Background: Ocular melanoma, the most common intraocular malignancy, frequently metastasizes to the liver but to date there is no established standard of care for hepatic-dominant ocular melanoma patients. The FOCUS trial began as a randomized, phase III trial (301) comparing PHP with best alternative care (BAC). The trial was subsequently amended (301A) to remove the BAC arm due to enrollment concerns. **Methods:** Eligible patients with hepatic-dominant ocular melanoma were randomized 1:1 to receive PHP or BAC (investigator's choice of TACE, pembrolizumab, ipilimumab, or dacarbazine) on the 301 trial. All eligible patients received PHP on the 301A trial. PHP patients could receive up to 6 PHP treatments, repeated every 6-8 weeks with melphalan dosed at 3.0mg/kg ideal body weight (IBW). Patients with progressive disease (PD) were discontinued from study treatment and all patients are followed until death. Patientswere imaged every 12 (±2) weeks until PD. The primary endpoint, ORR (per RECIST 1.1) as assessed by Independent Review Committee, will be characterized by the point estimate and 95% CI for each group (PHP and BAC). Categorical efficacy variables will be presented as frequency counts and percentages and 95% CI. Time-to-event variables will be summarized using Kaplan-Meier methods (median and 95% CI). **Results:** 144 patients were enrolled overall; 102 were assigned to PHP (301: n=43; 301A: n=59) and 42 were assigned to BAC. 91 PHP patients received treatment (301: n=40; 301A: n=51) and 32 BAC patients received treatment. At the time of this analysis, 4 PHP patients were still ongoing on study treatment with a minimum follow-up of 24 weeks. 79 PHP-treated patients and 29 BAC-treated patients were evaluable for response . ORR among PHP patients was 32.9% (26/79; 95% CI: 22.75-40.40%). ORR among BAC patients was 13.8% (4/29; 95% CI: 3.89-31.66%). The median PFS was 9.03 months (95% CI: 6.24-11.83) among PHP patients and was 3.06 months (95% CI: 2.69-5.65) among BAC patients; this difference was statistically significant (p=0.0004). Among the 94 patients assessed for safety after treatment with PHP, 40.4% of patients experienced a serious treatment-emergent adverse event, the majority of which were hematological and resolved without sequelae. There were no treatment related deaths in the trial. **Conclusions:** In this analysis of preliminary data from the FOCUS trial, PHP demonstrates a statistically superior ORR and significantly prolonged PFS in comparison with BAC in the treatment of hepatic metastases from ocular melanoma. The data is encouraging as efficacious treatments for hepatic metastases from ocular melanoma are desperately needed. These early data show an improvement over the previous phase III study in terms of both efficacy (ORR and PFS) as well as toxicity using second generation filters. Clinical trial information: NCT02678572. Research Sponsor: Delcath Systems, Inc.

9511 **Clinical Science Symposium**

Atezolizumab in combination with bevacizumab in patients with unresectable locally advanced or metastatic mucosal melanoma: Interim analysis of an open-label phase II trial. *First Author: Lu Si, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/ Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Mucosal melanoma is a rare malignant melanoma in Caucasians but ranks the second most common subtype in the Asian population. It is more often diagnosed at an advanced stage and responds poorly to current PD-1/PD-L1 inhibitors. Here we report the interim analysis results of ML41186, an open-label, multicenter, single-arm phase II study, aiming to evaluate the efficacy and safety of atezolizumab in combination with bevacizumab in patients (pts) with advanced mucosal melanoma. **Methods:** Eligible pts aged 18 to 75 years with histologically confirmed unresectable locally advanced or metastatic mucosal melanoma had at least one measurable lesion per RECIST version 1.1 at baseline, with an ECOG PS 0 or 1 and adequate hematologic and organ function. ML41186 is a Simon two-stage design study, if 22 pts completed ORR evaluation and more than 3 pts respond in stage I, the study then continue to Stage II. Atezolizumab and bevacizumab were administered at a fixed dose of 1200 mg and 7.5 mg/kg Q3W respectively (on day 1 of each 21-day cycle) until unacceptable toxicity or loss of clinical benefit. The primary endpoint is the objective response rate (ORR). The secondary endpoints include progression-free survival (PFS), duration of objective response (DoR), disease control rate (DCR), and safety. **Results:** By the cut-off date of 9th September 2020, 35 pts has been enrolled, among whom 22 pts in the stage I analysis set has completed two efficacy evaluation, while 28 pts (full analysis set) has completed at least one efficacy evaluation. In ITT populations (n=35), mean age was 58.9 years with 10 (28%) pts had ECOG PS of 1. LDH level elevated in 9 (25.7%) pts. More than half pts (19, 54.3%) had metastatic mucosal melanoma, of whom 3 (15.8%) pts had more than 3 metastasis sites and 4 (21.1%) pts had liver metastasis. In stage I analysis set (n=22), the best confirmed ORR was 36.4% (95% CI, 17.0%-59.3%). Median progression-free survival was 5.32 months (95% CI, 1.58-not reached), and the best confirmed DCR was 59.1% (95%CI, 36.4%-79.3%). The median confirmed DoR was not reached (95% CI, 2.76-NR). In the full analysis set (n=28), the unconfirmed ORR was 42.9% (95%CI, 24.5%-62.8%). In ITT populations (n=35), 28 pts (80%) experienced at least one adverse event (AE) and 5 pts (14.3%) experienced at least one grade 3-4 AEs. Only one patient experienced AE leading to treatment discontinuation. One patient died of autoimmune lung disease. **Conclusions:** The combination of atezolizumab plus bevacizumab showed promising benefit and was tolerable in pts with advanced mucosal melanoma. At the time of this interim analysis, the primary endpoint did not cross the futility boundary, thus the study will run into Stage II. Clinical trial information: NCT04091217. Research Sponsor: Shanghai Roche Pharmaceuticals Ltd., Shanghai, China.

