Median age was 64yr, 32% were female, 77% had non-squamous NSCLC and PD-L1 was ≥1% in 70% of the 213 assessable samples. *Akk* was detectable in 158 (51%) and absent in 153 (49%) patients. Baseline characteristics were well balanced between the two groups. When considering Akk-Pos *vs* Akk-Neg groups the primary endpoint ORR was 27% and 17% respectively ($p = 0.04$). Rates of partial response, stable disease and progressive disease (PD) were 62%, 50% and 46% respectively in the Akk-Pos group compared to 38%, 50% and 54% in the Akk-Neg group ($p = 0.04$). Moreover, 57% of patients were still alive after 12 months in the Akk-Pos group *vs* 43% in the Akk-Neg group ($p = 0.04$). Microbiome profiling demonstrated that Akk-Pos group was associated with increase bacterial diversity and enrichment of *Ruminococcus, Alistipes* and *Eubacterium.* When considering the variations of the relative abundance of *Akk* within the Akk-Pos group, we obtained a large interval ranging from 0.0022% up to 64.78% with a 75th percentile at 4.42%. The relative abundance of *Akk* within > 0% to < 4.42% range in stools at diagnosis was associated with increased ORR, overall survival (OS) in multivariate analysis, independent of PD-L1 expression and ECOG. This sub-group was associated with more inflamed tumors with upregulation of CD3e, *Ifng*TH1 and Vcam-1. Conversely, patients with overrepresentation of *Akk* > 4.42% experienced more PD and shorter OS. Antibiotic use was associated with a shift in favor of Gammaproteobacteria, enrichment of *Akk* (> 4.42%) and shorter OS. **Conclusions:** We validated the prognostic role of *Akk* in patients with NSCLC. Stratification based on *Akk* relative abundance represents a more accurate independent predictor than the binary modality. Our study provides the rationale to develop microbiome-based approach to study gut dysbiosis in routine clinical oncology care. Clinical trial information: NCT04567446. Research Sponsor: Torino Lumiere.

Capmatinib in *MET* exon 14-mutated, advanced NSCLC: Updated results from the GEOMETRY mono-1 study. *First Author: Juergen Wolf, Department of Internal Medicine, Center for Integrated Oncology, University Hospital of Cologne, Cologne, Germany*

Background: Capmatinib, a selective MET inhibitor, is approved in the USA and Japan for the treatment of patients (pts) with *MET* exon 14 skipping mutation (*MET*ex14) advanced non-small-cell lung cancer (NSCLC) based on the multi-cohort phase II GEOMETRY mono-1 study. This is the first report on expansion Cohort 7 in first line (1L) *MET*ex14 NSCLC pts, with updates to previously reported results (Wolf et al, *NEJM* 2020) for *MET*ex14 pts. **Methods:** In GEOMETRY mono-1, pts were assigned to cohorts based on previous lines of therapy and *MET* status (*MET*ex14 or *MET* amplification). This efficacy analysis includes patients with *MET*ex14 NSCLC who were treatment-naive (Cohort 5b and 7) and those who had previously received 1L or 2L of therapy (expansion Cohort 6 and Cohort 4) for their advanced disease (data cutoff: Sep 18, 2020). Evaluated outcomes included overall response rate (ORR), duration of response (DOR), and progression-free survival (PFS), all by BIRC; and overall survival (OS). The safety analysis includes all patients enrolled. **Results:** In total, 160 pts with *MET*ex14 who received capmatinib 400 mg BID were analyzed. ORR of 65.6% (95% CI 46.8-81.4) for the treatment-naive expansion Cohort 7 was in line with that previously reported for Cohort 5b (Table). Though Cohort 7 data are still immature, median PFS was 10.8 mo (95% CI 6.87-not estimable [NE]). Mature median OS was 20.8 mo (95% CI 12.4-NE) in Cohort 5b and 13.6 mo (95% CI 8.6-22.2) in Cohort 4. Median OS for Cohorts 6 and 7 and DOR for Cohort 7 are not yet reached. The safety profile remained unchanged across all study cohorts (N = 373): 98.4% of pts reported AEs (68.6% Grade [G] 3/4) regardless of causality and 16.1% reported AEs leading to discontinuation (10.5% G3/4). The most common AEs (≥20% all G) were peripheral edema (54.2%), nausea (45.0%), vomiting (28.2%), increased blood creatinine (26.5%), dyspnea (23.3%), fatigue (22.3%), and decreased appetite (21.2%). **Conclusions:** Results of Cohort 7 confirm those previously reported for Cohort 5b showing higher efficacy of capmatinib when used as 1L in *MET*ex14 NSCLC pts. A clinically meaningful median OS of 20.8 mo in 1L (Cohort 5b) and of 13.6 mo in relapse (Cohort 4) was also observed and, together with the continued manageable toxicity profile, the data support capmatinib as a valuable targeted treatment option for *MET*ex14 NSCLC pts. Clinical trial information: NCT02414139. Research Sponsor: Novartis Pharmaceuticals.

9021 **Poster Discussion Session**

Tepotinib in patients (pts) with advanced non-small cell lung cancer (NSCLC) with *MET* amplification (*MET*amp). *First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *MET*amp is an oncogenic driver occurring in 1–5% of NSCLCs that confers a poor prognosis and lacks approved targeted therapies. Tepotinib, a highly selective MET inhibitor, provided durable response in NSCLC with *MET* exon 14 (*MET*ex14) skipping in Cohort A of the Phase II VISION trial (NCT02864992). VISION Cohort B evaluated tepotinib in pts with advanced NSCLC and *MET*amp, as detected by a convenient and minimally invasive liquid biopsy assay, in the absence of *MET*ex14 skipping. **Methods:** Pts with locally advanced or metastatic NSCLC, Eastern Cooperative Oncology Group performance status (ECOG PS) 0–1, 0–2 prior lines of therapy, *EGFR*/*ALK* wild-type status, no *MET*ex14 skipping, and *MET*amp by liquid biopsy (Guardant360®; *MET* gene copy number ≥2.5) received oral tepotinib 500 mg QD (450 mg active moiety). The primary endpoint was objective response (RECIST v1.1) by independent review committee (IRC). Secondary endpoints included duration of response (DOR), progression-free survival (PFS) and safety. The data cut-off was July 1, 2020. **Results:** Among 24 enrolled pts, median age was 63.4 years (range: 38–73), 21 pts (88%) were male, 21 (88%) had ECOG PS 1 and 21 (88%) were smokers. Tepotinib was given to 7 pts (29%) in first line (1L), 10 pts (42%) in second line (2L) and 7 pts (29%) in third line (3L). As of November 2020, treatment was ongoing for > 1 year in 5 pts (1L, n = 2; 2L, n = 2; 3L, n = 1). Objective response rate (ORR) by IRC was 42% (10/24 pts) overall, 71% (5/7 pts) in 1L, 30% (3/10 pts) in 2L and 29% (2/7 pts) in 3L (Table). Median DOR by IRC was not estimable (NE; 95% confidence interval [CI]: 2.8 months–NE). Investigator-assessed outcomes were similar. Five pts (20.8%) discontinued due to adverse events (AEs), which were considered unrelated to tepotinib. Treatment-related AEs were reported in 16 pts (67%; Grade 3/4, 7 pts [29%]) and included peripheral edema (9 pts [38%]; Grade 3/4, 2 pts [8%]), generalized edema (4 pts [17%]; Grade 3/4, 2 pts [8%]) and constipation (4 pts [17%]; Grade 3/4, 0 pts). **Conclusions:** In the first study of a MET inhibitor in NSCLC with *MET*amp prospectively detected by liquid biopsy, tepotinib showed high and clinically meaningful activity, especially in 1L, and was generally well tolerated. Tepotinib warrants further evaluation in NSCLC with *MET*amp. Clinical trial information: NCT02864992. Research Sponsor: Merck KGaA, Darmstadt, Germany.

9022 **Poster Discussion Session**

Final OS analysis from the phase III j-alex study of alectinib (ALC) versus crizotinib (CRZ) in Japanese ALK-inhibitor naïve *ALK*-positive non-small cell lung cancer (*ALK*+ NSCLC). *First Author: Hiroshige Yoshioka, Department of Thoracic Oncology, Kansai Medical University Hospital, Osaka, Japan*

Background: The primary analysis of the J-ALEX (JapicCTI-132316) study for the ALK-inhibitor naïve *ALK*+ NSCLC demonstrated superior progression-free survival (PFS) in Japanese patients randomized to the ALC, compared with those assigned in the CRZ (HR 0.34, 99.7% CI 0.17–0.71, stratified log-rank p<0·0001) by the Independent Review Facility (IRF) (Hida et al., Lancet 2017). The final PFS and 2nd overall survival (OS) interim analysis (IA) data were subsequently reported (Nakagawa et al., Lung cancer 2020). Here, we report the final OS data. **Methods:** *ALK*+ NSCLC (by IHC and FISH or RT-PCR) patients were randomized 1:1 either to receive ALC (Japanese approved dose 300 mg BID, n = 103) or CRZ (250 mg BID, n = 104). Stratification factors included ECOG PS, treatment line, and clinical stage. The primary endpoint was PFS according to the blinded IRF. Secondary endpoints included OS, objective response rate, and safety. **Results:** After a median follow-up of 68.6 months in the ALC arm and 68.0 months in the CRZ arm, death events occurred in 40.8% and 39.4% in the ALC and the CRZ arms, respectively. Five-year survival rates for patients in the ALC and CRZ arm were 60.85% and 64.11%, respectively. The final OS HR was 1.03 (95%CI 0.67-1.58), however, median OS was not reached in either arm. Of note, patients in the CRZ arm tended to have their treatment switched earlier than those in the ALC arm (median time to treatment-switch: 12.3 months vs. NE). Most of the patients (78.8%) in the CRZ arm received ALC as a 1st subsequent therapy, whereas only 10.7% of patients in the ALC arm received CRZ. **Conclusions:** In this final J-ALEX OS analysis, prolongation of OS in the ALC arm was not observed compared to the CRZ arm. However, OS result may be substantially confounded since 78.8% of the patients in the CRZ arm received ALC as initial, subsequent therapy. Clinical trial information: 132316. Research Sponsor: Chugai pharmaceutical.

9023 **Poster Discussion Session**

Clinicogenomic real-world data analysis of patients (pts) with *KRAS G12C*-mutant advanced non-small cell lung cancer (aNSCLC) from the natural history cohort of the Blood First Assay Screening Trial (BFAST). *First Author: Rafal Dziadziuszko, Department of Oncology and Radiotherapy, Medical University of Gdańsk, Gdańsk, Poland*

Background: BFAST (NCT03178552) is a global, multicohort trial of targeted therapies or cancer immunotherapy (CIT) in treatment (tx)-naive aNSCLC. Pts are screened for the study using comprehensive blood-based next-generation sequencing (NGS). In the BFAST natural history cohort, data were collected for pts who received tx or care outside the study's interventional cohorts. Here, we analyzed the subset of pts whose tumors have *KRAS G12C* mutations (mut). **Methods:** Pts eligible for blood-based NGS screening had unresectable aNSCLC, ECOG PS 0-2 and no prior systemic tx for aNSCLC. Pts without tissue samples were eligible. Key genomic and molecular features, including bTMB, PD-L1 and ctDNA concentration; cancer tx; tx response and survival data were collected and analyzed in an exploratory analysis. **Results:** In the full BFAST screening population through December 2020 (N = 5917), 23% of pts had tumors with any *KRAS* mut; 9% were *KRASG12C*. Pts were enrolled in the natural history cohort from October 2018 to October 2020 (n = 1017); 63 pts had tumors with *KRAS G12C* mut. Median age was 68 y, 59% were male, 86% had ECOG PS 0-1 and 84% had non-squamous histology. Co-mut in *TP53* (60%) and *STK11* and/or *KEAP1* (25%) were detected; 8% of pts had bTMB ≥16. High PD-L1 expression per local testing was reported in 32% of pts; 38% were not tested. Among pts with 1L tx (n = 50), 50%, 28% and 20% received chemo, CIT or CIT + chemo, respectively, with real-world response rates (CR/PR per physician assessment) of 20%, 29% and 30%, respectively. Of the 13 pts (21%) without documented 1L tx, 7 died ≤3 mo from enrollment. Median OS was 14 mo overall, with differences found between key genomic subsets (Table). **Conclusions:** BFAST is the first study to identify *KRAS G12C* mut using blood-based NGS and describe the natural history, clinical characteristics and genomic landscape of this pt subset. Up to 21% of pts may not receive 1L tx. Pts with *TP53* co-mut appear to have favorable outcomes, while those with *STK11* and/or *KEAP1* co-mut appear to have inferior outcomes vs pts without these mut. The lack of PD-L1 testing in many pts indicates a lack of tissue for comprehensive tissue testing, highlighting a potential benefit of blood-based detection of biomarkers, including *KRASG12C*. Clinical trial information: NCT03178552. Research Sponsor: F. Hoffmann-La Roche, Ltd.

A phase II study of rucaparib in patients with high genomic LOH and/or BRCA 1/2 mutated stage IV non-small cell lung cancer (Lung-MAP Sub-Study, S1900A). *First Author: Jonathan W. Riess, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: While prior studies have shown robust efficacy leading to FDA approval of PARP inhibitors (PARPi) in BRCA-associated cancers, data in NSCLC are much less clear. S1900A, a LUNG-MAP substudy, evaluated the PARPi rucaparib in advanced stage NSCLC harboring BRCA1/2 mutations or genomic loss of heterozygosity (LOH) as a phenotypic marker of homologous recombination deficiency (HRD). **Methods:** Eligible patients (pts) were required to have a deleterious mutation in BRCA1/BRCA2 and/or high (≥21%) genomic LOH. Key eligibility criteria: advanced NSCLC patients (pts) with progression on or after platinum based chemotherapy and/or PD-(L)1 antibody and progressed on most recent line of systemic therapy, a Zubrod performance status of 0-1, adequate organ function, no ≥ grade 3 hypercholesterolemia, no previous PARPi exposure and no systemic therapy within 21 days of registration. Pts stratified by histology into two cohorts (squamous [sq] and non-squamous/mixed histology [nsq]). With 40 eligible pts per cohort, the design had 91% power to rule out an ORR of 15% if the true ORR was at least 35% at the 1-sided 5% level. A planned interim analysis on the first 20 pts evaluable for response per cohort required ≥ 3 responses to proceed to full enrollment. **Results:** 64 pts enrolled (27 sq cohort; 37 nsq cohort) of whom 59 are eligible. Median age 65.7 yrs; M/F 33/26 (56/44%); 98% of the pts received at least 1 prior line of treatment for stage IV disease. Biomarker selection included 36 pts (61%) LOH only, 4 pts (7%) BRCA1 only, 11 pts (19%) BRCA2 only, 4 pts (7%) BRCA1 + LOH high and 4 pts (7%) BRCA2 + LOH high. Both cohorts were closed for futility with insufficient responses in the interim analysis populations. In the full study, 4 responses (3 nsq/1 sq) were reported. ORR was 7% (95% CI: 0-13) (9% nsq/4% sq) and DCR was 62% (95% CI: 50-75) (62% nsq/64% sq); 3 of the 4 responders harbored BRCA1/2 mutations and 1 of 4 high LOH; ORR in BRCA1/2+ pts 3/23 (13%). Median PFS was 3.2 months (95% CI: 1.6-4.6) in nsq cohort and 2.9 months (95% CI 1.6-6.2) in sq cohort. Median OS was 7.8 months in nsq cohort and 7.9 months in sq cohort. The most frequent grade ≥3 adverse events were anemia (22%), lymphopenia (8%), fatigue (8%) and transaminitis (5%). **Conclusions:** S1900A failed to show the requisite level of efficacy for rucaparib in advanced NSCLC pts with high genomic LOH and/or a BRCA1/2 mutation. There were no new safety signals and hematologic toxicities were the most frequent adverse events. Genomic LOH as a phenotypic marker of HRD does not predict sufficient activity of rucaparib in NSCLC. These results stand in contrast to the high level of efficacy of PARPi in patients with BRCA-associated or high LOH cancers of other tumor types. Underlying biologic differences in the genomic characteristics of these cancers vs. NSCLC may be responsible. Studies examining this premise are ongoing. (NCT03845296). Clinical trial information: NCT03845296. Research Sponsor: U.S. National Institutes of Health.

Anti PD-(L)1 in KRAS mutant advanced nsclcs: A meta-analysis of randomized controlled trials. *First Author: Thierry Landre, UCOG-HUPSSD-APHP, Paris, France*

Background: KRAS comprise the most frequently found oncogene driver mutation in non-small cell lung cancer (NSCLC), accounting for 20-25% of these patients. Single-agent Anti PD-(L)1 clinical efficacy against KRAS mutant NSCLC is a topic of debate. **Methods:** This meta-analysis examined randomized-trial data comparing first-or second line Anti PD-(L)1 +/- chemotherapy (CT) vs CT alone for KRAS mutant advanced NSCLCs. Outcome measures included overall survival (OS) and progression-free survival (PFS). Analyses were computed using the Cochrane method of collaboration for meta-analyses, with Review Manager software (RevMan version 5.3; Oxford, UK). **Results:** We analyzed 3 trials in first line (IMPOWER-150, KEYNOTE-189 and KEYNOTE-042), as well as 3 trials in second line (OAK, POPLAR and CHECKMATE-057) including 1313 NSCLCs (386 KRAS mutant and 927 KRAS wild-type tumor). Anti PD-(L)1 +/- CT was significantly associated (hazard ratio [95% confidence interval]) with prolonged OS (0.59 [0.49-0.72]; $p < 0.00001$) and PFS (0.58 [0.43-0.78]; $p = 0.0003$) compared to CT alone in KRAS mutant NSCLCs. Survival benefits occured in both first and second line. Survival benefits observed in KRAS wild-type NSCLCs were (0.87 [0.76-0.99]; $p = 0.03$) and (0.79 [0.56-1.11]; $p = 0.17$) respectively. OS benefit in KRAS mutant was significantly superior compared to OS benefit in KRAS wild-type (p = 0,001). **Conclusions:** Anti PD-(L)1 (+/- CT) appears superior to CT alone both for mutant and wild-type KRAS in advanced NSCLCs for OS and PFS with higher magnitude of benefit in KRAS mutated group for OS. Research Sponsor: None.

Clinical performance of artificial intelligence-powered annotation of tumor cell PD-L1 expression for treatment of immune-checkpoint inhibitor (ICI) in advanced non-small cell lung cancer (NSCLC). *First Author: Hyojin Kim, Department of Pathology, Seoul National University Bundang Hospital, Seongnam, South Korea*

Background: Programmed death ligand 1 (PD-L1) expression is the standard biomarker for first line ICI in advanced NSCLC. However, manual evaluation of tumor proportion score (TPS) by pathologists has practical limitations including intra/inter-observer bias, variation in subjectivity on area of interest and intensive labor. We developed an artificial intelligence (AI)-powered TPS analyzer, namely Lunit SCOPE PD-L1, for objective annotation of tumor cell PD-L1 expression for prediction of ICI response in advanced NSCLC. **Methods**: Lunit SCOPE PD-L1 was developed by a total of 393,565 tumor cells annotated by board-certified pathologists for PD-L1 expression in 802 whole-slide images (WSI) stained by 22C3 pharmDx immunohistochemistry. A After excluding the in-house control tissue regions, the WSI were divided into patches, from which a deep learning-based model detected the location and PD-L1 positivity of tumor cells. The patch-level cell predictions were aggregated for TPS estimation. Clinical performance of the model was validated in an external cohort of 430 NSCLC tumor slides from patients treated with ≥ ICI at Seoul National University Bundang Hospital and Samsung Medical Center. Independent control TPS annotation of this external validation cohort was performed by three pathologists, and their consensus TPS was calculated by mean value of such. **Results**: AI-model (Lunit SCOPE PD-L1) predicts PD-L1-positive tumor cell with the area under the curves of 0.889 and PD-L1-negative tumor cells with that of 0.809 at cell-level analysis. At WSI-level, significant positive correlation was observed between TPS by AI model and control TPS by pathologists (Spearman coefficient = 0.9247, $P < 0.001$). Concordance rate between AI-model and control TPS by pathologists according to expression level of PD-L1 ≥ 50%, 1-49%, and < 1% status was 85.7%, 89.3%, and 52.4%, respectively. Median progression-free survival (mPFS) according to TPS by AI model ≥ 1% vs. < 1% were 2.8 vs. 1.7 months (hazard ratio, HR, 0.52, 95% confidence interval, CI, 0.38-0.71, $P < 0.001$). In contrast, mPFS according to control TPS was 2.8 vs. 2.1 months (HR 0.70, 95% CI 0.55-0.91, $P < 0.001$). Forty out of 84 patients (47.6%) annotated as control TPS < 1% by pathologists were considered as TPS ≥ 1% by AI-model and mPFS of this subgroup was 2.7 months. **Conclusions**: PD-L1 expression by AI-model correlates with PD-L1 expression by pathologists. Clinical performance of AI-model in WSI-level is comparable with assessment by pathologists. The AI-model can accurately predict tumor response and progression-free survival of ICI in advanced NSCLC. Research Sponsor: Lunit Inc.

Clinical outcomes for plasma-based comprehensive genomic profiling versus tissue testing in advanced lung adenocarcinoma. *First Author: Ray D. Page, The Center for Cancer and Blood Disorders, Fort Worth, TX*

Background: Somatic genomic testing is recommended by numerous expert guidelines to inform targeted therapy treatment for patients with advanced lung adenocarcinoma (aLUAD). The NILE study was a prospective observational study that demonstrated non-inferiority of cell-free circulating tumor DNA (cfDNA)-based tumor genotyping compared to tissue-based genotyping to find targetable genomic alterations in patients with newly diagnosed aLUAD. As the cohort has matured, clinical outcomes data can now be reported. **Methods:** This prospective, multicenter North American study (NCT03615443) enrolled patients with previously untreated aLUAD who had standard of care (SOC) tissue genotyping performed and concurrent comprehensive cfDNA analysis using the commercially available Guardant360 assay (Guardant Health, Redwood City, CA). After 12 months of study enrollment, objective response rates, disease control rate, and time to treatment data were collected for patients with targetable genomic alterations, as defined by NCCN guidelines, who were treated with physician's choice of therapy. **Results:** Among 282 patients on the study, 89 (31.6%) had an actionable biomarker detected by tissue (21.3%) and/or cfDNA (27.3%) analysis. Sixty-one (68.5%) of these patients were treated with an FDA-approved targeted therapy guided by somatic genotyping results (*EGFR*, *ALK*, *ROS1*). Thirty-three patients were eligible for clinical response evaluation and demonstrated an objective response rate of 58% and disease control rate of 94%. Twenty-five (76%) achieved a durable response > 6 months; 17 (52%) achieved a durable response > 12 months. Patients responded to targeted therapy regardless of the variant allele frequency of the target alteration. The time to treatment (TtT) was significantly faster for cfDNA-informed biomarker detection as compared to tissue genotyping (median 18 vs 31 days, respectively; p = 0.0008). **Conclusions:** This is the first prospective community-based study to find that cfDNA detects guideline-recommended biomarkers at a rate similar to tissue genotyping, and therapeutic outcomes based on plasma-based comprehensive genomic profiling are comparable to published tissue-based targeted therapy clinical outcomes. The NILE study complements and confirms findings in the prospective FLAURA and SLLIP studies, which exclusively enrolled at academic sites. Clinical trial information: NCT03615443. Research Sponsor: Guardant Health.

Changes in PD-L1 tumor proportion score are associated with *CD274* gene (encoding PD-L1) copy number variation in non-small cell lung cancer. *First Author: Stephanie Leigh Alden, Harvard Medical School, Boston, MA*

Background: PD-L1 tumor proportion score (TPS) is often used to determine eligibility for first line therapy with immune checkpoint inhibitors (ICIs) in advanced non-small cell lung cancer (NSCLC). However, PD-L1 expression can vary over time and between tumor sites, potentially leading to inaccurate patient stratification. Therefore, it is critical to understand the clinicopathologic and genomic factors that are associated with PD-L1 changes in NSCLC. **Methods:** Clinicopathologic and genomic data were collected from patients with NSCLC and quantitative PD-L1 immunohistochemistry (IHC) on at least two different biopsies. NSCLC biopsies were categorized as PD-L1 negative, low, and high if they had a PD-L1 TPS $<$ 1%, 1-49%, and $\geq$50%, respectively. Intrapatient changes in PD-L1 TPS between samples (DPD-L1) were defined as follows: major decrease (decrease in PD-L1 TPS from $\geq$50% to $<$ 50% or from $\geq$1% to $<$ 1%), major increase (increase in PD-L1 TPS from $<$ 1% to $\geq$1% or $<$ 50% to $\geq$50%), and non-major change (all other cases). Next-generation sequencing (NGS) was used to evaluate copy number (CN) variations at the *CD274* locus, which encodes PD-L1. Wilcoxon and Kruskal-Wallis rank sum tests were used to analyze continuous variables and Fisher's exact test was used to analyze categorical variables. **Results:** Among 250 patients with NSCLC with PD-L1 IHC assays performed on at least two distinct tissue samples, PD-L1 TPS of the first biopsy was $<$ 1% in 104 (41.6%), 1-49% in 80 (32.0%), and $\geq$50% in 66 (26.4%) samples, for a median PD-L1 TPS of 2% (range: 0% to 100%). When intrapatient DPD-L1 was examined, there were major decreases and major increases in PD-L1 TPS in 49 (19.6%) and 65 (26.0%) cases, respectively, and non-major changes were observed in the remaining 136 samples (54.4%), with a median DPD-L1 of 0% (range: -90% to +90%). Baseline PD-L1 TPS and DPD-L1 were not significantly affected by histology, smoking status, sex, or treatment. Among 219 NSCLC samples that underwent tissue NGS and had full CN data available, the median PD-L1 TPS differed significantly based on *CD274* CN: PD-L1 TPS 1% with single copy deletion vs. 5% with copy neutral vs. 42.5% with low amplification vs. 97.5% with high amplification ($p < 0.01$). Among 56 patients with paired PD-L1 TPS and NGS on both samples, there was a significant difference in median DPD-L1 according to *CD274* CN change: DPD-L1 TPS -49% with acquired *CD274* CN loss vs. 0% with no major change in *CD274* CN vs. +1.75% with acquired *CD274* CN gain ($p = 0.01$). **Conclusions:** PD-L1 TPS varies within the same patient in almost half of NSCLC cases, with few clinicopathologic correlates of change in expression. Variation in PD-L1 TPS correlates with changes in *CD274* CN across biopsies. These findings suggest a genomic correlate to predict PD-L1 TPS across samples, as well as a potential complementary method in determining in ICI initiation. Research Sponsor: None.

The combination of EGFR-TKIs and anlotinib as a first-line therapy for EGFR-mutant advanced non-small cell lung cancer: A multicenter, single-arm, phase II clinical trial. *First Author: Zhiyong He, Fujian Cancer Hospital & Fujian Medical University Cancer Hospital, Fuzhou, China*

Background: Currently,EGFR-TKIs are widely accepted as the standard treatment for EGFR-mutant advanced non-small-cell lung cancer (NSCLC); however, acquired resistance is inevitable. Combination therapy is considered as a strategy to overcome the resistance to EGFR-TKIs. Anlotinib, a novel multi-targeting, small-molecule TKI, has shown active to suppress tumor angiogenesis and growth. However, there is still a lack of evidence supporting the use of EGFR-TKIs in combination with anlotinib for the treatment of NSCLC until now. A multi-center, single-arm, phase II clinical trial was therefore designed to examine the efficacy and safety of EGFR-TKIs combined with anlotinib for treatment-naïve, advanced NSCLC patients, and unravel the possible mechanisms. **Methods:** This study was conducted in 14 research centers in Fujian, China. The main eligibility criteria were stage IV or relapsed nonsquamous NSCLC with EGFR mutations (exon 19 deletion, and L858R), ECOG score 0-2,and age 20 to 75 years and no previous systemic treatment. Patients with asymptomatic brain metastases were admitted.Eligible patients were given gefitinib (250 mg QD) or icotinib (125 mg TID) in combination with anlotinib (10 mg per day, on days 1–14; 21 days per cycle) until disease progression. The primary endpoint is progression-free survival (PFS) and safety, and the secondary endpoint is overall survival (OS), objective response rate (ORR) and disease control rate (DCR).Peripheral blood was sampled pre-treatment, once every two months during treatment and after disease progression, and T790M mutation was detected in plasma ctDNA using a droplet digital PCR (ddPCR) assay. **Results:** Of 60 patients enrolled (August 2, 2018 to May 28, 2020). As of February 1, 2021, 37 patients (61.7%) experienced PFS events and 10 (16.7%) died. The ORR was 78.3%, and the DCR was100%.Median PFS was 13.0 months (95%CI,10.7-15.3).The 5 most common treatment-related adverse events included rash (63.3%), fatigue (55.0%), hypertension (48.3%), diarrhea (33.3%) and hand-foot syndrome (30.0%), and grade 3 adverse events included hypertension (5.0%), rash (1.67%), hypertriglyceridemia (1.67%), vomiting (1.67%) and elevated ALT (1.67%); no grade 4 adverse events or drug-related deaths were observed. Peripheral blood samples were collected from 36 patients pre-treatment, and 30.6% were identified with low-frequency de novo T790M mutations, with the mutation-allele frequency (MAF) ranging from 0.01% to 0.28%. **Conclusions:** The combination of the first-generation EGFR-TKIs and anlotinib shows impressive ORR and DCR, and acceptable toxicity in treatment-naïve advanced NSCLC patients with activating EGFR mutations, and we observed a high proportion of patients harboring de novo EGFR T790M mutations in this study. Clinical trial information: NCT03720873. Research Sponsor: None.

A randomized phase III study comparing carboplatin with nab-paclitaxel versus docetaxel for elderly patients with squamous-cell lung cancer: Capital study. *First Author: Yoichiro Hamamoto, National Hospital Organization Nishisaitama-Chuo National Hospital, Tokorozawa, Japan*

Background: Cytotoxic monotherapy is one of the standard treatments for elderly patients with advanced non-small cell lung cancer (NSCLC). Carboplatin plus nab-paclitaxel demonstrated significantly higher objective response rate (ORR) than carboplatin plus paclitaxel in patients with squamous histology and could improve overall survival (OS) in patients aged $\geq$70 years. Here, we compared carboplatin plus nab-paclitaxel with docetaxel in elderly patients with squamous NSCLC. **Methods:** The CAPITAL study is a multicenter, open-label, phase 3, randomized trial at 92 institutions in Japan. Eligible patients had advanced squamous NSCLC with no prior systemic chemotherapy, aged $\geq$70 years, and had an ECOG performance status of 0 or 1. Patients were randomized 1:1 to docetaxel 60 mg/m^2 (D arm) or carboplatin AUC 6 mg/mL/min plus nab-paclitaxel 100 mg/m^2 weekly (nab-PC arm) for each 21-day cycle. The primary endpoint was OS. This trial is registered with the UMIN Clinical Trials Registry (UMIN000019843) and the Japan Registry of Clinical Trials (jRCTs041180110). **Results:** Between December 2015 and August 2020, 196 patients were randomly assigned to the two treatment arms (D arm, n=98; nab-PC arm, n=98). The median follow-up and age were 11.5 months and 76 years (range: 70–88 years), respectively, and 87% of the patients were male. After the planned interim analysis, the independent data monitoring committee confirmed that the study met the primary endpoint of improved OS in August 2020, and this report represents the final analysis. The nab-PC arm showed significant superiority in OS versus the D arm (hazard ratio [HR], 0.52; 90% CI, 0.38-0.70; median, 16.9 vs. 10.9 months; $p<0.001$). There were also significant improvements in progression-free survival (median, 5.8 vs. 4.0 months; HR, 0.42; 95% CI, 0.30-0.58; $p<0.001$) and objective response rate (66.3 vs. 28.0 %; $p<0.001$) in the nab-PC arm versus the D arm. The most common grade 3 or 4 adverse events were leukopenia (46.3 %), neutropenia (63.2 %), and anemia (38.9 %) in the nab-PC arm, and leukopenia (56.7 %), neutropenia (77.3 %), and febrile neutropenia (17.5 %) in the D arm. As notable adverse events, grade $\geq$2 sensory peripheral neuropathy was observed in 15 (15.8%) and 1 (1.0%) patient in the nab-PC and D arms, respectively. Moreover, serious treatment-related adverse events and treatment-related deaths occurred in 14 (14.7%) and 12 (12.4%) patients and in two and one patient in the nab-PC and D arms, respectively. **Conclusions:** The nab-PC arm had a significantly improved OS than the D arm among elderly patients with squamous NSCLC. Carboplatin plus nab-paclitaxel became a new standard treatment for these patients. Clinical trial information: UMIN000019843. Research Sponsor: Taiho Pharmaceutical.

Response to selpercatinib versus prior systemic therapy in patients (pts) with *RET* fusion+ non-small-cell lung cancer (NSCLC). *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Selpercatinib, a first-in-class highly selective, potent, CNS-active RET kinase inhibitor, is approved in multiple countries for treatment of *RET* fusion+ lung or thyroid cancers. Selpercatinib demonstrated durable antitumor activity in previously treated pts with *RET* fusion+ NSCLC in an ongoing Phase 1/2 trial, LIBRETTO-001 (Besse et al., ASCO 2021). **Methods:** Pts with *RET* fusion+ NSCLC enrolled in the global, multicenter, LIBRETTO-001 trial (NCT03157128; 16 countries, 89 sites). Primary endpoint was objective response rate (ORR). Secondary endpoints included progression-free survival, duration of response, and safety. This post-hoc intrapatient analysis was based on a 30 March 2020 data cutoff date. Historical physician-reported best overall response (BOR) from last systemic therapy received prior to enrollment was compared with selpercatinib BOR by independent review committee per RECIST v1.1, with each patient serving as his/her own control. **Results:** In efficacy-evaluable pts (N = 218) who previously received platinum-based chemotherapy (chemo), median pt age was 61 years, the majority with ECOG of 0/1 (37%/61%), with a median of 2 (range: 1-15) prior systemic therapies. Overall, 57% of patients responded to selpercatinib while 16% responded to the immediate prior therapy. ORR improvements with selpercatinib were observed regardless of prior therapy: chemotherapy + immune checkpoint inhibitor (ICI) (57% vs 14%), single-agent ICI (48% vs 3%), or chemotherapy (58% vs 15%). A total of 108 patients (49%) did not respond to immediate prior therapy but responded to selpercatinib. Fewer patients had progressive disease as their BOR with selpercatinib (2%) compared to the immediate prior therapy (28%). The median duration of therapy for selpercatinib was notably extended compared with that of the immediate prior therapy (11.8 vs. 3.4 months, respectively). **Conclusions:** In pts with *RET* fusion+ NSCLC treated on LIBRETTO-001, systemic therapies administered prior to enrollment achieved less meaningful clinical benefit than selpercatinib. Selpercatinib demonstrated consistent efficacy regardless of the type of prior therapy. Clinical trial information: NCT03157128. Research Sponsor: Eli Lilly and Company.

Second-line nintedanib plus docetaxel for patients with lung adenocarcinoma after failure on first-line immune checkpoint inhibitor combination therapy: Initial efficacy and safety results from VARGADO Cohort C. *First Author: Christian Grohé, Department of Pneumology, ELK Berlin, Berlin, Germany*

Background: The treatment landscape in advanced non-small cell lung cancer (NSCLC) has undergone significant changes, with immune checkpoint inhibitor (ICI) +/- chemotherapy now the preferred first-line (1L) regimen for metastatic, non-mutated NSCLC. However, only limited clinical data are available to guide subsequent treatment selection. Nintedanib (Vargatef), an oral triple angiokinase inhibitor targeting the vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR), and fibroblast growth factor receptor (FGFR) pathways, is approved in the EU and other countries in combination with docetaxel for the treatment of advanced adenocarcinoma NSCLC after failure on 1L chemotherapy. **Methods:** This analysis is part of the ongoing, prospective, non-interventional VARGADO study (NCT02392455) of nintedanib + docetaxel. Here, we present initial efficacy and safety results from 100 patients (pts) with adenocarcinoma NSCLC in Cohort C, who received second-line (2L) nintedanib + docetaxel after failure on prior 1L ICI in combination with chemotherapy. **Results:** In Cohort C, the median age was 63 years (range: 43–84); 58 pts (58.0%) were men, and 71 pts (71.0%) had ECOG PS 0/1. Ninety-five pts (95.0%) had received prior 1L pembrolizumab-based combination therapy. Thirty-nine pts (39.0%) had progressed within 6 months after the start of 1L therapy, and 66 pts (66.0%) had progressed within 9 months. Objective response rate with 2L nintedanib + docetaxel was 37.3% (22/59 pts), disease control rate was 67.8% (40/59 pts), and median progression-free survival (PFS) was 4.4 months (95% confidence interval [CI]: 2.6–6.6). Among pts who had experienced disease progression $<$ 9 months after the start of 1L therapy (n = 66), median PFS from the start of 2L nintedanib + docetaxel was 4.1 months (95% CI: 2.5–6.6). Among pts with disease progression $\geq$9 months after the start of 1L therapy (n = 34), median PFS from the start of 2L nintedanib + docetaxel was 8.5 months (95% CI: 2.4–not estimable). Grade $\geq$3 treatment-emergent adverse events (TEAEs), serious TEAEs, and TEAEs leading to treatment discontinuation were observed in 47 pts (47.0%), 37 pts (37.0%) and 28 pts (28.0%), respectively. **Conclusions:** Initial data from VARGADO Cohort C provide the first evidence that 2L nintedanib + docetaxel has encouraging and clinically meaningful efficacy, and a manageable safety profile in pts with advanced adenocarcinoma NSCLC following progression on 1L ICI in combination with chemotherapy. Clinical trial information: NCT02392455. Research Sponsor: Boehringer Ingelheim Pharma GmbH & Co. KG.

9034 **Poster Session**

Phase II trial of atezolizumab (A) + carboplatin (C) + pemetrexed (P) + bevacizumab (B) in pts with stage IV non-squamous non-small cell lung cancer (NSq-NSCLC): Big Ten Cancer Research Consortium Study LUN 17-139. *First Author: Fatemeh Ardeshir-Larijani, Indiana University, Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: The addition of A to C+ Paclitaxel (Pac) + plus B improved progression free survival (PFS) and overall survival (OS) compared with C + Pac + B alone in pts with metastatic NS-NSCLC. However, C + Pem is more commonly used for this patient population with a shorter infusion time and favorable toxicity profile compared with Pac. **Methods:** Multicenter single arm phase II clinical trial of chemo and immunotherapy-naïve pts with stage IV NSq-NSCLC. All pts received A (1200 mg, D1) + C (AUC 5, D1) + P (500 mg/m2, D1) + B (15mg/kg D1) q3 week x4. If non-PD, pts could receive maintenance APB until PD or intolerable side effects. The primary endpoint was 1 yr. PFS. Sample size of 42 planned with 87% power and two-sided type I error of 0.05 for 1 yr PFS. Secondary endpoints included ORR, disease control rate (DCR) [defined by CR + PR + SD], and toxicity. **Results:** 30 pts were enrolled from 11/15/2018 to 10/5/2020. The study was closed early due to 3 patient deaths, possibly related to treatment (VTE, Febrile neutropenia, colonic perforation). Median age 64 (range 38-83); M/F 20/10; mutations in EGFR/ALK/KRAS/BRAF (5/1/4/2); PD-L1 TPS $<$ 1%/ 1-49%/ $>$ 50% (9/14/6) and one pt did not have PDL-1 status. Median f/u was11.6 mos (range 1-20). ORR 35.71% (95% CI: 18.64%-55.95%), DCR 92.85% (95% CI: 83%-100%). 1yr PFS and OS were 55.27% and 82.90% respectively. The most common G III and G II toxicity were HTN (20%) and fatigue (33.3%).3 pts had G IV toxicity (Anemia, Febrile neutropenia and colonic perforation) and 2 pts had Grade (G) V toxicity (VTE, Hypoxia/Sepsis). **Conclusions:** Atezolizumab + Carboplatin + Pemetrexed + Bevacizumab was associated with longer DCR, PFS, and OS than historical controls. 3 on-treatment deaths, possibly related to therapy (more likely bevacizumab), prompted early closure. A phase 3 study evaluating this regimen is ongoing by another group NCT03786692. Clinical trial information: NCT03713944. Research Sponsor: Genentech.

Efficacy and safety of pan-ErbB inhibitor pyrotinib combined with antiangiogenic agent apatinib for HER2-mutant or amplified metastatic NSCLC: A phase II clinical study. *First Author: Guangjian Yang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Tumor angiogenesis could be induced by activation of HER2 receptor, and currently, there is lack of clinical evidence of anti-HER2 tyrosine kinase inhibitors (TKIs) combined with antiangiogenic therapy for HER2-mutant or amplified non-small cell lung cancer (NSCLC). We conducted a study to explore the efficacy and safety of a pan-ErbB inhibitor pyrotinib combined with apatinib for metastatic NSCLC patients harboring HER2 amplification or activating mutations. **Methods:** This was a single-center, single-arm phase II study with Simon's optimal two-stage design. Metastatic NSCLC patients with ECOG scores of 0-1 and harboring primary HER2 amplification, exon 20 insertion or activating missense mutations who had failed to prior chemotherapies or anti-HER2 TKIs were eligible to be enrolled. All patients received oral pyrotinib (400mg once daily) combined with apatinib (250mg once daily) therapy. The primary endpoint was objective response rate (ORR), and second endpoints included progression-free survival (PFS), duration of response (DoR), disease control rate (DCR), overall survival (OS) and safety. **Results:** Between March 5, 2019, and December 1, 2020, 33 metastatic NSCLC patients with HER2 alterations were enrolled, including exon 20 insertions (A775_G776insYVMA, 20/33; P780_Y781insGSP, 6/33; other variants, 2/33), missense mutations (3/33), and primary HER2 amplification (2/33). Seventeen patients (51.5%) were pretreated with first-line platinum-based chemotherapies or anti-HER2 TKIs, and the remaining had received at least 2 lines of prior therapies (range, 2-6). At the last follow-up time January 23, 2021, the overall ORR and DCR were 45.5% (15/33) and 93.9% (31/33), respectively. The median PFS was 6.8 (95%CI: 5.4-8.2) months. The median DoR and OS were 5.3 (95%CI: 0-11.8) and 12.9 (95%CI: 8.6-17.2) months, respectively. The mPFS was significantly longer in patients who received second-line pyrotinib combined with apatinib therapy than those in third- or above-line settings (9.8 *vs.* 5.3 months, P = 0.018, HR = 0.281 [95%CI: 0.098-0.807]). Although pyrotinib combined with apatinib therapy showed similar ORRs in patients with presence (46.2%, 6/13) or absence (45.0%, 9/20) of brain metastases, and those in second-line (47.1%, 8/17) or above-line settings (43.8%, 7/16). Common treatment-related adverse events (AEs) were grade 1-2, mainly including diarrhea (90.9%), hypertension (72.7%), asthenia (63.6%), anorexia (54.5%) and nausea (51.5%). Grade 3 AEs were diarrhea (3.0%) and hypertension (9.1%). No grade 4 or 5 AE or treatment-related deaths were reported. **Conclusions:** Pyrotinib combined with apatinib showed potent anti-tumor activity and acceptable safety profile in metastatic NSCLC with HER2 amplification or activating mutations. Clinical trial information: ChiCTR1900021684. Research Sponsor: None.