9512 **Clinical Science Symposium**

A phase 2 clinical trial of neoadjuvant anti-PD-1 ab (Toripalimab) plus axitinib in resectable mucosal melanoma. *First Author: Chuanliang Cui, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: The outcome of patients (pts) with resectable mucosal melanoma (MM) is still poor. Toripalimab combined with axitinib has shown impressive results in metastatic MM with an ORR of 48.3% and a median PFS of 7.5 months in a phase 1b trial. It was hypothesized that this combination therapy might cause pathologic response in neoadjuvant setting for resectable MM, so we conducted this single arm phase 2 trial. **Methods:** Eligible pts were adults (aged 18 to 75) with histologically confirmed resectable (localized or regional lymph node metastasis) MM disease. Exclusion criteria included ocular or unknown primary melanoma, distant metastatic disease or previous use of anti PD-1 ab. Pts received toripalimab 3 mg/kg Q2W plus axitinib 5 mg BID for 8 weeks as neoadjuvant therapy, then surgery and the adjuvant toripalimab 3 mg/kg Q2W starting 2±1week after surgery for totally 52 weeks. The primary end point is pathologic response rate according to the International Neoadjuvant Melanoma Consortium (pCR+pPR, pCR is defined as the complete absence of residual viable tumor and pPR $\leq$ 50% of viable tumor cells). The secondary end point is RFS in the ITT population. Clinical trial information: NCT04180995. **Results:** From Aug 2019 to Dec 2020, 21 pts have been eligible and enrolled. Basic characteristics: median age 62 years; M: F 28.6% : 71.4%; primary sites 8 femal genital(1urethra, 7vagina), 5 esophagus, 4 ano-rectal, 4 head & neck(3 nasal,1 oral), in which 47.6% localized disease (T3/4 60%), 52.4% regional lymphatic disease; Gene mutation: 4 cKit (1 amplification), 2 Nras,1 Braf (N581), 1mTOR. This therapy was tolerable with grade 3-4 treatment related AEs of 23.8% (liver dysfunction 14.3%, hyperglycemia 9.5% and hypertension 4.8%). 13 pts had received surgeries (local excision 30.8%, wide excision ± CLND72.7%)and 5 pts still in neoadjuvant treatment. One patient was inoperable for bone metastasis, and 2 pts withdrew for covid 19 epidemic. At a median follow up time of 59 weeks, the pathologic response rate was 28.6% (4/14, 2 pCR, 2pPR). Of the post-surgical specimens, 61.5% (8/13) showed significant TIL infiltration, with 38.5% Brisk and 23.1% Nonbrisk according to the definition of AJCC 8th edition. Plenty of plasma cells, histiocyte and pigment with hyaline fibrosis were also found in responders. No recurrence or metastasis was observed in responders until now, with a RFS reaching more than 58weeks. 5 pts with pNR($>$ 50% viable tumor cells) got disease progression, with 1 local recurrence, 1 regional lymphatic metastasis, and 3 distant metastases. The median RFS has not been reached. **Conclusions:** Neoadjuvant toripalimab plus axitinib in resectable MM has shown promising pathologic responses with good tolerance, which supports further investigation of neoadjuvant therapies in MM. Survival is still in follow-up. Clinical trial information: NCT04180995. Research Sponsor: Shanghai Junshi biosciences Co.

9514 **Poster Discussion Session**

Phase II study of ceralasertib (AZD6738), in combination with durvalumab in patients with metastatic melanoma who have failed prior anti-PD-1 therapy. *First Author: Minsuk Kwon, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Alterations in DNA damage response (DDR) and repair are associated with genomic instability and increased somatic tumor mutational burden, and modulating DNA repair is a promising strategy to boost the efficacy of cancer immunotherapy. Ceralasertib is an oral inhibitor of the serine/threonine protein kinase Ataxia Telangiectasia and Rad3 Related (ATR), which is crucial to the cell's response to replication stress. **Methods:** This phase 2 trial was designed to evaluate the efficacy and safety of ceralasertib in combination with durvalumab in patients with metastatic melanoma (MM) who had failed to anti-PD-1 therapy. The study drug schedule was: ceralasertib at 240 mg BD on days 15 to 28 in combination with durvalumab at 1500 mg on day 1 in a 28-day cycle. The primary end point was overall response rate (ORR) by RECIST (v1.1). To investigate markers predictive of clinical outcome, fresh tumor biopsies were obtained from all enrolled patients before treatment. **Results:** From August 2019 to May 2020, 30 MM patients (median # of lines, 2; range, 2 - 5) were enrolled. All enrolled patients were exposed to prior anti-PD-1 treatment (immediate failure, n = 23). The ORR was 30.0% (9 PRs, 10 SDs, 10 PDs), DCR 63.3%, median PFS 7.1 months (95% confidence interval (CI), 3.6-10.6), and median OS was 14.2 months (95% CI, 9.3-19.1). Common adverse events of any grade were anemia (n = 23, 76.7%), anorexia (n = 20, 66.7%) and thrombocytopenia (n = 19, 63.3%). Common adverse events of grade 3 or more included anemia (n = 10, 33.3%). One death occurred due to febrile neutropenia in a patient with a pre-existing wound infection. **Conclusions:** Ceralasertib in combination with durvalumab demonstrated a promising anti-tumor activity, particularly in melanoma patients who failed to standard of care including anti-PD1 treatment. Clinical trial information: NCT03780608. Research Sponsor: None.