9036 **Poster Session**

Treatment outcome and functional characterization of uncommon EGFR mutations in the German National Network Genomic Medicine Lung Cancer (nNGM). *First Author: Melanie Janning, Personalized Medical Oncology, German Cancer Research Center (DKFZ), Heidelberg, Personalized Oncology, University Hospital Mannheim, Department of Oncology, Hematology and BMT, University Medical Center Hamburg Eppendorf, Heidelberg, Germany*

Background: The nNGM centralizes molecular diagnostics, treatment recommendations and follow-up reporting in NSCLC in Germany. Uncommon EGFR mutations pose a clinical challenge because they comprise a heterogenous group and analyses of treatment outcome are still scarce. Here, we analyzed follow-up data of patients with rare EGFR mutations and performed functional characterization of recurrent mutations with unknown function. **Methods:** This multicenter, retrospective analysis of uncommon EGFR mutations (excluding L858R-, T790M mutations and exon 19 deletions) includes stage IV patients with NSCLC from 12 nNGM centers. We categorized EGFR-mutations into 3 groups: uncommon EGFR mutations with known driver function, for instance E709X, G719X, S768I and L861Q (group 1), exon 20 insertions (group 2) and all other very rare mutations (group 3). Functional characterization of unknown mutations was performed by insertion mutagenesis in Ba/F3 cells and monitoring of growth factor-independent proliferation. **Results:** In total, 834 cases with uncommon EGFR mutations were reported. Follow-up data after EGFR-TKI (Erlotinib, Gefitinib, Afatinib and Osimertinib), chemotherapy and/or mono-PD(L)1 blockade was available for 252 patients. Mean progression free survival (mPFS) on EGFR-TKIs vs. chemotherapy was 6.6 months vs. 5.0 months (HR 0.54, 95%CI 0.35 to 0.81, P = .003) in group 1 (n = 84), and 6.7 months vs. 3.4 months (HR 0.66, 95%CI 0.47 to 0.92, P = .015) in group 3 (n = 104). Mono-anti-PD(L1) blockade was not superior to chemotherapy (group 1, mPFS 3.0 months, HR 1.32, 95% 0.55 – 3.15, P = .535 and group3, mPFS 4.3 months, HR 1.02, 95% CI 0.64 – 1.62, P = 0.951). Exon 20 insertions (group 2, n = 63) did not benefit from EGFR-TKIs or anti-PD(L1) blockade vs. chemotherapy. Overall survival (OS) analysis (n = 218) following chemotherapy (56%) or EGFR-TKI treatment (44%) showed median OS (mOS) of 18.0 months vs. 13.9 months in patients treated with EGFR-TKI and chemotherapy, respectively in group 1 (HR 0.97, 95%CI 0.54 to 1.75, P = .929). In group 3 patients treated with EGFR-TKI and chemotherapy had a mOS of 35.4 months vs. 12.0 months, respectively (HR 0.59, 95%CI 0.35 to 1.01, P = .056). In the Ba/F3 system we could identify 8 recurrent driver and 12 non-driver mutations with a clinically applicable assay turnaround time of 4 weeks to inform clinical decision-making in the future. **Conclusions:** This real-world dataset confirms that patients with group 1(uncommon) EGFR mutations benefit from EGFR-TKIs and indicates that mono-anti PD(L)1 blockade is not superior to chemotherapy. Furthermore, patients with very rare EGFR mutations (group 3) also experienced a PFS benefit from EGFR-TKI compared to chemotherapy while immune therapy was not beneficial. Research Sponsor: Deutsche Krebshilfe, Hector Stiftung, Margarete Clemens Stiftung.

A randomized phase II study comparing nivolumab (NIVO) with carboplatin-pemetrexed (CbPEM) for patients (pts) with EGFR mutation-positive non-small cell lung cancer (NSCLC) who acquire resistance to tyrosine kinase inhibitors (TKIs) not due to a secondary T790M mutation (WJOG8515L). *First Author: Hidetoshi Hayashi, Kindai University Faculty of Medicine, Osaka, Japan*

Background: Although the efficacy of antibodies to programmed cell death–1 (PD-1) appears to be less pronounced in patients with NSCLC harboring epidermal growth factor receptor gene (*EGFR*) mutations, patients who develop disease progression (PD) to TKIs due to mechanisms other than secondary T790M mutation of *EGFR* might be more likely to benefit from NIVO. Here, we report the results of first randomized phase II trial to compare NIVO with the CbPEM in those population. **Methods:** Pts with advanced *EGFR* mt NSCLC who experienced PD after EGFR-TKIs were randomized 1:1 to NIVO or CbPEM. Eligibility criteria included the treatment history with TKIs as follow; no evidence of T790M after PD on 1st/2nd generation (gen) TKIs (A) after PD on 3rd gen TKIs as a 2nd line for T790M positive tumor (B) or 3rd gen TKIs as a front-line (C). The primary end point is progression-free survival (PFS) and biomarker analysis were included for exploratory analysis. **Results:** A total of 102 patients was randomized. Median PFS and overall survival (OS) were 1.7 and 20.7 months (mo), respectively, for NIVO arm (n = 52) versus 5.6 and 19.9 months for CbPEM (n = 50) (Hazard ratio [HR] = 1.92 and 0.88, respectively). Overall response rate and duration of response were 9.6% and 5.3 months for NIVO and 36.0% and 5.5 months for CbPEM. PD-L1 expression on tumor cells and tumor mutation burden (TMB) were evaluated in 77 (TPS 0%. 1-49%, > 50%, n = 46, 20, and 11) and 50 (Median TMB 6.2mt/mb). Immune-related gene expression profiling was under evaluation and the results will be demonstrated in the meeting. The efficacy of NIVO in PD-L1 strong positive (>50%, n = 8) and no evidence of T790M after PD on 1st/2nd gen TKIs (n = 29) was tended to be better than their counterparts. There was no significant correlation between TMB and the efficacy of NIVO. Pneumonitis was observed in one patient (1.0%) for NIVO arm and no new safety signals were noted. **Conclusions:** NIVO was not associated with longer PFS than CbPEM in selected pts with advanced *EGFR* mt NSCLC. OS was similar between groups. Baseline PD-L1 status and genetic alteration features may be relevant predictive markers to select pts who would benefit from NIVO. Clinical trial information: jRCTs051180133. Research Sponsor: Ono Pharmaceutical Co. Ltd.

Health-related quality of life for pembrolizumab (pembro) plus ipilimumab (ipi) versus pembro plus placebo in patients with metastatic NSCLC with PD-L1 tumor proportion score ≥ 50%: KEYNOTE-598. *First Author: Mehmet Nahit Sendur, Ankara Yõldõrõm Beyazõt University, Faculty of Medicine and Ankara City Hospital, Ankara, Turkey*

Background: In the phase 3 KEYNOTE-598 study (NCT03302234), OS (HR, 1.08; 95% CI, 0.85–1.37; $P = 0.74$) and PFS (1.06; 95% CI, 0.86–1.30; $P = 0.72$) were not improved for pembro + ipi vs pembro + placebo in patients (pts) with previously untreated metastatic NSCLC with PD-L1 tumor proportion score (TPS) ≥50% and without *EGFR/ALK* genomic alterations. Incidence of treatment-related grade 3–5 AEs, fatal AEs, and AEs leading to discontinuation was higher with pembro + ipi vs pembro + placebo. We present prespecified patient-reported outcome (PRO) analyses from KEYNOTE-598. **Methods:** Pts (n = 568) with previously untreated stage IV NSCLC with PD-L1 TPS ≥50% were randomized 1:1 to pembro 200 mg Q3W for up to 35 cycles + ipi 1 mg/kg or placebo Q6W for up to 18 cycles. The EORTC QLQ-C30, QLQ-LC13, EQ-5D-5L, and NSCLC-SAQ were administered at cycles 1–7, then every 3 cycles through cycle 19, and every 4 cycles until PD or a maximum of 35 cycles. Change from baseline in global health status (GHS)/quality of life (QoL) score from the QLQ-C30 and the time to true deterioration (TTD) in the composite endpoint of cough (LC13), chest pain (LC13), or dyspnea (C30) were secondary objectives in KEYNOTE-598. Change from baseline in GHS/QoL was analyzed using a constrained longitudinal data analysis model with missing at random assumption. Difference in TTD was evaluated using a Cox proportional hazards model and stratified log-rank test. PROs were analyzed in all pts who completed ≥1 PRO assessment and received ≥1 dose of study treatment. *P* values are two-sided and nominal. **Results:** As of data cutoff (Sept 1, 2020), PRO analyses included 280 pts in the pembro + ipi group and 280 pts in the pembro + placebo group. QLQ-C30 completion rates were 95.7% in the pembro + ipi group vs 96.1% in the pembro + placebo group at baseline and 63.6% vs 70.0% at week 18. QLQ-LC13 completion rates were 95.4% vs 96.4% at baseline and 63.6% vs 69.6% at week 18. Mean QLQ-C30 GHS/QoL scores at baseline were 62.8 in the pembro + ipi group and 64.2 in the pembro + placebo group and were similar between the groups across the follow-up period. Least squares (LS) mean (95% CI) change from baseline to week 18 in GHS/QoL scores was improved in both groups (pembro + ipi: 3.7 [0.9–6.5]; pembro + placebo: 4.1 [1.4–6.9]), with no significant difference between groups (LS mean difference −0.4 [−4.0 to 3.1], $P = 0.82$). Median TTD in composite of cough, chest pain, or dyspnea was not reached (NR; 95% CI, 13.0 mo–NR) in the pembro + ipi group vs 20.0 (95% CI, 12.7–NR) mo in the pembro + placebo group (hazard ratio, 0.98 [95% CI, 0.74–1.30]; $P = 0.91$). **Conclusions:** There was no difference in health-related QoL or TTD in lung cancer symptoms between pembro + ipi and pembro + placebo in pts with previously untreated metastatic NSCLC with PD-L1 TPS ≥50%. Clinical trial information: NCT03302234. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Whole-exome sequencing in advanced-stage sensitizing *EGFR* mutation non-small cell lung cancer: Explore resistance biomarkers to EGFR TKI treatment. *First Author: Chanida Vinayanuwattikun, Division of Medical Oncology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*

Background: Despite the development of predictive biomarkers to shape treatment paradigms and outcomes, 10-20% of *de novo* EGFR TKI resistance advanced non-small cell lung cancer (NSCLC) in the presence of *EGFR* mutation remains the issue of concern. **Methods:** We explored clinical factors in 332 advanced NSCLC who received EGFR TKI and molecular characteristics through 65 whole exome sequencing of various EGFR TKI responses including; *de novo* (progression within 3 months), intermediate response (IRs) and long-term response (LTRs) (durability > 2 year). **Results:** Uncommon *EGFR* mutation subtype was a significant variable in *de novo* resistance vs. IRs and LTRs with odd ratios of 6.83 ([95% CI 2.36 – 19.80], p-value < 0.001) and 16.84 ([95%CI 1.66 – 171.45, p-value 0.02), respectively. The remaining sensitizing *EGFR* mutation subtype (exon 19 del and L858R) accounted for 75% of *de novo* resistance. Genomic landscape analysis was conducted, focusing in 10 frequent oncogenic signaling pathways with functional contributions; cell cycle, Hippo, Myc, Notch, Nrf2, PI-3-Kinase/Akt, RTK-RAS, TGF-β, p53 and β-catenin/Wnt signaling. Cell cycle pathway was the only significant alteration pathway among groups with the FDR p-value of 6×10^{-4}. We found only significant q-values of < 0.05 in 7 gene alterations; *CDK6, CCNE1, CDK4, CCND3, MET, FGFR4* and *HRAS* which enrich in *de novo* resistance [range 36-73%] compared to IRs/LTRs [range 4-22%]. Amplification of *CDK4/6* was significant in *de novo* resistance, contrary to IRs and LTRs (91%, 27.9% and 0%, respectively). The presence of co-occurrence *CDK4/6* amplification correlated with poor disease outcome with HR of progression-free survival of 3.63 [95% CI 1.80-7.31, p-value < 0.001]. **Conclusions:** The presence of *CDK4/6* amplification in pretreatment specimen serve as a predictive biomarker for *de novo* resistance in sensitizing *EGFR* mutation. Phase II study of brigatinib in ROS1 positive non-small cell lung cancer (NSCLC) patients previously treated with crizotinib: Barossa cohort 2. *First Author: Haruko Daga, Department of Medical Oncology, Osaka City General Hospital, Osaka, Japan*

Background: Brigatinib is a next-generation tyrosine kinase inhibitor targeting ALK and ROS1. Crizotinib is the first drug approved for the treatment of ROS1 fusion-positive NSCLC. Standard treatment for crizotinib-resistant ROS1 positive NSCLC is not established. Barossa is a multicenter, phase II basket, study of brigatinib in patients with ROS1 positive solid tumors. This study is composed of three cohorts. ROS1 inhibitor-naïve ROS1 positive NSCLC patients were enrolled in the cohort 1, and ROS1 positive NSCLC patients previously treated with crizotinib were enrolled in the cohort 2. Patients with ROS 1 positive solid tumors other than NSCLC were enrolled in the cohort 3. This time we report the cohort 2 results. **Methods:** Patients with advanced, previously treated with crizotinib, ROS1 positive NSCLC received brigatinib at a dose of 180 mg once daily with a 7-day lead-in period at 90 mg. The primary end point was objective response rate (ORR; RECIST 1.1) by independent review. Key secondary endpoint was PFS, OS, and safety. The sample size was set at 19 patients, with a one-sided alpha of 0.05, beta of 0.2, and threshold and expected values for primary endpoint of 20% and 50%, respectively. **Results:** From July 2019 and Jan 2020, 19 patients were enrolled from 9 institutions. Baseline characteristics as follows: median age (range): 60 (31-75) years; women, n = 10 (53%); ECOG PS of 0 to 1, n = 18 (95%); never smoker, n = 11 (58%); tumor histopathological type: adenocarcinoma, n = 18 (95%). Five and 6 patients achieved PR and SD, respectively at data cutoff date of 30 Oct 2020. The ORR was 26.3% (90%CI, 11.0-47.6), and the disease control rate was 57.9% (95%CI, 33.5-79.7). The median duration of follow-up for PFS was 12.0 months. The median PFS was 7.3 months (95% CI, 1.3-9.3), and the 1-year PFS rate was 26.9% (95%CI, 9.2-48.6). Grade ≥3 TRAEs were CPK increased (21.1%), infection (5.3%), AST and/or ALT increased (5.3%), hypercalcemia (5.3%), anorexia (5.3%), hypoxia (5.3%), erythema (5.3%), hypertension (5.3%). Pneumonitis was observed in one patient (5.3%, Grade 2). No treatment-related death was observed. **Conclusions:** Brigatinib has modest activity for ROS1 positive NSCLC patients previously treated with crizotinib. The safety profile of brigatinib was consistent with previous studies. Enrollment of the cohort 1 for ROS1 inhibitor-naïve NSCLC patients is ongoing, and the data will be presented at a future congress. Clinical trial information: JapicCTI-194851. Research Sponsor: AMED.

9041 **Poster Session**

Determination of clinical benefit among patients with radiological stable disease to immune checkpoint inhibitors. *First Author: Jia Luo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: SD is a common but ambiguous outcome in patients receiving immune checkpoint inhibitors (ICIs) and likely represents a heterogenous mix of responders and non-responders. This study aimed to characterize SD and identify the subset of patients with SD who are benefiting from treatment. The ability to distinguish whom among patients with SD is actually benefiting from treatment would facilitate drug development and improve precision in correlative research. **Methods:** A systematic review was performed to characterize SD in ICI trials. SD and objective response was compared to proliferation index using TCGA gene expression data. To identify a subgroup of SD with outcomes mirroring responders, we examined a discovery cohort of NSCLC treated with ICIs and had RECIST assessment. In patients with best overall response (BOR) of SD, serial cutpoints of two variables, % BOR and PFS, were tested to define a subgroup with similar survival as PR-minor (patients with partial response [PR] and % shrinkage $<$ median among responders). Results were then tested in two external validation cohorts (n = 326, n = 381). **Results:** Among trials of ICIs (59 studies, 14,280 patients), SD ranged from 16-42% in different tumor types and was associated with disease-specific proliferation index (Spearman rho = -0.75, p = 0.03), a proxy of tumor kinetics, rather than relative response to ICIs. In a discovery cohort of 1220 patients with NSCLC who were treated with ICIs, 26% had SD, 19% had PR/CR, and 55% had PD. Outcomes among those with SD ranged widely (OS range 0.5-76 months, PFS range 0.2-49 months). The subset of SD with PFS $>$ 6 months and no tumor growth mirrored PR-minor (OS HR 1.0) and was proposed as the definition of "SD-responder". SD-responders (n = 87) represented 7% (95% CI 6-9%) of the overall population and 28% (95% CI 23-33%) of the SD population. This definition was confirmed in two validation cohorts from trials of NSCLC treated with durvalumab. **Conclusions:** RECIST-defined SD to immunotherapy is common, heterogenous, and may largely reflect tumor growth rate rather than ICI response. In patients with NSCLC and SD to ICIs, PFS $>$ 6 months and no tumor growth (~1/3 of SD) may be considered "SD responders." This definition may improve the efficiency of and insight derivable from clinical and translational research. Research Sponsor: NIH.

Brigatinib in Japanese patients with anaplastic lymphoma kinase (ALK)-positive non-small cell lung cancer (NSCLC): First results from the J-ALTA tyrosine kinase inhibitor (TKI)-naive expansion cohort. *First Author: Masashi Kondo, Department of Respiratory Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan*

Background: Brigatinib is a next-generation ALK inhibitor with demonstrated activity against ALK mutations. We report primary analysis results with brigatinib in Japanese patients with ALK-positive NSCLC who have not previously been treated with an ALK TKI in the phase 2 J-ALTA study (NCT03410108). **Methods:** J-ALTA, a multi-cohort study, included a TKI-naive expansion cohort. Patients in the TKI-naive cohort received brigatinib 180 mg qd with 7-day lead-in at 90 mg. Primary endpoint was 12-month progression-free survival (PFS) as assessed by an independent-review committee (IRC). Secondary endpoints included confirmed objective response rate (ORR; IRC- and investigator-assessed); IRC-assessed PFS and duration of response (DoR); overall survival (OS); intracranial PFS (iPFS by IRC); and safety. **Results:** A total of 104 patients were enrolled in the whole study; of these, 32 patients had TKI-naive NSCLC (median age, 60.5 y; 94% had adenocarcinoma; 22% had baseline brain metastases; 25% received prior chemotherapy). As of September 29, 2020, median follow-up was 14.2 months and 27 patients remained on treatment. IRC-assessed 12-month PFS was 93% (90% CI, 79–98). Confirmed ORR was 97% (90% CI, 84–100) by IRC, with 2 complete responses and 29 partial responses. Median DoR as assessed by the IRC was not mature; median PFS, iPFS, and OS were not reached. In the TKI-naive cohort, treatment-emergent adverse events (TEAEs) were reported in all 32 patients (most common: increased creatine phosphokinase, 81%; hypertension, 59%; diarrhea, 47%). Grade $\geq$3 TEAEs were reported in 91% of patients in this cohort (most common: increased creatinine phosphokinase, 44%; hypertension, 34%; increased lipase, 19%) and 75% of all patients. Three cases (9.4%) of interstitial lung disease/pneumonitis were reported in the TKI-naive cohort; all were grade 1 and occurred after day 15 of brigatinib treatment. Dose discontinuations/interruptions/reductions due to AEs in the TKI-naive cohort were 0%/94%/66%, respectively, and in the total study population were 5%/72%/41%. AE frequency and profile were similar in the TKI-naive and overall cohorts. **Conclusions:** In the J-ALTA TKI-naive cohort, brigatinib demonstrated substantial efficacy and manageable safety in the Japanese patient population. Brigatinib remains one of the treatment options in Japanese patients. Clinical trial information: NCT03410108. Research Sponsor: ARIAD Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

9043 **Poster Session**

A large real-world study on the effectiveness of the combined inhibition of *EGFR* and *MET* in *EGFR*-mutant advanced non-small cell lung cancer (NSCLC). *First Author: Liu Li, Hunan Cancer Hospital, Changsha, China*

Background: *MET* amplification is an important mechanism mediating acquired resistance to EGFR tyrosine kinase inhibitors (TKI). Until now, no consensus exists on the standard treatment strategy for this subset of patients due to the lack of clinical data from large cohort or controlled trials. In our clinical practice, three regimens were commonly administered to patients after *MET* amplification-mediated EGFR-TKI progression: EGFR-TKI and MET-TKI combination therapy, MET-TKI monotherapy, or chemotherapy. Our study aimed to compare the effectiveness of these three regimens. **Methods:** Seventy patients with *EGFR*-mutant advanced NSCLC who progressed from prior EGFR-TKI through the acquisition of *MET* amplification and received treatment between March 2015 and March 2020 were included in this study. Of them, 38 received EGFR-TKI plus crizotinib, 10 received crizotinib monotherapy, and 22 received platinum-based doublet chemotherapy. Somatic mutation profiling was performed on blood and tissue biopsy samples. Resistance mechanisms to the combination targeted therapy were also explored in 12 patients. **Results:** The objective response rate (ORR) and disease control rate (DCR) were 47.5% and 84.0% for EGFR-TKI+crizotinib group, 40.0% and 70.0% for crizotinib monotherapy group, and 18.2% and 50.0% for chemotherapy group, respectively. The EGFR-TKI+crizotinib group had significantly better ORR (P = 0.026) and DCR (P = 0.016) than the chemotherapy group but was not statistically different from the crizotinib monotherapy group (ORR, P = 0.73; DCR, P = 0.39). Progression-free survival (PFS) was significantly longer for the EGFR-TKI+crizotinib group than those who received crizotinib monotherapy (5.0 vs 2.3 months, P = 0.004) or chemotherapy (5.0 vs 2.9 months, P = 0.036), but overall survival was comparable (10.0 vs 4.1 vs 8.5 months, P = 0.088). *TP53* mutation (58.5%) and *EGFR* amplifications (42.9%) were the two common concurrent mutations in the three cohorts. PFS was significantly longer for patients with either concurrent *TP53* mutation (n = 17) (6.0 vs 2.3 vs 2.9 months, P = 0.009) or concurrent *EGFR* amplification (n = 13) (5.0 vs 1.2 vs 2.4 months, P = 0.016) who received EGFR-TKI+crizotinib. Potential molecular mechanisms of acquired resistance to EGFR-TKI+crizotinib therapy included *EGFR* T790M (n = 2), *EGFR* L718Q (n = 1), *EGFR* S645C (n = 1), *MET* D1228H (n = 1), *BRAF* V600E (n = 1), *NRAS* Q61H (n = 1), and amplifications in *KRAS* (n = 2), *ERBB2* (n = 1), *CDK4* (n = 1), and *MYC* (n = 2). **Conclusions:** Our study provides real-world clinical evidence, in the largest cohort to date, that simultaneous inhibition of *EGFR* and *MET* improves clinical outcomes of patients with *EGFR*-mutant NSCLC who acquired *MET* amplification from prior EGFR-TKI therapy, indicating that combinatorial regimen of EGFR-TKI and MET-TKI could be a more effective therapeutic strategy in this subset of patients. Differential immune-related microenvironment determines PD-1/PD-L1 blockade efficacy in advanced non-small cell lung cancer patients. *First Author: Masayuki Shirasawa, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Programmed death ligand-1 (PD-L1) expression is not a completely reliable predictive marker of the efficacy of anti-programmed cell death protein-1 (PD-1)/anti-PD-L1 therapy in advanced non-small cell lung cancer patients (NSCLC). Immune-related tumor microenvironment (TME) is classified into four different types based on the status of tumor-infiltrating lymphocytes (TILs) and PD-L1 expression. **Methods:** We retrospectively reviewed advanced NSCLC patients treated with anti-PD-1/anti-PD-L1 therapy between 2015 and 2019, and investigated the association between the efficacy of anti-PD-1/anti-PD-L1 therapy, the types of TME based on PD-L1 (clone: 22C3) expression, and the density of CD8-positive TILs by immunohistochemistry (/mm^2), and mutational profiles assessed by next-generation sequencing. **Results:** Overall, 228 patients without driver mutation (*EGFR*, *ALK*, *ROS1,* and *RET*) were included in the analysis. The patients were classified into four following groups: Type I: PD-L1$_{High}$ (tumor proportion score [TPS]$\geq$50%)/TIL$_{High}$ ($\geq$85/mm^2; n = 73), Type II: PD-L1$_{Low}$ (TPS $<$ 50%)/TIL$_{Low}$ ($<$ 85/mm^2; n = 70), Type III: PD-L1$_{High}$/TIL$_{Low}$ (n = 37), and Type IV: PD-L1$_{Low}$/TIL$_{High}$ (n = 48). The progression-free survival (PFS) and objective response rate (ORR) of anti-PD-1/anti-PD-L1 therapy clearly differed according to the different tumor microenvironment (TME) types (ORR and median PFS; Type I: 64%, 14.5 months, Type II: 12%, 2.1 months, Type III: 24%, 3.6 months, Type IV: 41%, 10.8 months). In patients with PD-L1$_{High}$ tumors, Type I tumors had significantly better ORR and PFS than Type III(ORR: p $<$ 0.001, and PFS: p $<$ 0.001) tumors. Regarding the association between mutational profiles, histology and the TME types, the presence of *TP53* mutation and *KRAS* mutation significantly related to TIL$_{High}$ (Type I and IV) and PD-L1$_{High}$ tumors (Type I and III), respectively. Pleomorphic and NSCLC- not otherwise specified histology were associated with Type I tumors, while LCNEC was associated with PD-L1 low tumors (Type II and IV). **Conclusions:** Various factors (mutational profile and histology) are related to TME classification based on the status of TILs and PD-L1 expression. Differential types of TME, including PD-L1 expression and TILs status, can accurately predict the efficacy of anti-PD-1/anti-PD-L1 therapy. Research Sponsor: None.

	ORR (95% CI) (%)	PFS (95% CI) (months)
All patients (n = 228)	36 (30-43)	5.5 (3.7-7.3)
Type I (PDL-1$_{High}$CD8$_{High}$, n = 73)	64 (52-75)	14.5 (8.3-NA)
Type II (PDL-1$_{Low}$CD8$_{Low}$, n = 70)	12 (5-21)	2.1 (1.8-2.4)
Type III (PDL-1$_{High}$CD8$_{Low}$, n = 37)	24 (12-41)	3.6 (2.3-4.9)
Type IV (PDL-1$_{Low}$CD8$_{High}$, n = 48)	41 (27-57)	10.8 (8.1-13.5)

Predicting response to pembrolizumab in non-small cell lung cancer, by analyzing the spatial arrangement of tumor infiltrating lymphocytes using deep learning. *First Author: Efrat Ofek, Department of Pathology, Sheba Medical Center, Ramat Gan, Israel*

Background: Immune checkpoint inhibitors (ICI) have become the standard treatment for metastatic NSCLC, although only a small proportion of patients derive durable benefit. PDL1 expression is the only approved biomarker to select NSCLC patients for treatment with single-agent pembrolizumab, however its predictive value is limited and better predictive biomarkers are needed. The spatial arrangement of immune cells in the tumor microenvironment (TME), namely tumor infiltrating lymphocytes (TILs), emerges as a potential biomarker for ICI efficacy. In this work, we utilized deep-learning (DL) models to extract TME features from digitized H&E slides and evaluated their predictive and prognostic role in patients with mNSCLC treated with Pembrolizumab. **Methods:** NSCLC patients (n=90) treated with single-agent 1st line pembrolizumab in two centers were identified. 47 patients from one center were used to train the model, and 43 patients from another center were used for validating the model. Pre-treatment H&E whole slide images (WSI) were analyzed using a deep-learning model to identify and classify tumor cells, TILs, tumor and stromal areas, and spatial features were calculated. Spatial features were correlated with clinical outcome data to train a binary classifier that identifies patients with a favorable clinical outcome. The resulting classifier combined three spatial features and three clinical features. The classifier was then applied to the validation set and differences in duration of treatment (DOT), and overall survival (OS) between patients with positive and negative scores were assessed. **Results:** The classifier identified patients in the validation set to have either positive (n=18) or negative (n=25) scores. Baseline patient characteristics and PDL1 score were similar between the positive and negative groups. In a Kaplan-Meier (KM) analysis, OS was significantly higher in patients with a positive score compared to patients with a negative score (HR=0.35, 95% CI 0.13-0.98; $p<0.05$). Positive patients had a significantly higher median OS (NR vs.17.8m, $p<0.05$) and 2-year OS (70.8% vs. 33%, p=0.02) than negative patients. Median DOT was also higher in positive patients compared to negative patients (10.1m vs. 6.5m). **Conclusions:** Deep-learning models that analyze the TME from H&E whole-slide images can identify NSCLC patients with durable benefit on Pembrolizumab. Identifying NSCLC patients who are exceptionally sensitive to anti-PD-1 therapy as monotherapy may improve clinical decision making and spare patients the unnecessary adverse effects associated with the addition chemotherapy or another IO agent. Research Sponsor: Nucleai.

Results from a phase II study of eftilagimod alpha (soluble LAG-3 protein) and pembrolizumab in patients with PD-L1 unselected metastatic non-small cell lung carcinoma. *First Author: Timothy Dudley Clay, St. John of God Hospital, Perth, Australia*

Background: Eftilagimod alpha (efti) is a soluble LAG-3 protein that binds to a subset of MHC class II molecules to mediate antigen presenting cell (APC) activation and CD8 T-cell activation. The stimulation of the dendritic cell network and subsequent T cell recruitment with efti may lead to stronger anti-tumor responses in combination than observed with pembrolizumab alone. We hereby report results of the 1st line non-small cell lung carcinoma (NSCLC) part of the phase II trial (NCT03625323). **Methods:** Patients (pts) with untreated, immunotherapy naïve, advanced NSCLC unselected for PD-L1 expression were recruited into part A. The study used a Simon's 2-stage design (17 pts planned for stage 1 and 19 pts for stage 2), with objective response rate (ORR) by iRECIST as the primary endpoint (EP). Secondary EPs include tolerability, disease control rate (DCR), progression free survival (PFS), overall survival (OS), PK, PD and immunogenicity. Efti is administered as 30 mg subcutaneous injection every 2 wks for 8 cycles and then every 3 wks for 9 cycles with pembrolizumab (200 mg intravenous infusion every 3 wks for up to 2 yrs). Imaging was performed every 8 weeks locally and with blinded independent central review (BICR) retrospectively. The study was approved by ethic committees and institutional review boards. **Results:** In total 36 pts were enrolled. At data cut-off (Jan 2021; median FU of 14 months), the median age was 69 yrs (range 53-84) and 69 % were male. The ECOG PS 0 and 1 was 42% and 58% respectively. Patients had squamous (42%) and non-squamous (58%) NSCLC and 95% presented with metastatic disease. All PD-L1 subgroups (TPS < 1 %, ≥ 1 % to ≤ 49 %; ≥ 50 %) were represented with 36% pts having ≥ 50% TPS. Pts received a median of 7.0 (range 1 – 31) pembrolizumab and 11.5 (range 1-22) efti administrations. Responses as per BICR and local read are shown in the table. ORR (local, iRECIST) by different PD-L1 subgroups was 27% for pts with TPS<1%, 39 % for TPS ≥ 1 %and 54% for ≥ 50 % TPS. Median PFS (n=36) was 8.2 months while median OS was not yet reached. The most common (> 20 %) treatment emergent adverse events (AEs) were asthenia (47 %), cough (36 %), decreased appetite (36 %), dyspnea (32 %), pruritus (31 %), fatigue (28 %), diarrhea (25 %), anemia (25 %), constipation (25 %) and back pain (22%). Two patients discontinued treatment due to adverse reactions (Grade 4 immune-mediated hepatitis, Grade 3 AST+ALT increase). **Conclusions:** Efti in combination with pembrolizumab is safe and shows encouraging antitumor activity in 1st line advanced NSCLC patients across all PD-L1 (TPS) levels. Clinical trial information: NCT03625323. Research Sponsor: Immutep S.A.

N=36	iRECIST (BICR)	iRECIST (local read)

Safety and efficacy of the anti-CD73 monoclonal antibody (mAb) oleclumab ± durvalumab in patients (pts) with advanced colorectal cancer (CRC), pancreatic ductal adenocarcinoma (PDAC), or EGFR-mutant non-small cell lung cancer (EGFRm NSCLC). *First Author: Johanna C. Bendell, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: Upregulation of CD73 in multiple cancers increases adenosine production, leading to local immunosuppression. Oleclumab, a human IgG1λ mAb, inhibits CD73 function and may increase antitumor immunity. Initial data from a Phase I, first-in-human, dose-escalation and expansion study showed that oleclumab ± durvalumab had manageable safety and encouraging clinical activity in pts with advanced CRC or PDAC. We report updated safety and activity in these cohorts and the first results in an expansion cohort of pts with advanced EGFRm NSCLC. **Methods:** Previously treated pts with histologically or cytologically confirmed microsatellite stable CRC, PDAC, or EGFRm NSCLC received oleclumab 5–40 mg/kg (escalation) and 40 mg/kg (expansion) IV Q2W, alone (escalation only) or with durvalumab 10 mg/kg IV Q2W. The primary objective was safety; secondary efficacy objectives included objective response (OR) per RECIST v1.1 and duration of response (DoR). **Results:** 66 pts were enrolled in the escalation phase (35 CRC, 31 PDAC) and 126 in the expansion phase (42 CRC, 42 PDAC, 42 EGFRm NSCLC). At data cutoff (DCO; June 9, 2020), the median number of oleclumab doses was 4 in pts on monotherapy (range 1–26) and 4 in pts on combination therapy across both phases (range 1–76). In the escalation phase, there were no DLTs in pts on monotherapy or combination therapy; treatment-related adverse events (TRAEs) occurred in 54.8% of pts on monotherapy (Grade 3–4 in 7.1%) and 54.2% of pts on combination therapy (Grade 3–4 in 20.8%); fatigue was the most common TRAE with both regimens. No TRAEs resulted in death. In previous interim analyses before this DCO, no ORs were reported in the escalation phase. In the expansion phase, 5 pts were treated for ≥ 12 mos; 6 pts were ongoing at DCO. TRAEs occurred in 54.0% (Grade 3–5 in 15.1%); the most common TRAEs were fatigue (15.1%), diarrhea (9.5%), and rash (7.1%). One pt had a TRAE resulting in death (systemic inflammatory response syndrome). ORs were seen in 1 CRC pt (DoR 35.9+ mos [+ = ongoing response]), 2 PDAC pts (DoR 22.1+ and 28.6+ mos), and 4 EGFRm NSCLC pts (DoR range 5.6 to 15.7+ mos, median not reached; only 1 of the 4 pts had $\geq 25\%$ programmed cell death ligand-1 [PD-L1]+ tumor cells). Nine CRC pts, 8 PDAC pts, and 9 EGFRm NSCLC pts had SD. Of 6 pts with matched biopsies who received combination therapy, 5 had increases in CD8+ T cells, PD-L1, and granzyme B. Baseline tumor CD73 expression and association with clinical response will be presented. **Conclusions:** Oleclumab ± durvalumab had a tolerable safety profile and combination therapy showed promising antitumor activity in EGFRm NSCLC. ORs and SD were durable, even in tumor types that are generally immunotherapy-resistant. Clinical trial information: NCT02503774. Research Sponsor: AstraZeneca.

Phase 1b/2 study of capmatinib plus gefitinib in patients with EGFR-mutated, MET-dysregulated non-small cell lung cancer who received prior therapy: Final overall survival and safety. *First Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong Provincial Peoples Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Primary findings from the phase 1b/2 study (NCT01610336) demonstrated clinical activity of combination therapy with capmatinib, a potent and selective MET inhibitor, and gefitinib, an epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) in heavily pre-treated patients with EGFR-mutated and MET dysregulated non-small cell lung cancer (NSCLC). The objective response rate (ORR) was 27% in patients across phase 1b/2 of the study. At the recommended phase 2 dose (R2PD) of capmatinib 400 mg twice-daily (bid) and gefitinib 250 mg once-daily (qd), the ORR was 47% in patients with high *MET*-amplified tumors (*MET* gene copy number ≥ 6). Here, we report the updated data on the efficacy and safety from the NCT01610336 study. **Methods:** Patients with locally advanced or metastatic NSCLC harboring *EGFR* exon 19 deletion or L858R mutation with a recorded clinical benefit on prior single-agent EGFR-TKI before progression and confirmed dysregulated MET pathway after progression on EGFR TKIs were included. Patients in phase 1b received capmatinib 100 to 800-mg capsules qd or 200 to 600-mg capsules or tablets bid, plus gefitinib 250 mg qd. Patients in phase 2 received the R2PD dose. Data on the overall survival (OS) and cumulative safety endpoints are reported in this final analysis. **Results:** Overall, 161 patients received the combination treatment in this study; phase 1b (n = 61) and phase 2 (n = 100). The median age of patients was 60.0 years, mostly Asian (67.1%) with an Eastern Cooperative Oncology Group performance status of 0/1: 18.0%/78.3%. At data cut-off on May 27, 2020, all patients had discontinued the study; 82 out of the 100 patients in phase 2 had died and 18 were censored (mostly lost to follow-up [n = 15]). One patient was still on treatment with a partial response and rolled over to another study. The median (range) follow-up time for OS was 12.2 (0.9-70.2) months. The median OS was 13.9 months (95% confidence interval, 11.6-15.7 months). The median (range) duration of exposure for capmatinib plus gefitinib was 16 weeks (0.4-209.7 weeks) during phase 1b and 18.5 weeks (0.4-268.0 weeks) during phase 2. Majority of the patients (98.8%) experienced ≥ 1 adverse event (AE); 87% of the patients had treatment-related AEs. Most common treatment-related AEs (reported in $\geq 20\%$) were nausea (28.0%), peripheral edema (23%), rash (21.7%), and decreased appetite (21.1%). Grade 3 or 4 treatment-related AEs occurred in 51 patients (31.7%) across both phases, of which, the most frequent (reported in $\geq 5\%$) were increased amylase and increased lipase (6.2% each) and peripheral edema (5%). **Conclusions:** Capmatinib 400 mg bid in combination with gefitinib 250 mg qd was well-tolerated and showed encouraging clinical activity in patients with EGFR-mutant and MET-dysregulated NSCLC. Clinical trial information: NCT01610336. Research Sponsor: Novartis.

Response to immune checkpoint inhibition as monotherapy or in combination with chemotherapy in metastatic *ROS1*-rearranged lung cancers. *First Author: Noura J. Choudhury, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *ROS1* fusions are oncogenic drivers in various cancers types, including 1-3% of non-small cell lung cancers (NSCLCs). Immunotherapy approvals for NSCLC include *ROS1*-rearranged carcinomas, but the activity of immune checkpoint inhibition (ICI) as monotherapy or in combination with chemotherapy (chemo-ICI) therapy, as well as the immunophenotypic characteristics of these tumors, have not been described in a large data set. **Methods:** In this multi-institutional study, patients with *ROS1*-rearranged NSCLC were identified retrospectively. Tumor PD-L1 expression and tumor mutational burden (TMB) were assessed as part of routine clinical care. In patients who received ICI monotherapy or chemo-ICI in the metastatic setting, time to treatment discontinuation (TTD) and objective response rate (ORR; RECIST v. 1.1) were calculated. TTD was assessed with Kaplan-Meier methods; patients remaining on treatment were censored at last follow up. **Results:** 184 patients with *ROS1*-rearranged NSCLC were identified. Among 146 PD-L1 evaluable cases, PD-L1 expression was $<$ 1% in 60 (41%), 1-49% in 35 (24%) and $\geq$50% in 51 (35%) tumors. Ninety-two of 100 (92%) TMB-evaluable tumors had $<$ 10 mutations/megabase (mut/Mb). TMB was significantly lower for *ROS1*-rearranged NSCLCs (n = 97) vs. *ROS1*-wild type tumors (n = 5,380) evaluated with next-generation sequencing using MSK-IMPACT (median 2.6 vs. 5.9 mut/Mb, p $<$ 0.001). Twenty-eight patients received ICI monotherapy and 11 patients received chemo-ICI. The median TTD was 2.1 months (95% CI: 1.0-4.2; n = 28) for single-agent ICI therapy and 10 months (95% CI: 4.7-14.1; n = 11) for chemo-ICI therapy. The ORR was 13% (2/16 RECIST-evaluable; 95% CI: 2-38%) for ICI monotherapy and 83% (5/6 RECIST-evaluable; 95% CI: 36-100%) for chemo-ICI therapy. There was no difference in PD-L1 tumor expression (p = 0.9) or TMB (p = 0.8) between responders and non-responders and no correlation between PD-L1 tumor expression (rho = 0.16, p = 0.6) or TMB (rho = 0.03, p = 0.9) and maximum change in sum of target lesions. **Conclusions:** Most *ROS1*-rearranged NSCLCs have low or no PD-L1 expression and low TMB. The activity of checkpoint inhibitor monotherapy is disappointing in ROS1-driven NSCLC. In contrast, combination chemoimmunotherapy can achieve clinically meaningful activity. Research Sponsor: None.

Complete metabolic response in advanced non-small cell lung cancer patients with prolonged response to immune checkpoint inhibitor therapy. *First Author: Daniel Christian Christoph, Evang. Kliniken Essen-Mitte, Essen, Germany*

Background: Recently reported, extended follow-up data from KEYNOTE-024 or -010 indicates that non-small-cell lung cancer (NSCLC) patients can experience long-term benefit from immunotherapy irrespective of discontinuation (per protocol: 35 cycles ~24 months) or type of response in computed tomography (CT). Similar results were observed in the pooled analysis of 5-year follow-up data from CheckMate-017 and -057. This raises the question, whether patients may safely discontinue immunotherapy after achieving durable response. However, recently published results from CheckMate-153 demonstrated inferior survival rates in patients ceasing immunotherapy after one year, therefore optimal treatment duration of immunotherapy in advanced NSCLC remains unknown. Protocols from published Phase-III trials implemented treatment for a period of approximately 24 months or until evidence of disease progression or unbearable toxicity. Therefore, the ideal duration of immunotherapy remains unclear, and finding markers of beneficial outcome is of great importance. Here, we determine the proportion of complete metabolic responses (CMR) in patients that have not progressed after 24 months of immunotherapy. **Methods:** This is a retrospective analysis of forty-five patients with positron emission tomography using 2-[18F]fluoro-2-deoxy-D-glucose (FDG-PET) imaging for assessment of residual metabolic activity after at least 24 months of immunotherapy. Lesion-uptake in FDG PET on or below background level (using mediastinum as reference) was considered as CMR. Time until best objective morphological response including disease stabilization was measured from start of immunotherapy until first stable CT-scan (i.e. no progression or further response compared to previous scan) using RECIST 1.1. **Results:** Out of 45 patients, 29 patients had a CMR (64%). CMR was observed more frequently in non-first line patients. Patients with CMR were younger (median 65.7 vs. 75.5, P = 0.03). Fourteen patients with CMR have discontinued therapy and have not progressed until time of analysis; however median follow-up was only 5.6 (range 0.8-17.0) months. **Conclusions:** After a minimum of 24 months of palliative immunotherapy for NSCLC, CMR occurred in almost two thirds of patients. Potentially, achievement of CMR might identify patients, for whom palliative immunotherapy may be safely discontinued. Research Sponsor: None.

Comprehensive investigation of mutational features of adenocarcinoma in situ and invasive adenocarcinoma among Chinese lung cancer patients. *First Author: Chan Xiang, Department of Pathology, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China*

Background: Lung adenocarcinoma (LUAD) is further classified into several histological subtypes with adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA), and invasive adenocarcinoma (IAC) as the three major subtypes according to the extent of invasion. AIS has been considered as a precursor of IAC. Considering the significantly higher mutation burden among IAC tumors than AIS tumors, it seems likely that AIS tumors undergo a process of accumulating various somatic mutations to gain invasive ability. To understand the gene mutations involved in this transformation, we compared the mutational features of AIS and IAC tumors. **Methods:** This retrospective study included 2,769 Chinese patients diagnosed with stage 0-IIIA LUAD. Targeted sequencing was performed on tissue DNA isolated from 246 AIS tumors and 2,523 IAC tumors using 68 lung cancer-related genes (Lung Core, Burning Rock Biotech). **Results:** Analysis of mutation profiles revealed that mutation count was significantly lower for AIS ($P<$ 0.01) as compared to IAC tumors. Moreover, AIS tumors had significantly higher mutation detection rates for *ERBB2* exon 20 insertion (20ins) ($P\leq$0.05), *EGFR* 20ins ($P\leq$0.05), non-V600E *BRAF* mutations ($P\leq$0.05), and *MAP2K1* small insertion-deletion variants ($P\leq$0.05). These 4 gene mutations were grouped and referred to as AIS-like mutations for further analysis. Detection rates of AIS-like mutations were 54.9% for AIS tumors and 7.8% for IAC tumors. Patients with AIS-like mutation-positive AIS tumors were significantly younger than those with AIS tumors without AIS-like mutations (P =0.018), while age were similar for IAC tumors with or without AIS-like mutations. Mutation count was similar between AIS tumors with or without AIS-like mutations. Interestingly, IAC tumors harboring AIS-like mutations had a significantly higher mutation count than those harboring known oncogenic drivers (P= 0.045). Further investigation of the molecular profiles of IAC tumors harboring AIS-like mutations (n = 198) revealed the presence of various concurrent mutations in 8 genes including *TP53* (39.4%), *EGFR* (non-20ins) (16.7%), *RB1* (7.1%), *PIK3CA* (6.6%), *MET* (5.1%), *ROS1* (4.0%), *FLT3* (4.0%), and *PTEN* (3.5%), which were absent among AIS tumors, particularly those that harbor AIS-like mutations. In addition to *TP53* (35.8%), *PIK3CA* (4.5%), and *RB1* (4.0%), IAC tumors without AIS-like mutations (n = 2,324) had additional concurrent mutations in 2 other genes *CDK4* (5.7%) and *STK11* (3.9%) as compared to AIS tumors. **Conclusions:** Our data suggest that AIS-like mutations could be involved in the early stages of tumorigenesis by initiating the accumulation of other gene mutations that are required for the transformation of AIS tumors into IAC tumors. Our study contributes to a deeper understanding of the distinct gene mutations between AIS and IAC tumors among Chinese LUAD patients. Amivantamab compared with real-world therapies in patients with NSCLC with EGFR Exon 20 insertion mutations who have progressed after platinum doublet chemotherapy. *First Author: Anna Rachel Minchom, Drug Development Unit, Royal Marsden/Institute of Cancer Research, Sutton, United Kingdom*

Background: Amivantamab is an epidermal growth factor receptor (EGFR)-MET bispecific antibody with immune cell-directing activity. Amivantamab has demonstrated efficacy and safety in patients (pts) with EGFR exon 20 insertion (Exon20ins) in the ongoing CHRYSALIS phase 1 study in advanced non-small cell lung cancer (aNSCLC). Because CHRYSALIS is a non-randomized, single arm study, external controls (EC) can add valuable context in interpreting amivantamab's efficacy and appreciating the unmet needs given real-world therapies. A protocol-driven treatment comparison was conducted of amivantamab vs real-world therapies in pts with Exon20ins aNSCLC who progressed after platinum chemotherapy. **Methods:** Custom curated, real-world data abstracting clinically relevant measures that are not typically available from off-the-shelf datasets were obtained from 3 US-based companies: Flatiron, COTA, and ConcertAI. Datasets were de-duplicated via a tokenization procedure, analyzed separately and as a single pooled database. Key eligibility for the EC included: Exon20ins aNSCLC, prior platinum chemotherapy, $\geq$1 line after platinum therapy, and ECOG PS 0 or 1. Propensity score weighting (average treatment effects on the treated) was used to adjust for differences in age, brain metastases, ECOG PS, and number of prior lines of therapy (LOT). **Results:** The amivantamab-treated population (N = 81) included post-platinum pts with EGFR Exon20ins aNSCLC treated at the recommended phase 2 dose (Sabari WCLC 2020 Abs #3031). After de-duplication of the custom real-world datasets, 126 unique pts formed the EC. Most frequent treatments after platinum doublet chemotherapy in the EC group were checkpoint inhibitors (CPI; 25%), single-agent, non-platinum chemotherapies (25%), and EGFR tyrosine-kinase inhibitors (TKIs; 16%). Baseline demographics were generally similar between amivantamab and the EC pts; notable differences included a higher percentage of Asian pts (56% vs 9%) and more prior LOT (median 2 vs 1) among the amivantamab compared to the EC pts. Median overall survival (OS) among amivantamab pts was 22.8 months and EC pts was 13.1 months (HR = 0.53 [95% CI, 0.33, 0.86]). Similarly, amivantamab pts had longer progression-free survival (8.3 vs 2.9 months; HR = 0.46 [95% CI, 0.33, 0.63]) and time to next treatment (14.8 vs 4.8 months; HR = 0.42 [95% CI, 0.29, 0.6]) compared to the EC pts. Confirmed overall response rate was 40% among amivantamab pts and 10% for the EC pts (odds ratio = 4.44 [95% CI 2.42, 8.14]). **Conclusions:** Amivantamab demonstrated a 10-month higher OS than real-world therapies in the post-platinum setting. The poor performance of the EC, frequently treated with CPI, single chemotherapies, and EGFR TKI, highlights the ineffectiveness of these agents and the urgent need to find more alteration-specific treatments in aNSCLC. Research Sponsor: Janssen R&D.

Totality outcome of afatinib sequential treatment in patients with EGFR mutation-positive NSCLC in Korea: KCSG LU-19-22. *First Author: Hyun Ae Jung, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: While osimertinib showed impressive efficacy and safety profile in 1st-line setting for EGFR mutation-positive (EGFR M+) NSCLC patients, there are no standard targeted therapy following progression. Thus, interest has been growing on sequential treatment of osimertinib as 2nd-line treatment for patients acquiring T790M resistance mutation after 2nd generation EGFR TKIs. We did a retrospective study to support the hypothesis that sequential approach of afatinib followed by osimertinib represents a practical treatment option in 'real-world' practice. **Methods:** In this non-interventional, multicenter study, EGFR M+ NSCLC patients had to start 1st-line afatinib treatment ≥ 13 months prior to data entry. They were categorized into 4 cohorts according to 2nd-line treatments with retesting results: T790M+ patients sequentially treated with osimertinib in cohort A, T790M patients treated with chemotherapy or other treatments in cohort B, and patients with unknown mutation status in cohort C. Cohort D included patients who were still ongoing with afatinib. Primary outcome was the time on treatment (TOT) of patients receiving 1st-line afatinib (TOT-1) followed by 2nd-line treatments (TOT-2). Secondary endpoints were acquisition rate of T790M after progression, objective response rates of afatinib (ORR-1) and 2nd-line treatments (ORR-2), and overall survival (OS). **Results:** Among a total of 761 enrolled patients, 737 patients excluding 24 screening failures were allocated into cohort A (n=116), B (n=143), C (n=111), and D (n=367). Median age was 62 years (22 - 90) with 53.05% of female proportion. Brain metastasis was discovered in 38.94% at initial diagnosis. Regarding genotypes of EGFR mutations, del19 was 57.53%, 31.48% for L858R, 7.33% for uncommon mutations, and 3.66% for compound mutation. Median TOTs in cohort A, B, C, and D were 35.09 months (95% CI, 30.09 to 43.53), 18.76 months (95% CI, 16.92 to 20.20), 12.02 months (95% CI, 10.22 to 14.98), and 42.61 months (95% CI, 30.95 to 59.23), respectively. Particularly, in cohort A, median TOT-1 and TOT-2 were 17.43 months (95% CI, 15.21 to 19.32) and 11.04 months (95% CI, 7.10 to 14.13), respectively. Retesting was attempted in 262 of 370 patients (70.81%) with 44.27% of T790M detection rate. ORR-1 and -2 in cohort A, B, and C were 84.48% and 56.03%, 82.52% and 29.08%, 54.95% and 21.70%, respectively and 68.94% of ORR for cohort D. Median OS has was not reached. **Conclusions:** These data suggest that, in real-world practice, sequential afatinib followed by osimertinib be a feasible and effective therapeutic strategy for EGFR M+ NSCLC patients acquiring T790M during the period of afatinib treatment. Of note, median TOT in cohort D is over 3.5 years, suggesting that 1st-line afatinib potentially allow certain patients to maintain long-term, chemotherapy-free state. Further analysis is currently being undertaken and will be presented. Research Sponsor: Boehringer Ingelheim.

Clinico-pathological and genomic features of *NRAS*- or *HRAS*-mutated non-small cell lung cancer (NSCLC) identified in large-scale genomic screening project (LC-SCRUM-Asia). *First Author: Yutaro Tamiya, National Cancer Center Hospital East, Kashiwa, Japan*

Background: *RAS* (*KRAS*, *NRAS* and *HRAS*) is a targetable oncogene family in several cancers, including NSCLC, and the clinical development of various RAS-targeted therapies are ongoing. However, the clinical relevance of uncommon *RAS* mutations, such as *NRAS* and *HRAS* mutations, in NSCLC patients (pts) remains unclear. **Methods:** In a large-scale genomic screening project (LC-SCRUM-Asia), we have prospectively analyzed lung cancer pts for genomic alterations by a targeted next-generation sequencing (NGS) system, Oncomine Comprehensive Assay. We evaluated clinico-pathological and genomic characteristics in *NRAS*- or *HRAS*-mutated NSCLC pts comparing with those in *KRAS*-mutated pts based on the LC-SCRUM-Asia database. **Results:** Since March 2015 to December 2020, 9131 NSCLC pts were enrolled in the LC-SCRUM-Asia, and 8374 of them (92%) were successfully analyzed by NGS. The *RAS* mutation frequencies were 1134 *KRAS* (14%), 50 *NRAS* (0.6%), and 15 *HRAS* (0.2%). The most frequent variant of *NRAS* and *HRAS* mutations was Q61X (78%) and G13X (80%), respectively, whereas that of *KRAS* was G12X (84%). Patient characteristics were summarized in Table. Male was significantly frequent in *NRAS*- than in *KRAS*-group (p=0.03), and smokers were frequent in all the three groups (overall, 79%). The majority of *NRAS* (70%) and *KRAS* mutations (89%) were detected in adenocarcinoma (Ad), whereas 60% of *HRAS* mutations were in squamous cell carcinoma (Sq). Tumor mutation burden (TMB) was significantly higher in *NRAS*-mutated tumors than in *KRAS*-mutated tumors (p=0.03). Concomitant *TP53* mutations were significantly frequent in *HRAS*-mutated pts than in *KRAS*-mutated pts (53% vs. 30%, p=0.05), and *STK11* mutations were also tended to be frequent in *HRAS*-mutated pts than in *KRAS*-mutated pts (20 vs. 7%, p=0.10). Therapeutic efficacy of PD-1/PD-L1 inhibitors was not different among the three groups in the current follow-up data, but *HRAS*-mutated tumors did not respond to PD-1/PD-L1 inhibitors (response rate, 0%; median PFS, 1.6 months). **Conclusions:** *NRAS*- or *HRAS*-mutated NSCLCs were different from *KRAS*-mutated NSCLCs in clinicopathological and genomic profiles. In particular, the immunotherapies were not effective for *HRAS*-mutated NSCLCs. Research Sponsor: Japan Agency for Medical Research and Development.

SHR-1701, a bifunctional fusion protein targeting PD-L1 and TGF-β, for advanced NSCLC with *EGFR* mutations: Data from a multicenter phase 1 study. *First Author: Meiqi Shi, Department of Oncology, Jiangsu Cancer Hospital, Nanjing, China*

Background: Despite the development of targeted therapies for advanced NSCLC harboring *EGFR* mutations (*EGFR*+), acquired resistance remains inevitable. Immune checkpoint inhibitor as monotherapy has limited efficacy. Blockade of the TGF-β pathway which plays a key role in immune suppression may enhance the tumor response to anti-PD-1/PD-L1 antibodies. Here, we assessed SHR-1701, a novel bifunctional fusion protein composed of a mAb against PD-L1 fused with the extracellular domain of TGF-β receptor II, in advanced NSCLC pts including one separate *EGFR+* cohort. **Methods:** This phase 1 study includes a 3+3 dose-escalation and dose-expansion period of pretreated advanced NSCLC and multiple clinical expansion cohorts of different tumor types, genetic aberrations, or prior therapies. During the dose-escalation and dose-expansion period, pathologically confirmed pts received SHR-1701 at 3, 10, or 20 mg/kg Q3W or 20 mg/kg Q2W by intravenous infusion. The primary objectives were to determine the safety profile, maximum tolerated dose (MTD), and recommended phase 2 dose (RP2D) of SHR-1701. In the *EGFR*+ NSCLC clinical expansion cohort, histologically or cytologically confirmed advanced pts after at least 1L standard EGFR TKI received SHR-1701 at RP2D, and the primary endpoint was objective response rate (ORR). Treatment beyond progression was allowed. **Results:** During the dose-escalation and dose-expansion period, 30 pts were recruited: all stage IV; 83.3% had ≥2 metastasis sites; 76.7% had received ≥2L prior systemic therapy. One dose-limiting toxicity (immune-mediated pneumonitis) in the 20 mg/kg Q2W group was observed, and the MTD was not reached. Population pharmacokinetics and exposure-response analysis of SHR-1701 based on this study and another phase 1 study for advanced solid tumors (NCT03710265) demonstrated 30 mg/kg Q3W as the RP2D. In the *EGFR*+ NSCLC cohort, 27 pts were enrolled: all stage IV; 77.8% had ≥2 metastasis sites; 70.4% had received ≥2L prior systemic therapy; 29.6% had 19-Del, 14.8% 19-Del and T790M, 7.4% 20-ins, 29.6% L858R, 18.5% L858R and T790M. With a median SHR-1701 exposure of 8.7 weeks (range, 3.0-24.0), 4 of the 24 pts who had at least one post-baseline radiographic assessment achieved objective responses, including 3 ongoing confirmed and 1 unconfirmed partial response. ORR was 16.7% (95% CI, 4.7%-37.4%), and disease control rate was 50.0% (95% CI, 29.1%-70.9%). Grade 3 treatment-related adverse events (TRAEs) occurred in 2 (7.4%) pts, including anemia, hypokalemia, and asthenia (1 [3.7%] for each). There were no grade 4 or 5 TRAEs. No pts discontinued treatment due to TRAEs. **Conclusions:** SHR-1701 monotherapy shows a manageable safety profile and encouraging antitumor activity in advanced *EGFR*+ NSCLC pts after failure of at least 1L standard EGFR TKI. Further investigation of SHR-1701 combination therapy for *EGFR+* NSCLC is warranted. Clinical trial information: NCT03774979. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

9056 **Poster Session**

Patient-reported outcomes in capmatinib-treated patients with *MET*ex14-mutated advanced NSCLC: Results from the phase II GEOMETRY mono-1 study. *First Author: Juergen Wolf, Department of Internal Medicine, Center for Integrated Oncology, University Hospital of Cologne, Cologne, Germany*

Background: Capmatinib, a potent, selective MET inhibitor, showed substantial antitumor activity and manageable tolerability in patients with *MET*ex14-mutated advanced non-small cell lung cancer (aNSCLC) in the GEOMETRY mono-1 trial (NCT02414139). Patient-reported outcomes (PROs) from this study are reported here. **Methods:** GEOMETRY mono-1 enrolled patients ≥18 years with *MET*ex14-mutated or *MET*-amplified, *ALK*-negative and *EGFR* wild-type, treatment-naïve (1L) or pre-treated (2L+) aNSCLC, to receive capmatinib orally 400 mg bid during 21-day treatment cycles. Here we report results for patients with *MET*ex14 mutations. PROs (EORTC QLQ-C30, QLQ-LC13 and EQ-5D-5L) were collected at baseline (BL) and every 6 weeks (Wks) until end of treatment. Key PROs (in patients with BL and ≥1 post-BL value) included change from BL in QLQ-C30 global health status (GHS), QLQ-LC13 symptoms (cough, chest pain and dyspnea), and EQ-5D-5L visual analogue scale (VAS), with a ≥10-point change from BL considered clinically meaningful. Time to definitive deterioration (TTDD) in QLQ-LC13 symptoms (time from treatment initiation to first date of ≥10% symptom change from BL with no later reduction) was assessed using Kaplan-Meier. QLQ-LC13 symptoms over time were explored by BIRC-assessed clinical response to capmatinib. **Results:** By Jan 6, 2020 cut-off, median capmatinib exposure was 48.2 (4.0 117.4) Wks and 22.1 (0.4 136.0) Wks for 1L and 2L+ patients, respectively. A total of 27/28 1L patients and 65/69 2L+ patients completed PROs at BL, and completion rate remained high (mostly > 70%) through treatment cycles. Mean [SD] BL PRO scores were moderate-to-high in 1L and 2L+ patients (GHS: 64.7 [21.6] and 58.8 [21.0.]; cough: 35.9 [32.6] and 28.7 [28.2]; chest pain: 12.8 [23.2] and 17.2 [22.7]; dyspnea: 23.5 [23.4] and 22.2 [20.8]; VAS: 67.7 [20.8] and 61.9 [18.8], respectively). Overall change from BL in PROs was maintained over time. Cough improved early, with meaningful improvements observed through cycles, notably in 1L patients (mean change from BL [SD] at Wk 7: 1L -13.0 [39.9], 2L+ -8.2 [28.4]; Wk 25: 1L -15.6 [33.0], 2L+ -6.0 [31.5]; Wk 43: 1L -28.2 [26.7], 2L+ -10.5 [27.3]). Median TTDD in GHS was 16.6 months (95% CI: 9.7, NE [not estimated]) and 12.4 months (95% CI: 4.2, 19.4) in 1L and 2L+ patients, respectively. Median TTDD for cough and chest pain was NE in both 1L and 2L+ patients, and for dyspnea was 19.4 months (95% CI: 12.4, NE) and 22.1 months (95% CI: 9.9, NE), respectively. QLQ-LC13 symptoms improved at all cycles in patients achieving clinical complete response or partial response, while symptom worsening was seen in those with no clinical response. **Conclusions:** Capmatinib was associated with clinically meaningful improvements in cough, delayed time to lung symptom deterioration, and preserved QoL, supporting its use as a treatment option in patients with *MET*ex14-mutated aNSCLC. Clinical trial information: NCT02414139. Research Sponsor: Novartis.

Patient-reported outcomes (PRO) from the phase 2 CodeBreaK 100 trial evaluating sotorasib in *KRAS* p.G12C mutated non-small cell lung cancer (NSCLC). *First Author: Alexander I. Spira, US Oncology Research/Virginia Cancer Specialists, Fairfax, VA*

Background: In the registrational phase 2 CodeBreaK 100 trial, sotorasib demonstrated a response rate of 37.1% with median duration of 10.0 months, a median progression-free survival of 6.8 months, and a tolerable safety profile in patients with pretreated *KRAS* p.G12C mutated NSCLC. Patients received a median of 2 prior lines of therapy. Here, we report PRO measures of health-related quality of life (QoL), physical functioning, and key lung cancer symptoms from this trial. **Methods:** Eligible patients had *KRAS* p.G12C mutated advanced NSCLC and received prior standard therapies. Sotorasib was given at an oral daily dose of 960 mg with 21-day treatment cycles until disease progression. Disease-related symptoms and health-related QoL were evaluated as exploratory endpoints on day 1 of each cycle from baseline to discontinuation, using the European Organization for Research and Treatment of Cancer Quality-of-life Questionnaire Core 30 (EORTC QLQ-C30) and its lung cancer module, EORTC QLQ-LC13. The single item, 5-point scale GP5, of the Functional Assessment of Cancer Therapy-General version was used to evaluate the impact of side effects. Predefined analyses included change from baseline using descriptive statistics and mixed model for repeated measures for global health status/QoL, physical functioning, and key lung cancer symptoms of cough, dyspnea and chest pain. **Results:** Of 126 patients enrolled, compliance rates for each of the questionnaires were high throughout the study ($>$ 70%). Data up to cycle 11 (where n $>$ 20) are presented. EORTC QLQ-C30 global health status/QoL and physical functioning were maintained over time (least-square mean changes ranged from -3.5 to 0.2 and 0.1 to 3.9, respectively). EORTC QLQ-C30 symptoms of fatigue, nausea/vomiting, pain, dyspnea, insomnia, appetite loss, and constipation were stable or improved. Similarly, key lung cancer-related symptoms, as measured by EORTC QLQ-LC13, remained stable or improved from baseline, with the greatest least-square mean change of -11.2 (95% CI: -16.2, -6.1) for cough, -4.9 (95% CI: -10.3, 0.4) for chest pain, and -3.4 (95% CI: -7.8, 1.0) for dyspnea. Most patients reported on the GP5 that they were "not at all" (54.2%-79.2%) or "a little bit" (8.3%-33.3%) bothered by side effects from sotorasib, with 0%-7.4% reporting being bothered as "quite a bit" and 0% as "very much". **Conclusions:** In patients from the single-arm phase 2 trial of sotorasib, PRO measures suggested maintenance or improvement of global health status/QoL, physical functioning, and the severity of key lung cancer-related symptoms, including cough, dyspnea, and chest pain. Self-reported side effect bother was minimal. These data, together with the encouraging efficacy and safety profiles, strongly support the use of sotorasib in this population. Clinical trial information: NCT03600883. Research Sponsor: Amgen Inc.

TROPION-PanTumor01: Dose analysis of the TROP2-directed antibody-drug conjugate (ADC) datopotamab deruxtecan (Dato-DXd, DS-1062) for the treatment (Tx) of advanced or metastatic non-small cell lung cancer (NSCLC). *First Author: Funda Meric-Bernstam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Datopotamab deruxtecan (Dato-DXd; DS-1062) is an ADC composed of a humanized anti-TROP2 IgG1 monoclonal antibody conjugated to a topoisomerase I inhibitor via a tetrapeptide-based cleavable linker. **Methods:** TROPION-PanTumor01 (NCT03401385) is a multicenter dose-escalation/expansion study evaluating Dato-DXd administered Q3W in patients (pts) with advanced NSCLC (since expanded to other tumor types, excluded from this analysis). Efficacy and safety were evaluated in 175 pts for dose analysis. Pharmacometric analyses (population pharmacokinetics [popPK] and exposure-response modeling) were conducted across doses to inform dose selection for further development. **Results:** At data cutoff (Sept 4, 2020), median follow-up was 7.4 mo (range, 0.10-21.7 mo). Select all-grade TEAEs were 1.5- to 2-fold higher in the 8 mg/kg vs 4 and 6 mg/kg cohorts: vomiting (34% vs 12% and 18%), anemia (28% vs 4% and 16%), diarrhea (20% vs 6% and 11%), and mucositis (29% vs 6% and 13%). Rates of grade $\geq$3 drug-related TEAEs and serious drug-related TEAEs were $\geq$2-fold higher with the 8 mg/kg dose (n = 80; 34% and 20%) relative to the 4 mg/kg (n = 50; 10% and 8%) and 6 mg/kg (n = 45; 16% and 9%) doses. Rates of drug-related interstitial lung disease (ILD), as determined by an independent adjudication committee, were higher in the 8 mg/kg cohort (15% vs 2% and 2% in the 4 and 6 mg/kg cohorts); 3 pts in the 8 mg/kg cohort experienced grade 5 ILD. Dose interruptions and reductions due to TEAEs increased with dose (4 mg/kg: 4% and 2%; 6 mg/kg: 20% and 9%; 8 mg/kg: 20% and 31%). More pts in the 8 mg/kg cohort discontinued Tx early due to AEs (15%) compared with those in the 4 mg/kg (4%) and 6 mg/kg (7%) cohorts. ORRs determined by blinded independent central review were similar: 8 mg/kg, 25% (20/80); 6 mg/kg, 21% (8/39); and 4 mg/kg, 23% (9/40). Preliminary median PFS (95% CI) was 5.4 mo (4.1-7.1 mo) in the 8 mg/kg cohort, 8.2 mo (1.5-11.8 mo) in the 6 mg/kg cohort, and 4.3 mo (2.0 mo-NE) in the 4 mg/kg cohort. PFS was limited by early censoring due to immature duration of follow-up, with the majority of pts having $\leq$3 mo of follow-up in the 4 (66%) and 6 mg/kg (67%) cohorts vs 8 mg/kg (46%) cohort. In pharmacometric analyses, tumor-size change from baseline and probability of complete response/partial response positively correlated with exposure (AUC) of Dato-DXd. Incidences of dose reduction and grade $\geq$2 stomatitis/mucositis were also positively correlated with exposure; projected probabilities in a virtual population bootstrapped from pts with NSCLC in the popPK data confirmed these trends. Updated results will be presented. **Conclusions:** A Dato-DXd dose of 6 mg/kg was selected for the randomized, phase 3, TROPION-Lung01 trial (NCT04656652) based on better tolerance and improved efficacy, including a trend toward increased PFS. Clinical trial information: NCT03401385. Research Sponsor: Daiichi Sanko Co., Ltd.

9059 **Poster Session**

The role of chemotherapy plus immune checkpoint inhibitors in oncogenic driven non-small cell lung cancer: A University of California Lung Cancer Consortium retrospective study. *First Author: Karen Kelly, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Immune checkpoint inhibitors (ICIs) have demonstrated limited efficacy in patients (pts) with actionable oncogenic drivers. As a result, pts with the prototypic oncogenic drivers (EGFR and ALK) have purposefully been excluded from many NSCLC ICI trials although ICI is commonly used in combination with chemotherapy for these pts. Data from one randomized trial that included pts with known EGFR and ALK alterations did not show a survival benefit with an ICI plus a platinum doublet. We sought to gain further insight into the role of chemotherapy plus ICI in pts with oncogenic driven tumors. **Methods:** We conducted a retrospective analysis of pts with oncogenic drivers (EGFR, ALK, ROS1, BRAF, MET, RET, HER2 and KRAS) who were treated with chemotherapy (C) or chemotherapy plus ICI (C+ICI) between 2018 and 2019 at the five University of California (UC) NCI Designated Cancer Centers (UC Irvine, UC Davis, UC Los Angeles, UC San Diego and UC San Francisco). Descriptive statistics were used. Kaplan-Meier plots and confidence intervals summarize PFS and OS in the overall cohort and oncogenic subgroups. **Results:** 125 pts were identified. Median age 64.1 years; M/F (45%/55%); White/Asian (59%/33%); Current/Former/Never Smokers (4%/39%/57%); PS 0/1/2(22%/68%/10%); prior number of tyrosine kinase inhibitors 0/1/2/ $>$ 3 (46%/23%/19%/11%); Oncogenic driver: EGFR mutations (60%), KRAS mutations (23%), ALK fusions (8%), MET mutations (2.4%), RET fusions (1.6%), ROS1 fusions (1.6%), HER2 mutations (1.6%), and BRAF mutations (0.8%). The table below displays the efficacy outcomes. **Conclusions:** There was no survival benefit for pts with oncogenic drivers treated with chemotherapy plus an immune checkpoint inhibitor in the overall cohort or any of the subsets. Pts with KRAS mutations treated with C+ICI had a numerically longer median PFS than their counterparts treated with C. Updated data and additional analyses including PD-L1, TMB, co-mutations and toxicity will be presented. Research Sponsor: None.

A phase 2, open-label, multicenter study to evaluate the efficacy, safety, and tolerability of KN046 in combination with chemotherapy in subjects with advanced non-small cell lung cancer. *First Author: Yunpeng Yang, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China*

Background: Dual blockade of PD-1 and CTLA-4 has shown improved overall survival (OS) in combination with a short course of chemotherapy. KN046 is a novel bispecific antibody that blocks both PD-L1 interaction with PD-1/CD80 and CTLA-4 interaction with CD80/CD86. We hypothesized that KN046 could be combined with a full course of chemotherapy and build more durable clinical benefit. **Methods:** This study enrolled systemic treatment naive, stage IV NSCLC patients (pts). Eligible pts received KN046 plus platinum doublet chemotherapy until progressive disease, unacceptable toxicity, withdrawal of informed consent or death. Efficacy evaluation was performed by investigators per RECIST 1.1. Safety and tolerability were assessed per NCI-CTCAE v5.0. **Results:** As of the Jan. 19, 2021, 87 pts [Cohort 1 (n = 51), Cohort 2 (n = 36)] have been enrolled with 83 pts having tumor PD-L1 expression data (PD-L1 $\geq$1%: 55.4%; PD-L1 $<$ 1%: 44.6%). 33.3% pts remained on the study treatment and 66.7% pts discontinued treatment due to disease progression (27.6%), TEAE (13.8%), death (9.2%) and other reasons (16%). The median treatment duration of KN046 was 21 weeks (range: 1.6~68.7 weeks). Treatment related TEAE (TRAE) occurred in 92% pts. 25.3% pts experienced Grade$\geq$3 TRAE [diarrhoea (5.7%), alanine aminotransferase increased (4.6%), infusion related reaction (3.4%), rash (3.4%), aspartate aminotransferase increased, dermatitis allergic and immune-mediated pneumonitis (2.3%, respectively), anaphylactoid reaction, autoimmune hepatitis, back pain, bilirubin conjugated increased, hypertension, neutrophil count decreased, platelet count decreased, pneumonitis, rash maculo-papular, septic shock and white blood cell count decreased (1.1%, respectively). In 81 efficacy evaluable pts, the overall objective response rate (ORR) was 50.6% (95% CI: 39.3%,61.9%) and disease control rate (DCR) was 87.7% (95% CI: 78.5%-93.9%). The ORR and DCR in pts with non-squamous NSCLC (n = 48) were 45.8% (95% CI: 31.4%, 60.8%) and 89.6% (95% CI: 77.3%, 96.5%). The ORR and DCR in pts with squamous NSCLC (n = 33) were 57.6% (95% CI: 39.2%, 74.5%) and 84.8% (95% CI: 68.1%, 94.9). Progression free survival (PFS) and OS events have occurred in 53% and 18% patients. Median PFS was 5.9 (95%CI: 5.3, 8.7) months. Median OS was not reached. OS rate at 12 and 15 months were both 74.9%. Similar OS curves have been observed in PD-L1 $\geq$1% and PD-L1 $<$ 1% pts. In PD-L1 $\geq$1% patients, median PFS was 6.7 months (10.8 months for PD-L1 $\geq$1% squamous NSCLC pts). **Conclusions:** KN046 combined with platinum doublet chemotherapy is tolerated and has shown promising clinical benefit as IL treatment for stage IV NSCLC particularly in PD-L1$\geq$1% tumors and squamous histology. Pivotal Phase III trial in advanced unresectable or metastatic squamous NSCLC is currently ongoing. Clinical trial information: NCT04054531. Research Sponsor: Alphamab oncology.

9061 **Poster Session**

Comparison of time to failure of pembrolizumab plus chemotherapy versus pembrolizumab monotherapy: A consecutive analysis of NSCLC patients with high PD-L1 expression. *First Author: Hiroshi Takumida, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: There are two types of pembrolizumab-containing strategies for patients with non-small cell lung cancer (NSCLC) exhibiting a high expression level of programmed death-ligand 1 (PD-L1) (tumor proportion score [TPS] ≥50%): the early combination of pembrolizumab plus chemotherapy, and chemotherapy after pembrolizumab failure. Which strategy is superior, however, remains unclear. Comparing progression-free survival (PFS) or progression after the next therapy line (PFS2) in previous clinical trials has not allowed any conclusions regarding superiority to be made. Instead, the time to failure of strategy (TFS), which represents the time until disease exacerbation when the same number of drugs has been used, should be used to compare the two strategies. **Methods:** We consecutively reviewed the efficacy and safety of first-line, pembrolizumab-containing regimens administered between December 2017 and November 2020. We divided the patients who received pembrolizumab as a first-line treatment into two groups according to whether they received chemotherapy: a pembrolizumab plus chemotherapy group (combo group), and a pembrolizumab monotherapy group (mono group). TFS was defined as the PFS in the combo group and the PFS2 in the mono group. We used the propensity score matching (PSM) method to reduce the bias. **Results:** Of the 964 patients with advanced NSCLC who underwent first-line treatment, 126 with a PD-L1 TPS ≥50% were eligible for inclusion in this analysis (89 in mono group, 37 in combo group). PSM matched 36 people from each of the two groups. The median follow-up period was 16.2 months (range, 0.1-34.3 months). The patient backgrounds were similar. The overall response rate (ORR) of the combo group was higher than that of the mono group (69.4% vs. 50.0%). The median PFS (mPFS) in the combo group was longer (11.4 months vs. 6.0 months). However, the median TFS (mTFS) of the two groups was almost the same (11.4 months vs. 11.7 months). At the time of the analysis, the median overall survival had not been reached. The frequency of all immune-related serious adverse events (irSAE) was similar, however, that of all SAE and AE leading to treatment discontinuation were larger in the combo group. **Conclusions:** The ORR of the combo group was higher than that of the mono group; however, the TFS was similar. We suggest that pembrolizumab plus chemotherapy, which can increase toxicity, might be of value in patients, producing a clinically meaningful increase in the ORR. Research Sponsor: None.

Characteristics, efficacy, and safety of two groups after PSM.

	Combo group (n = 36)	Mono group (n = 36)
Age in years, median (range)	64 (46-78)	66 (45-80)

EGFR Exon 20 insertion: Prognostic and predictive values in advanced non-small cell lung cancer, a real-world study. *First Author: Christos Chouaid, Pneumology, Centre Hospitalier Intercommunal (CHI) Creteil, Créteil, France*

Background: In Europe, 10-15% of non-squamous non-small cell lung cancer (nsqNSCLC) have EGFR mutations of which 5-12% are an Exon 20 insertion (20ins). **Methods:** Analysis of Epidemio-Strategy and Medical Economics (ESME) Advanced and Metastatic Lung cancer (AMLC) Data Platform (NCT03848052), a multicenter real-life database using a supervised, retrospective data collection process. The database includes 13737 advanced nsqNSCLC treated from January 2015 at participating centres. The cut-off date for patient follow-up for this analysis was June 30, 2020. The aim of the study was to assess real-world patient characteristics, treatment patterns and clinical outcomes of advanced nsqNSCLC EGFR 20ins. Overall survival (OS) of EGFR cohorts (20ins, 19del/L858R without 20ins, other EGFR mutations) and EGFR wild-type/not tested cohort were assessed. **Results:** 1549 (11.3%) nsqNSCLC had an EGFR mutation, 61 (3.9%) of whom being an EGFR 20ins. These 61 patients (pts) are mainly female (68.9%), non-smoker (55.7%), with de novo stage IIIB/IV disease (78.6%), PS 0-1 (76.9%). Median age was 68.0 years (q1-q3: 54-74). PD-L1 status was assessed in 34 (55.7%) pts, mainly (n = 20) before first line and 22 (64.7%) had negative result. Most (63.9%) pts had EGFR 20ins positive result available before first line. Almost all pts (95.1%, n = 58) received a systemic therapy with a median number of 3 (q1-q3: 1-4) lines. In first line setting, 74% of the pts received chemotherapy (mainly chemotherapy combination), 13.7% received EGFR TKI (mainly as monotherapy) and 8.6% received immunotherapy only. Median treatment duration for pts treated with CarboPem (n = 19), CisplatinPem (n = 16) and CarboTaxol (n = 6) were 4.7 (q1-q3: 2.6-6.6), 7.4 (q1-q3: 5.0-12.8) and 3.3 (q1-q3: 2.8-3.8) months, respectively. For afatinib (n = 3), erlotinib (n = 2) and gefitinib (n = 1), median treatment durations were 1.6 (q1-q3: 0.5-2.8); 1.8 (q1-q3: 1.4-2.1) and 2.3 months, respectively. After a median follow up of 36.3 (95%CI: 34.1-39.8) months, median OS was 24.3 (95%CI: 19.1-32.6) months; 1 and 2-years OS rates were 82.5% (95%CI: 69.7-90.2) and 52.6% (95%CI: 37.3-65.9), respectively. For pts with 19del/L858R without 20ins (n = 1049) and those with other EGFR mutations (n = 439) median OS were 35.4 (95%CI: 32.6-37.5) and 41.7 (95%CI: 31.9-53.5), respectively compared to 20.7 (95%CI: 20.0-21.8] months for pts EGFR wild type/not tested (n = 12188). **Conclusions:** This large, national real-world analysis based on medical chart data's confirm that EGFR 20ins is a rare disease (0.4% of advanced nsqNSCLC). Currently available EGFR TKIs appear to have low efficacy and response to chemotherapy seems identical to that of EGFR wild-type/not tested pts. Prognosis for NSCLC pts with EGFR 20ins mutations was in line with that of EGFR wild type/not tested but worse than common EGFR mutations highlighting the need for advancements for this rare population. Features in genomics and tumor immune microenvironment in NSCLC treated with neoadjuvant PD-1 blockade. *First Author: Shuhang Wang, Clinical Cancer Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Results from several clinical trials have preliminarily demonstrated the safety and effectiveness of single PD-1 inhibitors in neoadjuvant setting for resectable non-small cell lung cancer (NSCLC). However, only around 40% patients could achieve Major Pathological Response. How to select patients who could benefit from single PD-1 blockade remains elusive. **Methods:** In this study, we aimed to assess the association of PD-L1 expression, tumor mutation burden (TMB), copy number alteration (CNA, including copy number gain and loss) burden with the pathological response to neoadjuvant PD-1 blockade. We also evaluated the dynamic changes of tumor immune microenvironment (TIME) by analyzing pre-immunotherapy treatment tumor biopsy samples from twenty-nine NSCLC patients as well as the matched post-surgery samples after neoadjuvant sintilimab treatment and resection. Targeted DNA sequencing (543 genes), PD-L1 immunochemistry staining (22C3) and multiplex immunofluorescence (CD4, CD8, CD9) were applied. **Results:** The degree of pathological regression and major pathological response (MPR), were positively correlated with tumor proportion score (TPS) of PD-L1 ($R = 0.40$, $p = 0.04$) and negatively correlated with copy number gain (CNgain) burden ($R = -0.44$, $p = 0.04$). Of note, the combination of CNgain burden and TPS can better stratify MPR patients compared to CNgain or TPS alone. Whereas, TMB only had a marginal association with pathological response ($R = 0.32$, $p = 0.15$). Additionally, PD-1 blockade led to an increase in $CD8^+$PD-1-T cells in the tumor region ($p = 0.04$, Mann-Whitney U test for paired samples) and a reduction in Tregs and M2 macrophages in the stromal region ($p < 0.05$, Mann-Whitney U test for paired samples). Further investigation showed that the degree of $CD8^+$PD-1-T cell increase was significantly associated with MPR ($p < 0.05$, Mann-Whitney U test). Intriguingly, we also observed a substantial reduction in $CD19^+$ cells in the non-MPR group but not in the MPR group, indicating the involvement of B cells in improving neoadjuvant immunotherapy response in NSCLC patients. **Conclusions:** TPS and CNgain burden were correlated with pathological response to neoadjuvant immunotherapy in NSCLC patients. This may provide potential selective indicators for future clinical trials of neoadjuvant immunotherapy. The dynamic changes of components in the tumor immune microenvironment may provide novel insight into the immune responses induced by neoadjuvant PD-1 blockade therapy. Subgroup-level network meta-analysis for efficacy of first-line immunotherapy-based treatments in advanced non-small cell lung cancer. *First Author: Fang Wu, Department of Oncology, The Second Xiangya Hospital, Central South University, Changsha, China*

Background: Immunotherapy has unequal efficacies in populations with different clinical or histological features. This study aims to explore inter-subgroup differences in responses to immunotherapy in patients with advanced non-small cell lung cancer (NSCLC) and find the optimal treatments for each subgroup. **Methods:** We performed (network) meta-analyses of phase III random controlled trials, in which efficacies of 10 immunotherapy-based treatments were compared, including anti-programmed death receptor-1 (PD-1) (+chemotherapy), anti-programmed death ligand-1 (PD-L1) (+chemotherapy), anti-PD-L1+anti-cytotoxic T-lymphocyte protein 4 (CTLA-4), anti-PD-1+anti-CTLA-4 (+chemotherapy), anti-CTLA-4+chemotherapy, anti-PD-1+anti-angiogenic therapy (AT)+chemotherapy, and anti-PD-L1+AT+chemotherapy, for 19 subgroups by sex, age, smoking status, metastatic site (liver/brain/bone), histological type (squamous/non-squamous cancer), and PD-L1 expression, using hazard ratios (HRs) for overall survival (OS) and progression-free survival (PFS) and their 95% confidence intervals (CIs). **Results:** 22 studies comprised of 12678 patients with advanced NSCLC were included in our study. The results showed OS and PFS advantages of immunotherapy-based treatments in 16 out of 19 subgroups comparing with chemotherapy. Never-smokers (OS-HR 0.81, 95% CI 0.55-1.18; PFS-HR 0.73, 95% CI 0.51-1.07), ¡Ý75-year-old patients (OS-HR 0.9, 95% CI 0.71-1.13), and patients with liver metastases (OS-HR 0.88, 95% CI 0.77-1) showed indisposed responses to immunotherapy. In patients with PD-L1 tumor proportion score (TPS)<1%, anti-CTLA-4+anti-PD-1 and anti-PD-1+anti-CTLA-4+chemotherapy had significant OS benefit comparing with anti-PD-L1 monotherapy (HR 0.6, 95% CI 0.44-0.81; HR 0.6, 95% CI 0.41-0.87; respectively) and anti-PD-L1+AT+chemotherapy (HR 0.66, 95% CI 0.48-0.92; HR 0.66, 95% CI 0.45-0.98; respectively). In patients with liver metastases, anti-PD-L1+AT+chemotherapy showed significant PFS advantage comparing with anti-PD-L1+chemotherapy (HR 0.51, 95% CI 0.33-0.77). As for other populations, anti-PD-1+chemotherapy showed wide-ranging promising efficacies in multiple subgroups. **Conclusions:** Patients with advanced NSCLC generally benefit from immunotherapy. Specific immunotherapy treatments should be applied according to different clinical or histological features. Meanwhile, we expect more preclinical and clinical studies to focus on therapeutic strategies for populations with impaired responses towards immunotherapy. Updated overall efficacy and safety of selpercatinib in patients (pts) with *RET* fusion+ non-small cell lung cancer (NSCLC). *First Author: Benjamin Besse, Department of Medicine and Thoracic Pathology Committee, Gustave Roussy, Villejuif, France*

Background: Selpercatinib, a first-in-class highly selective and potent, CNS-active RET kinase inhibitor, is approved in multiple countries for treatment of *RET* fusion+ lung or thyroid cancers. Here we report an update of efficacy and safety results which provide a longer follow up and increased number of patients (safety population: N = 345 vs N = 329). **Methods:** Pts with *RET* fusion+ NSCLC enrolled in the global, multicenter, ongoing LIBRETTO-001 trial (NCT03157128; 16 countries, 89 sites) were included in this analysis. Pts with the opportunity to be followed ≥6 months from their first dose were included in the efficacy-evaluable population for these analyses. Integrated analysis set (IAS) included 218 NSCLC pts with prior platinum-chemotherapy. Primary analysis set (PAS) was a subset of the IAS and included the first 105 consecutively enrolled pts. The treatment-naïve population included 48 efficacy-evaluable pts. Primary endpoint was objective response rate (ORR, RECIST v1.1) by independent review committee (IRC). Secondary endpoints included ORR by investigator, duration of response (DoR), progression-free survival (PFS), clinical benefit rate (CBR; CR+PR+SD ≥16 weeks), and safety. Safety population (N = 345) included all pts with NSCLC who received ≥1 selpercatinib dose by data cutoff (30 Mar 2020). **Results:** In pts with prior treatment (N = 218) and treatment-naïve (N = 48) pts, 56% and 60% were female, with a median pt age of 61 and 64 years, respectively. The ORR with selpercatinib was 57% in the IAS, 64% in the PAS, and 85% in the treatment-naïve population (Table). In both the IAS and PAS, the median DoR was 17.5 months, median PFS was 19.3 months at median follow-up of 12.0 and 15.7 months, respectively (Table). The most common treatment-emergent adverse events (TEAEs) reported in ≥25% of pts were dry mouth, diarrhea, hypertension, increased ALT/AST, edema peripheral, and fatigue. Twenty-five pts (7%) permanently discontinued due to TEAEs, with 10 pts (3%) discontinuing selpercatinib due to treatment-related AEs as per investigator. **Conclusions:** In this updated data set, selpercatinib continued to demonstrate durable antitumor activity in pts with *RET*-fusion+ NSCLC. Selpercatinib was well-tolerated with a safety profile consistent with previous reports. A global, randomized, phase 3 trial (LIBRETTO-431) evaluating selpercatinib compared with standard frontline therapy is ongoing. Clinical trial information: NCT03157128. Research Sponsor: Eli Lilly and Company.

Taletrectinib (AB-106; DS-6051b) in metastatic non-small cell lung cancer (NSCLC) patients with ROS1 fusion: Preliminary results of TRUST. *First Author: Caicun Zhou, Department of Medical Oncology, Shanghai Pulmonary Hospital and Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai, China*

Background: Taletrectinib (AB-106; DS-6051b) is a potent, selective ROS1/NTRK inhibitor. In two phase I trials, NSCLC patients (pts) with ROS1 fusion who received taletrectinib as first line ROS1 TKI had an objective response rate (ORR) of 66.7% (6/9) and median progression-free survival (PFS) of 29.1 mo (Sai-Hong Ignatius Ou et al., *JTO Clinical and Research Reports*, 2020). TRUST (NCT04395677) is an ongoing, multicenter, phase II study of taletrectinib in Chinese NSCLC pts with ROS1 fusion. **Methods:** The ROS1 TKI naïve or crizotinib pre-treated NSCLC patients with ROS1 fusion were treated with taletrectinib 400 or 600 mg QD. ROS1 testing was performed in each center and confirmed by central lab using RT-PCR. The primary endpoint was ORR (complete response [CR] + partial response [PR]) by IRC assessment. Secondary endpoints were disease control rate (DCR; CR + PR + stable disease), PFS and safety, etc. The pharmacokinetics (PK) of taletrectinib following 400 or 600 mg QD regimen was also evaluated. **Results:** As of the data cutoff (15 Jan 2021), 22 pts had received taletrectinib treatment. Median age was 54.5 years (range, 32-77 years;); 18.2% (4/22) had central nervous system metastases; ECOG performance status was 0 in 13.6% (3/22) of pts and 1 in 86.4% (19/22) of pts. Most pts (54.5%, 12/22) had prior systematic chemotherapy; 31.8% (7/22) of pts had prior crizotinib treatment. ORR by investigator among the crizotinib naïve pts with tumor assessment (N = 11) was 100% (95% CI, 72%-100%); 81.8% (18/22) of pts had treatment-emergent adverse events (TEAEs), including nausea, vomiting, diarrhea, transaminase elevation, white blood cell count decrease/neutrophil count decrease, etc. 13.6% (3/22) were grade ≥ 3, including fatigue (4.5%, 1/22), white blood cell decrease (4.5%, 1/22) and transaminase elevation (4.5%, 1/22).TEAEs led to dose interruption in 3 pts (13.6%), including dose reduction in 2 pts (9.1%). Taletrectinib in plasma approximately reached steady state on Cycle 1 Day 8 with 2- to 3- fold accumulations of exposure, which was consistent with results observed in the phase I trials. **Conclusions:** Taletrectinib demonstrated promising clinical activity with high ORR and good tolerability in ROS1 fusion positive NSCLC patients. The safety and PK profiles following taletrectinib treatment was generally consistent with the phase I trials. Clinical trial information: NCT04395677. Clinical trial information: NCT04395677. Research Sponsor: AnHeart Therapeutics.