9515 **Poster Discussion Session**

Clinical activity of fianlimab (REGN3767), a human anti-LAG-3 monoclonal antibody, combined with cemiplimab (anti-PD-1) in patients (pts) with advanced melanoma. *First Author: Omid Hamid, The Angeles Clinic and Research Institute, a Cedars-Sinai Affiliate, Los Angeles, CA*

Background: Fianlimab and cemiplimab are two high-affinity, fully human, hinge-stabilized IgG4 monoclonal antibodies. In a Phase 1 dose escalation study, fianlimab combined with cemiplimab showed an acceptable safety profile and some clinical activity in pts with advanced malignancies. Here, we present safety and clinical activity data from two expansion cohorts of pts with advanced melanoma (anti–programmed cell death/ligand-1 [anti–PD-(L)1] naïve or experienced) who were treated with fianlimab + cemiplimab and had an opportunity for first on-treatment tumor assessment (cut-off date: Jan 4, 2021). **Methods:** Pts with advanced melanoma who had no prior anti–PD-(L)1 treatment (naïve) or prior anti–PD-(L)1 treatment within 3 months of screening (experienced) received fianlimab 1600 mg + cemiplimab 350 mg by IV infusion every 3 weeks. Tumor measurements were performed every 6 weeks for the first 24 weeks and subsequently every 9 weeks per RECIST v1.1. **Results:** 48 pts with advanced melanoma were treated with the combination therapy: 33 were anti–PD-(L)1 naïve and 15 were anti–PD-(L)1 experienced (median age: 69 years vs 59 years; male: 66.7% vs 46.7%; Caucasian: 87.9% vs 60%). The safety profile (including immune-related adverse events [AEs]) of fianlimab + cemiplimab combination therapy was similar to that of anti–PD-1 monotherapy with one exception. The rate of adrenal insufficiency, 8.3% (4/48) of pts, is similar to the rate previously observed with anti–PD-1 + anti–cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) combination therapy but higher than that observed with anti–PD-1 monotherapy. Grade $\geq$3 treatment-emergent AEs (TEAEs) occurred in 35.4% (17/48) of patients; Grade $\geq$3 serious TEAEs occurred in 22.9% (11/48) of patients; 8.3% (4/48) of patients discontinued treatment due to a TEAE. The most common TEAEs were fatigue (n = 15, 31.3%) and rash (n = 11, 22.9%). By investigator assessment, objective response rate (includes unconfirmed complete [CR] and partial responses [PR]) was 63.6% (3 CRs and 18 PRs) for anti–PD-(L)1 naïve pts and 13.3% (1 CR and 1 PR) for anti–PD-(L)1 experienced pts. Median progression-free survival and median duration of response for the anti–PD-(L)1 treatment naïve cohort have not been reached. Prognostic clinical markers and tumor biomarkers such as expression of LAG-3, PD-L1, and major histocompatibility complex II are being evaluated. Recruitment is ongoing. **Conclusions:** The safety profile of fianlimab + cemiplimab is similar to that observed with cemiplimab monotherapy and other anti–PD-1s, with the exception of higher rate of adrenal insufficiency. Fianlimab + cemiplimab combination has shown clinical activity for pts with advanced melanoma that is similar to anti–PD-1 + CTLA-4 combination therapy, but with lower demonstrated rates of TEAEs. Clinical trial information: NCT03005782. Research Sponsor: Regeneron Pharmaceuticals, Inc.

9516 **Poster Discussion Session**

Two dosing regimens of nivolumab (NIVO) plus ipilimumab (IPI) for advanced (adv) melanoma: Three-year results of CheckMate 511. *First Author: Celeste Lebbe, APHP Dermatology and CIC, U976, Université de Paris, Hôpital Saint-Louis, Paris, France*

Background: NIVO 1 mg/kg plus IPI 3 mg/kg (NIVO1 + IPI3) is approved for treatment (tx) of unresectable/adv melanoma, with demonstrated durable clinical benefit on long-term follow-up. Analysis of the phase 3b/4 CheckMate 511 study (NCT02714218) at 1 y showed that NIVO 3 mg/kg plus IPI 1 mg/kg (NIVO3 + IPI1) improves the safety profile of the combination; efficacy with the 2 regimens was similar in descriptive analyses. Here we present 3-y safety/efficacy results. **Methods:** Patients (pts) $\geq$ 18 y of age with previously untreated unresectable stage III/IV melanoma were randomized 1:1 to receive NIVO3 + IPI1 Q3W $\times$ 4 (N = 180) or NIVO1 + IPI3 Q3W $\times$ 4 (N = 178), both followed by NIVO 480 mg Q4W until progression/unacceptable toxicity. The primary endpoint was the incidence of grade (gr) 3–5 tx-related adverse events (TRAEs); secondary endpoints (descriptive analyses) included objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). The study was not powered to formally demonstrate noninferiority for efficacy endpoints. **Results:** At a median follow-up of 44.4 and 43.9 mo in the NIVO3 + IPI1 and NIVO1 + IPI3 groups, respectively, TRAEs led to tx discontinuation in 26% and 39% of pts; 57% and 42% of pts had received maintenance therapy. Gr 3–5 TRAE incidence remained significantly lower with NIVO3 + IPI1 than NIVO1 + IPI3 (33.9% vs 48.3%; odds ratio 0.55 [95% CI 0.36–0.84]). The most frequent TRAEs (any gr) were diarrhea (27%), fatigue (26%), and pruritus (26%) with NIVO3 + IPI1 and diarrhea (31%), pruritus (29%), and rash (27%) with NIVO1 + IPI3. In descriptive analyses, efficacy results were similar to those observed at 1 y. OS and tx-free–analysis outcomes were numerically similar in the 2 groups (table). **Conclusions:** At 3-y follow-up, NIVO3 + IPI1 continued to demonstrate an improved safety profile compared with NIVO1 + IPI3. In descriptive analyses, both groups demonstrated high 3-y OS rates that were numerically similar. This study provides important information regarding the benefit–risk profile of both dosing regimens of NIVO + IPI in pts with adv melanoma. Clinical trial information: NCT02714218. Research Sponsor: Bristol Myers Squibb.

9517 **Poster Discussion Session**

Avelumab in patients with previously treated Merkel cell carcinoma (JAVELIN Merkel 200): Updated overall survival data after more than five years of follow up. *First Author: Paul Nghiem, University of Washington Medical Center at South Lake Union, Seattle, WA*

Background: Merkel cell carcinoma (MCC) is a rare and aggressive skin cancer. Although MCC is considered chemosensitive, patients typically have limited survival benefit with chemotherapy. Before the approval of immune checkpoint inhibitors, patients with metastatic MCC (mMCC) had a poor prognosis, with a historical 5-year overall survival (OS) rate of approximately 14%. Avelumab (anti–PD-L1) became the first approved treatment for patients with mMCC, based on efficacy and safety data observed in the phase 2 JAVELIN Merkel 200 trial (NCT02155647), in which patients with mMCC received avelumab monotherapy. We report the long-term OS data from the cohort of patients with mMCC whose disease had progressed after ≥1 prior line of chemotherapy. **Methods:** Eligible patients had histologically confirmed, measurable (per RECIST 1.1) stage IV MCC. Patients received avelumab 10 mg/kg by intravenous infusion every 2 weeks until confirmed disease progression, unacceptable toxicity, or withdrawal. Long-term OS was analyzed; updated data for other efficacy endpoints, including response and progression-free survival, were not obtained. **Results:** A total of 88 patients were enrolled and received avelumab treatment. As of September 25, 2020 (data cutoff), median follow-up was 65.1 months (range, 60.8-74.1 months). Median OS was 12.6 months (95% CI, 7.5-17.1 months); the 48- and 60-month OS rates were 30% (95% CI, 20%-40%) and 26% (95% CI, 17%-36%), respectively. At data cutoff, treatment was ongoing in 1 patient (1.1%) and an additional patient (1.1%) had reinitiated avelumab after previously discontinuing treatment. Reasons for treatment discontinuation were disease progression (n = 45 [51.1%]), adverse event (AE; n = 11 [12.5%]), death (n = 10 [11.4%]), withdrawal of consent (n = 9 [10.2%]), loss to follow-up (n = 1 [1.1%]), protocol noncompliance (n = 1 [1.1%]), and other reason (n = 10 [11.4%]). At data cutoff, 19 patients (21.6%) had discontinued treatment but remained in follow-up, and 63 patients (71.6%) had died; causes of death were disease progression (n = 49 [55.7%]), unknown reason (n = 9 [10.2%]), AE not related to study treatment (n = 3 [3.4%]), and other reason (n = 2 [2.3%]). In total, 26 patients (29.5%) received subsequent anticancer therapy; the most common subsequent therapies after trial discontinuation were avelumab (n = 4 [4.5%]), carboplatin and etoposide (n = 4 [4.5%]), and pembrolizumab (n = 4 [4.5%]). **Conclusions:** Avelumab monotherapy led to meaningful long-term OS in a subset of patients with mMCC whose disease had progressed after chemotherapy. These results further support the role of avelumab as a standard-of-care treatment for patients with mMCC. Clinical trial information: NCT02155647. Research Sponsor: Funded by Merck KGaA, Darmstadt, Germany as part of an alliance between Merck KGaA and Pfizer.

9519 **Poster Discussion Session**

Intrathecal (IT) and intravenous (IV) nivolumab (N) for metastatic melanoma (MM) patients (pts) with leptomeningeal disease (LMD). *First Author: Ida John, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MM pts with LMD have a dismal prognosis, with median overall survival (OS) < 3 months, no approved therapies and extremely limited clinical trial options. We previously reported initial safety findings from an open label, single arm, single center phase I/IB trial (NCT03025256), in which IT and IV N were well tolerated, without any CNS-specific or unexpected toxicity. Here we report an update on safety and maximum tolerated dose (MTD) for all patients enrolled, and efficacy for the completed dose cohorts. **Methods:** MM patients aged >18 with evidence of LMD by MRI and/or CSF cytology, ECOG PS ≤2 were treated with IT and IV N. Dexamethasone ≤4mg/daily and concurrent BRAF/MEK inhibitor(i) treatment was allowed. For cycle 1, IT N was administered via intraventricular reservoir on day (D)1. For subsequent cycles (every 14 days), pts received IT N on D1, followed by IV N 240 mg on D2. IT N doses evaluated were 5, 10, 20 mg and 50 mg. Blood and CSF were collected at multiple time points for translational research. The primary objectives of this first-in-human study were to determine the safety and MTD of IT N given with IV N in MM pts with LMD. Bayesian mTPI methodology was used to define the MTD. **Results:** To date, 23 pts have been treated: two at 5, three at 10, fourteen at 20 mg and four at 50 mg IT N. Median age at LMD diagnosis was 42 (28-73); 12 pts are male. All pts had radiographic evidence of LMD and neurological symptoms; 14 pts had positive CSF cytology at baseline. 21 pts received prior therapies for their metastatic melanoma: anti-PD1 (n = 19), BRAFi/MEKi (n = 14), chemo (n = 2), IT IL2 (n = 4) other (n = 2). 19 pts had prior XRT, including whole brain RT (n = 7). Two pts were treatment-naïve. The median number of IT N doses was five (1- 66). The combination regimen was well tolerated by all evaluable pts (n=23), with only five pts (22%) experiencing gr 3 AEs, and no reported gr 4 or 5 toxicities. Nausea (30%), diarrhea (26%), and rash (22%) were the most common AEs. Eight pts (23%) experienced AEs after IT N administration, all gr 1. Initial efficacy analysis included only pts (n=19) treated with first three dose levels (5-20mg). Median follow-up for these pts is 4.5 months (mos) (1.1, 31.5 mos) and median OS is 63 % at 3 mos, 42 % at 6 mos and 30% at 12 mos. **Conclusions:** The trial demonstrates the feasibility and safety of IT administration of modern immunotherapy for MM pts with LMD. No unexpected systemic or neurological toxicity was observed with 20mg IT N. 2 additional patients are required to complete the 50mg IT N cohort. OS rates at 6 and 12 mos are encouraging and support further evaluation of IT administration of immunotherapy agents for pts with MM and LMD. Final presentation will include results of LMD for all dose cohorts, composite response assessment and comparative analysis of longitudinal CSF samples to assess immunologic effects. Clinical trial information: NCT03025256. Research Sponsor: Bristol Myers Squibb .