Physician concern about delaying lung cancer treatment while awaiting biomarker testing: Results of a survey of U.S. oncologists. *First Author: Kathryn Finch Mileham, Levine Cancer Institute/Atrium Health, Charlotte, NC*

Background: With rapid advancements in biomarker testing informing lung cancer treatment decisions, clinicians are challenged to maintain knowledge of who, what and when to test and how to treat based on test results. An ASCO taskforce including representatives from the American Cancer Society National Lung Cancer Roundtable and patient advocates conducted a study to assess biomarker testing and treatment practices for patients with advanced non-small cell lung cancer (aNSCLC) among U.S. oncologists. **Methods:** A survey was sent to 2374 ASCO members – lung cancer specialists and general oncologists. Eligibility required treating ≥1 lung cancer patient/month. Proportions were estimated across groups and compared using chi-square tests. **Results:** 170 responses were analyzed. 59% of respondents work at an academic center (i.e., have a fellowship program), while 41% work at a community (non-academic hospital/health system/private practice). Nearly all (98%) believe biomarker results should be received within 1 or 2 weeks of ordering, yet 37% wait an average of 3 or 4 weeks for results. Of respondents who usually wait 3 or 4 weeks, 37% initiate a non-targeted systemic treatment while waiting. Respondents from community practices were more likely to initiate non-targeted systemic treatment if results were not available after 2 weeks (59% compared to 40% of academic respondents; p = 0.013).). When asked about reasons for not testing, respondents <5 years since training were more likely to report that delaying treatment while waiting for results was always/often a concern compared to those >6 years from training (41% vs 19%). Respondents reported high testing rates in both non-squamous and squamous aNSCLC. Roughly equal representation of generalists/specialists and academic/community respondents helps mitigate potential concerns about external validity. **Conclusions:** Respondents indicated that treatment decisions are impacted by delays in biomarker test results. Clinicians should be informed about when it is safe and appropriate to defer treatment while biomarker testing is pending. Respondents suggest that diagnostic biomarker testing companies should strive to expedite results. Research Sponsor: ASCO.

Neratinib efficacy in a subgroup of patients with *EGFR* exon 18-mutant non-small cell lung cancer (NSCLC) and central nervous system (CNS) involvement: Findings from the SUMMIT basket trial. *First Author: Jonathan Wade Goldman, University of California, Los Angeles, Los Angeles, CA*

Background: The phase 2 SUMMIT basket trial (NCT01953926) demonstrated efficacy of neratinib in patients with *EGFR* exon 18-mutant NSCLC [Boni et al. WCLC 2020]. Neratinib also has documented activity in HER2+ metastatic breast cancer with CNS metastases [Saura et al. SABCS 2020 & J Clin Oncol 2020]. Here we report neratinib efficacy in a subgroup of patients with *EGFR* exon 18-mutant NSCLC and CNS involvement from SUMMIT. **Methods:** Patients with *EGFR* exon 18-mutant NSCLC were treated with single-agent neratinib (240 mg po daily). Prior EGFR tyrosine kinase inhibitors (TKIs), chemotherapy, and checkpoint inhibitors (IO) were allowed. Patients with stable, asymptomatic CNS metastasis were enrolled. Study endpoints: objective response rate (ORR) at week 8 (±1 week); ORR (RECIST 1.1 confirmed); duration of response (DOR); clinical benefit rate (CBR); progression-free survival (PFS); safety; biomarkers. **Results:** Baseline characteristics of 11 patients with *EGFR* exon 18-mutant NSCLC: median age 67 (range 56–83) years; ECOG PS 0/1 (45%/55%). Prior lines of therapies: 2 (range 1–3): EGFR TKIs (91%); chemotherapy (55%); IO (27%). 3/11 patients had baseline CNS metastasis and received radiation 8–22 months prior to study enrollment. Best CNS response in these 3 patients was stable disease with overall individual PFS of 1.9 (censored), 6.9 and 9.1 months and OS of 2.6 (censored), 17.7 (censored), and 17.9 months. Efficacy is summarized in Table. Efficacy summary: TKI-pretreated *EGFR* exon 18-mutant NSCLC cohort receiving neratinib monotherapy. **Conclusions:** Activity of single-agent neratinib was observed in prior TKI-exposed patients with *EGFR* exon 18-mutant NSCLC. Despite the small sample size of only 3 patients with baseline CNS metastases, findings suggest a potential role for neratinib as a systemic treatment option for patients with NSCLC and difficult-to-treat uncommon mutations with CNS involvement. The SUMMIT trial continues to enroll patients with *EGFR* exon 18-mutant NSCLC. Clinical trial information: NCT01953926. Research Sponsor: Puma Biotechnology Inc.

The effects of tislelizumab treatment on the health-related quality of life of non-small cell lung cancer patients who progressed on a prior platinum-containing regimen. *First Author: Cai Zhou, Shanghai Pulmonary Hospital, Shanghai, China*

Background: Anti-PD-1/L1 therapies have improved overall survival (OS) by 2-4 months vs docetaxel in patients with advanced non−small cell lung cancer (NSCLC) who progressed after receiving a platinum regimen. Tislelizumab, an anti-PD-1 antibody, has been tested as monotherapy in the RATONALE (NCT 03358875) trial, which found that tislelizumab prolonged OS (median OS difference 5.3 months in ITT population) as compared to docetaxel, improved progression-free survival (median 4.1 vs 2.6 months), as well as overall response rate (ORR difference = 14.9%).Here we report health-related quality of life (HRQoL) of patients receiving tislelizumab vs docetaxel in this clinical trial. **Methods:** NSCLC patients in this open-label, multicenter Phase 3 study were randomized to either the tislelizumab or docetaxel. HRQoL was measured using the QLQ-C30 global health status/quality of life score (GHS/QoL) from EORTC QLQ-C30 as well as the lung cancer specific subscales of the EORTC QLQ-LC13. Descriptive analysis for the GHS/QoL score was performed for baseline through cycle 10; changes from baseline to cycle 12 were examined for the symptom subscales. **Results:** 805 patients were randomized to tislelizumab (n = 535) or docetaxel (n = 270). Patients were 77% male with an average age of 60 years (range 28-88 years). The compliance rates were mostly $>$ 98% and were similar across arms. The GHS/QoL score in the tislelizumab arm improved relative to baseline from cycles 5 through 10 while declining in cycles 6 through 10 in the docetaxel arm. The tislelizumab arm showed a reduction from baseline at cycle 12 in the symptom scores of coughing, chest pain, and dyspnea while patients in the docetaxel arm experienced an increase in symptoms. **Conclusions:** The study results show that tislelizumab monotherapy improved HRQoL in patients who previously failed treatment with a platinum containing chemotherapy; this is especially important as the NSCLC patients treated with tislelizumab not only experienced improvements in OS, but also reductions in their symptomology. Clinical trial information: NCT 03358875. Research Sponsor: BeiGene LTD.

9071 **Poster Session**

Brigatinib (BRG) in ALK+ crizotinib (CRZ)-refractory non-small cell lung cancer (NSCLC): Final results of the phase 1/2 and phase 2 (ALTA) trials. *First Author: Scott N. Gettinger, Yale School of Medicine and Smilow Cancer Center, Yale New Haven Hospital, New Haven, CT*

Background: BRG is a kinase inhibitor approved for the treatment of patients (pts) with ALK+ metastatic NSCLC; specific details for BRG use vary by indication and country. We report long-term efficacy and safety results of the Phase 1/2 and Phase 2 (ALTA) trials of BRG. **Methods:** The Phase 1/2 study was a single-arm, open-label trial (NCT01449461) of BRG 30–300 mg/d in pts with advanced malignancies. ALTA (NCT02094573) randomized pts with CRZ-refractory ALK+ NSCLC to receive BRG at 90 mg qd (arm A) or 180 mg qd with 7-d lead-in at 90 mg (arm B). For the Phase 1/2 study, investigator assessments of confirmed objective response rate (cORR; RECIST v1.1), duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety in pts with ALK+ NSCLC are reported. The primary endpoint of ALTA was cORR per investigator; secondary endpoints included cORR per independent review committee (IRC), DoR, PFS, and OS. **Results:** In the Phase 1/2 study, 137 pts received BRG; of these, 79 pts had ALK+ NSCLC (71/79 had prior CRZ; 28/79 received 180 mg qd [7-d lead-in at 90 mg]; 14/79 received 90 mg qd). In ALTA, 222 pts with CRZ-refractory ALK+ NSCLC were randomized (n = 112/110, arm A/B). At the end of the Phase 1/2 study (Feb 18, 2020), with median 27.7 mo follow-up (~67 mo after last pt enrolled), 4 pts remained on BRG. At the end of ALTA (Feb 27, 2020), with median 19.6/28.3 mo follow-up in arm A/B (~53 mo after last pt enrolled), 10/17 pts in arm A/B were still on treatment. Table shows efficacy results from final analyses with long-term follow-up. In ALTA, the IRC-assessed intracranial cORR in pts with measurable baseline brain metastases was 50% (13/26) in arm A and 67% (12/18) in arm B; Kaplan-Meier (KM) estimated median intracranial DoR was 9.4 mo (95% CI, 3.7, not reached [NR]) in arm A and 16.6 mo (3.7, NR) in arm B. With long-term follow-up, no new safety signals were identified. Treatment-emergent adverse events led to dose interruption (Phase 1/2: 59%; ALTA arm A/B: 49%/61%), dose reduction (13%; 8%/33%), or discontinuation (10%; 4%/13%). **Conclusions:** BRG showed sustained long-term activity, PFS, and manageable safety in pts with CRZ-refractory ALK+ NSCLC. The 180 mg/d dose after 7-d lead-in at 90 mg/d led to numerically higher median PFS and OS. Final results are similar to those reported for other approved ALK tyrosine kinase inhibitors in this setting. Clinical trial information: NCT01449461, NCT02094573. Research Sponsor: ARIAD Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

Activity of epidermal growth factor receptor tyrosine kinase inhibitors (EGFR TKIs) in patients (pts) with NSCLC with uncommon *EGFR* mutations: A real-world cohort study (UpSwinG). *First Author: Satoru Miura, Department of Internal Medicine, Niigata Cancer Center Hospital, Niigata, Japan*

Background: EGFR TKIs are an established treatment (tx) option for pts with *EGFR* mutation-positive NSCLC with common mutations (Del19 or L858R); however, 7–23% of NSCLC tumors harbor uncommon *EGFR* mutations, where EGFR TKI efficacy is less established. These mutations are highly heterogeneous, and developments in detection by NGS are helping to identify mutations with little or no clinical data. **Methods:** In this non-interventional, global, multi-center study (NCT04179890), existing medical or electronic health records were identified for consecutive EGFR TKI-naïve pts with uncommon *EGFR* mutations (T790M, ex20ins, major uncommon [G719X, L861Q or S768I], 'other' or compound mutations) treated with erlotinib, gefitinib, afatinib, osimertinib or other systemic therapy. Endpoints were time to tx failure (TTF), ORR, OS and duration of response (DoR). **Results:** Overall, 246 pts (median age: 69.5 yrs; Asian: 84%; brain metastases: 8%; ECOG PS $\geq$2: 16%) were recruited from 9 countries. Most pts (n=226; 92%) received an EGFR TKI as 1st-line therapy; 132 (54%), 105 (43%) and 7 (3%) received afatinib, 1st-gen TKIs and osimertinib, respectively. 57% of pts received $>$1 line of therapy. Most pts (73%) had a major uncommon mutation, 9% had other mutations and 33% had a compound mutation; these were detected using PCR (75%) or sequencing (25%), mainly based on tissue biopsy (86%). Pathology reports varied in quality, often lacking detail on specific mutations e.g. 21% of ex18 and 72% of ex20ins were undefined. Median TTF and OS with EGFR TKIs were 9.9 and 24.4 mos; ORR was 42%. In pts treated with 1st-line chemotherapy (n=20), median TTF and ORR were 6.6 mos and 41%. Outcomes were most favorable in major uncommon and compound mutations (Table). TTF appeared to be higher with afatinib vs 1st-gen EGFR TKIs. In most mutation categories, median OS was $>$2 yrs, possibly reflecting high subsequent therapy uptake. **Conclusions:** In a real-world setting, EGFR TKIs were the preferred tx option in pts with uncommon *EGFR* mutations; strongest outcomes were seen in major uncommon and compound mutations, and in pts treated with afatinib. Data were in line with recent analyses of afatinib in uncommon mutations. Tx with an EGFR TKI should be considered as standard for most pts with uncommon mutations. Optimal tx for pts with uncommon mutations requires improvements in pathology reports, with more emphasis on NGS methodology and precise definition of mutations. Clinical trial information: NCT04179890. Research Sponsor: Boehringer Ingelheim.

A phase II trial of chemotherapy plus pembrolizumab in patients with advanced NSCLC previously treated with a PD-1 or PD-L1 inhibitor: Big Ten Cancer Research Consortium BTCRC-LUN15-029. *First Author: Nikhil Shukla, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Chemoimmunotherapy with a platinum doublet plus a checkpoint inhibitor (CPI) is a standard of care for pts with advanced NSCLC. While some pts experience prolonged responses to initial CPI therapy, the majority of pts will eventually experience PD. It is unknown if continuing CPI treatment beyond progression has any advantages in this setting. We report the results of a phase 2 trial of chemotherapy plus pembrolizumab in pts with advanced NSCLC previously treated with a PD-1 or PD-L1 inhibitor. **Methods:** Pts experiencing PD after clinical benefit to CPI (PFS $>$ 3 months) were enrolled. Pts received pembrolizumab 200 mg q3wks plus next-line chemotherapy (gemcitabine 1000 mg/m^2 IV D1 and D8 q3wks, or docetaxel 60-75 mg/m^2 IV D1 q3wks, or pemetrexed 500 mg/m^2 IV D1 q3wks [non-squamous histology only]). The primary endpoint was PFS by RECIST 1.1. Key secondary endpoints included ORR, OS, and toxicity. The null hypothesis was median 3-month PFS with pembrolizumab plus next-line chemotherapy and the alternative hypothesis was median 6-month PFS with pembrolizumab plus chemotherapy. **Results:** 35 pts were enrolled. Median follow-up was 18.1 months and median age 63 (44-80). 51.4% male and 48.6% female. 82.9% were current or former smokers. Histology included 74.3% with adenocarcinoma, 20% with squamous cell carcinoma, 5.7% with NSCLC NOS. Treatment regimens included pembrolizumab/docetaxel (40%), pembrolizumab/gemcitabine (45.7%), or pembrolizumab/pemetrexed (14.3%). Median number of cycles of pembrolizumab was 6 (1-31). Median PFS using RECIST 1.1 and irRECIST was 5.2 months (95% CI 3.6-11.2, p $<$ 0.05) and 6.9 months (95% CI 3.8-12), respectively. Median OS was 26.8 months (95% CI 13.4-30.9). Best response using RECIST 1.1 was PR (23.5%) and SD (53%). 45.7% of pts experienced G3 or higher treatment-related AEs (TRAEs). Most common TRAEs were fatigue (60%), anemia (51.4%), and nausea (42.9%). There were no treatment related deaths. **Conclusions:** Pembrolizumab plus next-line chemotherapy in pts with advanced NSCLC who experienced PD after clinical benefit to CPI was associated with prolonged PFS compared with historical controls of single agent chemotherapy. Further investigations into which pts would benefit from continued CPI treatment after progression is warranted. Clinical trial information: NCT03083808. Research Sponsor: Merck.

Phase I study of the aurora kinase A inhibitor alisertib in combination with osimertinib in EGFR-mutant lung cancer. *First Author: Collin M. Blakely, UCSF Helen Diller Comprehensive Cancer Center, San Francisco, CA*

Background: The 3rd generation EGFR tyrosine kinase inhibitor (TKI) osimertinib is effective for the treatment of advanced EGFR-mutant (mt) lung adenocarcinoma (LUAD). However, tumor resistance to osimertinib monotherapy invariably occurs. Activation of Aurora Kinase A (AURKA) drives resistance to osimertinib treatment in preclinical models of EGFR-mutant LUAD and is associated with TKI resistance in patients. Alisertib is a selective AURKA inhibitor with an acceptable safety profile established in early phase clinical trials. **Methods**: We performed a single institution phase Ia clinical trial of alisertib in combination with the 3rd generation EGFR inhibitor osimertinib in patients with metastatic EGFR-mutant LUAD who had experienced disease progression on osimertinib monotherapy (NCT04085315). The primary objective of the study was to determine the safety and tolerability of alisertib in combination with osimertinib in order to define the maximum tolerated dose (MTD) and to identify a recommended phase 2 dose (RP2D). Secondary efficacy endpoints included objective response rate (ORR), disease control rate (DCR) and progression-free survival (PFS). Utilizing a 3+3 trial design, patients receiving osimertinib 80 mg daily were treated with alisertib using an intermittent dosing strategy of 20-50 mg twice daily (BID) oral alisertib on days (d) 1-3, 8-11, and 15-17 of a 28-day cycle. **Results:** A total of 10 patients were treated with osimertinib 80 mg and received at least one dose of alisertib. 6 patients were treated at the 30 mg BID and 4 patients at the 40 mg BID intermittent dosing schedule of alisertib. The most commonly reported adverse events (AEs) were diarrhea (70%), fatigue (60%), alopecia (50%) and neutropenia (50%). All AEs, except neutropenia, were grade 1 or 2. Two patients (20%) experienced grade 3 or grade 4 neutropenia; both patients were treated at the 40 mg BID intermittent dose of alisertib. Intermittent alisertib 30 mg BID was identified as the MTD and RP2D in combination with osimertinib 80 mg daily. The ORR was 10% (1/10) and DCR 70% (7/10), with the majority of patients, 60% (6/10), achieving stable disease (SD). 30% (3/10) experienced progressive disease (PD) as their best response. The median PFS was 9.4 months (2.0 months - N.R.). **Conclusions:** Intermittent dosing of alisertib 30 mg BID on d1-3, 8-11, and 15-17 of a 28-day cycle in combination with osimertinib 80 mg daily demonstrates an acceptable toxicity profile. Preliminary efficacy analysis suggests that alisertib + osimertinib may result in clinically meaningful disease control in EGFR-mt LUAD patients whose disease is resistant to osimertinib monotherapy. Clinical trial information: NCT04085315. Research Sponsor: Takeda, Other Foundation.

9075 **Poster Session**

Phase II randomized study of ramucirumab plus pembrolizumab versus standard of care for advanced non-small cell lung cancer previously treated with a checkpoint inhibitor: Toxicity update (Lung-MAP non-matched substudy S1800A). *First Author: Karen L. Reckamp, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: The therapeutic landscape in metastatic NSCLC has dramatically changed with approvals of immunotherapy agents in both treatment-naïve and previously treated cancer patients (pts) and irrespective of histology. Pts with tumors that develop resistance is a significant area of unmet need. Vascular endothelial growth factor (VEGF) has been shown to modulate the tumor immune microenvironment and combination immune checkpoint and VEGF/VEGF receptor inhibition have shown benefit in multiple tumor types. Lung-MAP is a master protocol for pts with stage IV, previously treated NSCLC. Pts who were not eligible for a biomarker-matched substudy enrolled in S1800A. The adverse event profile will be presented. **Methods:** S1800A is a phase II randomized trial for pts who previously received PD-1 or PD-L1 inhibitor therapy for at least 84 days and platinum-based doublet therapy with ECOG 0-1 stratified by PD-L1 expression, histology and intent to receive ramucirumab in the standard of care (SOC) arm. Pts were randomized 1:1 to pembrolizumab and ramucirumab P+R or SOC (docetaxel +R [SOC w R]; docetaxel, pemetrexed or gemcitabine [SOC wo R]). The primary endpoint was overall survival. Secondary endpoints included response, duration of response, investigator assessed-progression free survival and evaluation of toxicity. **Results:** From May 17, 2019 to November 16, 2020, 166 pts enrolled and 140 determined eligible [69 (49%) P+R; 46 (33%) SOC w R; 25 (18%) SOC wo R]. Treatments for those who received SOC wo R included 3 on docetaxel (19%); 12 on gemcitabine (75%); and on 1 on pemetrexed (6%). 131 were eligible for adverse event (AE) assessment. The most common AE were fatigue (38%), proteinuria (28%), hypertension (23%), diarrhea (22%) and hypothyroidism (22%) on P+R; fatigue (61%), anemia (48%), diarrhea (41%) and neutropenia (39%) on SOC w R and anemia (56%), leukopenia (56%), fatigue (44%) and neutropenia (44%) on SOC wo R. Grade $\geq$ 3 treatment-related AEs occurred in 32% of pts on P+R, 54% of pts on SOC w R and 56% of pts on SOC wo R. Cardiac and thromboembolic events occurred in 12% of pts on P+R, 11% of pts on SOC w R and 0% of pts on SOC wo R. Grade 5 AE occurred in 2 pts on P+R (respiratory failure and cardiac arrest), 3 pts on SOC w R (2 respiratory failure and sepsis) and 1 pt on SOC wo R (sepsis). Four patients were diagnosed with COVID-19 (1 on P+R and 3 on SOC) and 3 died (1 on P+R and 2 on SOC). **Conclusions:** Grade 3 toxicities were lower in P+R compared to SOC arms with or without R. Cardiac and thromboembolic events were similar in arms that included R. P+R was generally well-tolerated. Efficacy outcomes will be presented when data matures. Clinical trial information: NCT03971474. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Eli Lilly and Company and MSD International GmbH.

PD-(L)1 inhibitors as monotherapy for the first-line treatment of non-small cell lung cancer patients with high PD-L1 expression: A network meta-analysis. *First Author: Margarita Majem, Department of Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Background: PD-L1 has emerged as a potential biomarker for predicting responses to immunotherapy and as a prognostic factor in non-small cell lung cancer (NSCLC). In this network meta-analysis, we aimed to evaluate the efficacy of first-line PD-(L)1 monotherapy in advanced NSCLC patients with high PD-L1 expression. **Methods:** We conducted a systematic search in PubMed to identify all eligible trials from inception until 1 November 2020, with no start date limit applied. Only phase III trials evaluating the efficacy of first-line (1L) PD-(L)1 monotherapy in patients with stage IIIB/stage IV NSCLC and high PD-L1 expression were included. **Results:** Six clinical trials (KEYNOTE-024, KEYNOTE-042, EMPOWER Lung-01, IMpower110, MYSTIC and CheckMate-026) with 2,111 patients were included. In head-to-head comparisons, immunotherapy showed a significant improvement in progression-free survival (PFS: HR_{pooled} = 0.69, 95% CI: 0.52-0.90, p = 0.007), overall survival (OS: HR_{pooled} = 0.69, 95% CI: 0.61-0.78; $p <$ 0.001) and overall response rate (ORR) (Risk ratio $[RR]_{pooled}$ = 1.354, 95% CI: 1.04-1.762, p = 0.024) compared to chemotherapy (CT). In the assessment of relative efficacy for PFS through indirect comparisons, pembrolizumab (results from KEYNOTE-024) ranked highest followed by cemiplimab and atezolizumab, with statistical significance determined across some of the drugs. In terms of OS, cemiplimab ranked highest followed by atezolizumab and pembrolizumab, although non-significant OS was determined across these drugs. Overall, 1L PD-(L)1 monotherapy improved OS in almost all subgroups, reaching statistical significance in men (HR_{pooled} = 0.624, 95% CI: 0.51-0.72, $p <$ 0.001), non-Asian patients (HR_{pooled} = 0.66, 95% CI: 0.55-0.79, $p <$ 0.001), all patients regardless of age ($<$ 65 years [HR_{pooled} = 0.72, 95% CI: 0.57-0.90, p = 0.005]; $\geq$65 years [HR_{pooled} = 0.61, 95% CI: 0.48-0.77, $p <$ 0.001]), ECOG PS status (ECOG PS = 0 [HR_{pooled} = 0.68, 95% CI: 0.56-0.82, $p <$ 0.001; ECOG PS = 1 [HR_{pooled} = 0.59, 95% CI: 0.43-0.82, p = 0.001) and histological tumour type (Squamous [HR_{pooled} = 0.49, 95% CI: 0.37-0.67, $p <$ 0.001; Non-squamous [HR_{pooled} = 0.67, 95% CI: 0.52-0.87, p = 0.003). In the case of smokers and NSCLC stage, only current/former smokers (HR_{pooled} = 0.623, 95% CI: 0.47-0.83, p = 0.001) and patients with stage IV disease* (HR_{pooled} = 0.687, 95% CI: 0.59-0.81, $p <$ 0.001) benefited from single PD-(L)1 monotherapy over CT. **Conclusions:** PD-(L)1 inhibitor monotherapy improves efficacy outcomes in the 1L setting of advanced NSCLC patients with high PD-L1 expression. Current/former smokers $\geq$65 years, with ECOG PS = 1 and squamous NSCLC benefited most from this therapy. *KEYNOTE-042 was the only study including patients with stage IIIB NSCLC. Research Sponsor: ROCHE FARMA.

9077 **Poster Session**

Safety and activity of CLN-081 (TAS6417) in NSCLC with EGFR Exon 20 insertion mutations (Ins20). *First Author: Zofia Piotrowska, Massachusetts General Hospital, Boston, MA*

Background: NSCLC with EGFR ins20 represents a significant area of unmet need, with no approved targeted therapies. While several agents targeting EGFR ins20 are in development, wild-type (WT) EGFR-related adverse events (AEs) have been common and challenging to manage. CLN-081 is a novel oral EGFR TKI with broad activity against clinically relevant EGFR mutations, including ins20, and has attenuated activity against WT EGFR relative to EGFR ins20 *in vitro*, suggesting that CLN-081 may have a more favorable clinical therapeutic window. We present interim results of a multicenter, Phase (Ph) 1/2a trial evaluating CLN-081 in advanced, EGFR ins20 NSCLC (NCT04036682). **Methods:** Patients (pts) with EGFR ins20 previously treated with platinum-based therapy (tx) were eligible to enroll. Ph 1 dose escalation in this adaptive trial began with an accelerated titration (AT) design, and converted to a rolling six design based upon prespecified safety criteria or at clinically active doses. Cohort expansion in Ph 1 occurred at any dose where responses were seen. Transition from Ph 1 to 2a was based on a Simon-Two Stage design. Prior tx with EGFR ins20-specific inhibitors was allowed in AT cohorts only. CLN-081 was dosed twice daily (BID) in 21-day cycles. **Results:** As of 10 November 2020, 37 pts [median age 64 years (44-82); median 2 (1-9) prior lines of tx] received CLN-081 at doses of 30 mg (n = 8), 45 mg (1), 65 mg (12), 100 mg (13), and 150 mg (3) BID. The most common all-grade (gr) treatment-related AEs (TRAEs) were rash (49%), diarrhea (24%), paronychia (16%), nausea (14%), stomatitis (14%), and dry skin (11%). Gr 3 TRAEs included anemia (5%), diarrhea (3%), and increased alkaline phosphatase (ALP) (3%). There was 1 DLT, gr 3 diarrhea at 150 mg BID. No gr $\geq$ 3 rash or gr 4/5 TRAEs were reported. Four pts (11%) required dose reductions for rash (2), diarrhea (1), and increased ALP (1). Two pts (5%) discontinued tx due to TRAEs of gr 2 hypersensitivity reaction (1) and gr 2 pneumonitis (1); the latter also experienced pneumonitis while receiving prior osimertinib. Among the 25 response evaluable pts (RECIST 1.1), 10 (40 %) had a partial response (PR) (6 confirmed, 2 pending confirmation, 2 unconfirmed), 14 (56%) had stable disease (SD), and 1 (4%) had progressive disease as best response. Of the 4 pts that received prior EGFR ins20 inhibitors, 2 had PR and 2 SD. Of pts with SD or PR as best response, 20/24 (83 %) experienced tumor regression [median regression: -18 % (-100 to +3)]. Enrollment is ongoing and updated data will be presented. **Conclusions:** CLN-081 has an acceptable safety profile, including diarrhea in $<$ 25% of pts treated to date. CLN-081 has demonstrated encouraging preliminary anti-tumor activity across the full dose range tested, in multiple distinct EGFR ins20 variants, and in heavily pre-treated pts that are either naïve or refractory to other EGFR ins20 inhibitors. Since the time of the data cut, a Ph 2a expansion has been initiated at 100 mg BID. Clinical trial information: NCT04036682. Research Sponsor: Cullinan-Pearl.

9078 **Poster Session**

Patient-reported symptoms, functioning, and quality of life (QoL) in patients treated with cemiplimab monotherapy for first-line treatment of advanced NSCLC with PD-L1 ≥ 50%: Results from EMPOWER-Lung 1 study. *First Author: Mahmut Gumus, Istanbul Medeniyet University, Istanbul, Turkey*

Background: Cemiplimab, a PD-1 inhibitor, improved survival and progression-free survival vs platinum doublet chemotherapy (chemo) in patients (pts) with advanced NSCLC and PD-ligand(L)1 expression ≥50% in the EMPOWER-Lung 1 Phase 3 study (NCT03088540). Since pts with advanced NSCLC have a high symptom burden that adversely impacts QoL and functioning, these outcomes were evaluated as secondary endpoints in the clinical trial. **Methods:** Pts with advanced NSCLC with PD-L1 expression ≥50% and ECOG performance status ≤1 were randomized to IV cemiplimab 350 mg Q3W (n=356) or platinum doublet chemo (n=354). At baseline (BL) and day 1 of each treatment cycle (C) to C15, pts were administered the EORTC core questionnaire (QLQ-C30) and its lung cancer specific module (QLQ-LC13) to assess symptoms, functioning, and Global Health Status (GHS)/QoL. In the intent-to-treat population, mixed-effects repeated measures models were used to estimate least squares (LS) mean change from BL on all scales. Kaplan–Meier analysis estimated time to definitive deterioration, defined as worsening ≥10 points from BL observed at all subsequent time points or patient withdrawal after worsening; hazard ratios (HR) with 95% CIs estimated the likelihood of definitive deterioration. **Results:** BL scores showed moderate to high levels of functioning and low symptom burden. Cemiplimab-treated pts had lower likelihood of definitive deterioration vs chemo on key symptoms of dyspnea, cough, pain in chest, pain in other body parts, fatigue, nausea/vomiting, appetite loss, constipation, and diarrhea vs chemo (all $P<.05$). Treatment-related symptoms of peripheral neuropathy and alopecia had a lower likelihood of definitive deterioration with cemiplimab vs chemo (both $P<.05$). Cemiplimab resulted in significantly greater improvements vs chemo on all functioning scales and reduced the likelihood of definitive deterioration as indicated by HR <1 (Table). GHS/QoL improvements with cemiplimab at C2 were maintained to C15; LS mean change (SE) from BL across all timepoints was 7.1 (1.0) for cemiplimab vs 1.7 (1.2) for chemo ($P<.0001$). **Conclusions:** In pts with advanced NSCLC and PD-L1 expression ≥50%, cemiplimab significantly improved GHS/QoL, functioning, and most symptoms vs chemo. Over 1 year of treatment, cemiplimab delayed worsening of key lung cancer symptoms and functioning. Clinical trial information: NCT03088540. Research Sponsor: Regeneron Pharmaceuticals, Inc, and Sanofi.

	Difference in LS mean change from BL (95% CI)[a]	HR (95% CI) for definitive deterioration
GHS/QoL	5.4 (2.7–8.1)*	0.73 (0.52–1.03)

Real-world patterns of biomarker testing and targeted therapy in metastatic non-small cell lung cancer (mNSCLC) in the community oncology setting. *First Author: Eric S. Nadler, Texas Oncology-Baylor Charles A. Sammons Cancer Center, Dallas, TX*

Background: National guidelines recommend biomarker testing in mNSCLC, and targeted therapy is associated with improved outcomes. The aim of this study was to understand the real-world biomarker testing and treatment patterns in the community setting. **Methods:** This was a retrospective study of adult patients diagnosed with de novo mNSCLC between 01-Jan-2016 and 30-Sep-2019, with follow-up through 31-Dec-2019 using The US Oncology Network structured electronic health records data. Patients who received systemic treatment for mNSCLC were included. **Results:** A total of 3213 patients were identified with median age 68 years (24, 90+); 52.7% were male and 10% were current smokers. ECOG score was 0-1 in 55.2%; 60% had adenocarcinoma, 16% had squamous cell carcinoma, and the rest had other/unknown histology. Since most of the biomarker-guided therapies were approved after 2016, testing patterns are described for 2017-2019 (n=2257). Overall, 23.6% were not tested for any biomarker (PD-L1 or driver mutation [DM]) at any time during the study period, and only 49% had a biomarker test result prior to 1L treatment. We observed similar patterns when assessing DM specifically; 35.8% were never tested for DM, and only 39.3% had a DM test result prior to 1L treatment. As an example, out of 42 ALK+ patients in this study population, only 5 had test results prior to 1L treatment and only 3 received an ALK inhibitor as their 1L treatment (Table). Similar patterns were observed for the other biomarkers. **Conclusions:** Despite availability of promising biomarker-based therapies, the lack of adequate testing in the community oncology setting means that not all eligible patients are receiving the most effective therapies upfront. Nearly 61% of patients had no DM test reported before 1L treatment in this mNSCLC cohort (all histologies), and some were determined to be DM positive at a later time, highlighting a missed opportunity to employ the most effective biomarker-directed front-line treatment. Next steps in this study will include assessing patterns by histology. Structured data, which are recorded for clinical management, might have gaps; future research with chart reviews could provide a more comprehensive assessment. Research Sponsor: Genentech.

Identification of recurrence-associated gene signature and tumor immune microenvironment features in resected stage I NSCLC. *First Author: Fang Wu, Hunan Key Laboratory of Early Diagnosis and Precision Therapy in Lung Cancer, The Second Xiangya Hospital, Central South University, Changsha, China*

Background: Surgery is the primary treatment for stage I NSCLC, but postoperative recurrence leads to poor prognosis. Alterations of tumor genes and immune microenvironment may be crucial factors for tumor recurrence; however, the detailed mechanisms remain unclear. **Methods:** A total of 130 resected stage I NSCLC patients were enrolled, 69 developed recurrence within three years and 61 without recurrence over five years. Whole exome sequencing (WES) was performed to evaluate genomic alterations. Immunohistochemistry was carried out to assess the expression of PD-L1, CD3 and CD8. We calculated density of CD3+ and CD8+ T cells in the center of tumors (CT) and invasive margins (IM), defined six immunoscore types based on the location and density of both cells, and performed ROC analysis to evaluate prognostic value of them. We further verified our results using stage I NSCLC cohorts from the Cancer Genome Atlas (TCGA) and Tumor immune estimation resource (TIMER) database. **Results:** In univariate analysis, lung adenocarcinoma (LUAD) patients showed significantly higher risk of recurrence (p = 0.008). There was no statistically significant correlation between recurrence and other clinical factors, including TNM stage. Although driver gene mutations, such as those of EGFR, had no correlation with recurrence, *MUC4* mutation and high tumor mutation burden (TMB) were significantly associated with higher risk of recurrence (p = 0.001 and 0.0032, respectively). Enrichment analysis of KEGG pathways showed that Ras pathway mutations were significantly enriched in *MUC4* mutant group and recurrence group (p = 0.02 and 0.05, respectively). 9.6% patients had PD-L1 positive expression (TPS≥1%), but showed no association with recurrence. Recurrence group had much lower density of $CD8_{CT}$, $CD8_{IM}$ and $CD3_{CT}$ +T cells(p = 0.0026, 0.0022 and 0.0308, respectively). Immunoscore type V, based on the average of $CD8_{CT}$, $CD8_{IM}$ and $CD3_{CT}$ + T cells, had the highest prognostic value (AUC = 0.764) and was used as the final immunoscore in our study. In multivariate analysis, we found *MUC4* mutation and low immunoscore were independent predictors of higher risk of recurrence. Smoking history was also an independent prognostic factor in LUAD. While in LUSC, only immunoscore correlated with recurrence. In TCGA cohort, *MUC4* mutation rate was significantly lower (3.6% vs. 24.3%, p < 0.001) and had no correlation with risk of recurrence (p = 0.765). Besides, the tumor infiltrating CD8+ T cells also had no correlation with risk of recurrence (p = 0.469). **Conclusions:** In this study, we established a refined immunoscore with high prognostic value for tumor recurrence in stage I NSCLC. In addition, we showed for the first time a strong association between *MUC4* mutation and recurrence, which might be mediated by the Ras pathway. Finally, the recurrence mechanisms might vary among different histological subtypes. Update analysis of NEJ009: Gefitinib alone (G) versus gefitinib plus chemotherapy (GCP) for non-small cell lung cancer with mutated EGFR. *First Author: Eisaku Miyauchi, Department of Respiratory Medicine, Tohoku University Hospital, Sendai, Japan*

Background: NEJ009 study is the first randomized phase III trial that compared gefitinib plus chemotherapy with gefitinib in patients with untreated NSCLC harboring EGFR mutations. We report an updated OS and long-term tolerability analysis, including subgroup analyses focusing on a type of EGFR mutation and metastatic sites. **Methods:** Patients were randomly assigned to gefitinib (gefitinib 250 mg PO, QD) and GCP regimen (gefitinib 250 mg PO, QD combined with carboplatin AUC 5 and pemetrexed 500 mg/m2 in a 3-week cycle for up to six cycles, followed by concurrent gefitinib and pemetrexed maintenance). This study tested multiple primary endpoints, PFS, PFS2, and OS, which were analyzed using a preplanned hierarchical sequential testing method. **Results:** Three hundred forty-five patients were randomly assigned (gefitinib, n = 172; GCP, n =170). At latest data cut-off (May 22, 2020), although there was no significant difference in OS between the groups (HR, 0.82; 95% CI, 0.64 to 1.06; P=0.13), GCP still demonstrated significantly better PFS and PFS2 compared to G. The updated median PFS, PFS2, and OS was 11.2 months, 18.0 months, and 38.5 months in the gefitinib group and 20.9 months, 20.9 months, and 49.0 months in the GCP group, respectively. No severe adverse events occurred in the period since the first report. **Conclusions:** This updated analysis confirmed that the GCP regimen achieved significantly better PFS and PFS2 with an acceptable safety profile compared with gefitinib alone. The efficacy outcome of GCP is more favorable than gefitinib monotherapy as first-line treatment of NSCLC with EGFR mutation. Clinical trial information: UMIN000006340. Clinical trial information: UMIN000006340. Research Sponsor: grant-in-aids from the Japan Society for Promotion of Science and Japanese Foundation for the Multidisciplinary Treatment of Cancer.

Discontinuation of immune checkpoint inhibitor (ICI) above 18 months of treatment in real-life patients with non-small cell lung cancer (NSCLC): INTEPI, a multicentric retrospective study. *First Author: Geoffroy Bilger, Centre Hospitalier Universitaire de Grenoble, Grenoble, France*

Background: The optimal treatment duration of ICIs for patients with NSCLC remains uncertain. In phase 3 clinical trials, treatment continued for two years or until disease progression, and results from CheckMate 153 trial suggest to continue beyond one year. Real life data are missing. **Methods:** This multi-centric retrospective study presents data on real-life patients who discontinued treatment after at least 18 months of ICI monotherapy, their tumour being still controlled. Their characteristics, the causes of discontinuation of ICI, and their outcome are described. **Results:** Between July 2015 and May 2018, 107 patients had their tumour controlled after at least 18 months of treatment. Among them, 54 (50%) patients discontinued ICI: 76% male, median age 63, 91% PS 0-1, 54% adenocarcinoma, 20% with brain metastases, PD-L1 expression level available for 18 (33%) patients (2 $<$ 1%, 8 btw 1-50% and 8 $>$ 50%), 93% treated after 1st line. The median duration of treatment was 26 months. Treatment was stopped by choice of the prescriber and toxicity in 46% and 22% respectively. With a median follow up of 21 months from ICI discontinuation, 18 (33%) patients had a tumor progression with a median time of 10 months (2-33). From discontinuation, overall survival (OS) and progression free survival (PFS) were 90% and 71% respectively at 12 months and 84% and 63% respectively at 24 months. Duration of disease control after ICI cessation seemed to be correlated to the best tumor response at treatment discontinuation, with a PFS rates at 12 months of 73% for complete response (CR n = 11), 77% for partial response (PR n = 37), 22% for patients with stable disease (SD n = 6), 80% for CR and/or complete metabolic response with 18F-FDG PET/CT (CMR) and 65% for others. Fourteen patients out of the 18 in the relapse group received a subsequent treatment : 7 were retreated with ICI (with best response 14% PR and 86% SD) and 5 received a localized therapy with 60% CR. **Conclusions:** Our study in real life provides new insight into the long-term outcomes of patients treated with ICI for at least 18 months before discontinuation in the absence of PD. CR and CMR with FDG-PET before therapy discontinuation may be a positive factor for a prolonged disease control upon discontinuation. Research Sponsor: None.

Intracranial activity of tepotinib in patients (pts) with *MET* exon 14 (*MET*ex14) skipping NSCLC enrolled in VISION. *First Author: Jyoti D. Patel, Lurie Cancer Center, Northwestern University-Feinberg School of Medicine, Chicago, IL*

Background: Brain metastases (BMs) are reported in 20–40% of pts with *MET*ex14 skipping NSCLC and present a high unmet need with poor prognosis. Tepotinib is a highly selective MET inhibitor that has demonstrated intracranial activity in preclinical MET-driven lung cancer orthotopic BM models, and has high binding in brain tissue with 25% of free tepotinib levels in brain, relative to plasma. In VISION Cohort A (N = 152), tepotinib had robust and durable clinical activity in pts with *MET*ex14 skipping NSCLC, with an objective response rate (ORR) of 45% and a median duration of response (mDOR) of 11.1 months. Here, we report the intracranial activity of tepotinib. **Methods:** In the Phase II VISION study, pts with *MET*ex14 skipping NSCLC received 500 mg QD (450 mg active moiety) oral tepotinib. Study eligibility allowed for pts with BM (neurologically stable on symptomatic therapy with stable steroids, and pts with asymptomatic BM). Primary endpoint: systemic OR per RECIST v1.1; subgroup analysis in pts with BM (determined by RECIST v1.1) was predefined. An *ad hoc* retrospective analysis of brain lesions determined by CT/MRI was conducted by an IRC using Response Assessment in Neuro-Oncology Brain Metastases (RANO-BM) criteria, which accounts for pts' clinical status and steroid use. Responses were determined in pts with $\geq$1 evaluable post-baseline tumor assessment (due to the retrospective nature and resulting incomplete data, confirmation was not required). For pts with non-measurable lesions per RANO-BM (enhancing and non-enhancing non-target lesions [NTL]), disease control in the brain was defined as non-complete response/non-progressive disease. Data cut-off: July 1, 2020. **Results:** Based on RECIST v1.1, 23 pts in Cohort A had BM at baseline. Systemic efficacy in pts with BM (ORR 47.8% [95% CI: 26.8, 69.4], mDOR 9.5 months [95% CI: 5.5, not estimable]) was consistent with the overall population. 15 pts were evaluable by RANO-BM; 12 received prior radiotherapy for BM (median 6.4 weeks before tepotinib initiation [range 2.6–44]). Systemic best objective responses (BORs) were partial response (PR, n = 9), stable disease (SD, n = 3), and progressive disease (PD; n = 3). Of 7 pts with measurable CNS disease per RANO-BM (all of whom received prior radiotherapy), intracranial BORs were PR (n = 5; including 3 with complete disappearance of target lesions), SD (n = 1) and PD (n = 1). Of 8 pts with NTL only, 7 achieved intracranial disease control and 1 had PD. Of the 7 pts with disease control, 3 had CR of the enhancing NTL. **Conclusions:** Tepotinib demonstrated robust systemic activity in pts with *MET*ex14 skipping NSCLC with BM; this is complemented by intracranial activity in an *ad hoc* analysis using RANO-BM. Small pt numbers, a large proportion of pts with prior radiotherapy for BM, and the retrospective nature of analysis should be considered. Prospective evaluation of intracranial activity data from VISION Cohort C is ongoing. Clinical trial information: NCT02864992. Research Sponsor: Merck KGaA, Darmstadt, Germany.