9520 **Poster Discussion Session**

Phase II Study of TRIplet combination Nivolumab (N) with Dabrafenib (D) and Trametinib (T) (TRIDeNT) in patients (pts) with PD-1 naïve or refractory BRAF-mutated metastatic melanoma (MM) with or without active brain metastases. *First Author: Elizabeth M. Burton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Targeted therapies (TT) & immunotherapies (IMT) have improved survival for pts with BRAF V600 mutated stage IV MM, however many pts still progress and ultimately die from their disease. Preclinical data support the rationale for combining TT and IMT, but trials evaluating triplet combinations in IMT-naïve pts have reported mixed results. Notably, pts with untreated brain metastases (BM) were excluded from prior triplet trials and have a median PFS of 5.6 months when treated with TT. Further, there remains an unmet need for effective therapies for pts after IMT failure, as retrospective studies have reported short median PFS (5 mos) for TT in this setting. We hypothesized that N in combination with DT is safe and will demonstrate clinical activity in BRAF-mutated pts naïve or refractory to PD1 therapy and in pts with BM. **Methods:** We conducted a single arm phase II study (NCT02910700) of NDT in pts with BRAF-mutated, unresectable stg III or stg IV MM. Prior IMT was allowed, but prior BRAF/MEKi was not. Pts with untreated BM and asymptomatic or mildly symptomatic/requiring steroids were also allowed. Pts received 3mg/kg IV Q2wks of N (later amended to 480 mg IV Q4wks), 150mg PO BID of D and 2mg PO QD of T, all starting on Day 1. The primary objective was to determine safety and efficacy (ORR by RECIST 1.1). Monitoring for safety and futility using Bayesian stopping rules was performed. Longitudinal tissue and blood samples were collected to perform correlative analyses. **Results:** Following a 6 pt safety run-in with no observed DLTs, 27 pts were treated w NDT. 17 pts were PD1 refractory, 10 were PD-1 naïve. 10 of these 27 pts had a history or presence of BM, including active BM. Median follow up was 18.4 months (range 3.2-45.9). ORR in 26 evaluable pts was 92% (3 CR, 21 PR). Among the PD1 refractory pts evaluable for response (n = 16), ORR was 88% (2 CRs, 12 PR). All 10 evaluable PD-1 naïve pts achieved a response. 4 of 7 evaluable pts w BM achieved an intracranial response (57%), including 2 CRs. The median PFS for all pts was 8.5mos (8.5mos in PD1 naïve pts, 8.2mos in PD1 refractory pts). Median PFS for pts without BM was 8.5mos, 8.0 mos for those with BM. Median OS for all pts was not reached, and no statistically significantly difference in OS by PD1 exposure or presence of BM. 78% of pts experienced treatment related grade 3/4 AEs and 6 pts (22%) discontinued all 3 drugs due to toxicities. **Conclusions:** NDT at full doses of all 3 agents has a toxicity profile consistent with previously reported triplet combinations and shows promising clinical activity in pts with IMT refractory disease and with BM. There were no significant differences in outcomes between pts with and without BM. Translational studies to delineate predictors and mechanisms of response and resistance are ongoing. Clinical trial information: NCT02910700. Research Sponsor: BMS.

9521 **Poster Discussion Session**

An immunogenomic analysis of melanoma brain metastases (MBM) compared to extracranial metastases (ECM). *First Author: Lucy Kennedy, Duke University Medical Center, Durham, NC*

Background: Previous work has shown that MBM have a unique molecular profile compared to ECM. Description of the biology of MBM will facilitate the design of rational therapies for patients (pts) with MBM. **Methods:** We analyzed a previously published dataset from MD Anderson Cancer Center, which includes RNA-seq on surgically resected FFPE MBM (88 tumors from 74 pts) and surgically resected ECM from the same pts (50 from 34 pts). WES on 18 matched pairs of MBM and ECM was available. The STAR pipeline was used to estimate mRNA abundance. The DESeq2 package was used to perform differential gene expression (DGE) analyses. Pathway analysis was performed using Gene Set Enrichment Analysis (GSEA). Paired DGE and GSEA analyses comparing MBM vs. lymph node metastases (LN mets, n = 16) and MBM vs. skin mets (n = 10) were performed. CIBERSORT estimated relative abundance of immune cell types in MBM and ECM. The GATK Mutect2 pipeline was used to call somatic mutations using paired normal tumor samples. Mutations were annotated using the Ensembl Variant Effect Predictor and visualized using the Maftools package in R. RNA-seq was available on 54 primary cutaneous melanoma (CM) pt samples, including 19 CM which did not recur, 19 CM which recurred as MBM, and 16 CM which recurred as ECM. Gene Ontology or KEGG Pathway analysis was performed using goana function of limma package in R. **Results:** Comparing MBM vs. LN and MBM vs. skin mets, paired DGE identified 136 and 89 up-regulated genes with a fold change > 2 and false-discovery rate (FDR) q-value < 0.05. Moreover, 308 and 659 down-regulated genes with a fold change < 0.5 were identified in MBM vs. LN and MBM vs. skin mets, respectively ($q < 0.05$). Paired GSEA found that autophagy signaling pathways may be up-regulated in MBM vs. LN and MBM vs. skin mets. On a single-gene level, comparing both MBM vs. LN and skin mets, the most strongly up-regulated genes in autophagy pathways were GFAP and HBB, whereas fold changes in the majority of other autophagy-related genes were low and did not reach significance. Comparison between CM which recurred in brain vs. CM which did not recur identified up-regulation of autophagy pathways. No difference in autophagy pathway expression was observed comparing between CM with any recurrence vs. without recurrence. CIBERSORT identified an increased proportion of immune suppressive M2 macrophages compared to tumor suppressive M1 macrophages in both MBMs and ECMs. **Conclusions:** Up-regulation of autophagy pathways was observed in pt-matched MBM vs. LN and skin mets. This finding seemed to be driven by up-regulation of GFAP and HBB, which could reflect changes in the tumor microenvironment (TME). Future studies using single-cell RNA-seq or spatial transcriptomic technology will dissect the TME. A higher M2:M1 ratio may contribute to an immune suppressive tumor microenvironment in MBM and ECM and is targetable. Validation of our findings in an independent Duke dataset is ongoing. Characterizing the tumor and immune landscape of melanoma patients treated with combined checkpoint blockade and MAPK targeted therapy.

First Author: Liron Zisman, Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel

Background: Melanoma therapy has been revolutionized by two novel therapeutic approaches: mitogen activated protein kinase (MAPK) targeted therapy (MTT) and immune checkpoint blockade therapy (ICB). Less than half of patients respond to ICB monotherapy, in part due to non-responsive tumor microenvironment (TME). It previously has been shown that MTT enhances anti-tumor immunity within the TME, thus providing a strong rationale for its combination with immunotherapy. Regimens combining MTT with ICB have had mixed results, and which patients should be treated with these combinations is unknown. **Methods:** The first arm (NCT03149029) of a planned two stage design was to enroll 14 patients (pts) harboring $BRAF^{V600}$ mutation treated with 2 weeks (wks) of MTT (dabrafenib plus trametinib) then 6 wks of concomitant MTT and pembrolizumab, followed by single-agent pembrolizumab thereafter. The primary endpoint is clinical benefit (CB) defined as partial/complete response or stable disease (per RECIST1.1) persisting at 24 wks. If 9 of 14 pts had CB, then 11 more pts would be enrolled for a total cohort of 25. Serial biopsies were performed prior to MTT, following the 2-week lead-in of MTT, and following six wks of combination immune therapy and MTT. Single-cell RNA-seq profiling of $CD45^+$ and $CD45^-$ cells was performed using both the smart-seq2 plate-based protocol and 10x genomics platform. **Results:** Sixteen pts were enrolled, with 14 receiving both MTT and ICB. Two pts did not receive ICB due to MTT toxicity. Only 5 had CB, and the second stage did not open. A 6th pt had CB extracranially with a new small brain met at wk 24 scans was considered CB for tumor analysis. A clustering analysis of 25 samples (n = 9 pts) showed that following MTT the abundance of CD8 T-cells as well as tumor IFNγ levels were significantly elevated in CB vs. no CB (NCB) patients. In addition, tumor associated macrophages (TAM) in NCB patients possessed mainly an M2 phenotype and expressed a significantly higher level of immune suppressor genes, such as HLA-G and CD52. Interestingly, NCB pts had a significantly higher expression of tumor TGFβ, which is a strong inducer of M2 macrophages. In contrast, most of the TAMs occupying the tumor of the CB pts had the M1 phenotype, and significantly expressed CD9, CD81 and CD82, important factors during antigen recognition and immunological synapse formation. **Conclusions:** Abbreviated MTT with ICB did not lead to increased clinical benefit at 24 wks in this small study. It is theorized that the tumor's ability to create a unique microenvironment by producing certain factors (e.g. TGFβ), modifies the immune system and may tilt its path into immune suppression thereby reducing the efficacy of this combinatorial therapy in melanoma pts with metastatic disease. These results may help identify pts most likely to benefit from combined MTT plus ICB and new targets to overcome resistance to these regimens. Clinical trial information: NCT03149029. Research Sponsor: Merck, U.S. National Institutes of Health.

9523 **Poster Discussion Session**

Effects of baseline lactate dehydrogenase (LDH), interferon gamma (IFN-g) expression, and tumor mutational burden (TMB) on treatment response to first-line atezolizumab (A) + vemurafenib (V) and cobimetinib (C) in $BRAF^{V600}$ mutation–positive advanced melanoma.

First Author: Caroline Robert, Gustave Roussy and Université Paris-Saclay, Villejuif-Paris, France