9085 **Poster Session**

Cemiplimab monotherapy as first-line (1L) treatment of patients with brain metastases from advanced non-small cell lung cancer (NSCLC) with programmed cell death-ligand 1 (PD-L1) $\geq$ 50%: EMPOWER-Lung 1 subgroup analysis. *First Author: Mustafa Ozguroglu, Cerrahpaşa Medical Faculty, Istanbul University-Cerrahpaşa, Istanbul, Turkey*

Background: In the Phase 3, EMPOWER-Lung 1 study, cemiplimab monotherapy provided significant survival benefit and an acceptable safety profile vs chemotherapy in patients with advanced NSCLC and PD-L1 $\geq$50%. EMPOWER-Lung 1 included patients with brain metastases at baseline who are typically underrepresented in clinical trials. Other published exploratory analyses in single-cohort studies suggest benefit from immunotherapy in this patient population. Here, we present subgroup analysis of patients with brain metastasis from EMPOWER-Lung 1. **Methods:** Patients were randomized 1:1 to cemiplimab 350 mg IV every 3 weeks or investigator's choice of chemotherapy (NCT03088540). Patients with treated, clinically stable brain metastases (radiological stability not required) were eligible to enroll and are the focus of this subgroup analysis from the PD-L1 $\geq$50% population (n=563) of the EMPOWER-Lung 1 study. **Results:** A total of 68 of 563 (12.1%) cases had treated stable brain metastases at time of randomization. Patients were evenly distributed between cemiplimab (n=34) and chemotherapy (n=34), with similar median duration of follow-up (Table). Baseline characteristics were generally similar; median (range) age: 60.0 (45–76) vs 62.0 (48–77); male: 97.1% vs 85.3%; and non-squamous histology: 85.3% vs 76.5%; between cemiplimab vs chemotherapy, respectively. Per independent review committee, median overall survival (OS, 18.7 vs 11.7 months), median progression-free survival (PFS, 10.4 vs 5.3 months), and objective response rate (ORR, 41.2% vs 8.8%) were superior with cemiplimab vs chemotherapy (Table). After baseline, central nervous system (CNS) disease progression occurred in 2 (5.9%) patients with cemiplimab vs 4 (11.8%) patients with chemotherapy; extra-CNS disease progression occurred in 9 (26.5%) patients with cemiplimab vs 15 (44.1%) patients with chemotherapy. **Conclusions:** 1L cemiplimab monotherapy improved OS, PFS, and ORR vs chemotherapy, in patients with advanced NSCLC with PD-L1 $\geq$50%, and clinically stable brain metastases at baseline. Cemiplimab monotherapy represents a suitable option for this subgroup of patients. Clinical trial information: NCT03088540. Research Sponsor: Regeneron Pharmaceuticals, Inc. and Sanofi.

Clinical outcomes in patients with advanced NSCLC and brain metastases.

Real-world outcomes and clinical characteristics of patients with brain metastases from EGFR mutated non-small cell lung cancer: Data from a large retrospective study (REFLECT). *First Author: Urska Janzic, University Clinic of Respiratory and Allergic Diseases Golnik, Golnik, Slovenia*

Background: Brain metastases (BM) frequently occur in patients (pts) with epidermal growth factor receptor mutated non-small cell lung cancer (EGFRm NSCLC) and represent a poor prognostic marker. This study aimed to describe the clinical characteristics, treatment patterns and survival outcomes in EGFRm NSCLC pts treated with 1st or 2nd generation tyrosine-kinases inhibitors (TKIs) in first-line (1L). **Methods:** The retrospective real-world study REFLECT (NCT04031898) collected data from 896 pts initiating 1L TKI between 1 January 2015-30 June 2018 in Europe and Israel. Descriptive statistics were used to assess demographic and clinical characteristics in subgroups of patients with and without BM. Kaplan-Meier methods were used to estimate median real world progression free survival (mPFS) and overall survival (mOS) from start of 1L. **Results:** Out of 896 pts, 198 (22.1%) had BM at start of 1L, 134 (15%) developed BM later (any time), and 564 (62.9%) had no sign of BM at the time of data collection. Among pts who later developed BM the median time between the start of 1L and first diagnosis of BM was 13.5 months. Median duration of follow-up was 21.5 months. Of 332 pts with BM at any time 64.2% were female, similar to the ratio in pts without BM (64.0%). At diagnosis, median age was 65 years in pts with BM vs. 70 in those who never developed BM. Of pts with BM at any time, 50.9% had exon 19 deletion, 30.4% L858R point mutation and 18.7 % uncommon EGFR mutations at baseline, compared to 56.6%, 31.7% and 11.7% in pts without BM, respectively. At data collection, 94.9% of the pts with BM at diagnosis had progressed compared to 79.8% among those with no BM. Overall, whole brain radiation was the most frequently used treatment for BM (31.0%) followed by stereotactic radiosurgery (18.1%) and targeted therapies (13.3%). T790M testing rates were highest among pts developing BM later (85.7%) and lowest among those with BM from start (66.1%). The T790M positivity rate was highest in pts developing BM later (65.7%) and lowest among those with BM from start (50.4%). More pts received osimertinib in later lines among those with BM at any time compared to those without BM (51.3% vs 43.8%). Median real world PFS and OS (95% CI) were shorter among pts with BM at baseline compared to those never developing BM: 10.2 (8.8, 11.5) vs 15.2 (13.7, 16.1) months, and 19.4 (17.1, 22.1) vs 30.3 (27.1, 33.8) months, respectively. At the time of data collection, 77.3% of pts with BM at baseline were deceased compared to 52.5% pts with no BM. **Conclusions:** More than one third of pts included in REFLECT had BM at any time. Uncommon EGFR variants at baseline were observed more frequently in pts with BM. mPFS and mOS were shorter in pts with BM at baseline compared to those never developing BM. These data highlight the need for improved treatment and CNS control in pts with EGFRm NSCLC. Clinical trial information: NCT04031898. Research Sponsor: AstraZeneca.

9087 **Poster Session**

STK11/_TP53_ co-mutated non-small cell lung cancer (NSCLC) to display a unique tumor microenvironment (TME) and metabolic profile. *First Author: Abdul Rafeh Naqash, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: Recent data suggest inferior responses to immune checkpoint inhibitors (ICIs) in *STK11*-mt NSCLC. *TP53* is a critical tumor suppressor gene regulating DNA repair by arresting cells in the G1 phase in response to critical double strand breaks. We hypothesized that accumulated DNA damage from mutations in the *TP53* gene might increase immunogenicity and potentially enhance benefit of ICIs in *STK11-mt* NSCLC. **Methods:** A total of 16,896 NSCLC tumors submitted to Caris Life Sciences (Phoenix, AZ) for targeted NGS (DNA-Seq, 592 genes) were analyzed. A subset (N = 5034 tumors) had gene expression profiling (RNA-Seq, whole transcriptome). PD-L1 (TPS) was tested with 22c3 antibody (Dako). Exome-level neoantigen load for *STK11*-mt NSCLC was obtained from published TCGA Pan-immune analysis (Thorsson et al. 2018). Non-parametric tests were used for comparing differences in tumor mutational burden (TMB) and neoantigen load. Transcriptomic analysis included differential gene expression and hierarchical clustering. Tumor immune cell content was obtained from transcriptome using Microenvironment Cell Population-counter (MCP). Publicly available data from the POPLAR/OAK trials of atezolizumab in advanced NSCLC were used to model PFS and OS for *STK11*-mt with *TP53*-mt (n = 14) and without *TP53*-mt (n = 20). **Results:** Of 16,896 NSCLC samples, 12.6% had an *STK11*-mt with the proportions of TMB-high (≥10 Mut/Mb), PD-L1 ≥ 50% and MSI-high being 55.9%, 11.8%, and 0.72%, respectively. *STK11*-mt vs. *STK11*-wt NSCLC did not differ in median TMB (Caris:10 vs. 10 Mut/Mb; $p > 0.1$) or neoantigen load (TCGA: 154.5 vs. 165; $p > 0.1$). Median TMB (13 vs. 9 Mut/Mb; $p < 0.001$) and neoantigen load (263 vs. 134; $p < 0.001$) were higher in *STK11*-mt/*TP53*-mt vs. *STK11*-mt/*TP53*-wt. MCP analysis showed higher CD8, NK-cell and lower myeloid dendritic cell infiltration in *STK11*-mt/*TP53*-mt vs. *STK11*-mt/*TP53*-wt ($p < 0.01$) . Expression of *MYC* and *HIF-α* were increased in the *STK11*-mt/*TP53*-mt vs. *STK11*-mt/*TP53*-wt ($p < 0.01$) along with higher expression ($p < 0.01$) of genes associated with both glycolysis (*HK2, LDHA, ALDOA*) and glutamine metabolism (*GOT2, PPAT2*). Hierarchical clustering of *STK11*-mt adenocarcinomas (n = 463) for STING pathway genes (CCL5, CXCL10, cGAS) identified a STING-high and a STING low cluster. The STING high cluster was significantly enriched in *TP53*-mt (48 vs. 32%; $p < 0.01$).In the OAK/POPLAR cohort, median OS (HR is 1.14, 95% CI 0.53 - 2.48); $p > 0.1$) and PFS (HR 1.88, 95% CI 0.89-3.97, $p = 0.098$) were not statistically different between *STK11*-mt/*TP53*-mt vs. *STK*-mt/*TP53*-wt. However, the 15-months PFS was 21% in the *STK11*-mt/*TP53*-mt vs 0% in the *STK11*-mt/*TP53*-wt. **Conclusions:** *STK11*-mt NSCLC with *TP53*-mt are associated with an immunologically active TME with metabolic reprogramming. These intrinsic properties could be exploited to improve outcomes to ICIs in combination with metabolically directed agents. Research Sponsor: None.

Chemo-immunotherapy outcomes of KRAS-G12C mutant lung cancer compared to other molecular subtypes of KRAS-mutant lung cancer. *First Author: Kathryn Cecilia Arbour, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *KRAS* mutations are identified in approximately 30% of NSCLC, with G12C mutations being the most common subtype and representing 12% of all non-small cell lung cancer cases. Novel direct inhibitors are in clinical development and have shown promising activity, although the efficacy of these agents compared to other standard therapies for lung cancer is not yet known. We hypothesized that patients with *KRAS*-G12C mutations may have distinct responses to chemo-immunotherapy regimens both with respect to STK11 and KEAP1 co-mutation status and compared to patients with non-G12C subtypes. **Methods:** Patients with KRAS-mutant lung cancers at Memorial Sloan Kettering Cancer Center and Dana Farber Cancer Institute treated with chemo-immunotherapy regimens as first line therapy for advanced/metastatic disease were identified. Subset with KRAS G12C mutations non-G12C subtypes were compared and response to therapy was assessed by investigator. Baseline characteristics were compared with the Chi-square and Fisher's exact test for categorical data and Wilcoxon rank-rum test for continuous data. Response evaluations where performed by investigators and compared between groups with the Fisher's exact test. Progression free survival and overall survival was calculated from start of therapy to date of progression or death/last follow up, respectively and compared between groups using the Cox proportional-hazards model. **Results:** We identified 137 patients with KRAS-mutant NSCLC treated with chemo-immunotherapy: 45% (62/137) had mutations in *KRAS*-G12C and 55% harbored non-G12C mutations (17% G12V, 15% G12D, 4% G12A, 4% G12S, 3% G13D). The median OS was 21 and 14 months for G12C and non-G12C patients, respectively ($p = 0.24$). ORR to chemo-immunotherapy for patients harboring a *KRAS*-G12C mutation was 40% (25/62) compared to 31% (23/75) in non-G12C subtypes ($p = 0.3$). Median PFS was similar for both G12C and non-G12C subtypes (7.3 vs 6.1 months, respectively, $p = 0.12$). Concurrent *STK11* mutation was identified in 40% of patients with *KRAS*-G12C and *KEAP1* alterations were observed in 32% of patients. In patients with *KRAS*-G12C, co-mutation in *STK11* and/or *KEAP1* was associated with shorter PFS (15.8 vs 5.1 months, $p = 0.01$). **Conclusions:** *KRAS*-G12C mutations are present in 12% of patients with NSCLC and represent a relevant subtype of NSCLC given KRAS G12C inhibitors now in clinical development. Treatment outcomes to chemo-immunotherapy are similar in patients with G12C and non-G12C subtypes. Outcomes are poor for patients with concurrent *STK11* and/or *KEAP1* mutations representing a significant unmet need. Research Sponsor: None.

Safety and efficacy of pralsetinib in patients with advanced _RET_ fusion-positive non-small cell lung cancer: Update from the ARROW trial. *First Author: Giuseppe Curigliano, European Institute of Oncology, IRCCS and University of Milano, Milan, Italy*

Background: *RET* fusions are targetable oncogenic drivers in 1–2% of non-small cell lung cancer (NSCLC). ARROW (NCT03037385) supported the US FDA approval of pralsetinib, a highly potent oral selective RET inhibitor for *RET*-altered NSCLC and thyroid cancer. Here, we present updated results for a larger population of patients with *RET* fusion–positive NSCLC enrolled in ARROW. **Methods:** ARROW is a phase 1/2 open-label study conducted at 84 sites in 13 countries. Phase 2 expansion cohorts included patients with *RET* fusion–positive NSCLC. Initially, all treatment-naïve patients were not candidates for platinum-based therapy, a requirement removed by protocol amendment in July 2019. Primary objectives are overall response rate (ORR; blinded independent central review [BICR] per RECIST v1.1), assessed for patients with baseline measurable disease, and safety. **Results:** Updated analyses were completed as of Nov 6, 2020 (data cut-off), for patients who initiated pralsetinib 400 mg QD by May 22, 2020 (enrollment cut-off). Efficacy results, including analyses for treatment-naïve patients enrolled after eligibility criteria were revised to allow candidates for platinum-based therapy, are shown in the Table. **Conclusions:** Pralsetinib showed rapid, potent, and durable clinical activity in patients with *RET* fusion-positive NSCLC (regardless of prior therapies), including poor prognosis patients not eligible for platinum-based therapy. Overall, pralsetinib was well-tolerated. These data highlight the need for *RET* testing early in the course of disease to identify candidates who may benefit from treatment with pralsetinib.Clinical trial information: NCT03037385. Research Sponsor: Blueprint Medicines Corporation.

	Prior Platinum[a] (n = 126)	Treatment-Naïve[a] (n = 68)	Treatment-Naïve: Subset Enrolled After Eligibility Revision[a] (n = 25)

Association between improvements in survival of metastatic NSCLC patients and targeted- and immuno-therapy. *First Author: Sreeram Ramagopalan, F. Hoffmann-La Roche Ltd., Basel, Switzerland*

Background: Significant improvements in mortality among NSCLC cancer patients in the US over the past two decades have recently been reported based on SEER data. The timing of these improvements led to suggestions that they are primarily a result of the introduction of new and innovative treatments, however few studies have directly investigated this. **Methods:** We utilised the US Flatiron Health database to identify a cohort of non-biomarker (EGFR/ALK/ROS1/BRAF) positive metastatic NSCLC (mNSCLC) patients and a separate cohort of ALK positive (ALK+) patients diagnosed between 2012 and 2019. Multivariable Cox models adjusting for baseline characteristics and receipt of targeted and immunotherapy were utilised to explore the relationship between these variables and changes in the hazard of death by calendar year in each cohort. **Results:** We identified cohorts of 30,076 (54.7% Males) non-biomarker positive and 652 (45.4% males) ALK+ mNSCLC cancer patients in the database eligible for the analysis. Survival in both cohorts improved over time. After adjustment for differences in baseline characteristics the hazard of death in non-biomarker positive patients diagnosed in 2015, 2016, 2017, 2018 and 2019 was observed to be 14%, 13%, 16% 19% and 21% lower respectively than that in those diagnosed in 2012. Upon additionally adjusting for receipt of first line or second line immunotherapy the decrease in the hazard of death by calendar year was no longer observed, suggesting improvements in survival observed over time may be explained by the introduction of these innovative treatments. Similarly, decreases in the hazard of death were only observed in ALK+ patients diagnosed in 2018 and 2019 relative to 2012 and were no longer observed following adjustment for the use of ALK inhibitors. **Conclusions:** Our findings expand on the SEER data and provide direct evidence linking improvements in survival of NSCLC patients over the past decade with the introduction of innovative therapies. Research Sponsor: F. Hoffmann-La Roche AG.

Hazard ratios for death in metastatic NSCLC patients in years 2013 to 2019 relative to 2012, adjusting only for differences in baseline characteristics (model 1) and adjusting for baseline characteristics and treatment (model 2).

First-line pembrolizumab monotherapy for PD-L1-positive (TPS ≥ 50%) advanced non-small cell lung cancer (aNSCLC) in the real world: A national French bispective multicentric cohort—ESCKEYP trial (GFPC 05-2018). *First Author: Renaud Descourt, Thoracic Oncology Department, Hospital Morvan, Brest, France*

Background: To determine real-world outcomes with first line pembrolizumab monotherapy, for aNSCLC with PD-L1 TPS ≥50%. **Methods:** Bispective, national and multicentric study including consecutively aNSCLC patients who initiated first-line pembrolizumab monotherapy from May 5, 2017 (marketing authorization of pembrolizumab monotherapy in France) to Nov 22, 2019 (marketing authorization of pembrolizumab-chemotherapy for non-squamous aNSCLC). Data were collected on medical charts. Responses were locally assessed according to RECIST v1.1; overall survival (OS) and real-world progression-free survival (rwPFS) were assessed by Kaplan-Meier method. **Results:** 845 patients (pts) were included by 33 centres: 67.8% were men, PS 0/1/≥2: 25.5%/46.9%/27.6%, active/former/non-smokers: 39.1%/51.7%/6.4%, adenocarcinoma: 70.8%; stage IV at diagnosis: 91.6%; median number of metastatic sites at baseline: 2±1 (brain (20.8%), liver (13.9%) and bone (35%)); KRAS mutated: 27.7%, PDL1 TPS > 75%: 53.7% At the cut off date (31 December 2020), on the 783/845 (92.7%) evaluable pts, CR, PR, disease stabilization and progression were reported on 4.7%, 42.6%, 24.1% and 28.6% of cases, respectively; 588 (69.6%) pts had discontinued pembrolizumab, 390 (66.4%) had a first disease progression; 320/390 (82.1%) received a second line treatment, mainly platinum-based chemotherapy (90.6%). With a median follow up of 25,8 [95%CI: 24,8-26,7] months, median rwPFS and median OS were 8,2 [95%CI: 6,9-9,5] and 22,6 [95%CI: 18,5-27,4] months, respectively; 6, 12, 18-months survival rates were 76,8%, 64,8% and 54,3%. 835 adverse events were reported in 48% of the patients, grade ≥3 in 13.8% of cases, mainly asthenia, colitis, pneumonitis. For evaluable patients receiving a platinum-based doublet in second line (266/290, 89%), CR, PR, disease stabilization and progression were reported on 1.9%, 41%, 35.3% and 21.8% of cases, respectively. Uni and multivariate analysis of factors related to OS will be presented at the congress. **Conclusions:** Despite a less stringent selection of patients, pembrolizumab as a single agent achieves similar tumor shrinkage, rwPFS and OS than those of pivotal clinical trials. Research Sponsor: GFPC.

Beyond steroids: Immunosuppressants in steroid-refractory/resistant immune related adverse events. *First Author: Jia Luo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The optimal management for immune related adverse events (irAEs) in patients who do not respond or become intolerant to steroids is unclear. Guidelines suggest additional immunosuppressants based on case reports and expert opinion. **Methods**: We examined patients with advanced lung cancers at MSK treated with immune checkpoint blockade (ICB) from 2011-2020. Pharmacy records were queried to identify patients who received systemic steroids as well as an additional immunosuppressant (eg TNFα inhibitor, mycophenolate mofetil). Patient records were manually reviewed to examine baseline characteristics, management, and outcomes. **Results**: Among 2,750 patients with lung cancers treated with ICB, 51 (2%) received both steroids and an additional immunosuppressant for a severe irAE (TNFα inhibitor (73%), mycophenolate mofetil (20%)). The most common events were colitis (53%), pneumonitis (20%), hepatitis (12%), and neuromuscular (10%). At 90 days after start of an additional immunosuppressant, 57% were improved from their irAE, 18% were unchanged, and 25% were deceased. Improvement was more common in hepatitis (5/6) and colitis (18/27) but less common in neuromuscular (1/5) and pneumonitis (3/10). All patients with hepatitis received mycophenolate mofetil 500-1000mg BID for a median of 3 months, range 2-5 months. Of the 18 patients with colitis who improved with a TNFα inhibitor, 10 needed just one dose. Of 13 patients who died, 4 were related to toxicity from immunosuppression (3, infection-related deaths; 1, drug-induced liver injury leading to acute liver failure). Those who died from immunosuppressive therapy received higher amounts of systemic steroids than those who did not (max median 525 vs 132 mg prednisone equivalent, Mann Whitney U p = 0.004, total median 5.9k vs 2.3k mg prednisone equivalent, p = 0.004). Of 31 patients who received at least 3 weeks of prednisone ≥ 20mg, most (90%, 28/31) had at least one side effect that was brought to clinical attention (most commonly altered mood/ sleep, 52%, increase in BMI > 1kg/m2, 45%, and infection, 32%). **Conclusions**: Steroid-refractory/resistant immune related adverse events are rare. While existing treatments help patients with hepatitis and colitis, most patients with other irAEs remain refractory and/or experience toxicities from immunosuppression. Systemic steroid use likely contributed to side effects and mortality. A more precise understanding of the pathophysiology of specific irAEs is needed to guide biologically informed treatment regimens for severe irAEs to realize the true benefit of ICB therapy. Research Sponsor: U.S. National Institutes of Health.

CNS activity of poziotinib in NSCLC with exon 20 insertion mutations. *First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment addressing non-small cell lung cancer (NSCLC) harboring EGFR or HER2 exon 20 insertion mutations remains an unmet need. These tumors are associated with a high incidence of CNS metastases and unfavorable survival rates. Poziotinib is a potent, irreversible, tyrosine kinase inhibitor (TKI) with a structure that can overcome the steric hindrance of the exon 20 limited binding pocket. Preclinical data suggest poziotinib CNS penetration, and here we show meaningful poziotinib CNS activity in patients with NSCLC harboring exon 20 insertion mutations in an ongoing multi-cohort, multi-center Phase 2 study (ZENITH20; NCT03318939). **Methods:** ZENITH20 enrolled previously treated and naïve patients with advanced/metastatic NSCLC and EGFR or HER2 exon 20 insertion mutations in several cohorts: Cohort 1 (C1) EGFR previously treated; Cohort 2 (C2) HER2 previously treated and Cohort 3 (C3) EGFR treatment-naïve. All patients with stable CNS metastases at baseline were included. Poziotinib (16 mg) was administered orally QD, with follow-up for up to 24 months. The primary endpoint was Objective Response Rate (ORR) evaluated centrally using RECIST v1.1 by an independent image review committee. Secondary endpoints included Disease Control Rate (DCR), Duration of Response (DOR), Progression-Free Survival (PFS) and safety. Primary efficacy results have been previously released. Intracranial response was determined based on the modified RECIST criteria. **Results:** A total of 284 patients across 3 cohorts (C1 n=115; and C2 n=90; and C3 n=79) with a median age of 60.5 years were enrolled. The median follow-up was 7.3, 8.3, and 9.2 months for all patients in C1, C2, and C3, respectively. In NSCLC patients that had baseline CNS lesions (N=36), the analysis showed a patient-based ORR of 22.2% (8/36) and a DCR of 88.9% (32/36). One patient in each cohort had a complete intracranial response and stable disease was 80.6% across 3 cohorts and 92.9% in C2. Two patients each in C1 and C3 had progressive disease (PD) and none had CNS progression in C2 (Table). **Conclusions:** Poziotinib exhibited clinically meaningful CNS activity in patients with EGFR or HER2 exon 20 mutations in ZENITH20 Cohorts 1-3. The majority of the patients had no CNS progression and 3/36 patients had intracranial complete responses. The preliminary data suggest that poziotinib may provide a meaningful treatment alternative for patients with NSCLC that harbor EGFR or HER2 exon 20 mutations and who present with CNS metastases that have poor prognosis. Clinical trial information: NCT03318939. Research Sponsor: Spectrum Pharmaceuticals, Inc.

Impact of rapid multigene assays with short turnaround time (TAT) on the development of precision medicine for non-small cell lung cancer (NSCLC). *First Author: Shingo Matsumoto, National Cancer Center Hospital East, Kashiwa, Japan*

Background: A variety of oncogene drivers have been identified in NSCLC and molecularly-stratified precision medicine has led to improved survival in advanced NSCLC. Next-generation sequencing (NGS)-based testing is utilized to detect actionable gene alterations; however, the TAT of NGS is often too long to translate into clinical decision making. Thus, rapid multi-gene testing alternatives are needed. **Methods:** A lung cancer genomic screening project (LC-SCRUM-Asia) capturing clinical outcome was established in 2013 to identify patients with oncogene drivers and to support the development of novel targeted therapies. Since February 2013 to May 2019 (LC-SCRUM-Asia 1st-phase), single gene testing and/or a targeted NGS assay, Oncomine Comprehensive Assay (OCA), were used for the genomic screening. Since June 2019 to December 2020 (2nd-phase), a multi-gene PCR assay (Amoy 9-in-1 test) and a rapid NGS assay (Genexus/Oncomine Precision Assay [OPA]) were also implemented as rapid multi-gene testing. **Results:** A total of 10667 Japanese NSCLC patients, including 6826 in the 1st-phase and 3841 in the 2nd-phase, were enrolled in the LC-SCRUM-Asia. Success rate for OCA: 93%, for 9-in-1 test: 98%, for Genexus/OPA: 96%. Median TAT for OCA: 21 days, for 9-in-1 test: 3 days, for Genexus/OPA: 4 days. The frequencies of genetic alterations detected in the 1st-/2nd-phase were *EGFR*: 17/24%, *KRAS*: 15/16%, *HER2* ex20ins: 4/3%, *ALK* fusions: 3/3%, *RET* fusions: 3/2%, *ROS1* fusions: 3/2%, *MET* ex14skip: 2/2%, *BRAF* V600E: 1/1%, *NRG1* fusions: 0/0.2% and *NTRK3* fusions: 0.05/0.04%. Overall percent agreement of 9-in-1 test compared with OCA for *EGFR/KRAS/HER2/BRAF/MET/ALK/ROS1/RET/NTRK3* alterations was 98%, and that of OPA compared with OCA was 95%. The rate of patients who received targeted therapies as 1st-line treatment was significantly elevated in the 2nd-phase compared with the 1st-phase (510/3841 [13%] vs. 567/6826 [8%], p < 0.001). Through the genomic screening, 1410 (37%) and 1269 (18%) candidate patients for clinical trials of KRAS, HER2, BRAF, MET, ALK, ROS1, RET or TRK-targeted drugs were identified in the 2nd-phase and in the 1st-phase, respectively. The rate of patients who were actually enrolled into the genotype-matched clinical trials were also significantly higher in the 2nd-phase than in the 1st-phase (222 [6%] vs. 186 [3%], p < 0.001). In 1st-line treatments for advanced NSCLC patients, the median progression-free survival was 8.5 months (95% CI, 7.7−9.4) in the 2nd-phase (n = 1839) versus 6.1 months (95% CI, 5.9−6.3) in the 1st-phase (n = 4262) (p < 0.001). **Conclusions:** Both the 9-in-1 test and Genexus/OPA had short TATs (3−4 days), high success rates (96−98%) and good concordance (95−98%) compared with another NGS assay (OCA). These rapid multi-gene assays highly contributed to enabling precision medicine and the development of targeted therapies for advanced NSCLC. Research Sponsor: AMED (Japan Agency for Medical Research and Development), Pharmaceutical/Biotech Company.

Maintenance targeted therapy compared to standard of care (SoC) in patients (pts) with metastatic non-small cell lung cancer (NSCLC): Results from the phase II randomized UNICANCER/IFCT1301- SAFIR02-LUNG intergroup trial. *First Author: Benjamin Besse, Department of Medicine and Thoracic Pathology Committee, Gustave Roussy, Villejuif, France*

Background: Targeted therapies (TT) are approved in NSCLC based on a limited number of oncogenic drivers. Numerous additional TT can be matched to other molecular alterations found in comprehensive profiles. We investigated the effect of 8 TT compared to SoC as a maintenance strategy after chemotherapy in pts with metastatic NSCLC. **Methods:** In SAFIR02-LUNG trial (NCT: 02117167), open-label multicentric phase II randomized trials, PS 0-1 pts with *ALK/EGFR* WT NSCLC after a CR/PR/SD to 4 cycles of platinum-based chemotherapy were selected. All pts underwent a fresh biopsy, followed by targeted sequencing on 70 genes and SNP-array when > 30% cancer cells were present on HES slides. In case of genomic alteration (including *KRAS*, *ERBB2*, *BRAF, BRCA* mutations), pts were randomized 2:1 between 8 TT and SoC. TT allocation was decided during weekly national tumor board, based on predefined guidelines. The primary endpoint was Progression-Free Survival (PFS) and the secondary endpoint was Overall Survival (OS). **Results:** 999 patients were enrolled and 394 had a molecular alteration eligible for the study. Among the 175 randomized pts (between July 2014 and May 2019), 116 received TT (65 selumetinib, 18 vistusertib, 9 capivasertib, 8 AZD4547, 5 AZD8931, 5 vandetanib, 4 olaparib, 1 savolitinib) and 59 SoC (54 pemetrexed, 4 gemcitabine and 1 erlotinib). Median age was 60, 40.6% were female, 4.6% never-smoker, 44% were PS 0, 88.6% had a non-squamous NSCLC and 26.9% a PR to chemotherapy. At data cut-off, 168 pts had progressed or died. With a median follow-up of 42.0 months (mo), median PFS was 2.7 mo (95% confidence interval (CI) 1.6 to 2.7) with TT vs. 2.7 mo (95%CI 1.6-4.1) with SoC (HR for disease progression or death 1.00; 95%CI = 0.73 to 1.38; p = 0.978). There was no significant PFS differences among the molecular subgroups; in the cohort with *KRAS* or *BRAF* mutation without *STK11* mutations the HR for disease progression or death was 0.76; 95%CI = 0.52 to 1.13; p = 0.17. Median OS was 14.3 mo (95%CI 11.0-18.3) with TT vs. 14.1 mo (95% CI 8.0-30.9) with SoC (HR for death 1.12; 95%CI = 0.75-1.65; p = 0.581). Grade 3 or 4 treatment-related adverse events occurred in 31 pts (26.7%) on TT (G3: 30 pts (25.9%), G4: 1 pt (0.8%)) and in 13 (22%) on SoC (G3 8 pts, G4 5 pts). **Conclusions:** The SAFIR02-LUNG trial demonstrated the feasibility of a routine precision medicine for advanced NSCLC. However, the monotherapy TT used as maintenance therapy after platinum-based chemotherapy failed to improve PFS or OS in this advanced *ALK/EGFR* WT NSCLC pts population. Newly available therapeutic options (ex. for *KRASG12C, RET, NTRK, ERBB2, NRG1*, etc) need to be evaluated. Clinical trial information: 2013-001653-27. Research Sponsor: Astrazeneca.

Time-dependent efficacy of checkpoint inhibitor nivolumab in metastatic lung cancer patients. *First Author: Abdoulaye Karaboué, Medical Oncology Unit, GHT Grand Paris Est, Montfermeil Hospital, Montfermeil, France*

Background: Nivolumab (NIV) is a Programmed-cell-Death-1 inhibitor approved as 2nd line treatment for metastatic Non-Small Cell Lung Cancer (NSCLC). NIV mainly targets T(CD8) cells, whose functions and trafficking are regulated by circadian clocks (Nobis et al. PNAS 2019), hence suggesting possible dosing time-dependent changes in NIV efficacy. **Methods:** Consecutive metastatic NSCLC patients (pts) received single agent NIV (240 mg iv q 2 weeks) at a single institution. NIV timing slots were randomly allocated for each course by the day hospital coordinator on a logistics basis and recorded. The median NIV timing and its intra-pt coefficient of variation (CVar) were computed over the whole treatment span. The study population was split into two NIV timing groups based upon the median value of the median treatment times of all the pts. CTCAE-toxicity rates were compared between groups with c2 or Fisher exact. Progression free survival (PFS) and overall survival (OS) were compared between both NIV timing groups with Log Rank. **Results:** From 9/2015 to 11/2020, the study accrued 95 stage 4 NSCLC pts (males, 83%; PS 0-1, 96%), aged 41-83 years (median, 67). Primary histological types were adenocarcinoma (55 pts, 58%), squamous cell carcinoma (37 pts, 39%) or unspecified (3 pts, 3%). The pts had a median of 4 metastatic sites, including bone (52% of the pts), pleura (41%), liver (25%), brain (24%) and adrenal gland (20%). A total of 1818 NIV courses were given as 2nd line for 72 pts (76%), or as 3rd or later line for 22 pts (23%). Median PFS and OS (months, mo.) were 3.9 mo. [95% CL, 2.1 – 5.8], and 14.0 mo. [9.5 – 18.4] respectively, for the 95 pts. The majority of NIV administrations occurred between 9:27 and 12:54 for 48 pts ('morning' group) and between 12:55 and 17:14 for 47 pts ('afternoon' group), with intra-pt NIV timing CVar ranging from 2% to 21% (median, 10%). Main pts characteristics were similar for both groups, except for fewer females (8% vs 26%) and younger age (median, 66 vs 69 years) in the 'morning' group compared to the 'afternoon' one. Grade 3-4 fatigue, anorexia or myalgias were less in the 'morning' group compared with the "afternoon' one (6% vs 15%; 2% vs 6%; 0% vs 4%, respectively). Strikingly, median PFS [95% CI] were 11.3 mo. [5.5 - 17.1] for the 'morning' group as compared to 3.1 mo. [1.5 - 4.6] for the 'afternoon' one ($p<0.001$). Median OS were 34.2 mo. [15.1 - 53.3] for the 'morning' group *vs* 9.6 mo. [4.9 - 14.4] for the 'afternoon' group ($p<0.001$). Multivariate analyses identified NIV 'morning' timing and 2nd line administration, as significant independent predictors of longer PFS and OS. **Conclusions:** NIV was both less toxic and four times as effective following 'morning' as compared to 'afternoon' dosing in this study in Stage 4 NSCLC pts, possibly as a result of dosing time-dependent pharmacology. Translational and clinical nivolumab timing validation studies are needed, in order to optimize pts benefits from cancer immunotherapy. Research Sponsor: None.

Optimal next-generation sequencing (NGS) panel for estimating tumor mutation burden (TMB) and its clinical implication for non-small cell lung cancer (NSCLC). *First Author: Takaya Ikeda, National Cancer Center Hospital East, Kashiwa, Japan*

Background: TMB estimation using targeted NGS panels is widely performed in clinical practice. The objective of this study was to determine the optimal NGS panel for estimating TMB and to evaluate its clinical implications for NSCLC. **Methods:** Two NGS panels, Oncomine Tumor Mutation Load Assay (OMLA) and FoundationOne (F1), were compared to select the most accurate TMB prediction panel. From February 2017 to May 2018, 350 lung cancer patients were analyzed by whole-exome sequencing (WES), and the concordance rate of OMLA and F1 to WES was examined. In addition, its clinical utility as a biomarker for immune checkpoint inhibitors (ICIs) was evaluated in our international genome screening network (LC-SCRUM-Asia). From June 2019 to December 2020, 3141 patients with NSCLC from 185 institutions were enrolled, and genomic analysis was successful. The clinico-genomic database of LC-SCRUM-Asia was used for this analysis. **Results:** The linear correlation with WES was 0.80 for OMLA and 0.78 for F1. This indicated that OMLA was more strongly correlated with WES. The cutoff value of F1 was 10 mut/Mb, which corresponded to 9 mut/Mb (OMLA) and 194 mutations (WES). The sensitivity of the OMLA for WES was 79%, and the specificity was 85%. Meanwhile, the sensitivity of the F1 was 74%, and the specificity was 80%. OMLA more accurately predicted TMB, and its clinical utility was evaluated. 3141 NSCLC patients, consisting of 2282 adenocarcinomas, 593 squamous cell carcinomas, and 266 others, were analyzed for TMB, estimated using OMLA. The median number of mutations was 4.2 mut/Mb (range, 0-718.4/Mb). High TMB (≥9 mut/Mb) was observed in 17.2% (393/2282) of adenocarcinoma cases and 25.8% (153/593) in squamous cell carcinoma cases. 778 patients were treated with ICI or ICI plus chemotherapy as the first-line treatment. Patients' characteristics were as follows: male/female; 595/183, median age (range); 67 (25-90), stage II/III/VI/recurrence; 11/90/649/28, TMB high/low; 177/601, ICI/ICI plus chemotherapy; 114/664. The progression-free survival (PFS) was significantly longer in patients with high TMB than in those with low TMB (median PFS, 7.5 vs. 5.9 months, p = 0.0314). The overall survival (OS) was significantly longer in patients with high TMB than in those with low TMB (median OS, 27.4 vs. 20.4 months, p = 0.006). **Conclusions:** The TMB estimated by OMLA correlated more strongly with the WES-derived TMB comparing with F1. TMB estimated by OMLA was correlated with PFS and OS in NSCLC patients treated with ICIs. Prospective clinical trials are needed to determine whether TMB estimated by OMLA is a biomarker for ICI. Real-world response and outcomes in NSCLC patients with EGFR exon 20 insertion mutations. *First Author: Sai-Hong Ignatius Ou, Chao Family Comprehensive Cancer Center, University of California Irvine, Orange, CA*

Background: There is currently no targeted therapy approved for patients with EGFR exon 20 insertion mutations (exon20ins) in NSCLC. Real world treatment outcome evidence for this rare population is limited. This study describes treatment patterns and outcomes in US patients with advanced NSCLC with EGFR exon20ins. **Methods:** The nationwide Flatiron Health electronic health record-derived deidentified database (cut-off 29 Feb 2020) was used to select 4 separate cohorts: (1) first-line (1L): patients receiving 1L therapy after documented exon20ins (1L start date as index date); (2) second or later line (≥2L): patients receiving ≥2L therapy after documented exon20ins (start date of ≥2L as index date); (3) ≥2L trial-aligned: ≥2L patients with baseline characteristics aligned with the key eligibility criteria of mobocertinib Trial NCT02716116 Part 3; and (4) ≥2L post platinum: ≥2L trial-aligned patients previously treated with platinum-based chemotherapy. Real-world endpoints were: confirmed overall response rate (cORR), PFS, and OS. Additional analyses were conducted for patients treated with immune-oncology therapy (IO). **Results:** Of 237 EGFR exon20ins patients, 129 patients were included in 1L cohort and 114 were in ≥2L cohort, including 63 ≥2L trial-aligned and 50 ≥2L post platinum patients. In 1L patients, EGFR TKI (28.7%) and platinum-based chemotherapy ± IO (56.6%) were the most common 1L regimens. In ≥2L patients, 28.1% received IO monotherapy, 17.5% received EGFR TKI, and 23.7% received platinum-based chemotherapy ± IO as index treatment. In the 1L setting, median PFS (mPFS) was 5.7 months for platinum-based chemotherapy and 4.5 months for IO + platinum-based chemotherapy. In the ≥2L setting, mPFS was 3.7 months for any therapy and 2.3 months for IO monotherapy. Full effectiveness data are provided in the accompanying table. **Conclusions:** This real world study provided a benchmark on the treatment outcome in patients with advanced NSCLC with EGFR exon20ins. Platinum-based chemotherapy was the most common 1L therapy and provided the longest mPFS. Immunotherapy, either as monotherapy or in combination with chemotherapy, appeared less effective for treatment of NSCLC with EGFR exon20ins. There is an unmet medical need for improved therapeutic options. Research Sponsor: Takeda Pharmaceutical Company Limited.

Cohort	N	cORR (95% CI)	Median OS (95% CI), months	Median PFS (95% CI), months
1L: any therapies	129	18.6% (12.3%, 26.4%)	17.0 (11.2, 19.5)	5.2 (3.1, 6.9)
1L: IO monotherapy	11	9.1% (0.2%, 41.3%)	11.0 (1.2, n/r)	3.1 (1.1, 5.2)
1L: IO + Platinum	16	18.8% (4.0%, 45.6%)	11.3 (5.6, n/r)	4.5 (1.2, 10.3)
1L: Platinum	41	19.5% (8.8%, 34.9%)	17.0 (10.5, 33.2)	5.7 (3.0, 10.9)

Impact of immune checkpoint inhibitor (CPI) and EGFR tyrosine kinase inhibitor (TKI) sequence on time to treatment failure (TTF) among EGFR plus NSCLC treated in a community-based cancer research network.

First Author: Carissa Jones, Sarah Cannon Research Institute, Nashville, TN

Background: The development of CPIs and driver-targeted TKIs has transformed the treatment of NSCLC and increased survival rates. However, the role of CPIs in patients with oncogenic-driven NSCLC remains an area of investigation. We sought to examine the impact of CPI sequence on treatment response among patients with oncogenic-driver mutation-positive NSCLC. **Methods**: Patients with NSCLC being treated within the Sarah Cannon Research Institute network were identified through Genospace, Sarah Cannon's clinico-genomic analytics platform. Advanced stage oncogenic-driven tumors (driver+) were defined as those with a record of receiving an FDA-approved TKI targeting EGFR, ALK, RET, ROS1, NTRK, MET, or BRAF. Kaplan-Meier estimates were used to examine TTF (defined as time from therapy start to start of next therapy, death, or loss to follow-up) and overall survival (OS). **Results**: We identified 12,352 patients with lung cancer and available therapy data (2005-2020), including 2,270 (18%) driver+ patients. Eleven percent (N=245) of driver+ patients received a CPI, including 120 (49%) with CPI prior to TKI, 122 (50%) with CPI post TKI, and 3 (1%) who received CPI both pre and post TKI. The CPI TTF was significantly longer for those who received CPI post TKI compared to those who received it prior (Table). EGFR+ tumors accounted for 82% (N=1,867) of driver+ patients, 10% of whom (N=188) received a CPI. Of the EGFR+/CPI+ patients, 78 patients (41%) received CPI prior to TKI, 107 (57%) received CPI post TKI, and 3 (2%) received CPI both pre and post TKI. EGFR+ tumors exposed to a CPI post TKI had a longer CPI TTF compared to patients who received it prior (Table). In contrast, there was no difference in length of benefit from TKI if it was received pre vs. post CPI (Table). There was also no difference in OS based on sequence of TKI and CPI (p=0.88). Larger sample sizes are needed for analysis of additional driver-stratified cohorts. **Conclusions**: Patients with oncogenic-driven NSCLC benefited from CPI longer when it was administered after TKI compared to before. Importantly, therapy sequence only affected length of benefit from CPIs and did not affect length of benefit from TKIs. This effect was present in EGFR+ NSCLC, but sample sizes were too small to determine if the same is true for other oncogenic-drivers. Therapy sequence had no impact on OS, indicating the presence of additional clinical, therapeutic, and/or genomic factors contributing to disease progression. Continued research is needed to better understand markers of CPI response in driver+ NSCLC. Research Sponsor: None.

Median TTF (mTTF) for driver+ NSCLC based on therapy sequence.

	mTTF (days)	P-value

Interim results of viagenpumatucel-L (HS-110) plus nivolumab in previously treated patients (pts) with advanced non-small cell lung cancer (NSCLC) in two treatment settings.

First Author: Roger B. Cohen, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Background: Viagenpumatucel-L (HS-110) is an allogeneic cell therapy derived from a human lung adenocarcinoma cell line incorporating multiple cancer testis antigens and transfected with a gp96-Ig fusion protein. **Methods:** We report interim results of cohort A (previously treated pts who had not received a checkpoint inhibitor [CPI]) and cohort B (pts who progressed after CPI treatment) in an ongoing phase 2 trial evaluating HS-110 plus nivolumab (NIVO) in advanced NSCLC pts (NCT02439450). Pts received HS-110 (1×10^7 cells) intradermally QW for 18 wk and NIVO Q2W until tumor progression. Stratified analyses were performed by injection site reaction (ISR), yes (+) or no (–); baseline blood tumor mutational burden (bTMB), bTMB-L (<10 mutations/ megabase [mut/Mb]) or bTMB-H (≥10 mut/Mb) by FoundationACT test; and baseline PD-L1 expression, – (<1%) or + (≥1%). **Results:** As shown in the Table, median progression-free survival (PFS) in cohort A (n=47) was 1.8 mo (95% CI 1.8-7.8) and median overall survival (OS) was 24.6 mo (95% CI 11.7-36.0) after a median follow-up (MFU) of 19.5 mo. We observed significantly longer PFS and OS in ISR+ pts (hazard ratio [HR] 0.43, p=0.01; HR 0.23, p<0.001) and longer OS in PD-L1+ pts (HR 0.25, p=0.02). In cohort B (n=68), median PFS was 2.8 mo (1.8-3.9) and median OS was 11.9 mo (9.7-16.3) after a MFU of 11.9 mo. We observed significantly longer OS in ISR+ pts (HR 0.48, p=0.03) and a trend toward extended OS in bTMB-L pts (HR 0.58, p=0.20). HS-110 TEAEs were reported in 21 (44.7%) pts in cohort A and 18 (26.5%) pts in cohort B. TEAEs in >5% of pts included fatigue, maculopapular rash, nausea, diarrhea, and pruritus. Few HS-110–related TEAEs led to discontinuation of treatment [cohort A, 5 (10.6%); cohort B, 3 (4.4%)], and no serious AEs were considered related to HS-110. **Conclusions:** HS-110 was well tolerated when administered in combination with NIVO. In previously treated pts with advanced NSCLC, we observed (1) significantly longer PFS and OS in ISR+ pts in both CPI naïve and CPI progressor cohorts; (2) significantly longer OS in PD-L1+ patients in the CPI naïve cohort; and (3) a trend of improved OS in bTMB-L pts in the CPI progressor cohort. Further clinical evaluation of HS-110 is warranted in both CPI naïve and CPI progressor NSCLC patients. Clinical trial information: NCT02439450. Research Sponsor: HEAT Biologics.