Background: The phase 3 IMspire150 study showed that first-line A+V+C improved investigator-assessed PFS vs placebo (P)+V+C in $BRAF^{V600E/K}$ mutation–positive advanced melanoma (hazard ratio 0.78; P= .0249). Prior biomarker analyses showed that IFN-g or TMB > 10 mut/Mb were associated with greater PFS benefits with A+V+C (Lewis et al. *J ImmunoTher Cancer* 2020;8:A188-A189). We further evaluated the association of these biomarkers with outcomes. **Methods:** Exploratory recursive partitioning analysis (RPA) was used to model associations between PFS and age (< 65 vs ≥65 y), Eastern Cooperative Oncology Group performance status (0 vs 1), liver metastases (yes vs no), metastatic sites (≤3 vs > 3), sum of longest tumor diameters (< 44 mm vs ≥44 mm), baseline LDH (normal [n] vs elevated [e]), TMB (< 10 vs ≥10 mut/Mb), PD-L1 (negative vs positive), and IFN-g (high [h; > Quartile 3; Q3] vs intermediate [> Q1 and ≤Q3] vs low [≤Q1]). Time-to-event analyses were summarized using Kaplan-Meier estimates. **Results:** The RPA analysis included 208/256 (81.3%) patients (pts) from the A+V+C arm of IMspire150 for whom LDH, TMB, IFN-g, and PD-L1 data were available. RPA showed that LDH was associated with PFS. In pts treated with A+V+C and n-LDH, h-IFN-g signature was associated with longer PFS and higher rates of objective response (OR) and complete response (CR) vs low/intermediate (l/i) IFN-g (2-y PFS: 59% vs 38%; ORR: 77% vs 69%; CR: 38% vs 15%, respectively); TMB ≥10 mut/Mb was associated with more favorable outcomes in pts with e-LDH (Table). In contrast, neither IFN-g nor TMB discriminated PFS outcomes in n-LDH or e-LDH pt subgroups receiving P+V+C. Pts with e-LDH and TMB < 10 mut/Mb had poor PFS outcomes, with 2-y PFS rates of 9% and 3% and lower rates of OR (51% and 62%) and CR (5% and 9%) in the A+V+C and P+V+C arms, respectively. Similar trends were observed for duration of response (DOR), and for the subset of pts with $BRAF^{V600E}$ mutation–positive melanoma. A+V+C improved PFS vs P+V+C across all subgroups with the exception of e-LDH and TMB < 10. **Conclusions:** IFN-g and TMB discriminated PFS benefit in pts receiving A+V+C but not for those receiving P+V+C. Durable responses were observed for pts treated with A+V+C in the n-LDH + h-IFNg subgroups. Research Sponsor: F. Hoffmann-La Roche.

TMB and *BRAF* mutation status are independent predictive factors in stage IIIC/D/IV melanoma patients receiving adjuvant PD-1 antibodies.

First Author: Andrea Forschner, Department of Dermatology, University Hospital of Tuebingen, Tuebingen, Germany

Background: High tumor mutational burden (TMB) is associated with a favorable outcome in metastatic melanoma patients treated with immune checkpoint inhibitors. However, data are limited in the adjuvant setting. As BRAF mutated patients have an alternative with targeted adjuvant therapy, it is important to identify predictive factors for relapse and recurrence-free survival (RFS) in patients receiving adjuvant PD-1 antibodies. **Methods:** We systematically evaluated all melanoma patients who started adjuvant PD-1 antibody therapy at our center between March 2018 and September 2019 to identify predictive factors for outcome. The median follow-up time from start of adjuvant anti-PD-1 therapy was 22 months. Tumor and normal tissue of all stage IIIC/D/IV patients and of stage IIIA/B patients with relapse were sequenced using a 700 genes panel. Predictive factors for relapse and RFS were identified using univariate and multivariate logistic and Cox regression analysis. RFS was estimated by the Kaplan-Meier method. TMB high was defined as the top 20 % of the cohort, corresponding to TMB values ≥ 20 Var/Mb. **Results:** A total of 165 patients were included in this study. According to AJCC 8th the initial tumor stages at the beginning of adjuvant anti-PD-1 therapy were as follows: N = 80 stage IIIA/B (48 %), N = 85 stage IIIC/D/IV (52 %). 72/165 patients (44 %) suffered a relapse, 44/72 (61 %) with loco regional and 28/72 (39 %) with distant metastases. Sequencing results were available from 79 / 85 patients with stage IIIC/D/IV. Here we present the results of this cohort. TMB low (OR 17.46, 95%CI 4.03-75.55; p < 0.0001) or absence of BRAF V600E/K mutation (OR 4.13, 95%CI 1.36-12.53; p = 0.012) were statistically significant, independent predictive factors for relapse. Also, with regard to RFS, BRAF mutation status and TMB were statistically significant and independent predictive factors. In the table below we display results for the combined variables. Patients with BRAF V600E/K mutation and TMB high had the best outcome. **Conclusions:** We identified TMB high as positive predictive marker in stage IIIC/D/IVmelanoma patients with adjuvant PD-1 antibody therapy. In tumors with *BRAF* V600E/K mutation and concurrent low TMB, adjuvant targeted therapy with BRAF- and MEK-inhibitors may be an alternative. This is also supported by the data on adjuvant dabrafenib and trametinib, which showed a greater advantage in patients with low TMB, presumably due to less tumor heterogeneity. Research Sponsor: None.

Characteristic	No relapse N = 34	Relapse N = 45	*p*	1-year RFS (%; 95%CI)	2-year RFS (%; 95%CI)	*P*

Improved pyrexia-related outcomes associated with an adapted pyrexia adverse event (AE) management algorithm in patients (pts) treated with adjuvant dabrafenib + trametinib (dab + tram): Primary results of COMBI-APlus.