Incidence and heterogeneity of C797S and other EGFR resistance mutations on routine comprehensive genomic profiling (CGP).

First Author: Pasi A. Janne, Dana-Farber Cancer Institute, Boston, MA

Background: The emergence of osimertinib (osi) as standard of care therapy for *EGFR*-mutant NSCLC has led to investigations into understanding and overcoming drug resistance. There are now a number of therapeutic approaches aimed at overcoming *EGFR* resistance mutations (muts). We sought to understand the biology of *EGFR* C797S and other *EGFR* resistance muts through querying our clinico-genomic database (CGDB). **Methods:** CGP results from tissue (n = 60,889) or circulating tumor DNA (ctDNA; [n = 9,922]) samples from 70,811 NSCLC patients (pts) were queried for known osi resistance muts in *EGFR* (C797, L792, G796, L718, G724). Clinical outcomes were evaluated for a cohort of NSCLC pts with osi resistance from the Flatiron Health-Foundation Medicine CGDB, a nationwide de-identified EHR-derived database linked to CGP data. **Results:** Between 12/2014 and 11/2020, 261 osi resistance mutations in *EGFR* were detected in 228 samples. The most common were C797S (66%), L718X (14%), G724S (11%), and others (9%). 173 C797S muts were detected in 155 samples (123 ex19del, 30 L858R, 2 other *EGFR* muts); 100 tissue, 55 ctDNA (median VAF = 7.6%). *EGFR* T790M co-occurred with C797S muts (96% cis, 3.7% trans) in 118 (76%) samples and decreased over time, occurring in 92% (24/26) of C797S samples tested in 2017 vs 56% (20/36) of samples tested in 2020 (p = 0.002). In 19/155 (12%) samples with C797S (14 ctDNA), multiple changes resulting in *EGFR* resistance muts were present: 16 samples had > 1 nucleotide changes resulting in C797S (100% trans), 3 samples had other resistance muts (L718Q/V, L792H, L792F) and 3 samples had multiple C797S changes with other resistance muts (C797G, L792H/F + G796S, L718Q + G796S+C797G). 29 pts (14 ctDNA) had C797S with potential off-target resistance (17 *PIK3CA* muts, 4 *BRAF* muts, 3 *CCDC6-RET* fusions, 3 *KRAS* muts, 2 *ERBB2* amplifications (amps), 1 *ERBB2* ex16 del, 1 *STRN-ALK* fusion, 1 *FGFR3-TACC3* fusion). In the CGDB, 527 *EGFR*-mut NSCLC pts had documented receipt of osi. Pre and post osi-treated specimens were available for 19 of these pts (12 ex19del, 6 L858R, 1 G719A/S768I). Heterogeneous acquired resistance mechanisms were observed in the post-osi specimen, including 2 *CCDC6-RET* fusions, 2 *MET* amps, 2 *BRAF* fusions, *BRAF* V600E, and secondary *EGFR* muts (C797S, L704F, L718V). 161/527 pts had a documented line of therapy after osi discontinuation and most frequently received platinum doublet + immunotherapy (27%) or platinum doublet alone (23%); 17 (11%) pts received another *EGFR* tyrosine kinase inhibitor. 214/527 had documented osi progression and median post-progression survival was 11.8 months. **Conclusions:** Osi resistance in *EGFR*-mutant NSCLC is a poor prognosis condition. *EGFR* C797S is a recurring resistance mut which, in a minority of cases, can co-occur with alternate on and off target resistance muts detected with tissue and liquid biopsy. RATIONALE-307: Tislelizumab plus chemotherapy versus chemotherapy alone as first-line treatment for advanced squamous NSCLC in patients aged ≥ 65.

First Author: Jie Wang, State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/ National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Tislelizumab is a humanized, monoclonal antibody with high affinity and specificity for the programmed cell death protein 1 (PD-1). It has demonstrated antitumor activity in advanced lung cancers. We conducted a Phase 3, multicenter, randomized open-label study (NCT03594747) to assess the safety and efficacy of tislelizumab plus chemotherapy in patients (pts) with advanced squamous NSCLC. As previously reported, tislelizumab (TIS) significantly improved progression free survival (PFS) and reduced the risk of progression. Here, we report results from a sub-group of pts aged ≥ 65 years. **Methods:** Eligible pts (aged 18-75 years) enrolled in China were treatment-naive for locally advanced or metastatic squamous NSCLC. Pts were stratified by disease stage (IIIB vs IV), and programmed death-ligand 1 (PD-L1) expression (<1% vs 1-49% vs 50% tumor cells), and randomized 1:1:1 to Arm A: TIS 200 mg + paclitaxel (P) 175 mg/m^2 and carboplatin (C) area under the plasma concentration 5 (every 3 weeks [Q3W] on day 1); Arm B: TIS + *nab*-paclitaxel (*nab*-P) 100 mg/m^2 (Q3W on days 1, 8 and 15) + C (Q3W on Day 1); or Arm C: P + C (Q3W on day 1). P, *nab*-P and C were administered for 4 to 6 cycles. TIS was administered until loss of benefit, withdrawal of consent or start of a new anticancer therapy. In this sub-group analysis, pts aged ≥ 65 years were evaluated according to the primary endpoint (PFS) and key secondary endpoints (objective response rate and safety). **Results:** Overall, 127 pts aged ≥ 65 years were randomized to receive treatment. Median age of pts aged ≥ 65 was 68.0 years and 120 pts (94.5%) were male. In total, 18 (46.2%), 20 (38.5%), and 34 (94.4%) pts in Arms A, B and C, respectively, had discontinued treatment. In Arm C 22/34 pts had completed chemotherapy. The primary and secondary endpoints, PFS and ORR, were longer and higher, respectively, in Arms A and B, compared with Arm C (Table). Grade ≥ 3 treatment related adverse events (TRAEs) occurred in 33 (84.6%), 44 (84.6%) and 28 (82.4%) pts aged ≥ 65 years in Arms A, B and C, respectively, compared with 103 (85.8%), 99 (83.9%) and 94 (80.3%) pts aged ≥ 18 years enrolled in the study. The most commonly reported TRAEs in pts aged ≥ 65 years were anemia, decrease in neutrophil count, and alopecia. **Conclusions:** In this sub-group analysis, PFS and ORR were longer and higher, respectively, with TIS in pts aged ≥ 65 years with advanced squamous NSCLC. The safety profile of TIS in pts aged ≥ 65 years was similar to the safety profile for all aged pts aged ≥ 18 years. Clinical trial information: NCT03594747. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Tamsin Grewal, MSc, of Ashfield Medcomms, an Ashfield Health Company, and funded by BeiGene, Ltd.

Chronic immune checkpoint inhibitor (ICI) pneumonitis in patients (pts) with non-small cell lung cancer (NSCLC). *First Author: Jessica Stuart, Brigham and Women's Hospital, Boston, MA*

Background: ICI pneumonitis is an immune-related adverse event (irAE) of the lung and often requires discontinuation of ICI. While some pneumonitis cases resolve within the recommended 4-6-week period of corticosteroid therapy, others either fail to improve or have multiple flares necessitating longer or repeated courses of steroids. We investigated the clinical features and courses of pts with chronic pneumonitis. **Methods:** We analyzed 869 pts with NSCLC initiated on ICIs at our institution between 2011 and 2019 for development of ICI pneumonitis. Chronic pneumonitis was defined as any pneumonitis requiring a total of ≥12 weeks of steroids, given either continuously or over multiple courses of treatment. Cases of chronic pneumonitis in which the initial course of steroids lasted ≥12 weeks without interruption were termed "primary refractory pneumonitis". Subsequent episodes of pneumonitis were categorized as either "recurrent pneumonitis" from ICI rechallenge or "pneumonitis flare" after steroid taper without ICI rechallenge. Chest CT scans were analyzed to classify the imaging patterns. **Results:** Of the 869 pts analyzed, 44 developed ICI pneumonitis (5.1%) and 22 of the 44 (50%) experienced chronic pneumonitis (Grade 2 in 11, Grade 3 in 9, and Grade 4 in 2). A cryptogenic organizing pneumonia (COP) pattern was the most common CT pattern among all pneumonitis cases (30/44) and in chronic pneumonitis cases (14/22). Among chronic pneumonitis cases, the median number of total weeks on corticosteroid therapy was 25.9 (range: 12.4 – 114.4 weeks). Four pts required additional immunosuppressive agents including mycophenolate or infliximab. Fourteen of 22 pts with chronic pneumonitis had primary refractory pneumonitis, while the remaining 8 pts were weaned off of steroids within 12 weeks but later developed additional episode(s) of pneumonitis, ultimately resulting in a total steroid duration of ≥12 weeks. The 14 pts with primary refractory pneumonitis had significantly shorter time to pneumonitis onset compared to the other 8 pts (median time to onset: 1.8 vs. 5.5 months, Wilcoxon ranksum p = 0.04). Seventeen of 22 patients had their ICI permanently discontinued; of these, 9 pts subsequently experienced pneumonitis flare after steroid taper, necessitating additional course(s) of steroid therapy. 5 of the 22 patients were rechallenged with ICI, and 4 of them had recurrent pneumonitis with ICI rechallenge. **Conclusions:** Half of the pts diagnosed with pneumonitis developed chronic pneumonitis requiring at least 12 weeks in aggregate of glucocorticoid therapy. Some patients had an initial prolonged steroid course while others initially improved and then flared, even after ICI discontinuation. Recognition of chronic pneumonitis as a distinct and common clinical entity is important in management of pts with ICI pneumonitis. Research Sponsor: None.

Genomic markers associated with hyperprogression in patients with lung cancer treated with immune checkpoint inhibitors. *First Author: Eyob ale Tadesse, Aurora Cancer Care, Advocate Aurora Health, Milwaukee, WI*

Background: Immune checkpoint inhibitor (ICI) therapy has become a mainstay of non-small cell lung cancer (NSCLC) treatment. However, not all patients (pts) benefit with a subset paradoxically experiencing accelerated tumor growth while on ICI. Hyperprogression (HP) refers to accelerated tumor growth on ICI with worsening clinical status. Various gene alterations may be associated with HP including MDM2/MDM4 amplifications, EGFR alterations, and STK11/LKB1 mutations. Kato et al. (doi: 10.1158/1078-0432.CCR-16-3133) showed HP in 6/6 pts with MDM2/MDM4 amplification and in 2/10 pts with EGFR alterations. This report describes HP in pts with NSCLC treated with ICIs in a large health system. **Methods:** Pts with NSCLC treated with ICIs from Jan 2012 to Jan 2021 at Advocate Aurora Health were reviewed after IRB approval. Pts with NSCLC histology (ICD diagnosis codes and/or manual chart review), ICI treatment, and molecular testing were identified via the real world data integrated within the Syapse Learning Health Network platform. Additional chart review to ascertain HP was performed, and molecular results were analyzed. HP criteria include: 1) time-to-treatment failure < 2 months (from start to discontinuation of ICI for any reason), 2) > 50% increase in tumor burden by RECIST, 3) spread of the disease to a new organ between baseline and first radiologic evaluation or clinical deterioration, and 4) ECOG PS ≥ 2 during the first 2 months of treatment. Based on the number of criteria fulfilled, HP = > 3, Progression = 1-2, and non-progressor = 0. Pts with and without HP were compared using Chi-squared and Fisher Exact tests. T-tests were performed for continuous variables. **Results:** Out of 7,078 NSCLC pts, 1,389 (20%) were treated with ICI including atezolizumab (40 pts, 3%), durvalumab (17 pts, 1%), nivolumab (167 pts, 12%), pembrolizumab (190 pts, 14%), and multiple ICIs (12 pts, 1%). Of those pts treated with ICIs, molecular testing was performed in427 (31%). 98 of 427 pts (23%)had HP and an additional 86 pts (20%) had progressive disease without meeting the definition of HP. Biomarker associations with HP are shown in the table. By tumor gene alterations, HP was seen in pts with: EGFR (20/60), STK11/LKB1 (16/25); and MDM2/4 (4/7). **Conclusions:** EGFR, STK11/LKB1, and MDM2/4 gene alterations were all statistically significantly associated with HP. Clinical and molecular predictors of HP need to be explored in order to optimize selection of pts for ICI therapy. Research Sponsor: None.

Impact of *STK11* mutation on first-line immune checkpoint inhibitor (ICI) outcomes in a real-world KRAS G12C mutant lung adenocarcinoma cohort. *First Author: Rebecca Suk Heist, Massachusetts General Cancer Center, Boston, MA*

Background: The introduction of KRAS G12C inhibitors into clinical trials has demonstrated promise and may provide a new therapeutic option for patients (pts) harboring *KRAS* G12C mutations. Recent data has also indicated that immune checkpoint inhibitors (ICI) have shown benefit in *KRAS* G12C mutant lung adenocarcinoma (LUAD); however, data on the impact of co-occurring *STK11* mutations on outcomes are conflicting. We utilized the Guardant INFORM real-world clinical-genomic database to assess the impact of co-occurring *STK11* mutations on outcomes in pts with *KRAS* G12C mutant LUAD treated with a first-line ICI containing regimen. **Methods:** This retrospective matched cohort observational study was conducted in a nationally representative clinical-genomic database covering over 137,000 pts with comprehensive ctDNA results and associated clinical information. Adult pts with metastatic LUAD who received ≥ 1 dose of first-line anti-PD1/PD-L1 ± chemotherapy and had at least 90 days follow-up after first *KRAS* G12C detection were included. A cohort of pts without *KRAS* G12C, including *KRAS* wildtype pts and pts with other *KRAS* mutations, were matched 3:1 for age, gender, year of index and baseline comorbidity. Time to next treatment (TTNT), time to discontinuation (TTD), real-world overall survival (rwOS) were compared with vs. without *STK11* mutations for both cohorts using cox proportional-hazards model. **Results:** Among 330 pts in the *KRAS* G12C cohort, 21% (n = 70) had an *STK11* mutation. Among the matched cohort (n = 938), 754 pts were *KRAS* wildtype, of whom 6% (n = 49) had *STK11* mutations. Within the *KRAS* G12C cohort, pts with *STK11* mutations had statistically significant shorter TTNT (hazard ratio [HR] 2.7, 95% confidence internal [CI] 1.8-4.0, p < 0.0001), TTD (HR 1.4, 95% CI 1.0-2.0, p < 0.04) and rwOS (HR 3.2, 95% CI 2.0-5.1, p < 0.0001) than pts without *STK11* mutations. Within the matched *KRAS* wildtype cohort, the differences in TTD (HR 1.4, 95% CI = 1.0-2.0, p = 0.08) and rwOS (HR 1.4, 95% CI = 0.8-2.4, p = 0.3) in patients with vs. without *STK11* mutation did not reach statistical significance (Table). **Conclusions:** This study provides real-world evidence that *STK11* co-mutations are associated with worse outcomes among pts with *KRAS* G12C mutant LUAD treated with first-line ICI. These inferior outcomes indicate a high unmet medical need among LUAD pts harboring co-occurring *KRAS* G12C and *STK11* mutations and demonstrate the need for effective targeted and/or combination therapies in this patient population. Research Sponsor: Mirati Therapeutics.

Association of concomitant NSAID and immunotherapy on outcomes in patients with non-small cell lung cancer: Analysis of the National Veterans Health Administration Database. *First Author: Drew Moghanaki, Atlanta Veterans Affairs Health Care System, Decatur, GA*

Background: Preclinical data suggests the efficacy of immune checkpoint inhibitors (ICI) may be enhanced with concomitant nonsteroidal anti-inflammatory (NSAID) medications. Real-world evidence to support investigating this hypothesis in prospective randomized trials are needed. **Methods:** A retrospective cohort study queried the VA Corporate Data Warehouse (VA-CDW) to identify patients diagnosed with NSCLC who were treated with ICI between 2010-18. Exposure to concomitant NSAID was determined whenever NSAID prescriptions were released from the VA pharmacy within 90 days of the first ICI infusion. Chi-square and ANOVA tests were used to compare baseline characteristics. The outcome of overall survival (OS) was measured from the start of ICI. Cox proportional hazard regression was used to adjust for demographic, clinical, tumor, and treatment characteristics. **Results:** The study cohort consisted of 3,415 patients with NSCLC treated with ICI, and 2,336 (64%) were exposed to concomitant NSAID. The median age was 69, male 97%, race: white 73%, black 21%, and 66% lived in urban areas. Most patients were initially diagnosed with stage III or IV disease (68%); tumor histology: adenocarcinoma 48% and squamous cell 38%. Comorbidity counts were 0 in 40%, 1-3 in 30%, and 4+ in 30%. Chemotherapy was delivered before ICI in 54% and concurrently with ICI in 31%. The most commonly used NSAIDs were aspirin (35%), ketorolac (11%), and ibuprofen (7%); 44% were exposed to more than one NSAID. With a median follow-up of 8 months, exposure to concomitant NSAIDs was associated with a longer OS (HR = 0.90; 0.83-0.98, p = 0.01) after adjusting for all available potential confounders on multivariable analyses. Longer OS persisted following propensity score matching (HR = 0.89; 0.82-0.97 p = 0.007). Other factors significant for OS on multivariable testing included use of chemotherapy after ICI (HR = 0.53 [0.40-0.69], p < 0.001), concurrent chemotherapy during ICI (HR = 0.68 [0.62-0.74], p < 0.001), younger age, black race, female gender, and adenocarcinoma histology. Among the various NSAIDs analyzed on the multivariable analyses, only diclofenac approached statistical significance (HR = 0.78 [0.59-1.03], p = 0.08). Limiting the comparison to patients exposed to diclofenac (n = 101) versus no NSAIDs (n = 1,298), the comparison demonstrated a similar trend for OS (HR = 0.79 [0.60-1.04], p = 0.094), although the association was attenuated after propensity-score matching (HR = 0.90 [0.63-1.29], p = 0.57). **Conclusions:** This retrospective cohort study of Veterans with NSCLC who were treated with ICI identified that concomitant receipt of NSAIDs is associated with longer OS. Genomic landscape differences in patients with advanced non-small cell lung cancer by sex and age. *First Author: ErinMarie Kimbrough, Mayo Clinic, Jacksonville, FL*

Background: Non-small cell lung cancer (NSCLC) remains a leading cause of cancer-related death in the U.S. The median age at diagnosis is 70 years, and NSCLC is uncommon among younger individuals (< 50 years).Overall, outcomes in NSCLC have improved significantly with targeted therapy. A prior study demonstrated patients < 50 are more likely to have targetable alterations including EGFR, ALK, ERBB2, and ROS1. Another study reported an increased prevalence of EGFR mutations in females and KRAS mutations in males with NSCLC. The comprehensive genomic landscape of NSCLC patients in different age groups and genders remains largely unknown. In our study, we aim to investigate the genomic alterations in patients with advanced NSCLC according to age and sex. Efforts that are focused on identifying targetable alterations in NSCLC will likely help personalize treatment and improve outcomes. **Methods:** We performed a retrospective review of de-identified data from the Guardant Health database from March 2018 through October 2020. We reviewed 34,237 profiles from patients with NSCLC who underwent molecular profiling using the plasma-based circulating-tumor DNA (ctDNA) Next-Generation Sequencing (NGS) assay Guardant360. Single nucleotide variants (SNV), fusions, indels and copy number variations (CNV) of up to 83 genes were analyzed. We assessed for genomic differences among patients with advanced NSCLC by both sex and age (≥70 and < 70). We conducted two-tailed tests of equality of proportions comparing males to females and ≥70 to < 70. **Results:** Of the 34,237 profiles reviewed, somatic alterations were seen in 81.7% (n = 27,972) of the patients. The median age was 70 (range 16-102) and 55% were female. Our study demonstrated that the most common genomic alterations in both age groups and genders were TP53, EGFR, KRAS, ATM, and MET. Patients ≥70 were more likely to have ATM (21% versus 14%, $p < 0.0001$) and MET (12% versus 10 %, $p < 0.0001$) mutations than those < 70. Patients < 70 were more likely to have EGFR (30% versus 27%, $p < 0.0001$), STK11 (14% versus 11%, $p = 0.0056$), and KRAS (26% versus 24%, $p < 0.0001$) alterations. EGFR was seen more frequently in females (33% versus 26%, $p < 0.0001$). ATM (11% versus 6%, $p < 0.0001$) and MET (8% versus 5%, $p = 0.0050$) were seen more frequently in males. **Conclusions:** Significant differences in the distribution of targetable genomic alterations were identified among different age groups and genders in patients with advanced NSCLC. These findings highlight the importance of taking personalized approaches to diagnostic testing and treatment of advanced NSCLC. Research Sponsor: None.

Long-term efficacy and safety of larotrectinib in patients with TRK fusion-positive lung cancer. *First Author: Jessica Jiyeong Lin, Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions have been identified as oncogenic drivers in a diverse array of tumor types including lung cancer. Larotrectinib is a first-in-class, highly selective, central nervous system (CNS)-active tropomyosin receptor kinase (TRK) inhibitor approved for the treatment of adult and pediatric patients (pts) with TRK fusion cancer, with an objective response rate (ORR) of 78% across multiple non-CNS cancers (McDermott et al, ESMO 2020). Here, we report the updated data on pts with lung cancer treated with larotrectinib. **Methods:** Pts with lung cancer harboring a *NTRK* gene fusion enrolled in two clinical trials (NCT02576431 and NCT02122913) were identified for this analysis. Larotrectinib 100 mg PO BID was administered on a continuous 28-day schedule until disease progression, withdrawal, or unacceptable toxicity. Response was assessed by the investigator per RECIST v1.1. **Results:** As of July 20, 2020, a total of 20 pts with TRK fusion-positive lung cancer (19 with non-small cell lung cancer and 1 with small cell lung cancer) were enrolled. Median age was 48.5 years (range 25.0–76.0). The gene fusions involved *NTRK1* (n = 16; 80%) or *NTRK3* (n = 4; 20%). Pts were heavily pre-treated with a median of 3 systemic therapies (range 0–6). Among 15 evaluable pts, the confirmed ORR was 73% (95% CI 45–92): 1 complete response, 10 partial responses (PR), 3 stable disease (SD) and 1 progressive disease (PD). The median time to response was 1.8 months. Among 8 evaluable pts with baseline measurable and non-measurable CNS metastases, the ORR was 63% (95% CI 25–91): 5 PR, 2 SD, and 1 PD. In all evaluable pts, the 12-month rates for duration of response and progression-free survival were 81% and 65%, respectively. Median overall survival was 40.7 months (95% CI 17.2 to not estimable) at a median follow-up of 16.2 months. Duration of treatment ranged from 0.03+ to 51.55+ months. Adverse events (AEs) were predominantly Grade 1–2. Treatment-related AEs were reported in 16 pts, of which 2 experienced Grade 3 events (myalgia, hypersensitivity, weight increase). There were no treatment discontinuations due to AEs. **Conclusions:** These data confirm that larotrectinib is highly active with rapid and durable responses, extended survival benefit, and a favorable long-term safety profile in pts with advanced lung cancer harboring *NTRK* gene fusions, including in pts with CNS metastases. These results underscore the importance of screening for *NTRK* gene fusions in pts with lung cancer. Clinical trial information: NCT02576431 and NCT02122913. Research Sponsor: Bayer HealthCare and Loxo Oncology.

Ph I/II study of oral selective AXL inhibitor bemcentinib (BGB324) in combination with erlotinib in patients with advanced EGFRm NSCLC: End of trial update. *First Author: Lauren Averett Byers, MD Anderson Cancer Center, Houston, TX*

Background: AXL, a receptor tyrosine kinase, is over-expressed in many cancers, and has been identified as a marker of poor prognosis in NSCLC. AXL overexpression is implicated in development of resistance to EGFR inhibitors including erlotinib (Erl) and osimertinib. AXL inhibition by bemcentinib (Bem), a first-in-class, oral, selective and potent AXL kinase inhibitor, abrogates resistance to EGFR inhibitors *in vivo*. Bem is currently under evaluation as a monotherapy and in combination with EGFRi, CPIs and chemotherapy across several PhII trials. **Methods:** Phase I of this study was designed to confirm safety/tolerability of Bem in NSCLC pts as monotherapy and in combination with Erl in pts previously progressing on Erl (arm A). In Phase II, pts who had progressed on an approved EGFRi (arm B) or who were responding/stable on Erl in the 1L setting (arm C) were treated with Bem 200mg and Erl 150mg od to evaluate the safety and activity of the combination, assessing reversal or prevention of resistance to EGFR inhibition in these 2 groups, respectively. Plasma protein biomarker levels were sequentially measured using the DiscoveryMap v3.3 panel (Myriad RBM). **Results:** As of 7 Oct 2020, all arms have completed recruitment. Median exposure to Bem was 63d (mean: 200d, range: 2d-1175d). Treatment was generally well-tolerated. Common TRAEs (>20% pts) were diarrhea (70%; G3 20%), nausea (50%; G3 0%), QTc prolongation (35%; G3 3%), vomiting (35%; G3 0%), and fatigue (25%; G3 5%). 1 unrelated G4, 0 G5 reported. In the run-in arm (5 female, median age 61 yrs [57-76]), 2/8 pts achieved SD for ~1 yr, including 19% tumor shrinkage in 1 pt. In arm A (5 female, median age 58 yrs [38-67]), 1/8 pts (68 F) achieved tumor shrinkage of 38%, with treatment duration of 2 yrs until progression. A further 5 pts reported SD. In arm B, 11 pts (7 female, median age 63 yrs [49-78]) had received a median of 1 (0 - 4) prior lines of chemotherapy and a median of 2 prior lines of EGFRi. One achieved a PR (51M) and one a SD (62F) on the combination (CBR of 18%); durations on treatment were 1 yr, and 6 mos, respectively. Neither had EGFR T790M. mPFS was 1.4 mos. In arm C, 13 pts (10 female, median age 66 yrs [32-80]) were enrolled. 11/13 pts were evaluable for efficacy. 1 PR (58M) was reported with 47% tumor shrinkage, duration of treatment was 315d. 9 other pts achieved SD (CBR of 91%), including 4 (3 F/1 M, age range 64-71yrs) who continued on trial for 772+ to 1008+ d. mPFS is currently 12.2 mos. Protein biomarkers predictive of pt benefit upon Bem treatment are being explored. **Conclusions:** Bem with Erl combination is feasible and tolerable in NSCLC pts, with benefit was seen in a subset of pts who either progressed on an EGFRi or were receiving Erl concurrently in remission in the first line. Further studies of Bem + EGFRi are warranted to explore the potential benefits of this combination. Clinical trial information: NCT02424617. Research Sponsor: Privately.

Capmatinib efficacy in patients with NSCLC identified as *MET*ex14 using an NGS-based liquid biopsy assay: Results from the GEOMETRY mono-1 study. *First Author: Rebecca Suk Heist, Massachusetts General Cancer Center, Boston, MA*

Background: Capmatinib, a highly selective and potent MET inhibitor, was approved for patients (pts) with advanced MET exon 14 skipping mutation (METex14) NSCLC in the US and Japan, with the FoundationOne CDx (tissue NGS assay), based on results of the ongoing GEOMETRY mono-1 study (NCT02414139). Here, we report efficacy findings in pts from GEOMETRY mono-1, who were identified as *MET*ex14 using a next-generation sequencing (NGS)-based liquid biopsy test (LDx), which detects *MET*ex14 in circulating tumor (ct)DNA. **Methods:** During the GEOMETRY mono-1 study, pts were screened for *MET*ex14 status using a *MET*ex14 RT-PCR clinical trial assay (CTA) on FFPE tissue. Clinical validation of the LDx was performed using plasma samples from pts enrolled in the GEOMETRY mono-1 study, which include *MET*ex14-positive samples from Cohort (C)4 (pretreated) and C5b (treatment-naïve), in addition to *MET*ex14-negative samples from C1b, C2, and C3, and 21 tissue-matched NSCLC plasma samples from commercial sources to supplement the total number of *MET*ex14 deletion negative patients. Concordance of the CTA and LDx were evaluated by positive percent agreement (PPA) and negative percent agreement (NPA). This retrospective analysis reports overall response rate (ORR), duration of response (DOR), and progression-free survival (PFS), all by BIRC, and overall survival (OS) in pts identified as *MET*ex14 by the LDx (data cutoff: Sep 18, 2020). **Results:** Of the 97 pts with *MET*ex14 NSCLC in C4 (n = 69) and C5b (n = 28), 88 pts had plasma volume ≥2.5 mL and cell free DNA ≥20 ng (minimum input); of these 57 were LDx positive (C4, n = 41; C5b, n = 16), 26 were negative; 5 had invalid sequencing results. Of the 97 CTA *MET*ex14-negative patients who met minimum input requirements, 88 were LDx negative and 9 had invalid sequencing results; none of the CTA *MET*ex14-negative pts (N = 97) were reported as positive by the LDx. The PPA and NPA for these were 68.7% (95% CI: 57.6%, 78.4%) and 100% (95% CI: 95.9%, 100%), respectively, when excluding LDx invalid results. In pts identified as *MET*ex14 positive by LDx, the ORR (95% CI) was 81.3% (54.4–96.0; n = 16) in C5b and 48.8% (32.9–64.9; n = 41) in C4; median DOR (95% CI) was 20.3 (4.2, NE; n = 13) months in C5b and 9.8 (4.2–19.5; n = 20) months in C4; median PFS (95% CI) was 12.4 (4.5–NE; n = 16) months in C5b and 5.4 (4.0–6.6; n = 41) months in C4; median OS was 17.9 (9.8–NE; n = 16) months in C5b and 13.6 (6.6–23.3; n = 41) months in C4. Clinical findings in those identified as *MET*ex14 positive by LDx were comparable with those identified by the CTA. **Conclusions:** Current findings from the GEOMETRY mono-1 study support the activity of capmatinib in advanced NSCLC pts with *MET*ex14 identified using LDx. For pts identified as *MET*ex14-negative by the LDx, further testing should be performed on tissue samples, as a negative LDx result does not preclude a positive result by tissue biopsy. Clinical trial information: NCT02414139. Research Sponsor: Novartis.

Interim results of a phase II single arm trial combining afatinib with cetuximab in patients with EGFRex20ins positive NSCLC. *First Author: Bianca van Veggel, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Epidermal growth factor receptor exon 20 insertions (EGFRex20ins) are identified in 4-10% of all EGFR mutations in non-small cell lung cancer (NSCLC) and are associated with primary resistance to EGFR tyrosine kinase inhibitors (TKIs). Treatment options are limited. A case series showed that dual EGFR blockade with afatinib and cetuximab can induce tumor responses with manageable toxicity. We report on the first seventeen EGFRex20ins patients treated with afatinib in combination with cetuximab. **Methods:** In this Simon's two stage, single-arm, phase II trial, patients with advanced NSCLC harboring an EGFRex20ins mutation were treated with afatinib 40 mg once daily, in combination with cetuximab 500 mg/m^2, every two weeks, in five institutions in the Netherlands. Supportive medication consisted of minocycline, loperamide and skin creams. No previous line of treatment was required and asymptomatic brain metastases were allowed. The primary endpoint was disease control rate (DCR) after 18 weeks of treatment. Secondary endpoints included safety, response rate (RR), duration of response (DOR) and progression-free survival (PFS). Patients were treated until progression or unacceptable toxicity. A Simon's two stage optimal design was used in order to minimize the number of patients being treated in the event that the regimen proves to be inactive. The estimated sample size of the first stage was 17 patients. At least four successes were required to enter stage 2 of the trial (alpha = 0.10; power = 0.90). **Results:** Eighteen patients were enrolled between Jan 2019 and Aug 2020; one patient did not meet the eligibility criteria due to absence of measurable disease. Median age was 66.0 years, 65% female, 53% never smoker. 47% of patients were treated as first-line therapy. Median prior lines of treatment was 1 (range 0-6). 53% received prior platinum-based chemotherapy. The primary endpoint was met as disease control was achieved by 10 patients (59%) after 18 weeks of treatment. Median PFS was 5.5 months. Best responses were partial (n = 8, RR 47%), stable (n = 7) or progressive disease (n = 2). Four patients were still on treatment at the cut-off date (Feb 2021). Most common treatment-related adverse events (TRAEs) were diarrhea (71%), rash (65%), paronychia (59%) and dry skin (53%). Grade III TRAEs were reported in 59% of all patients. Grade III TRAEs $\geq$ 10% included rash (n = 3; 18%) and diarrhea (n = 3; 18%). No grade IV toxicity was observed. One patient died due to respiratory failure after infusion of study medication, probably related to disease progression, possibly treatment related. 82% of patients required a dose reduction. Rate of treatment discontinuation due to AEs was 12% (n = 2). **Conclusions:** Combination treatment with afatinib and cetuximab demonstrated antitumor activity with a DCR of 59% at 18 weeks and a 47% RR, with manageable toxicity. Clinical trial information: NCT03727724. Research Sponsor: Merck Healthcare, Schiphol-Rijk, Netherlands, an affiliate of Merck KGaA, Darmstadt, Germany, and Boehringer Ingelheim.

9113 **Poster Session**

***DNMT3A* mutation to identify a subset of non-small cell lung cancers with increased sensitivity to PD-(L)1 blockade.** *First Author: Biagio Ricciuti, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Despite significant improvements in overall survival with PD-(L)1 inhibition, the majority of patients with metastatic NSCLC do not respond to immune checkpoint inhibition (ICI). Growing evidence suggests the importance of genomic alterations in modulating anti-cancer immune response and predicting ICI efficacy in solid tumors. However, the genomic correlates of response and resistance to ICI in NSCLC are still largely unknown. **Methods:** Patients with advanced NSCLC treated with PD-(L)1 blockade whose tumors underwent comprehensive genomic profiling were included. Mutation enrichment analysis was performed to identify genomic alterations enriched in responders versus (vs) non-responders to ICI. Loss-of function mutations annotated as oncogenic by OncoKB, and missense mutations predicted to be deleterious by SIFT/Polyphen-2 were considered. Cox proportional hazards models was used to estimate hazard ratios (HRs) in univariable and multivariable models. **Results:** : Among 600 NSCLCs, we identified deleterious mutations in the DNA methyltransferase 3A (*DNMT3A*) gene as the most significant alteration enriched in responders versus non-responders to PD-(L)1 blockade (q-Value $<$ 0.05). *DNMT3A*^{MUT} (7.3%, N = 44) and *DNMT3A* wild-type (*DNMT3A*^{WT}) cases (92.7%, N = 556) were well balanced in terms of baseline clinicopathologic features, including PD-L1 expression, sex, performance status, age, concurrent genomic alterations, and smoking history. *DNMT3A*^{MUT} tumors had a significantly higher median TMB compared to *DNMT3A*^{WT} cases (12.1 vs 9.8 mutations/megabase, P = 0.03). *DNMT3A* loss was associated with significantly higher objective response rate (ORR, 50% vs 20.5%, P $<$ 0.001), longer median progression-free (mPFS, 9.2 vs 2.9 months, HR 0.60, P $<$ 0.01) and overall survival (mOS, 23.1 s 12.1 months, HR 0.59, P = 0.01) among *DNMT3A*^{MUT} compared to *DNMT3A*^{WT} NSCLCs. Loss-of function mutation in *DNMT3A* was confirmed be an independent predictor of improved PFS (HR 0.61, P = 0.01) and OS (HR 0.62, P = 0.04) at multivariable analysis. *DNMT3A* mutation had no impact on OS among patients with advanced NSCLC who did not receive ICI (HR 1.18, P = 0.22), nor among those with early-stage resected NSCLC (HR 1.17, P = 0.48), suggesting that *DNMT3A* mutation is predictive, rather than prognostic, of ICI efficacy. Although a subset of *DNMT3A* mutations could have potentially arisen from tumor-associated hematopoietic cells, the *DNMT3A* allele fraction-to-tumor purity ratio was $\geq$0.5 in more than 50% of cases, suggesting that a proportion of these mutations were derived from lung cancer cells. **Conclusions:** Loss-of-function mutation in DNMT3A may identify a new genomically defined subset of NSCLC with increased sensitivity to PD-(L)1 blockade. Additional studies are ongoing to determine the exact source of DNMT3A mutation (clonal hematopoiesis vs tumor) and their relative contribution to ICI efficacy. Research Sponsor: None.

Nitroglycerin (NTG) plus whole intracranial radiotherapy for brain metastases (BM) in non-small cell cancer patient (NSCLC): A randomized open label, phase II clinical trial. *First Author: Oscar Gerardo Arrieta Rodriguez, Instituto Nacional de Cancerologia (INCan), Mexico City, Mexico*

Background: Hypoxia has been associated with chemo-radioresistance secondary to Vascular Endothelial Growth Factor Receptor induced by Hypoxia Induced Factor (HIF). Nitroglycerin (NTG) can reduce HIF-1 in cell lines, and this may have anti-angiogenic, pro-apoptotic, and anti-efflux effects. Particularly, *EGFR* mutated (EGFRm) tumor cell lines have been shown to overexpress both VEGF and HIF. In this phase II study, we evaluated the effect of transdermal NTG on intracranial objective response rate (iORR), intracranial progression-free survival (ICPFS), and overall survival (OS) of NSCLC patients with BM. **Methods:** We performed an open-label, phase II clinical trial among ninety-six histologically confirmed NSCLC patients with BM. Patients were randomized 1:1 to receive NTG plus WBRT (30 Gy in 10 fractions) or WBRT alone. iORR and ICPFS were evaluated by MRI by two independent, blinded radiologists. Nitroglycerin was administered using a transdermal 36 mg patch, which released 10 mg in 24 hours with a rest interval of 12 hours from Monday-Friday throughout WBRT administration (10 days). **Results:** Fifty patients were allocated to the control group, while 46 were allocated to the experimental group (NTG); among these 26 (55.3%) had *EGFR*m in the control group and 21 (44.7%) had *EGFR*m in the NTG arm. In terms of the iORR, patients in the NTG group had a significantly higher response when compared to controls (56.6% vs. 43.5%; p = 0.024). Additionally, patients who received NTG in addition to WBRT had an independently prolonged ICPFS compared with those who received WBRT alone (27.7 vs. 9.6; HR: 0.470 [95%CI: 0.24-0.89]; p = 0.021). PFS was also positively impacted (HR: 0.519 [95%CI: 0.27-0.98]; p = 0.043). The benefit in terms of iORR and ICPFS (HR: 0.38 [95%CI: 0.16-0.91]; p = 0.030) was particularly important in the *EGFRm* patient subgroup. No differences were observed in OS. A significantly higher rate of vomiting presented in the NTG arm of the study (p= 0.016). **Conclusions:** The concurrent administration of NTG and chemo-radiotherapy improves iORR and ICPFS among NSCLC patients with BM. The benefit is particularly significant in the *EGFR*m patient subgroup. Clinical trial information: NCT04338867. Research Sponsor: Consejo Nacional de Ciencia y Tecnología (CONACyT).

Stereotactic body radiation therapy and in situ oncolytic virus therapy followed by immunotherapy in metastatic non-small cell lung cancer. *First Author: Carlo Guerrero, Houston Methodist Hospital, Houston, TX*

Background: The introduction of immunotherapy has altered the treatment paradigm for metastatic non-small cell cancer (mNSCLC). Unfortunately, many patients with mNSCLC have limited or no benefit from immune checkpoint inhibitors (ICIs). A variety of approaches have been explored to augment the efficacy of ICIs. Our study's aim was to determine whether the addition of stereotactic body radiation therapy (SBRT) and intratumoral injection of the oncolytic virus ADV/HSV-tk (adenovirus-mediated expression of herpes simplex virus thymidine kinase) to a monoclonal antibody targeting programmed cell death-1 (PD-1) would improve the ICI's efficacy in the treatment of mNSCLC. **Methods:** In this single-arm, open-label phase II study, patients with mNSCLC (squamous or non-squamous) who were ICI-naive or who were previously treated with a maximum of one line of therapy that included an ICI received an intratumoral injection of ADV/HSV-tk (5 x 10^{11} vp) followed by SBRT (30 Gy in 5 fractions) to the same tumor. An anti-PD-1 agent (pembrolizumab 200 mg IV every 3 weeks or nivolumab 240 mg IV every 2 weeks) was then given for up to 24 months (pembrolizumab) or 12 months (nivolumab), or until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR) as defined by the Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1. A secondary endpoint was clinical benefit rate (CBR). **Results:** A total of 35 patients were enrolled, with 28 (80%) receiving pembrolizumab and 7 (20%) receiving nivolumab; 14 (40%) had previous ICI therapy while 21 (60%) were ICI-naive. The ORR and CBR were 28.5% and 61.9% in the ICI-naive group, and 14.2% and 64.2% in the group that previously received an ICI, respectively. Grade 3 or higher toxicity was seen in five patients (26.3%) in the ICI-naive group and in one patient (7.1%) in the previously ICI-treated group. No treatment-related deaths were observed. **Conclusions:** The addition of SBRT and intratumor injection of ADV/HSV-tk to anti-PD-1 therapy in mNSCLC resulted in a CBR of over 60% for both ICI-naive and previously ICI-treated patients without the use of chemotherapy. The combination was able to reinstitute sensitivity to ICIs in patients previously treated with an ICI, and also benefited some patients whose tumors did not express PD-L1. These findings should be further explored in a larger study population. Clinical trial information: NCT03004183. Research Sponsor: Merck.

Genomic landscape of non-small cell lung cancer (NSCLC) with methylthioadenosine phosphorylase (*MTAP*) deletion. *First Author: Stephen L. Graziano, Regional Oncology Center, Syracuse, NY*

Background: NSCLC remains a major cause of cancer-associated mortality despite major advancements in treatments. In addition to immune checkpoint inhibitors (ICPI), new strategies for clinically advanced NSCLC now include the development of new synthetic lethality targets focused on protein arginine methyl transferases such as PRMT5 that exploit the impact of tumor cell genomic loss of *MTAP*. **Methods:** 29,379 advanced/metastatic NSCLC cases underwent hybrid-capture based comprehensive genomic profiling to evaluate all classes of genomic alterations (GA). Tumor mutational burden (TMB) was determined on up to 1.1 Mb of sequenced DNA and microsatellite instability (MSI) was determined on up to 114 loci. PD-L1 tumor cell expression was determined by DAKO 22C3 immunohistochemistry (IHC); low positive was a tumor proportion score (TPS) 1-49% and high positive was a TPS ≥50%. **Results:** 3,928 NSCLC exhibited *MTAP* homozygous loss. Cases had the following subtypes: adenocarcinoma (59%), squamous cell ca (22%), NSCLC NOS (16%), and large cell neuroendocrine, sarcomatoid, adenosquamous ca (all 1%). GA/tumor were similar when *CDKN2A/B* losses associated with 9p21 co-deletion with *MTAP* loss are excluded. Significant differences in currently targetable GA included *KRAS* G12C higher in *MTAP*-intact NSCLC (P = .0003) and *EGFR* short variant mutations higher in *MTAP*-deleted NSCLC (P < .0001). *MTAP*-intact NSCLC had higher frequencies of GAs in *TP53* (P < .0001) and *RB1* and a lower frequency of *SMARCA4* (P < .0001). GAs frequencies in *ERBB2, MET, ALK, ROS1* and *NTRK1* were similar. Biomarkers for potential ICPI efficacy were higher in *MTAP*-intact including TMB ≥10mut/Mb (P = .0002) and low and high PD-L1 IHC staining (P = .01). Biomarkers potentially predictive of ICPI resistance (*STK11* and *KEAP1*) were similar in both groups. **Conclusions:** *MTAP* loss occurs in 13% of NSCLC, supporting the development of novel targeted therapies designed to exploit PRMT5 hyper-dependence in these tumors. *MTAP* loss in NSCLC is accompanied by differences in targeted and ICPI options for these patients which may impact future combination strategies. Further study of anti-PRMT5 drugs that are enabled by *MTAP* loss in NSCLC appears warranted. Research Sponsor: Foundation Medicine Inc.

Superior overall survival (OS), progression-free survival (PFS), and clinical response (CR) predictions for patients with non-small cell lung cancer (NSCLC) using Cellworks Singula: myCare-022-05. *First Author: Vamsidhar Velcheti, Cleveland Clinic Foundation, Cleveland, OH*

Background: The Cellworks Singula Therapeutic Response Index (TRI) has been developed to assist clinicians and NSCLC patients in choosing between competing therapeutic options. In contrast to approaches that consider single aberrations, which often yield limited benefit, Cellworks utilizes an individual patient's next generation sequencing results and a mechanistic multi-omics biology model, the Cellworks Omics Biology Model (CBM), to biosimulate downstream molecular effects of cell signaling, drugs, and radiation on patient-specific *in silico* diseased cells. For any individual patient and alternative therapy, Cellworks integrates this biologically modeled multi-omics information into a continuous Singula TRI Score, scaled from 0 (low therapeutic benefit) to 100 (high therapeutic benefit). We demonstrate that Singula is strongly associated with overall survival, progression-free survival and relative therapeutic benefit beyond standard clinical factors, including patient age, gender, and physician prescribed treatments (PPT). **Methods:** In this study, Singula's ability to predict response was evaluated in a retrospective cohort of 446 NSCLC patients with OS, PFS, and CR data from The Cancer Genome Atlas (TCGA) project, treated with PPT. As a primary analysis of the CBM and TRI Score, Cox Proportional Hazards (PH) regression and likelihood ratio (LR) tests were used to assess the hypothesis that Singula is predictive of OS, PFS, and CR above and beyond standard clinical factors. A p-value < 0.05 for the corresponding likelihood ratio statistic was required to be considered significant. **Results:** Multivariate analyses were performed to assess the performance of the Singula Therapy Response Index above and beyond physician's choice of treatment. The same Singula TRI algorithm and clinical cutoffs were used for all clinical outcome measures. For OS the median survival times for the high and low benefit groups were 60.16 and 28.57 months respectively, based on the median Singula value. Also, the hazard ratio per 25 Singula units for OS was 0.5103 (95% CI: 0.3337 - 0.7804) and the odds ratio for CR was 1.6161. These and further analyses, shown in Table, suggest that Singula TRI provides predictive value of OS, PFS, and CR above and beyond standard clinical factors. **Conclusions:** The Singula TRI Score provides a continuous measure for alternative NSCLC therapeutic options. In this retrospective cohort, Singula was strongly predictive of OS, PFS, and CR and provided predictive value of OS beyond PPT, patient age and gender. These results will be further validated in prospective clinical studies. Research Sponsor: None.

Use of brain radiotherapy as part of first course of treatment for NSCLC with de novo brain metastasis. *First Author: Rafael Arteta-Bulos, Cleveland Clinic Florida, Weston, FL*

Background: Loco-regional management of brain metastases from non-small cell lung cancer (NSCLC) are surgery and/or brain radiotherapy, either whole brain (WBRT) or stereotactic (SRS). We used a national registry to evaluate trends in the use of brain radiotherapy as part of the first course of management in patients diagnosed with de novo brain metastasis. **Methods:** We retrospectively analyzed the National Cancer Database (NCDB) to identify patients with NSCLC and de novo brain metastasis diagnosed from 2004-2016. We described the socio-demographic and clinical characteristics of this population, then used chi-squared testing to evaluate for an association between these variables and the use of brain radiotherapy (either SRS or WBRT). Significant variables ($p < 0.05$) were included in a multiple logistic regression model. **Results:** Of n = 41,454 patients with NSCLC and de novo brain metastasis, n = 27,949 (67.4%) received either SRS or WBRT as part of their first course of treatment, while n = 13,505 (32.6%) did not receive primary brain radiation. Of those that did not receive radiation: n = 9,927 (73.5%) were < 70 years old while n = 3,578 (26.5%) were ≥70. N = 11,081 (82.7%) were White, n = 1,550 (11.6%) were Black and n = 768 (5.7%) were Asian. Variables significantly associated with the use of primary brain radiotherapy at the multivariate level were: treatment facility type (p = 0.004), tumor histology (p < 0.001), clinical T-staging (p < 0.001), and clinical N-staging (p < 0.001). Age, sex, race, comorbidity, grade, insurance status, and setting (metro vs. rural vs. urban) were not significantly associated with the use of radiotherapy. Compared to patients treated at community cancer programs (CPs), those treated at comprehensive community CPs (OR 1.152, 95% CI 1.027-1.291, p = 0.015) and academic CPs (OR 1.242, 95% CI 1.104-1.398, p < 0.001) were more likely to receive primary brain radiotherapy. Patients with squamous NSCLC were less likely (OR 0.680, 95% CI 0.619-0.747, p < 0.001) to receive brain radiotherapy compared to those with adenocarcinoma. Finally, patients with advanced T-staging (p < 0.001) and N-staging (p < 0.001) were less likely (OR < 1) to receive brain radiotherapy as part of the first course of treatment. **Conclusions:** While insurance status and setting were not significantly associated with the use of brain radiotherapy, facility type was. Further research is needed to evaluate whether this is a true disparity in medical practice, or the differences can be explained by characteristics of the patient population undocumented by the NCDB (e.g. severity of brain metastasis). Additionally, patients with larger primary tumors were less likely to receive brain radiation as part of the first course of treatment, which may reflect the need for local therapy prior to treating metastatic sites. Research Sponsor: None.

Clinicopathologic, genomic, and tumor microenvironment correlates of aneuploidy and immunotherapy outcomes in NSCLC. *First Author: Joao Victor Machado Alessi, Dana-Farber Cancer Institute, Boston, MA*

Background: Cancer aneuploidy, an unbalanced number of chromosomes, is associated with somatic mutation rate, expression of proliferative genes, and altered immune signaling. Whether aneuploidy correlates to a distinct immunophenotype or impacts clinical outcomes to immune checkpoint inhibitors (ICIs) in NSCLC is unclear. **Methods:** In NSCLCs which underwent targeted next-generation sequencing, we retrospectively analyzed the aneuploidy score (AS), defined as the sum of the number of altered chromosome arms. An unbiased recursive partitioning (URP) algorithm was used to investigate an AS cutoff to discriminate responders from non-responders to ICIs. Multiplexed immunofluorescence to quantify CD8+, Foxp3+, PD-1+, and PD-L1 expression was performed to determine differences in tumor immune cells subsets according to AS cutoff. **Results:** Among 436 NSCLCs identified, stage I tumors (median AS 1) had significantly lower median AS (mAS) than stage IV cancers (mAS 7, P < 0.001), stage III (mAS 4, P = 0.03), and numerically lower compared to stage II cancers (mAS 3, P = 0.18). We found no difference in the mAS across tumors with a PD-L1 tumor proportion score of ≥50%, 1-49%, or < 1% (mAS 5 vs 7 vs 6, respectively, P = 0.26), nor was there any correlation between aneuploidy and TMB when taken as continuous variables (Spearman R: 0.074, P = 0.12). A total of 279 advanced NSCLCs with available aneuploidy scores were treated with ICIs. An URP analysis identified an AS of 2 as the strongest discriminator of objective response to ICI. Compared to pts with an AS > 2 (N = 207, 74.2%), pts with AS ≤2 (N = 72, 25.8%) had a significantly higher objective response rate (ORR 43.0% vs 19.8%, P < 0.001), a significantly longer median progression-free survival (mPFS 6.2 vs 2.9 months, HR: 0.70 [95% CI: 0.52-0.94], P = 0.02), and a significantly longer median overall survival (mOS 19.8 vs 13.8 months, HR: 0.66 [95% CI: 0.47-0.94], P = 0.02) to treatment with ICIs. After adjusting for other variables such as performance status, presence of oncogenic driver mutation, PD-L1, TMB, and line of treatment, AS was significantly associated with improved mPFS (HR: 0.72 [95% CI: 0.52-0.99], P = 0.04) and mOS (HR: 0.64 [95% CI: 0.44-0.94], P = 0.02). By contrast, among pts who received first-line platinum doublet chemotherapy without ICI, an AS ≤2 (N = 29), when compared to an AS > 2 (N = 56), did not correlate with improved ORR (55.2% vs 44.6%, P = 0.4) or PFS (5.3 vs 4.8 months, HR 0.83 [95% CI: 0.5-1.3], P = 0.43). Among 179 NSCLCs profiled by multiplex immunofluorescence, compared to cancers with an AS > 2, those with low aneuploidy had significantly higher numbers of CD8+, Foxp3+, PD-1+ immune cells, and PD-1+ CD8+ T cell, both intratumorally and when looking at the total numbers of cells within the tumor and at the tumor-stroma interface. **Conclusions:** NSCLCs with low aneuploidy have a distinct immune microenvironment and more favorable outcomes to ICIs. Research Sponsor: None.

Population-based impacts of new therapies on outcomes for stage IV non-small cell lung cancer. *First Author: Rebekah Rittberg, CancerCare Manitoba, Winnipeg, MB, Canada*

Background: Over 15 years, diagnostic and therapeutic algorithms for Stage IV non-small cell lung cancer (NSCLC) have dramatically progressed. While clinical trials demonstrate overall survival (OS) advantages, population level impact remains uncertain. Here we evaluate real world, population-based outcomes for Stage IV NSCLC to assess impact of changing therapies on referral, treatment patterns and OS, which may help explain ongoing stigma/nihilism. **Methods**: A retrospective cohort analysis was completed to evaluate *de novo* Stage IV NSCLC diagnosed in Manitoba from 2006 to 2015. We evaluated treatment received (not seen by specialist, saw a specialist but did not receive therapy, radiation therapy (RT) only, and systemic therapy (mutation unknown and known)) and treatment era of diagnosis (2006-2009, 2010-2013 and 2014-2015). Multivariable logistic regression assessed systemic therapy predictors. Kaplan-Meier curve and Cox proportional hazard models evaluated OS. **Results**: 3,601 patients were diagnosed with Stage IV NSCLC, 53% male. Only 21% received systemic therapy, mean age of 62. Within the cohort, 973 (27%) patients did not see a specialist, 610 (17%) saw a specialist but did not receive therapy, 1248 (35%) only received RT, and 771 (21%) received systemic therapy (17% mutation status unknown and 4% known). Younger patients and those with confirmed histology were more likely to see a specialist and receive treatment, each ($p < 0.001$). Patients who received systemic therapy had lower comorbidity and higher income quintile, each ($p < 0.001$). Median OS did not differ between treatment era with median OS of 3.0, 2.9 and 2.8 months for 2006-2009, 2010-2013 and 2014-2015 respectively, $p = 0.082$. When survival analysis was restricted to patients who received systemic therapy, median OS improved by era to 10.9, 11.2 and 15.6 months respectively, $p = 0.001$. Variables found to be independently associated with survival included treatment type, age, sex and comorbidity. **Conclusions**: Improved systemic therapy and molecular testing has improved OS for patients who receive systemic therapy. However, due to the large proportion of Stage IV NSCLC patients who never receive systemic therapy we do not see improved survival at a population level between treatment eras. Research Sponsor: CancerCare Manitoba Foundation.

Clinicopathologic and genomic correlates of tumor-infiltrating immune cells and immunotherapy efficacy in NSCLC. *First Author: Joao Victor Machado Alessi, Dana-Farber Cancer Institute, Boston, MA*

Background: Tumor-infiltrating immune cells and PD-L1 expression are associated with improved clinical outcomes in patients (pts) with NSCLC treated with immune checkpoint inhibitors (ICIs). However, as tumor-infiltrating immune cells are not a well-established biomarker for NSCLC, further data are needed to integrate and identify clinicopathological and genomic factors that influence the tumor microenvironment. **Methods:** We collected clinicopathologic and genomic data from pts with NSCLC who underwent multiplexed immunofluorescence. Uniform Manifold Approximation and Projection (UMAP) was used to identify distinct immunophenotypic clusters according to the number of intratumoral PD-1+ immune cells (ICs), CD8+, and Foxp3+ T cells, as well as PD-L1 on tumor and immune cells. An unbiased recursive partitioning (URP) algorithm was used to investigate an optimal cluster with respect to objective response rate (ORR) in the subset of pts treated with ICIs. **Results:** Among 304 pts, UMAP identified 5 clusters: PD-L1-high with high vs low CD8+ and PD-1+ ICs (clusters A & B, respectively); PD-L1-low with high vs low CD8+ and PD-1+ ICs (clusters C & D respectively); PD-L1-low and moderate levels of CD8+ and PD-1+ ICs (cluster E). Clinicopathological characteristics of the clusters shown in Table. URP analysis identified immune rich clusters A and C as optimal responders to ICIs. From the start of ICIs, we observed a significantly higher ORR (53.3% vs 4.3%; $P<0.001$), a significantly longer median progression-free survival (mPFS 25.6 vs 3.7 months; HR: 0.12 [95% CI: 0.05-0.32]; $P<0.001$), and longer median overall survival (mOS 45.1 vs 22.3 months; HR: 0.25 [95% CI: 0.1-0.68]; $P=0.006$) in clusters A + C (N=15) vs other clusters (N=23). After adjusting for other variables such as performance status, histology, presence of oncogenic driver mutation, and line of treatment, clusters A + C were significantly associated with improved mPFS (HR: 0.08 [95% CI: 0.03-0.24], $P<0.001$) and mOS (HR: 0.11 [95% CI: 0.03-0.40], $P<0.001$). **Conclusions:** Incorporation of multiplex immunofluorescence may improve prediction of response and resistance to immunotherapy in NSCLC. Research Sponsor: None.

Patterns of survival in NSCLC with de novo brain metastasis: SRS, WBRT, and no radiotherapy cohorts. *First Author: Diana Saravia, Cleveland Clinic Florida, Weston, FL*

Background: Prognostic determinants in metastatic non-small cell lung cancer (mNSCLC) include numerous sociodemographic and clinical characteristics. We provide granular, real-world survival data in different cohorts of this heterogeneous population, stratifying by: age, Charlson/Deyo scoring (CDS) of comorbidity, tumor histology, and use of immunotherapy. **Methods**: This retrospective analysis uses the National Cancer Database (NCDB) to explore patterns of survival in patients diagnosed between 2010-2016 with mNSCLC involving the brain. Kaplan-Meier (KM) modeling was used to evaluate for differences in overall survival (OS) between 3 cohorts of patients: those undergoing 1) stereotactic radiosurgery (SRS), 2) whole-brain radiotherapy (WBRT), and 3) those not undergoing brain radiotherapy (NR) as part of the first course of treatment. As per Table, we ran 8 KM models to generate median OS (mOS) data across stratifications for age (<70 vs. ≥ 70), CDS (0-1 vs. 2-3), tumor histology (adenocarcinoma vs. squamous), and use of immunotherapy (yes vs. no). We provide a ranked order of these 3 cohorts by mOS ('survival sequence', or 'SS'), as well as differences in mOS ('ΔmOS') between NR and WBRT – the two cohorts most comparable in life expectancy. **Results:** A total of n=38,119 patients were included in this study. Most received WBRT (n=18,052, 47.4%), n=6,562 (17.2%) received SRS, while n=13,505 (35.4%) did not receive brain radiation as part of their first course of treatment. In all subgroups, patients treated with SRS for brain metastasis had the highest mOS. Survival for those receiving WBRT was better or comparable (difference in mOS <0.5 months) to those that did not receive radiotherapy, except in patients aged ≥ 70 (SS: NR > WBRT; KM p-value <0.05; ΔmOS of 1.6 months), those with Charlson-Deyo comorbidity scores of 2-3 (SS: NR > WBRT; KM p-value <0.05; ΔmOS: 0.6 months), those with squamous carcinoma (SS: NR > WBRT; KM p-value <0.05; ΔmOS: 0.7 months), and those already receiving immunotherapy (SS: NR > WBRT; KM p-value <0.05; ΔmOS: 0.6 months). **Conclusions:** SRS for de novo brain metastases is associated with improved OS in mNSCLC. In contrast, the burden of WBRT may outweigh the survival benefit it affords in patients ≥ 70, and those with comorbidities. Squamous cell carcinomas may be associated with more radio-resistance than adenocarcinomas to WBRT. Finally, as previously described in melanoma, the survival benefit afforded by brain radiotherapy may be lower in patients on immunotherapy. Research Sponsor: None.

Stratifications	Kaplan Meier Models	NR mOS	SRS mOS	WBRT mOS	SS	ΔmOS (WBRT-NR)
Age	1) <70	8.9	14.5	9.2	SRS > WBRT > NR	0.3
	2) ≥ 70	7.7	11.7	6.1	SRS > NR > WBRT	-1.6
CDS	3) 0-1	8.8	13.8	8.7	SRS > NR = WBRT	-0.1
	4) 2-3	7.1	10.6	6.5	SRS > NR > WBRT	-0.6
Histology	5) Adenocarcinoma	9.9	15.5	9.5	SRS > NR > WBRT	-0.4
	6) Squamous	6.9	9.3	6.2	SRS > NR > WBRT	-0.7
Immunotherapy	7) None	8.5	13.3	8.4	SRS > NR = WBRT	-0.1
	8) Received	11.5	15.7	10.9	SRS > NR > WBRT	-0.6

Analysis of patterns of care and benefit of thoracic radiotherapy for patients with stage IV NSCLC in the immunotherapy-era from a national hospital-based registry. *First Author: Michael Kharouta, University Hospitals, Case Medical Center - Seidman Cancer Center, Cleveland, OH*

Background: Metastatic non-small cell lung cancer (mNSCLC) has classically been treated with platinum-doublet chemotherapy. Recent studies have established immunotherapy as an integral part of therapy for mNSCLC without targetable mutations. There are limited data on the role of consolidative thoracic radiotherapy (TRT) for patients with mNSCLC in the immunotherapy-era. A secondary analysis of KEYNOTE-001 showed significant improvement in overall survival in patients who received radiotherapy with pembrolizumab compared to patients not previously receiving radiotherapy. **Methods:** We queried the National Cancer Database (NCDB) for patients with metastatic presentation, stage IVA/IVB non-small cell lung cancer between the ages of 18-90 years treated between 2012-2017 with a combination of chemotherapy, immunotherapy, and thoracic radiotherapy. Patients with unknown treatment status, follow up time, or vital status were excluded. Overall survival (OS) was estimated using the Kaplan-Meier method and compared between treatment groups utilizing log-rank testing. A 3:1 nearest-neighbor propensity-score matching was performed utilizing clinical and demographic covariates to reduce the impact of potential confounders of overall survival on the probability of receipt of TRT. Cox proportional hazards regression was used to identify predictors of overall survival. **Results:** A total of 81,382 patients were identified that met inclusion criteria. The median age was 68 (18-90) years. The majority of patients (n = 51,681, 64%) had chemotherapy, while 7,929 (10%) patients received immunotherapy, and 15,984 (20%) received TRT. The median follow-up was 6.18 (range 0-76.9) months. For the entire cohort of patients receiving immunotherapy, 2 year OS was 29.4% with TRT compared to 32.7% without. Following propensity matching by age, sex, race, and comorbidity score, a total number of 4,264 patients receiving immunotherapy were matched. The 2 year OS was 27.7% in patients receiving TRT and immunotherapy vs. 22.2% in patients with immunotherapy alone ($p = 0.004$). On multivariable analysis receipt of TRT was a significant predictor of OS after adjustment for age, race, comorbidity score, sex, and median income ($p = 0.0003$, HR 0.87, 95% CI 0.80 - 0.94). For patients receiving BED10 $>$ 39 Gy (equivalent to 30 Gy in 10 fractions), 2 year OS was significantly improved at 37.0% vs 18.1% ($p < 0.0001$). **Conclusions:** In patients with mNSCLC, the addition of TRT to immunotherapy is associated with improved overall survival at 2 years. Receipt of a higher BED10 is associated with further improved survival. Selection of mNSCLC patients receiving immunotherapy for TRT approaching definitive doses warrants further investigation. Data from prospective, randomized trials may better elucidate this benefit and identify a potential mechanism. Research Sponsor: None.

Effect of continuing osimertinib with chemotherapy in the post-progression setting on progression-free survival among patients with metastatic epidermal growth factor receptor (EGFR) positive non-small cell lung cancer. *First Author: Tejas Patil, University of Colorado Cancer Center, Aurora, CO*

Background: Continuing a 1st generation EGFR TKI with chemotherapy upon TKI progression was not shown to be beneficial in the IMPRESS trial. However, the validity of this approach with osimertinib remains under explored. We attempted to characterize the efficacy of continuing osimertinib with chemotherapy in the post-progression setting. **Methods:** A single-center retrospective review of patients with metastatic EGFR mutant NSCLC who had progressed on osimertinib was performed. Clinical characteristics and treatment outcomes were noted. Progression free survival (PFS), duration of treatment (DOT), overall survival (OS) and rates of intracranial progression were captured. ANOVA or a Fisher exact test were used to identify associations between cohort characteristics and treatment outcomes. Differences in PFS, DOT and OS were assessed using a log-rank test. A Cox proportional hazard model was used to adjust for potential confounders. **Results:** 73 patients with EGFR mutant NSCLC with post-osimertinib treatment outcomes were identified. Cohort characteristics are summarized in Table. Median duration of follow up was 41 months. Upon progression, osimertinib was discontinued in 34 patients (Cohort A) and continued with next line of therapy in 39 patients (Cohort B). Survival analyses were adjusted for prior lines of therapy, use of platinum doublet chemotherapy, and use of immune checkpoint inhibitors in the post-progression setting. After adjusting for covariates, continuing osimertinib post-progression was associated with an improved PFS (7 vs 4 months; HR 0.58; 95% CI 0.34 – 1.00; p = 0.003) and DOT (7 vs 4 months; HR 0.52; 95% CI 0.31 – 0.87; p = 0.006). There was no difference in OS between Group A and B (52 vs 41 months; HR 0.73; 95% CI 0.43 – 1.24; p = 0.234). Rates of intracranial progression were similar between Group A and B (28% vs 23%; p = 0.649). **Conclusions:** After adjusting for covariates, continuing osimertinib with chemotherapy in the post-progression setting was associated with a significant difference in PFS and DOT, but with no differences in OS. Continuing osimertinib does not appear to influence the rate of subsequent intracranial progression. Prospective studies are needed to identify the optimal practice pattern. Research Sponsor: International Association for the Study of Lung Cancer (IASLC).

Lung cancer in HIV versus non-HIV population: Nationwide analysis of mortality, morbidity, demographics, and healthcare utilization. *First Author: Muhammad Junaid Tariq, Department of Internal Medicine, John H. Stroger Jr. Hospital of Cook County, Chicago, IL*

Background: Lung cancer (LC) is the most common non-AIDS defining cancer with a high cancer-related mortality in patients with HIV. With improving survival in HIV patients, the incidence of LC is increasing. We attempted to evaluate the characteristics and outcomes, including healthcare utilization in patients with HIV-LC compared to non-HIV-LC using a national sample. **Methods:** Healthcare Cost and Utilization Project National Inpatient Sample (HCUP-NIS) was queried to identify HIV and non-HIV-LC admissions between 2016-2018. We studied socio-demographic differences, medical comorbidities (including hypertension (HTN), diabetes (DM), Coronary artery disease (CAD), Chronic kidney disease (CKD), Heart failure (HF), dialysis (HD), COPD), all-cause mortality, mean length of stay (LOS), mean total hospital charges (THC). Secondary outcomes included sepsis, septic shock, acute kidney injury (AKI), influenza, pneumonia, respiratory failure, lung collapse, ICU care, hemoptysis, anemia, pain, and protein energy malnutrition (PEM). Statistics were performed using the t-test, univariate and multinomial logistic regression. **Results:** A total 4,105 HIV-LC and 1,204,365 non-HIV-LC admissions were identified. HIV-LC were younger (mean age 48.7 vs 53.4 $p<0.05$), male (67% vs 51%, $p<0.01$), African American (52% vs 12% $p<0.01$), on Medicaid (35% vs 10% $p<0.01$), from lowest quartile income zip codes (51% vs 30% $p<0.01$). HIV-LC had significantly high rates of CKD and HD ($p<0.05$) while non-HIV-LC had significantly higher rates of HTN, DM, Dyslipidemia, CAD, COPD, obesity, HF and smoking (all $p<0.05$). Odds of adjusted all-cause mortality were significantly lower in HIV-LC (aOR 0.47 CI 0.36-0.63 $p<0.001$). HIV-LC had higher LOS (8.1 vs 6 days $p<0.001$) and higher THC ($83,328 vs $65,642 $p<0.001$), amounting to over $72 million over 3 years. Significantly different secondary outcomes between the two groups are shown in Table, the rest were similar between the groups. **Conclusions:** HIV-LC patients were younger, minority with a significantly lower all-cause mortality despite higher rates of complications and significantly higher LOS and THC compared to non-HIV-LC cohort. A higher comorbidity burden may be responsible for higher mortality in the non-HIV group while higher rates of secondary complications, CKD, HD may be driving up healthcare utilization in HIV-LC. More studies are needed to clarify these findings. Research Sponsor: None.

TPS9126 **Poster Session**

Blood-based biomarker analysis in high PD-L1 expressing NSCLC treated with PD-1/PD-L1 based therapy with or without the addition of platinum-based chemotherapy. *First Author: Mary J. Fidler, Rush University Medical Center, Chicago, IL*

Background: Immunotherapy directed against the programmed death-1 / ligand-1 (PD-1/L1) axis has revolutionized the treatment of advanced non-small cell lung cancer (aNSCLC). Tumor PD-L1 is currently the only biomarker validated for predicting patient response to front line PD-1/L1 directed immunotherapy, yet 20% of patients with ≥50% PD-L1 expression die within six months of starting therapy (Reck et al. 2016). Blood-based agents such as autoantibodies and circulating inflammatory biomarkers have stratified patient outcomes on anti-PD-1/L1 immunotherapy in preliminary studies (Tarhoni, Kollipara et al. 2019; Tarhoni, Fidler et al. 2019). Moreover, a serum-based proteomic test that uses mass spectrometry and machine learning to provide three classifications (Good, Intermediate and Poor) has stratified non-treatment naïve aNSLCC patients treated with nivolumab based on their outcomes (Mueller et al. 2020) and identified a subset of patients who progressed rapidly. This study will evaluate these blood-based biomarkers as predictors of response and early progression in patients with >50% PD-L1 positive aNSCLC treated with immunotherapy regimens. **Methods:** This is a prospective, observational, multicenter study (NCT04676386) designed to assess biomarkers (serum and plasma) as predictive of early progression in 390 patients with aNSCLC treated with anti-PD 1/PD-L1 immunotherapy with or without platinum-based chemotherapy. Key eligibility criteria are treatment naïve aNSCLC with tumor biopsy PD-L1 tumor proportion score > 50%, Eastern Cooperative Oncology Group performance status (ECOG PS) 0-2, and ability to consent to participate. Prior to enrollment, tumor specimens will be tested for PD-L1 expression according to participating centers' standard operating procedures. For each treatment cohort of 195 patients, enrollment will proceed in sub-cohorts to ensure a population with 20% patients with ECOG PS2 and a total of 40 patients with squamous cell carcinoma per treatment arm. Patients will be followed for a maximum of 3 years. Blood draw for biomarker assessment will be performed prior to treatment initiation, start of 3rd cycle and investigator assessed progression. Biomarker analysis will be performed retrospectively. As a secondary objective, this study will evaluate proteomic test performance in predicting early overall survival (OS) and rapid progression, and in stratifying patient survival and response. Exploratory analyses will correlate baseline and serial circulating protein analytes and autoantibodies with the proteomic test, response measures (RECIST 1.1) and toxicities. Enrollment opened in February 2021. Clinical trial information: NCT04676386. Research Sponsor: Biodesix, Inc.

TPS9127 **Poster Session**

A randomized, phase 3 study of datopotamab deruxtecan (Dato-DXd; DS-1062) versus docetaxel in previously treated advanced or metastatic non-small cell lung cancer (NSCLC) without actionable genomic alterations (TROPION-Lung01). *First Author: Kiyotaka Yoh, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa-Shi, Chiba, Japan*

Background: Treatment options are limited for patients with advanced/metastatic NSCLC without driver genomic alterations after failure of a platinum-based chemotherapy and immunotherapy; median survival is < 1 year. Datopotamab deruxtecan (Dato-DXd; DS-1062) is an antibody-drug conjugate consisting of a humanized anti-TROP2 IgG1 monoclonal antibody attached to a topoisomerase I inhibitor payload via a tetrapeptide-based cleavable linker. Results from the ongoing phase 1 study (TROPION-PanTumor01; Spira, WCLC 2020) demonstrated an overall response rate (ORR) of 21%, a disease control rate (DCR) of 67%, and a preliminary median progression-free survival (PFS) of 8.2 months (all by blinded independent central review [BICR]), with a manageable safety profile, in patients with NSCLC who were treated with 6 mg/kg of Dato-DXd. This phase 3 study (NCT04656652) will compare the efficacy of Dato-DXd with that of docetaxel as 2/3L therapy in patients with advanced/metastatic NSCLC. **Methods:** TROPION-Lung01 is an open-label, phase 3, randomized study of Dato-DXd vs docetaxel in patients with advanced/metastatic NSCLC without *EGFR*, *ALK*, or other actionable genomic alterations. Patients must have been previously treated with platinum-based chemotherapy and a PD-(L)1 monoclonal antibody in combination or sequentially and have radiographic disease progression on or after the most recent therapy. Those with asymptomatic and stable/treated brain metastases are eligible. A tumor specimen is required for biomarker analyses. Patients (N = 590) are randomized 1:1 to either Dato-DXd 6 mg/kg or docetaxel 75 mg/m^2 given intravenously on day 1 of each 3-week cycle. Randomization is stratified by histology (squamous vs nonsquamous), immunotherapy in last regimen (yes vs no), and region (US/Japan/Western Europe vs rest of world). Treatment continues until disease progression or intolerance or other discontinuation criteria are met. The study will be conducted globally at approximately 184 study sites. Dual primary endpoints are PFS by BICR and overall survival. Secondary outcome measures include PFS by investigator, ORR, duration of response, DCR, and time to response (all assessed by BICR and by investigator per RECIST version1.1), patient-reported outcomes, safety, pharmacokinetics, and proportion of patients who develop antidrug antibodies. Biomarkers will be evaluated for potential associations with efficacy. Clinical trial information: NCT04656652. Research Sponsor: Daiichi Sankyo, Inc.

TPS9128 **Poster Session**

AdvanTIG-302: Anti-TIGIT monoclonal antibody (mAb) ociperlimab (OCI) plus tislelizumab (TIS) versus pembrolizumab (PEM) in programmed death ligand-1 (PD-L1) selected, previously untreated, locally advanced, unresectable or metastatic non-small cell lung cancer (NSCLC). *First Author: Mark A. Socinski, Advent Health Hematology and Oncology, Orlando, FL*

Background: Monotherapy with programmed death 1 (PD-1)/PD-L1 antibodies has improved clinical outcomes for patients (pts) with non-oncogenic driven NSCLC but clinical responses are limited by primary and secondary resistance, and improvements in durability of response are required. T-cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibition motif domain (TIGIT) is a co-inhibitory, immune checkpoint receptor upregulated on T-cells and natural killer cells in multiple solid tumors, which can inhibit anticancer immune responses. OCI (BGB-A1217) is a novel, humanized mAb that binds to TIGIT with high affinity and specificity, which has demonstrated competent binding with C1q and all Fcγ receptors while inducing antibody-dependent cellular cytotoxicity. Preclinical and clinical studies suggest that dual targeting with anti-TIGIT and anti-PD-1 antibodies produces synergistic immune cell activation and enhanced antitumor activity. **Methods:** AdvanTIG-302 is a Phase 3, multicenter, international, randomized, double-blind study (NCT04746924) investigating OCI in combination with TIS compared with PEM in adult pts ($\geq$ 18 years of age) with PD-L1 selected, previously untreated, locally advanced, unresectable or metastatic NSCLC without oncogenic *EGFR* or *ALK* mutation. Approximately 605 pts will be randomized 5:5:1 to receive: OCI 900 mg intravenously (IV) plus TIS 200 mg IV every three weeks (Q3W; Arm A), PEM 200 mg IV plus placebo IV Q3W (Arm B) or TIS 200 mg IV plus placebo IV Q3W (Arm C). Pts will be treated until disease progression, loss of clinical benefit, intolerable toxicity or withdrawal of consent. Stratification factors include histology (squamous vs non-squamous) and region (Asian vs non-Asian). Crossover is not permitted. Key eligibility criteria include histologically confirmed disease, PD-L1 expression $\geq$ 50%, no known *EGFR* or *ALK* mutations and no prior checkpoint inhibitor therapy. Dual primary endpoints are investigator-assessed progression-free survival (PFS; RECIST v1.1) and overall survival (Arms A and B) in the Intention-to-Treat population. Secondary endpoints include PFS (assessed by Blinded Independent Review Committee), investigator-assessed overall response rate and duration of response, safety and tolerability, and patient-reported health-related quality of life (EORTC-QLQ-C30, QLQ-LC13 and EQ-5D-5L; Arms A and B). Exploratory endpoints include disease control rate, clinical benefit rate and time to response. This study will also evaluate the association between biomarkers and response or resistance. Study enrollment has begun and recruitment is ongoing. Clinical trial information: NCT04746924. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Jessica Jones, PhD, of Ashfield Medcomms, an Ashfield Health company, and funded by BeiGene, Ltd.

KRYSTAL-12: A randomized phase 3 study of adagrasib (MRTX849) versus docetaxel in patients (pts) with previously treated non-small-cell lung cancer (NSCLC) with KRAS^{G12C} mutation. *First Author: Tony S. K. Mok, State Key Laboratory of Translational Oncology, Chinese University of Hong Kong, Hong Kong, China*

Background: Despite significant advances in chemotherapy and immunotherapy for advanced NSCLC, the majority of pts ultimately develop progressive disease associated with poor outcomes. KRAS is a key mediator of the RAS/MAPK signaling cascade that promotes cell growth and proliferation. KRAS^{G12C} mutations occur in 14% of NSCLC (adenocarcinoma), and mutations in KRAS are associated with a poor prognosis. Although KRAS has historically been undruggable, recent research into the development of agents that specifically bind mutant KRAS has led to the development of direct inhibitors of KRAS^{G12C}. Adagrasib, an investigational agent, is a potent, covalent inhibitor of KRAS^{G12C} that irreversibly and selectively binds to and locks KRAS^{G12C} in its inactive state. Adagrasib was optimized for favorable pharmacokinetic (PK) properties, including oral bioavailability, long half-life (~24 h), and extensive tissue distribution. Initial results have demonstrated encouraging antitumor activity and tolerability of adagrasib monotherapy in pts with NSCLC harboring a KRAS^{G12C} mutation. **Methods:** KRYSTAL-12 is a multicenter, randomized Phase 3 study evaluating the efficacy of adagrasib (600 mg BID) vs docetaxel in pts with advanced NSCLC harboring a KRAS^{G12C} mutation who have progressed during or after treatment with a platinum-based regimen and an immune checkpoint inhibitor. The study is designed to demonstrate improvement in the dual primary endpoints of progression-free survival (PFS) and overall survival (OS). Secondary endpoints include safety, objective response rate (ORR) per RECIST 1.1, duration of response (DOR), plasma PK parameters of adagrasib, and patient-reported outcomes (PROs). The study will also explore correlations between gene alterations (at baseline and upon development of treatment resistance) and efficacy. Approximately 450 patients will be randomized in a 2:1 ratio to receive adagrasib or docetaxel and will be stratified by region (United States/Canada vs other countries) and sequential vs concurrent administration of prior platinum-based chemotherapy and anti–PD-1/PD-L1 antibody. The planned sample size is sufficiently powered for the hypothesized treatment effect of the endpoints. Pts will receive study treatment until disease progression, unacceptable adverse events, investigator decision to terminate treatment, or patient withdrawal. This study is currently enrolling and will be open at sites in the United States, Europe, and Asia. Clinical trial information: NCT04685135. Research Sponsor: Mirati Therapeutics, Inc.

TPS9130 **Poster Session**

Camrelizumab monotherapy or in combination with apatinib for PD-L1-positive advanced pulmonary sarcomatoid carcinoma: A multicenter, open-label, single-arm, phase II study. *First Author: Mingfang Zhao, Department of the Second Medical Oncology, The First Hospital of China Medical University, Shenyang, China*

Background: Pulmonary sarcomatoid carcinoma (PSC) is a rare subtype of non-small cell lung cancer (NSCLC) with a fairly poor prognosis. As a highly aggressive malignancy, PSC is insensitive to conventional chemotherapy or radiotherapy and no optimal treatment for PSC has been established yet. Immune checkpoint inhibitors (ICIs) were documented to possess encouraging therapeutic efficacy in PSC patients, which is demonstrated to be associated with high expression of programmed death-ligand 1 (PD-L1) in PSC. However, because of the rarity of PSC, most of the existed data were derived from case repots which could not reflect the true clinical efficacy of ICIs for PSC treatment. This clinical trial was designed to investigate the clinical outcomes of camrelizumab in treating PD-1-positive PSC. Apatinib may be used simultaneously based on the expression level of PD-L1 in PSC as the combination of camrelizumab and apatinib exhibited treatment potential in NSCLC in previous researches. **Methods:** In this multicenter, open-label, single-arm, phase II study conducted in 44 sites in China, 30 patients with an age of 18-80 years old, an Eastern Cooperative Oncology Group (ECOG) performance score of 0–2, positive PD-L1 expression, no EGFR, ALK, ROS1, and MET gene mutations, and histologically or cytologically confirmed stage IIIB-IV PSC regardless of prior lines of standard therapy will be enrolled. Patients with PD-L1 expression 1-49% will receive Camre (200 mg, IV, Q3W) and Apa (250mg, QD). Patients with PD-L1 expression$\geq$50% receive Camre (200 mg IV Q3W) alone. The treatment will continue until a maximum treatment duration of 36 months, disease progression, intolerable toxicity, death or consent withdrawal. The primary endpoint is objective response rate (ORR). The secondary endpoints are progression-free survival (PFS), overall survival (OS), disease control rate (DCR), time to objective response (TTR), duration of response (DOR) and safety. This study is ongoing. Clinical trial information: ChiCTR2000032649, China. Research Sponsor: None.

TPS9131 **Poster Session**

A multicenter, randomized, double-blind study of gefitinib in combination with anlotinib or placebo in previously untreated patients with EGFR mutation-positive advanced non-small cell lung cancer (FL-ALTER). *First Author: Li Zhang, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Preclinical and clinical evidence has demonstrated that the dual blockade of the EGFR and VEGF pathways is a viable strategy in the EGFR-mutated advanced NSCLC population. Anlotinib is an oral multi-targeted tyrosine kinase inhibitor (TKI) that effectively inhibits VEGFRs, FGFRs, PDGFRs, c-kit and MET. It has been proved to be safe and effective in advanced lung cancer after second-line standard chemotherapy failure. A cohort study of Anlotinib plus Erlotinib has shown a favorable safety profile and promising antitumor activity with an objective response rate (ORR)92.6%. This phase III study aims to evaluate the efficacy and safety of Anlotinib or placebo plus Gefitinib in patients(pts) with untreated EGFR-mutated metastatic NSCLC. **Methods:** Eligible pts were aged 18~75 years old, had stage IIIB or IV NSCLC, with an EGFR 19del or 21L858R mutation, an ECOG PS of 0 or 1, measurable lesion according to RECIST v1.1 and adequate organ function. We randomly assigned eligible pts in a 1:1 ratio to receive oral Gefitinib (250 mg QD) plus either Anlotinib (12 mg QD from day 1 to 14 of a 21-day cycle) or matching placebo until progressive disease or unacceptable toxicity. Randomization was done by an interactive web response system with a computer-generated sequence and stratified by EGFR mutation status, gender, ECOG PS and pathological type . The primary endpoint is progression-free survival(PFS). Secondary endpoints include overall survival, ORR, disease control rate, time to progression, duration of response, quality of life and the safety profile. The peripheral blood of the pts will be detected three times by polygenic detection to monitor the resistance mechanism (before treatment, during the first evaluation, during tumor progression, each time 10ml peripheral blood). Independent Data Monitoring Committee and Independent Review Committee will be used in this study. According to previous report (Erlotinib plus Bevacizumab vs. Erlotinib alone: 16.0 vs. 9.7 mos, HR 0.54, *Lancet Oncol, 15(11):1236-1244*), the sample size was determined based on a median PFS of 15 months for the Anlotinib + Gefitinib group and median PFS of 10 months for the Placebo + Gefitinib group. To achieve 80% power at a two-sided α = 0.05 and an anticipated dropout rate of 20%, 310 patients (with 192 events required for the analyses) were needed. In total, 310 patients will be enrolled in this trial at 16 sites in China. From April 2019, 224 patients have been enrolled. Clinical trial information: NCT04028778. Research Sponsor: None.

TPS9132 **Poster Session**

CHRYSALIS-2: A phase 1/1b study of lazertinib as monotherapy and in combination with amivantamab in patients with EGFR-mutant NSCLC. *First Author: Catherine A. Shu, Columbia University Medical Center, New York, NY*

Background: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have improved clinical outcomes for patients with EGFR mutant (EGFRm) non-small cell lung cancer (NSCLC); however, patients will inevitably progress due to acquired resistance mutations. Lazertinib is a potent, brain-penetrant, 3rd-generation EGFR TKI with efficacy against activating EGFR and resistance T790M mutations. Amivantamab is an EGFR-MET bispecific antibody with immune cell-directing activity that targets activating EGFR and MET mutations. Synergistic inhibition of the EGFR by targeting the receptor's extracellular domain with amivantamab and the kinase domain with lazertinib, may lead to more potent inhibition of the EGFR pathway and potentially delay resistance. In the ongoing CHRYSALIS phase 1 study (NCT02609776), preliminary antitumor activity has been demonstrated with the combination of lazertinib and amivantamab in patients with treatment-naïve and osimertinib-relapsed EGFRm NSCLC (Cho *Ann Oncol* 2020;31:S813). **Methods:** CHRYSALIS-2 is an ongoing phase 1/1b open-label study of lazertinib as monotherapy and in combination with amivantamab in patients with advanced EGFRm NSCLC (NCT04077463; https://clinicaltrials.gov/ct2/show/NCT04077463). Phase 1 of the study has confirmed the safety and tolerability of lazertinib monotherapy in Japanese patients. The objective of phase 1b is to characterize the preliminary efficacy of lazertinib in combination with amivantamab in subpopulations of patients with EGFRm NSCLC (Phase 1b Expansion Cohorts) at the recommended combination dose of 1050 mg (1400 mg, ≥80 kg) IV amivantamab dosed weekly in cycle 1 (28-day cycle), every other week thereafter, and 240 mg oral lazertinib QD. Global enrollment in Phase 1b Expansion Cohorts is currently ongoing. Expansion Cohort A is enrolling patients who have progressed on 1st or 2nd-line osimertinib followed by platinum chemotherapy; Expansion Cohort B is enrolling patients with EGFR exon 20 insertion (Exon20ins) mutation who have progressed on prior therapy; and Expansion Cohort C is enrolling patients with uncommon non-Exon20ins EGFR mutations (i.e., S768I, L861Q, G719X) who are treatment-naïve or received 1st or 2nd-generation EGFR TKI as last therapy. The primary endpoints of the study are frequency of dose-limiting toxicity for phase 1 and 1b combination cohorts, and overall response rate for phase 1b expansion cohorts. Key secondary endpoints include safety (adverse events), pharmacokinetics, duration of response, clinical benefit rate, progression-free survival, and overall survival. Safety assessments will include monitoring AEs, clinical laboratory tests, ophthalmologic examination, ECG, and ECHO/MUGA. Blood samples will be collected to access PK. Tumor response will be assessed every 6 weeks by the investigator using RECIST, v1.1. Clinical trial information: NCT04077463. Research Sponsor: Janssen R&D.

TPS9134 **Poster Session**

CONTACT-01: A phase III, randomized study of atezolizumab plus cabozantinib versus docetaxel in patients with metastatic non-small cell lung cancer (mNSCLC) previously treated with PD-L1/PD-1 inhibitors and platinum-containing chemotherapy. *First Author: Joel W. Neal, Stanford Cancer Institute, Stanford, CA*

Background: Patients with mNSCLC who progress on anti–PD-L1/PD-1 therapy administered in combination with or after platinum-based chemotherapy (PBC) are mainly treated with docetaxel or pemetrexed monotherapy. These therapies only have modest clinical activity, leaving a high unmet medical need. Cabozantinib, a tyrosine kinase inhibitor (TKI), promotes an immune-permissive environment and may enhance the efficacy of PD-L1/PD-1 inhibitors, offering a promising second/third-line therapeutic opportunity for patients with mNSCLC. In a Phase Ib multi-cohort study (COSMIC-021; NCT03170960), cabozantinib plus atezolizumab (anti–PD-L1) showed an acceptable safety profile and promising efficacy (ORR: 27%; mDOR: 5.7 mo [range: 2.6-6.9]; disease control rate [CR + PR + SD]: 83%) in 30 patients with mNSCLC who had progressed after prior anti–PD-L1/PD-1 therapy plus chemotherapy (Neal et al. J Clin Oncol 2020). The Phase III CONTACT-01 study will further evaluate the efficacy and safety of atezolizumab plus cabozantinib versus docetaxel monotherapy in patients with mNSCLC who have progressed during or after prior treatment with anti–PD-L1/PD-1 therapy and PBC. **Methods:** CONTACT-01 (NCT04471428) is a Phase III, multi-center, randomized, open-label study that will enroll ≈350 patients from 150 to 200 sites internationally. Key eligibility criteria include histologically or cytologically confirmed mNSCLC, disease progression with concurrent or sequential anti–PD-L1/PD-1 treatment and PBC, measurable disease (RECIST 1.1), ECOG PS of 0-1 and the availability of tissue specimens for centralized PD-L1 testing or known PD-L1 status using a health authority–approved PD-L1 assay. Patients with NSCLC previously treated with cabozantinib, docetaxel or anti–PD-L1/PD-1 + VEGFR TKIs are excluded. Patients with known sensitizing *EGFR/ALK* mutations and active or untreated CNS metastases are also excluded. Patients will be randomized 1:1 to receive either atezolizumab (1200 mg IV every 3 weeks) + cabozantinib (40 mg orally once daily) or docetaxel (75 mg/m^2 IV every 3 weeks). The primary endpoint is OS. Secondary endpoints include investigator-assessed PFS, ORR and DOR per RECIST 1.1; TTD in patient-reported physical function and global health status (EORTC QLQ-C30); investigator-assessed PFS rates at 6 months and 1 year; OS rates at 1 and 2 years; safety and PK. Clinical trial information: NCT04471428. Research Sponsor: F. Hoffmann-La Roche.

TPS9135 **Poster Session**

Phase I trial of *in situ* vaccination with autologous *CCL21*-modified dendritic cells (CCL21-DC) combined with pembrolizumab for advanced NSCLC. *First Author: Aaron Elliott Lisberg, University of California, Los Angeles, Los Angeles, CA*

Background: Effective immunotherapy options are lacking for patients with advanced non-small cell lung cancer (NSCLC) who progress on a programmed cell death-(ligand)1 [PD-(L)1] inhibitor and for those that are epidermal growth factor receptor (EGFR) mutation or anaplastic lymphoma kinase (ALK) rearrangement positive after progression on tyrosine kinase inhibitor (TKI) therapy. One potential approach to improve immune checkpoint efficacy in these patient populations is to promote cytolytic T cell infiltration into tumors. This can be accomplished via *in situ* vaccination with functional antigen presenting cells (APCs) which can take advantage of the full repertoire of tumor antigens and convert the tumor into a lymph node-like environment promoting both local and systemic T cell activation. The chemokine CCL21 promotes co-localization of naive T cells and antigen-experienced dendritic cells (DCs) to facilitate T cell activation. Our preclinical studies and phase I trial of intratumoral (IT) administration of DC genetically modified to overexpress CCL21 (CCL21-DC) revealed augmentation of tumor antigen presentation *in situ*, resulting in systemic antitumor immunity. However, increased PD-L1 expression was observed in some patient tumors, suggesting that tumor-mediated impairment of T cell function may be forestalling a more robust CCL21-DC mediated antitumor response. Similarly, improved PD-(L)1 inhibitor efficacy may be possible with enhanced T cell infiltration and augmented APC function following IT CCL21-DC. Therefore, we are conducting a phase I trial, combining IT CCL21-DC with pembrolizumab in patients with advanced NSCLC that are either (1) EGFR/ALK wild-type after progression on a PD-(L)1 inhibitor or (2) EGFR/ALK mutant after progression on TKI therapy. **Methods:** Phase I, dose-escalating, multi-cohort trial followed by dose expansion. Maximum of 24 patients (9-12 escalation + 12 expansion) with stage IV NSCLC will be evaluated who have tumors accessible for IT injection and are either (1) EGFR/ALK wild-type after progression on a PD-(L)1 inhibitor or (2) EGFR/ALK mutant after progression on TKI therapy. Three IT injections of autologous CCL21-DC (days 0, 21, 42) will be concurrently administered with pembrolizumab, followed by q3wk pembrolizumab up to 1 year. Primary objective of dose escalation is safety and determination of maximum tolerated dose (MTD) of IT CCL21-DC ($5x10^6$, $1x10^7$, or $3x10^7$) when combined with pembrolizumab. Primary objective of dose expansion is objective response rate at MTD. Secondary objectives include adverse event profiling and determination of drug target activity by immune monitoring studies. This trial, NCT03546361, is currently open for enrollment. Clinical trial information: NCT03546361. Research Sponsor: California Institute for Regenerative Medicine (CIRM).

TPS9136 **Poster Session**

Phase II two-arm study of tepotinib plus osimertinib in patients with *EGFR*-mutant NSCLC and acquired resistance to first-line osimertinib due to *MET* amplification: INSIGHT 2. *First Author: Viola Weijia Zhu, Chao Family Comprehensive Cancer Center, University of California Irvine, Orange, CA*

Background: *MET*amp is a mechanism of acquired resistance to EGFR tyrosine kinase inhibitors (TKIs). *MET*amp occurs in ~30% of patients who progress on EGFR TKI therapy as measured using fluorescence in situ hybridization (FISH). There is an unmet need for targeted treatment options in these patients. Combination treatment with a MET TKI may overcome *MET*-related osimertinib resistance. Tepotinib is an oral, once daily (QD), highly selective, potent MET TKI. In the INSIGHT study (NCT01982955), the combination of tepotinib and the EGFR TKI gefitinib improved outcomes in patients with *EGFR*-mutant *MET*amp NSCLC and EGFR TKI resistance compared to chemotherapy (INSIGHT). Median progression-free survival (PFS) was 16.6 vs 4.2 months (hazard ratio [HR] = 0.13; 90% confidence interval [CI]: 0.04, 0.43) and median overall survival (OS) was 37.3 vs 13.1 months (HR = 0.08; 90% CI: 0.01, 0.51). **Methods:** INSIGHT 2 is a global, open-label, Phase II trial of tepotinib + osimertinib in patients with advanced *EGFR*-mutant NSCLC. Following a protocol amendment in Apr 2020, the study is enrolling patients with acquired resistance to 1L osimertinib (radiological documentation of disease progression following previous objective clinical benefit) due to *MET*amp by FISH (GCN ≥5 or MET/CEP7 ratio ≥2). Patients must be ≥18 years old, have an Eastern Cooperative Oncology Group performance status of 0/1, and normal organ function. Both tissue and liquid biopsy, obtained at the time of progression to osimertinib, will be sent for central confirmation of *MET*amp. Liquid biopsy samples will also be used for exploratory biomarker evaluation. Enrollment is allowed based on local FISH testing while awaiting central confirmation of *MET*amp. Patients will receive 500 mg QD (450 mg active moiety) tepotinib + 80 mg QD osimertinib until disease progression, unacceptable toxicity, or consent withdrawal. The study is anticipated to enroll 120 patients. The primary endpoint is objective response rate (ORR) by independent review (RECIST v1.1) in patients with *MET*amp, centrally confirmed by FISH. Secondary endpoints include ORR by investigator assessment, duration of response, disease control, PFS, OS, pharmacokinetics, health-related quality of life, tolerability, and safety. An exploratory tepotinib monotherapy arm will enroll 12 patients to assess the contribution of tepotinib to the activity of the combination. At progression (determined by independent review committee), monotherapy patients can switch to combination treatment. These patients will be analyzed separately. Recruitment is ongoing, with > 300 patients prescreened. Approximately 100 sites in 17 countries in Europe, Asia, and North America are expected to participate. Approximately 15 sites will recruit patients in the US. Clinical trial information: NCT03940703. Research Sponsor: Merck KGaA, Darmstadt, Germany.

TPS9137 **Poster Session**

Phase 2 study of PD-1 inhibitor JTX-4014 alone and in combination with vopratelimab, an ICOS agonist, in biomarker-selected subjects with metastatic NSCLC after one prior platinum-containing regimen (SELECT). *First Author: Oleh Kobziev, Communal Non-profit Enterprise Regional Center of Oncology, Kharkiv, Ukraine*

Background: Immune checkpoint inhibitors have led to durable remissions for some patients with advanced malignancies, including NSCLC; however, only a minority of patients benefit. The field of oncology is addressing this via the development of novel therapies, combinations and identification of biomarkers to select patients most likely to derive clinical benefit. ICOS, a novel therapeutic target, is a costimulatory molecule upregulated on activated T cells. Vopratelimab is an investigational IgG1 ICOS agonist monoclonal antibody that results in activation and proliferation of primed CD4 T effector cells. The preliminary efficacy of vopratelimab +/- nivolumab was assessed in the phase 1/2 ICONIC study in which durable responses were observed in a subset of patients who demonstrated on treatment emergence of peripheral ICOS hi CD4 T effector cells. Patients with peripheral ICOS hi CD4 T cells achieved significantly greater clinical benefit than patients whose CD4 T cells remained ICOS lo. An RNA based tumor inflammation signature (TIS) comprised of 18 genes associated with immune cell infiltration was previously identified as a predictive biomarker of response to anti-PD-1 therapy (Ayers et al, 2017); it was also associated with ICOS hi CD4 T cell emergence in ICONIC (ASCO-SITC 2020). The pre-treatment tumor TIS score, coupled with a specific threshold established by Jounce, referred to as TIS^{vopra}, was predictive of ICOS hi CD4 T cell emergence. TIS^{vopra} positive patients had improved RECIST response, PFS, and OS compared to those with a TIS^{vopra} negative score. Therefore, we hypothesize that patient selection by TIS^{vopra} will identify those who will display emergence of ICOS hi CD4 T cell populations and importantly, improved clinical outcomes when treated with vopratelimab in combination with JTX-4014 (a novel PD-1 inhibitor in development by Jounce) vs JTX-4014 alone. **Methods:** This Phase 2 open-label multicenter study is investigating JTX-4014 alone and in combination with vopratelimab in TIS^{vopra} selected patients with metastatic NSCLC after one prior platinum-containing regimen (NCT04549025). Patients must be PD-1/L1 inhibitor naïve and negative for activating EGFR mutations. TIS^{vopra} eligibility is determined using RNA isolated from a tumor sample. Eligible patients will be randomized to receive either JTX-4014 as monotherapy or in combination with one of two dose levels of vopratelimab. The primary endpoint is mean percent change from baseline tumor size of all measurable existing and new lesions averaged over 9 and 18 weeks. Secondary endpoints include ORR and PFS according to RECIST v1.1, OS, safety, and association of baseline TIS score with clinical outcomes. The study has a target enrollment goal of approximately 75 patients; the first patient was dosed October 2020. Clinical trial information: NCT04549025. Research Sponsor: Jounce Therapeutics.

TPS9138 **Poster Session**

An open-label, multicenter phase I/IIa study evaluating the safety and clinical activity of clonal neoantigen reactive T cells in patients with advanced non-small cell lung cancer (CHIRON). *First Author: Mariam Jamal-Hanjani, University College London, London, United Kingdom*

Background: Lung cancer is the most common cause of cancer-related death worldwide with over 1.6 million deaths per year. Non-small cell lung cancer (NSCLC) accounts for 80% of cases, the majority of which are adenocarcinomas. 75% of patients present with inoperable tumours and/or with distant metastatic spread, with 5-year survival for stage IV disease as low as 5%. Treatment options include chemotherapy, targeted therapies for specific mutations, and - increasingly - immune checkpoint inhibitors (CPI). Adoptive cell therapies (ACT) can produce durable responses in pre-treated NSCLC. Evidence also suggests potential benefit of combining ACT with CPIs, even after acquired resistance. Efforts to improve efficacy include the expansion of T cells able to recognise patient-specific clonal tumour neoantigens. Clonal tumour neoantigens arise early in cancer evolution and represent a subset of patient-specific mutations present in all cancer cells. Developing ACTs that target clonal neoantigens represents a personalised approach to treating all cancer cells concurrently, minimising the risk of tumour escape and reducing potential for off-target toxicities. Insights gained from applying the PELEUS bioinformatic platform (developed using UK TRACERx study data) to matched tumour and blood samples from NSCLC patients – as part of a tissue acquisition study (NCT03517917) – has enabled the manufacture of a personalized clonal neoantigen-reactive T cell (cNeT) product (ATL001), which is now in clinical development. **Methods:** The CHIRON Study (NCT04032847), is a first-in-human, open-label, multi-centre, phase I/IIa study to characterise the safety and clinical activity of ATL001 administered intravenously in up to 40 adults with advanced unresectable or metastatic NSCLC. Following consent and screening, patients enter the study for procurement of tumor tissue and blood to manufacture ATL001. Tissue may be procured during treatment with standard systemic therapies. Patients in Cohort A receive cyclophosphamide/fludarabine on days -6 to -4, followed by a single dose of ATL001 and 10 daily doses of subcutaneous IL-2; Patients in Cohort B will additionally receive one dose of pembrolizumab between days -13 and -6 before receiving ATL001, then restart pembrolizumab 2 weeks after receiving ATL001 and continue for up to 12 months. Key eligibility criteria include treatment with at least one prior systemic therapy (including a PD-1 inhibitor). Primary endpoints are the safety and tolerability of ATL001 as a monotherapy and in combination with pembrolizumab. Secondary endpoints include change in tumor size and response rate by RECIST 1.1 and imRECIST. Correlative studies will investigate the effects of cNeT dose and engraftment kinetics on clinical activity. The study began enrolling patients in Cohort A in August 2019. Clinical trial information: NCT04032847. Research Sponsor: Achilles Therapeutics.

TPS9139 **Poster Session**

HERTHENA-Lung01: A randomized phase 2 study of patritumab deruxtecan (HER3-DXd) in previously treated metastatic *EGFR*-mutated NSCLC. *First Author: Pasi A. Janne, Dana-Farber Cancer Institute, Boston, MA*

Background: Few treatment options have demonstrated therapeutic benefit in epidermal growth factor receptor–mutated (*EGFR*m) non–small cell lung cancer (NSCLC) that has progressed after treatment with EGFR tyrosine kinase inhibitors (TKIs) and platinum-based chemotherapy. HER3, a member of the human epidermal growth factor family, is detectable in most *EGFR*m NSCLC, and its expression has been linked to worse clinical outcomes. There are no approved HER3 directed therapies for the treatment of NSCLC. HER3-DXd is a novel, potentially first-in-class HER3 directed antibody drug conjugate that has demonstrated preliminary evidence of safety and antitumor activity in patients (pts) with *EGFR*m TKI–resistant NSCLC in an ongoing Phase 1 study, providing proof of concept of HER3-DXd. The Phase 2 study (HERTHENA-Lung01) is further evaluating HER3-DXd in pts with previously treated metastatic or locally advanced *EGFR*m NSCLC. **Methods:** This randomized, open-label Phase 2 study will enroll up to 420 pts at approximately 135 study sites in North America, Europe and the Asia-Pacific region. Eligible pts will have metastatic or locally advanced NSCLC with an activating *EGFR* mutation (exon 19 deletion or L858R), progression during or after systemic treatment with $\geq$1 EGFR TKI and $\geq$1 platinum-based chemotherapy regimen, and $\geq$1 measurable lesion confirmed by blinded independent central review (BICR) per RECIST v1.1. Pts with an *EGFR* T790M mutation must have received and progressed on prior osimertinib. Pts with stable brain metastases are eligible. Exclusion criteria include evidence of previous small cell or combined small cell/non–small cell histology or any history of interstitial lung disease. Tumor tissue will be assessed retrospectively for HER3 expression and molecular mechanisms of TKI resistance. HER3 expression will not be used to select pts for enrollment. Pts will be randomized 1:1 to receive 1 of 2 HER3-DXd Q3W dose regimens that will be independently evaluated: a 5.6 mg/kg fixed-dose regimen (Arm 1) or an up-titration dose regimen (Arm 2: Cycle 1, 3.2 mg/kg; Cycle 2, 4.8 mg/kg; Cycle 3 and beyond, 6.4 mg/kg). After review of data from an ongoing Phase 1 study with similar patients treated with either of these dose regimens, a decision could be made to continue enrollment into 1 or both arms. The primary objective is to evaluate the efficacy of HER3-DXd as measured by objective response rate (ORR) by BICR. Secondary objectives are to evaluate the efficacy and safety/tolerability of HER3-DXd and to assess the relationship between efficacy and HER3 expression. Secondary endpoints include duration of response, progression-free survival, ORR by investigator, disease control rate, time to response, best percentage change in the sum of diameters of measurable tumors, and overall survival. The study is enrolling and is planned to finish in 2023. Clinical trial information: NCT04619004. Research Sponsor: Daiichi Sankyo.

9500 **Oral Abstract Session**

Crossover and rechallenge with pembrolizumab in recurrent patients from the EORTC 1325-MG/Keynote-054 phase 3 trial, pembrolizumab versus placebo after complete resection of high-risk stage III melanoma. *First Author: Alexander M. Eggermont, Princess Máxima Center, Utrecht, Netherlands*

Background: The phase 3 double-blind EORTC 1325/KEYNOTE-054 trial evaluated pembrolizumab (pembro) vs placebo in stage III cutaneous melanoma patients (pts) with complete resection of lymph nodes. Pembro improved RFS (hazard ratio [HR] 0.57) and DMFS (HR 0.60) (Eggermont, NEJM 2018, TLO 2021). In the pembro group, the incidence of immune related AE (irAE) grade 1-5 was 37%, and of grade 3-5 was 7%. We present the safety profile, response rate and PFS for the subset of pts who had a recurrence and crossed over or were rechallenged with pembrolizumab, within protocol. **Methods:** Pts were randomized to receive iv. pembro 200 mg (N=514) or placebo (N=505) every 3 weeks for a total of 18 doses (~1 year). Upon recurrence with no brain metastases, pts with an ECOG PS 0-2 were eligible to enter part 2 of the study, i.e. to receive pembro 200 mg iv. every 3 weeks for a maximum of 2 years, for crossover (those who received placebo) or rechallenge (those who recurred ≥6 months after completing one year of pembro therapy). Treatment was stopped in case of disease progression (RECIST 1.1) or unacceptable toxicity. **Results:** At the clinical cut-off (16-Oct-2020), 298 (59%) pts had a disease recurrence in the placebo group; 155 pts participated in the crossover part 2 of the trial. A total of 297 (58%) pts completed the 1-yr pembro adjuvant treatment, of whom 47 had a recurrence ≥6 mths from the stop of treatment and 20 entered in the rechallenge part of the trial. Among 175 pts who started pembro in Part 2, 160 discontinued due to completion of therapy (N=24), disease progression (N=88), toxicity (N=20), investigator's decision (N=21), or other reason (N=7); 15 pts were still on-treatment. Results for the 2 groups are provided in the table. The median number of doses was 12 and 5.5, respectively (resp), and the median follow-up was 41 and 19 mts, resp. Among the 175 pts, 51 (29%) had a grade 1-4 irAE (by group: 47 [30%] and 4 [20%] resp) and 11 (6%) a grade 3-4 irAE. **Conclusions:** Pembrolizumab treatment after crossover yielded a 39% ORR in evaluable pts and an overall 3-yr PFS of ~32%, but after rechallenge the efficacy was lower. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA The median PFS (95% CI) from start of Part 2 was 14 (5-27) and 8 (5-15) mts for stage III-resected and III/IV various, resp. Among the 80 stage IV crossover pts with evaluable disease, 31 (39%) had an objective response: 14 (18%) CR, 17 (21%) PR. The 2-yr PFS rate from response was 69% (95% CI 48-83%). For these 80 pts, the median PFS was 6.1 mts and the 3-yr PFS rate was 31% (95% CI 21-41%). Among 9 stage IV rechallenged pts with an evaluable disease, 1 (11%) reached CR, 3 had SD and 5 PD.Clinical trial information: NCT02362594.

	Crossover (N=155)	Rechallenge (N=20)
Stage at baseline of Part 2, n		
III-resected	50	7
III/IV various	105	13
IV unresected	83	9
III-C unresected	10	
IV resected	12	4
PFS events in Part 2, n	103	12
Median PFS (95% CI), mts	8.5 (5.7-15.2)	4.1 (2.6-NE)
3-yr PFS rate (95% CI), %	32 (25-40)	NE

9501 **Oral Abstract Session**

Final analysis of overall survival (OS) and relapse-free-survival (RFS) in the intergroup S1404 phase III randomized trial comparing either high-dose interferon (HDI) or ipilimumab to pembrolizumab in patients with high-risk resected melanoma. *First Author: Kenneth F. Grossmann, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: We assessed whether or not adjuvant pembrolizumab given over 1 year would improve OS and RFS in comparison to high dose ipilimumab (ipi10) or HDI - the two FDA-approved adjuvant treatments for high risk resected melanoma at the time of study design. **Methods:** Patients age 18 or greater with resected stages IIIA(N2), B, C and IV were eligible. Patients with CNS metastasis were excluded. At entry, patients must have had complete staging and adequate surgery to render them free of melanoma including completion lymph node dissection for those with sentinel node positive disease. Prior therapy with PD-1 blockade, ipilimumab or interferon was not allowed. Two treatment arms were assigned based on stratification by stage, PD-L1 status (positive vs. negative vs. unknown), and intended control arm (HDI vs. Ipi10). Patients enrolled between 10/2015 and 8/2017 were randomized 1:1 to either the control arm [(1) interferon alfa-2b 20 MU/m2 IV days 1-5, weeks 1-4, followed by 10 MU/m2/d SC days 1, 3, and 5, weeks 5-52 (n=190), or (2) ipilimumab 10 mg/kg IV q3w for 4 doses, then q12w for up to 3 years (n=465)], or the experimental arm [pembrolizumab 200 mg IV q3w for 52 weeks (n=648)]. The study had three primary comparisons: 1) RFS among all patients, 2) OS among all patients, 3) OS among patients with PD-L1+ baseline biopsies. Results: 1,426 patients were screened and 1,345 patients were randomized with 11%, 49%, 34%, and 6% AJCC7 stage IIIA(N2), IIIB, IIIC and IV, respectively. This final analysis was performed per-protocol 3.5 years from the date the last patient was randomized, with 512 RFS and 199 OS events. The pembrolizumab group had a statistically significant improvement in RFS compared to the control group (pooled HDI and ipi10) with HR 0.740 (99.618% CI, 0.571 to 0.958). There was no statistically signifcant improvement in OS in the 1,303 eligible randomized overall patient population with HR 0.837 (96.3% CI, 0.622 to 1.297), or among the 1,070 (82%) patients with PD-L1 positive baseline biopsies with HR 0.883 (97.8% CI, 0.604 to 1.291). Gr 3/4/5 event rates were as follows: HDI 69/9/0%, ipi10 43/5/0.5% and pembrolizumab 17/2/0.3%. **Conclusions:** Pembrolizumab improves RFS but not OS compared to HDI or ipi10 in the adjuvant treatment of patients with high-risk resected melanoma. Pembrolizumab is a better tolerated adjuvant treatment regimen than HDI or Ipi10. Support: NIH/NCI NCTN grants CA180888, CA180819, CA180820, CA180863; and in part by Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA. 9502 **Oral Abstract Session**

Neoadjuvant and adjuvant nivolumab (nivo) with anti-LAG3 antibody relatlimab (rela) for patients (pts) with resectable clinical stage III melanoma. *First Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Neoadjuvant therapy (NT) for pts with clinical stage III melanoma remains an active area of research interest. Recent NT trial data demonstrates that achieving a pathologic complete response (pCR) correlates with improved relapse-free (RFS) and overall survival (OS). Checkpoint inhibitor (CPI) NT with either high or low dose ipilimumab and nivolumab regimens produces a high pCR rate of 30-45% but with grade 3-4 toxicity rate of 20-90%. In metastatic melanoma (MM), the combination of nivo with rela (anti Lymphocyte Activation Gene-3 antibody) has demonstrated a favorable toxicity profile and responses in both CPI-naïve and refractory MM. We hypothesized that NT with nivo + rela will safely achieve high pCR rates and provide insights into mechanisms of response and resistance to this regimen. **Methods:** We conducted a multi-institutional, investigator-initiated single arm study (NCT02519322) enrolling pts with clinical stage III or oligometastatic stage IV melanoma with RECIST 1.1 measurable, surgically-resectable disease. Pts were enrolled at 2 sites and received nivo 480mg IV with rela 160mg IV on wks 1 and 5. Radiographic response (RECIST 1.1) was assessed after completion of NT; surgery was conducted at wk 9 and specimens were assessed for pathologic response per established criteria. Pts received up to 10 additional doses of nivo and rela after surgery, with scans every 3 mo to assess for recurrence. The primary study objective was determination of pCR rate. Secondary objectives included safety, radiographic response by RECIST 1.1, event-free survival (EFS), RFS, and OS analyses. Blood and tissue were collected at baseline, at day 15, day 28, and at surgery for correlative analyses. **Results:** A total of 30 pts (19 males, median age 60) were enrolled with clinical stage IIIB/IIIC/IIID/IV (M1a) in 18/8/2/2 pts, respectively. 29 pts underwent surgery; 1 pt developed distant metastatic disease while on NT. pCR rate was 59% and near pCR (< 10% viable tumor) was 7% for a major pathologic response (MPR, pCR + near pCR) of 66%. 7% of pts achieved a pPR (10-50% viable tumor) and 27% pNR (≥50% viable tumor). RECIST ORR was 57%. With a median follow up of 16.2 mos, the 1 -year EFS was 90%, RFS was 93%, and OS was 95%. 1-year RFS for MPR was 100% compared to 80% for non-MPR pts (p = 0.016). There were no treatment related gr 3/4 AEs that arose during NT; 26% of pts had a gr 3/4 AE that began during adjuvant treatment. **Conclusions:** Neoadjuvant and adjuvant treatment with nivo and rela achieved high pCR and MPR rates with a favorable toxicity profile in the neoadjuvant and adjuvant settings. Pts with MPR had improved outcomes compared to non-MPR pts. Translational studies to discern mechanisms of response and resistance to this combination are underway. Clinical trial information: NCT02519322. Research Sponsor: Bristol Myers Squibb, MD Anderson Melanoma Moonshot Program.

Relatlimab (RELA) plus nivolumab (NIVO) versus NIVO in first-line advanced melanoma: Primary phase III results from RELATIVITY-047 (CA224-047). *First Author: Evan J. Lipson, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Immune checkpoint inhibitor therapy has revolutionized the treatment of patients with advanced melanoma. However, novel combinations are needed to optimize the benefit-risk profile. Lymphocyte-activation gene 3 (LAG-3) regulates an immune checkpoint pathway, which inhibits T-cell activity, and is upregulated in many tumor types including melanoma. Relatlimab (RELA), a human IgG4 LAG-3-blocking antibody, restores effector function of exhausted T cells. RELA in combination with nivolumab (NIVO; anti-programmed death [PD]-1) modulates potentially synergistic immune checkpoint pathways and can enhance antitumor immune responses. RELATIVITY-047 is a global, randomized, double-blind, phase II/III study evaluating a novel immune checkpoint inhibitor combination of RELA+NIVO as a fixed-dose combination (FDC) treatment in first-line advanced melanoma. **Methods:** Patients with previously untreated advanced melanoma were randomized 1:1 to receive RELA 160 mg + NIVO 480 mg FDC intravenously (IV) every 4 weeks (Q4W) or NIVO monotherapy 480 mg IV Q4W, stratified by LAG-3 expression, programmed death ligand 1 expression, *BRAF* mutation status, and AJCC (v8) M stage. The primary endpoint was progression-free survival (PFS) per RECIST v1.1 as assessed by blinded independent central review. Secondary endpoints were overall survival and objective response rate. PFS in prespecified subgroups and safety were additional objectives. **Results:** 714 patients were randomized to RELA+NIVO FDC (n = 355) or NIVO (n = 359). Patient characteristics were well balanced between treatment groups. Median follow-up was 13.2 months. Median PFS in the RELA+NIVO FDC group (10.1 months [95% CI, 6.4–15.7]) was significantly longer than in the NIVO group (4.6 months [95% CI, 3.4–5.6]; hazard ratio, 0.75 [95% CI, 0.6–0.9]; $P = 0.0055$). PFS rates at 12 months were 47.7% (95% CI, 41.8–53.2) and 36.0% (95% CI, 30.5–41.6) for RELA+NIVO FDC and NIVO, respectively. PFS favored RELA+NIVO FDC across key prespecified subgroups. The incidence of grade 3/4 treatment-related adverse events (TRAEs) was higher in the RELA+NIVO FDC group (18.9%) versus NIVO (9.7%). There were 3 treatment-related deaths with RELA+NIVO FDC and 2 with NIVO. TRAEs (any grade) led to treatment discontinuation in 14.6% and 6.7% of patients in the RELA+NIVO FDC and NIVO groups, respectively. **Conclusions:** First-line treatment with RELA+NIVO FDC demonstrated a statistically significant PFS benefit compared to NIVO monotherapy in patients with advanced melanoma. RELA+NIVO FDC was well tolerated with a manageable safety profile and without unexpected safety signals. This is the first phase III study of a novel FDC to demonstrate a clinically meaningful benefit by dual inhibition of the LAG-3 and PD-1 pathways. Clinical trial information: NCT03470922. Research Sponsor: Bristol-Myers Squibb.

Lenvatinib (len) plus pembrolizumab (pembro) for patients (pts) with advanced melanoma and confirmed progression on a PD-1 or PD-L1 inhibitor: Updated findings of LEAP-004.

First Author: Ana Arance, Hospital Clinic Barcelona, Barcelona, Spain

Background: Initial results of the open-label, single-arm, phase 2 LEAP-004 study (NCT03776136) showed that len and pembro in combination had promising efficacy and manageable safety in pts with unresectable stage III-IV melanoma and confirmed PD on a PD-(L)1 inhibitor given alone or in combination. ORR was 21.4% with a 6.3-mo median DOR; ORR was 31.0% in patients with PD on prior anti–PD-1 + anti–CTLA-4. We present updated data from LEAP-004 and additional ORR subgroup analyses. **Methods:** Eligible pts with PD confirmed per iRECIST within 12 wk of the last dose of a PD-(L)1 inhibitor given alone or with anti–CTLA-4 or other therapies for ≥2 doses received len 20 mg/d once daily plus ≤35 doses of pembro 200 mg Q3W until PD or unacceptable toxicity. Primary end point is ORR per RECIST v1.1 by blinded independent central review (BICR). Secondary end points are PFS and DOR per RECIST v1.1 by BICR, OS, and safety. ORR was calculated for pts with PD on prior anti–PD-1 + anti–CTLA-4, pts whose only prior anti–PD-(L)1 was in the adjuvant setting, pts with primary resistance (ie, best response of SD or PD to prior anti–PD-(L)1 in the advanced setting) and pts with secondary resistance (ie, PD following best response of CR or PR on prior anti–PD-(L)1 in the advanced setting). **Results:** 103 pts were enrolled. Median age was 63 y, 68.0% of pts had stage M1c/M1d disease, 55.3% had LDH > ULN (20.4% ≥2 × ULN), 58.3% received ≥2 prior treatments, 94.2% received therapy for advanced disease, and 32.0% received BRAF ± MEK inhibition. With median study follow-up of 15.3 mo (range 12.1-19.0), 17.5% of pts were still receiving study drug. ORR by BICR remained 21.4% (95% CI 13.9-30.5), although the number of CRs increased from 2 to 3. DCR was 66.0%. Median DOR increased to 8.2 mo, and the KM estimate of DOR ≥9 mo was 37.2%. ORR was 33.3% in pts with PD on prior anti–PD-1 + anti–CTLA-4 (n = 30), 18.2% in pts whose only prior anti–PD-1/L1 was in the adjuvant setting (n = 11), 22.6% in pts with primary resistance (n = 62), and 22.7% in pts with secondary resistance (n = 22). Median (95% CI) PFS and OS in the total population were 4.2 mo (3.8-7.1) and 14.0 mo (95% CI 10.8-NR); 12-mo PFS and OS estimates were 17.8% and 54.5%. Incidence of treatment-related AEs was as follows: 96.1% any grade, 45.6% grade 3-4, 1.0% grade 5 (decreased platelet count), 7.8% led to discontinuation of len and/or pembro, and 56.3% led to len dose reduction. **Conclusions:** The combination of len and pembro continues to show clinically meaningful, durable responses in pts with advanced MEL with confirmed progression on a prior PD-(L)1 inhibitor, including those with PD on anti–PD-1 + anti–CTLA-4 therapy, and regardless of primary or secondary resistance to prior anti–PD-(L)1 therapy. The safety profile was consistent with prior studies of len + pembro. These data support len + pembro as a potential regimen for this population of high unmet need. Clinical trial information: NCT03776136. Research Sponsor: Eisai Inc., Woodcliff Lake, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Lifileucel (LN-144), a cryopreserved autologous tumor infiltrating lymphocyte (TIL) therapy in patients with advanced melanoma: Evaluation of impact of prior anti-PD-1 therapy.

First Author: James Larkin, Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom

Background: Immune checkpoint inhibitors (ICI) have become standard of care for treatment of metastatic melanoma. Most patients with advanced melanoma progress on ICI and treatment options are limited for these patients. Progression may be through primary resistance (lack of response) or secondary resistance (initial response then progression). Lifileucel is an adoptive cell therapy using TIL, that has shown efficacy in patients with advanced melanoma who progress on/after an anti-PD-1 (Sarnaik, 2020). We present the 28-month (mos) follow-up data and highlight the impact of prior anti-PD-1 response and duration of exposure on outcome with lifileucel. **Methods:** C-144-01 is a Phase 2, open-label, multicenter study of efficacy and safety of lifileucel in patients with advanced melanoma who have progressed on anti-PD-1 therapy and BRAFi ± MEKi, if BRAF V600$^+$. We report long-term follow up on Cohort 2 (N = 66). Tumors were resected at local sites, processed in central GMP facilities for TIL production in a 22-day manufacturing process. Therapy consisted of nonmyeloablative lymphodepletion using 2 days of cyclophosphamide and 5 days of fludarabine, a single infusion of lifileucel, and up to six doses of IL-2. Objective response rate (ORR) was assessed by RECIST 1.1. Data cutoff was Dec. 14, 2020. **Results:** Baseline characteristics: 3.3 mean prior therapies (100% anti-PD-1; 80% anti-CTLA-4; 23% BRAFi/MEKi), high baseline tumor burden (106 mm mean target lesion SOD), 42% liver/brain lesions, 40.9% LDH > ULN. ORR by investigator was 36.4% (3 CR, one new CR developed at 24 mos; 21 PR). Median duration of response (mDOR) was not reached at median follow-up of 28 mos (DOR range: 2.2- 35.2 mos). In responders, the median cumulative duration and median prior lines of anti-PD-1 therapy was 4.4 mos (range: 1.4-22.5 mos), and 1.5 (range: 1-4). Data in Table demonstrates a meaningful increase in DOR to TIL with primary anti-PD-1 resistance and lower duration of time on prior anti-PD-1 therapy. No new safety risks have been identified for lifileucel during long-term follow-up. **Conclusions:** One-time lifileucel treatment results in a 36.4% ORR, and mDOR was not reached at 28 mos of median study follow up. One PR converted to a new CR at 24 months as responses continue to deepen. DOR is positively associated with primary resistance to prior anti-PD-1 therapy and with shorter cumulative prior duration of anti-PD-1 therapy. Lifileucel may offer a better clinical outcome when used earlier upon detection of progression on prior anti-PD-1 rather than retreatment with anti-PD-1 based regimens. Clinical trial information: NCT02360579. Research Sponsor: Iovance Biotherapeutics, Inc.

CheckMate 067: 6.5-year outcomes in patients (pts) with advanced melanoma.

First Author: Jedd D. Wolchok, Medical Oncology, Memorial Sloan Kettering Cancer Center, and Weill Cornell Medical College, New York, NY

Background: In the phase 3 CheckMate 067 trial, a durable and sustained clinical benefit was achieved with nivolumab (NIVO) + ipilimumab (IPI) and NIVO alone vs IPI at 5-y of follow-up (overall survival [OS] and progression-free survival [PFS] rates: 52%, 44%, 26% and 36%, 29%, 8%, respectively). Here we report 6.5-y efficacy and safety outcomes. **Methods:** Eligible pts with previously untreated unresectable stage III or IV melanoma were randomly assigned in a 1:1:1 ratio and stratified by PD-L1 status, *BRAF* mutation status, and metastasis stage. Pts received NIVO 1 mg/kg + IPI 3 mg/kg for 4 doses Q3W followed by NIVO 3 mg/kg Q2W (n = 314), NIVO 3 mg/kg Q2W + placebo (n = 316), or IPI 3 mg/kg Q3W for 4 doses + placebo (n = 315) until progression or unacceptable toxicity. Co-primary endpoints were PFS and OS with NIVO + IPI or NIVO vs IPI. Secondary endpoints included objective response rate (ORR), descriptive efficacy assessments of NIVO + IPI vs NIVO alone, and safety. **Results:** With a minimum follow-up of 6.5 y, median OS was 72.1 mo with NIVO + IPI, 36.9 mo with NIVO, and 19.9 mo with IPI (table). Median time from randomization to subsequent systemic therapy was not reached (NR; 95% CI, 59.6–NR) with NIVO + IPI, 25.2 mo (95% CI, 16.0–43.2) with NIVO, and 8.0 mo (95% CI, 6.5–8.7) with IPI; 36%, 49%, and 66% of pts, respectively, received any subsequent systemic therapy. Median treatment-free interval (which excluded pts who discontinued follow-up prior to initiation of subsequent systemic therapy) was 27.6 mo (range, 0–83.0), 2.3 mo (range, 0.2–81.6), and 1.9 mo (range, 0.1–81.9) with NIVO + IPI, NIVO, and IPI, respectively. Of the pts alive and in follow-up, 112/138 (81%; NIVO + IPI), 84/114 (74%; NIVO), and 27/63 (43%; IPI) were off treatment and never received subsequent systemic therapy; 7, 8, and 0 pts, respectively, were still on treatment. Grade 3/4 treatment-related adverse events were reported in 59% of NIVO + IPI-treated pts, 24% of NIVO-treated pts, and 28% of IPI-treated pts. Since the 5-y analysis, no new safety signals were observed and no additional treatment-related deaths occurred. **Conclusions:** This 6.5-y analysis represents the longest follow-up from a phase 3 melanoma trial in the modern checkpoint inhibitor combination therapy and targeted therapy era. The results show durable improved outcomes with NIVO + IPI and NIVO vs IPI in pts with advanced melanoma. We observed improvement in OS, PFS, and ORR with NIVO + IPI over NIVO alone. Clinical trial information: NCT01844505. Research Sponsor: Bristol Myers Squibb.

Five-year overall survival (OS) in COLUMBUS: A randomized phase 3 trial of encorafenib plus binimetinib versus vemurafenib or encorafenib in patients (pts) with *BRAF* V600-mutant melanoma.

First Author: Reinhard Dummer, University Hospital Zürich, Zurich, Switzerland

Background: Combined BRAF/MEK inhibitor therapy has demonstrated benefits on progression-free survival (PFS) and OS and is standard of care for the treatment of advanced *BRAF* V600-mutant melanoma. Here we report a 5-year update from the COLUMBUS trial. **Methods:** In Part 1 of COLUMBUS, 577 pts with advanced/metastatic *BRAF* V600-mutant melanoma, untreated or progressed after first-line immunotherapy, were randomized 1:1:1 to encorafenib 450 mg QD + binimetinib 45 mg BID (COMBO450), encorafenib 300 mg QD (ENCO300), or vemurafenib 960 mg BID (VEM). An updated analysis including PFS, OS, objective response rate (ORR; by blinded independent central review), and safety was conducted after minimum follow-up of 65.2 months (mo). Data are as is; study is ongoing. **Results:** At data cut-off (Sep 15, 2020), there were 131 (68%), 117 (60%), and 145 (76%) deaths in the COMBO450, ENCO300, and VEM treatment arms, respectively. The median OS (95% CI) and 5-year OS rate (95% CI) with COMBO450 were 33.6 (24.4–39.2) mo and 34.7% (28.0–41.5), respectively (median follow-up: 70.4 mo). The 5-year OS rate (95% CI) in COMBO450 pts who had normal lactate dehydrogenase (LDH) levels at baseline was 45.1% (36.5–53.2). Median OS and 5-year OS rates for ENCO300 and VEM, as well as for pts with normal and high LDH levels and > 3 organs involved at baseline, are shown in the table. For COMBO450, ENCO300, and VEM, the 5-year PFS rate was 22.9%, 19.3%, and 10.2%; ORR (95% CI) was 64.1% (56.8–70.8), 51.5% (44.3–58.8), and 40.8% (33.8–48.2); and the median duration of response (DOR) was 18.6, 15.5, and 12.3 mo, respectively. Safety results were consistent with the known tolerability profile of COMBO450. Additional efficacy and updated safety analyses will be presented. Following study drug discontinuation, the most common subsequent treatment in all arms was checkpoint inhibitors. **Conclusions:** Updated OS and DOR results with COMBO450 demonstrate continued long-term benefits in pts with *BRAF* V600-mutant melanoma. Clinical trial information: NCT01909453. Research Sponsor: Pfizer.

Five-year overall survival from the anti-PD1 brain collaboration (ABC Study): Randomized phase 2 study of nivolumab (nivo) or nivo+ipilimumab (ipi) in patients (pts) with melanoma brain metastases (mets). *First Author: Georgina V. Long, Melanoma Institute Australia, University of Sydney, and Royal North Shore and Mater Hospitals, Sydney, Australia*

Background: Preliminary data from the ABC (76 pts) and CheckMate 204 (94 pts) trials showed that nivo and nivo+ipi have activity in active melanoma brain metastases, with durable responses in a subset of pts. Here, we report updated 5-yr data from all pts enrolled on the ABC trial (NCT02374242). **Methods:** This open-label ph2 trial enrolled 3 cohorts of pts with active melanoma brain mets naïve to anti-PD1/PDL1/PDL2/CTLA4 from Nov 2014-Apr 2017. Pts with asymptomatic brain mets with no prior local brain therapy were randomised to cohort A (nivo 1mg/kg + ipi 3mg/kg, Q3Wx4, then nivo 3mg/kg Q2W) or cohort B (nivo 3mg/kg Q2W). Cohort C (nivo 3mg/kg Q2W) had brain mets i) that failed local therapy, ii) with neuro symptoms and/or iii) with leptomeningeal disease. Prior BRAF inhibitor (BRAFi) was allowed. The primary endpoint was best intracranial response (ICR) ≥wk12. Key secondary endpoints were IC PFS, overall PFS, OS, & safety. **Results:** A total of 76 pts (med f/u 54 mo) were enrolled; median age 59y, 78% male. For cohorts A, B and C: elevated LDH 51%, 58% and 19%; V600BRAF 54%, 56% and 81%; prior BRAFi 23%, 24%, 75%. Efficacy and toxicity are shown in the table. There were no treatment-related deaths. 1/17 deaths in cohort A & 4/16 in cohort B were due to IC progression only. **Conclusions:** Nivo monotherapy and ipi+nivo are active in melanoma brain mets, with durable responses in the majority of patients who received ipi+nivo upfront. A study of upfront ipi+nivo+/-SRS is underway (NCT03340129).Clinical trial information: NCT02374242. Research Sponsor: BMS, Other Foundation.

Overall survival benefit from tebentafusp in patients with best response of progressive disease. *First Author: Anthony M. Joshua, Kinghorn Cancer Centre, St Vincent's Hospital, Darlinghurst, NSW, Australia*

Background: Tebentafusp (tebe) is the first T cell receptor (TCR) therapeutic to demonstrate an overall survival (OS) benefit in a randomized Phase 3 (Ph3) study [NCT03070392]. In Ph2, 42% of pts with best overall response (BOR) of progressive disease (PD) survived > 1 year (yr), suggesting RECIST-based radiographic assessments underestimate OS benefit of tebe. Here we analyzed OS in the Ph3 study in a cohort of pts with BOR of PD by comparing tebe to the control arm of investigator's choice (IC). **Methods:** 378 pts were randomized in a 2:1 ratio to tebe vs. IC. BOR was assessed by investigators using RECIST v1.1. Treatment beyond first disease progression (TBP) was permitted for both arms. On the IC arm, only patients receiving pembrolizumab (pembro) continued with TBP and were included in the TBP-related analyses. No crossover to tebe was permitted; investigators were free to choose subsequent therapy. This analysis was conducted on the first interim analysis (data extracted Nov-2020). Kaplan-Meier estimates of OS were based on Day 100 landmark to eliminate immortal time bias and to capture majority of the PDs. **Results:** By Day 100, PD as BOR occurred in 52% (130/252) of tebe pts (PD-tebe) vs. 60% (76/126) of IC pts (PD-IC). Key baseline characteristics including lactate dehydrogenase, alkaline phosphatase, ECOG performance, age, and sex were similar between PD-tebe vs PD-IC. The proportion of pts with PD due to progression of target lesions (TL), non-TL, or new lesions were also similar between the two groups. More pts received TBP among PD-tebe 53% (69/130) vs PD-pembro 16% (10/61). Median duration of TBP was longer for PD-tebe (7 weeks) vs PD-Pembro (3 weeks). The safety profile of PD-tebe pts during TBP was similar to all tebe-treated pts. OS was superior for PD-tebe vs PD-IC, HR = 0.41 (95% CI 0.25-0.66), even when considering key baseline covariates. While some pts had regression of TL despite diagnosis of PD (< 10% of pts), the OS benefit remained even when limited to pts with best change of tumor growth of TL, HR 0.46 (0.29, 0.73). 58% (75/130) PD-tebe and 52% (40/76) PD-IC pts received subsequent therapies. In a landmark OS analysis of these pts beginning on 1st day of subsequent therapy, prior tebe was associated with better OS vs. prior IC, HR 0.59 (95%CI 0.36-0.96). **Conclusions:** Tebe is the first TCR therapeutic to demonstrate an OS benefit in a solid tumor. Surprisingly, a strong OS benefit from tebe is observed even in pts with BOR of PD, suggesting that RECIST-based radiographic assessments do not capture the complete benefit from tebe. The safety profile of tebe during TBP was consistent with that for long-term tebe treatment. Clinical trial information: NCT03070392. Research Sponsor: Immunocore.