First Author: Victoria Atkinson, Princess Alexandra Hospital, University of Queensland, Greenslopes, Brisbane, QLD, Australia

Background: The long-term benefit of adjuvant dab + tram in pts with resected stage III *BRAF* V600E/K–mutant melanoma was demonstrated in COMBI-AD where AEs led to permanent discontinuation of dab + tram in 26% of pts, most often due to pyrexia (9%). The COMBI-APlus trial (NCT03551626) is designed to evaluate whether an adapted pyrexia management algorithm could reduce high-grade pyrexia and other pyrexia-related adverse outcomes, such as treatment cessation and hospitalization. **Methods:** COMBI-APlus is an open-label, Phase IIIb trial evaluating an adapted pyrexia management algorithm in pts with high-risk resected stage III BRAF V600E/K–mutant melanoma treated with 12 mo of adjuvant dab + tram. In the adapted algorithm, both dab and tram were interrupted promptly at the onset of pyrexia (temperature ≥ 38°C). In the event of suspected recurrent pyrexia, treatment may be interrupted in the presence of pyrexia syndrome (ie, chills, rigors, night sweats, or influenza-like symptoms without temperature ≥ 38°C) at investigator discretion. Treatment with dab + tram was restarted at the same dose level once pts were symptom free for ≥ 24 hours. The primary endpoint is the composite rate of grade 3/4 pyrexia, hospitalization due to pyrexia, or permanent discontinuation due to pyrexia vs a historical control from COMBI-AD (20%; 95% CI, 16.3%-24.1%). Secondary endpoints include relapse-free survival (RFS) and safety. **Results:** A total of 552 pts were enrolled. At the data cutoff (5 Oct 2020), all pts had completed 12 mo of treatment; median duration of follow-up was 18.4 mo. COMBI-APlus met its primary endpoint of significant improvement in composite rate of pyrexia. The composite rate was 8.0% (95% CI, 5.9%-10.6%), with rates of 3.8% for grade 3/4 pyrexia, 4.3% for hospitalization due to pyrexia, and 2.4% for discontinuation due to pyrexia. The estimated 12-mo RFS rate was 91.8% (95% CI, 89.0%-93.9%). The most common AEs (≥ 20%) were pyrexia (67.8%), headache (31.7%), blood creatine phosphokinase increase (27.9%), diarrhoea (27.0%), chills (26.4%), fatigue (25.7%), asthenia (23.6%), nausea (23.4%), rash (21.4%), and arthralgia (21.0%). AEs of any type led to permanent dab + tram discontinuation in 14.7% of pts. **Conclusions:** This primary analysis suggests the new adapted pyrexia management algorithm is effective in reducing grade 3/4 pyrexia, pyrexia-related hospitalization, and treatment discontinuation in pts receiving adjuvant dab + tram. The early efficacy appears consistent with that observed in COMBI-AD. The growing experience of oncologists in managing pyrexia with this simple algorithm may reduce the need for hospitalization or visits to a healthcare provider, which is highly desirable during the current COVID-19 pandemic. Thus, more pts can remain on treatment and derive benefit. Clinical trial information: NCT03551626. Research Sponsor: Novartis.

9526 **Poster Session**

Overall survival in patients who received checkpoint inhibitors after completing tebentafusp in a phase 3 randomized trial of first-line metastatic uveal melanoma. *First Author: Marlana Orloff, Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA*

Background: Tebentafusp (tebe) is a bispecific consisting of an affinity-enhanced T cell receptor fused to an anti-CD3 effector that can redirect T cells to target gp100+ cells. Tebe significantly improved OS compared to investigator's choice (IC) in first line (1L) mUM [NCT03070392]. In a phase (ph) 2 study of tebe in 2L+ mUM (NCT02570308), several checkpoint inhibitor (CPI) refractory pts who were retreated with CPI after tebe achieved durable clinical benefit [1]. We therefore evaluated clinical outcomes of post-tebe CPI in patients treated on the ph3 trial of tebe versus investigator's choice (IC) [NCT03070392]. **Methods:** In the ph3 trial, 378 HLA-A*02:01+ 1L mUM pts were randomized 2:1 to tebe (n=252) or IC (n=126) [pembrolizumab (82%), ipilimumab (12%) or dacarbazine (6%)]. No crossover to tebe was permitted, investigators were free to choose subsequent therapy, and there was no re-randomization at time of subsequent therapy. This analysis was conducted on the first interim analysis (data extracted Nov-2020). When pts received more than one subsequent therapy, the first was used in these analyses. Medians and 1-yr OS from the start of post-study therapy are obtained from standard Kaplan-Meier analyses; hazard ratios (HR) are from Cox regression models adjusted for age and gender. **Results:** 106/252 (42%) tebe pts received ≥ 1 subsequent therapy: 35% CPI, 9% chemo, 6% liver directed therapy (LDT), 6% other. 55/126 (44%) of IC pts received ≥ 1 subsequent therapy: 21% CPI, 10% chemo, 12% LDT, 10% other. Median time to first subsequent therapy was longer for tebe pts at 5.2 mo vs. IC pts at 3.8 mo. The median duration from start of first subsequent CPI to end date was longer in the prior tebe pts at 4 mo vs prior IC pts at 2.8 mo. From the start of any first subsequent therapy, prior tebe pts had longer OS compared to prior IC pts, HR 0.67 (95% CI 0.42, 1.07). Most of the subsequent therapy was CPI, and the OS benefit was also seen in this subset, HR 0.62 (95% CI 0.34, 1.14). For prior tebe pts, the median and 1-yr OS rates from start of any first subsequent therapy were 13 mo and 53% and from start of first subsequent CPI were 16 mo and 63%. Both were higher than the sequence of IC followed by any therapy (11 mo and 44%), IC followed by CPI (9 mo and 47%) and a recent meta-analysis of 2L+ mUM (7 mo and ~35% 1-yr OS rate). **Conclusions:** Pts who progressed on tebe and then received CPI had better OS compared to pts who progressed on IC and then received CPI. Further analysis will explore whether confounding factors are influencing this effect. These exploratory data suggest that tebe, relative to IC, may improve outcomes to subsequent CPI. 9527 **Poster Session**

Co-primary endpoint of overall survival for tebentafusp (tebe)-induced rash in a phase 3 randomized trial comparing tebe versus investigator's choice (IC) in first-line metastatic uveal melanoma. *First Author: Jessica Cecile Hassel, Department of Dermatology and National Center for Tumor Diseases (NCT), Heidelberg University Hospital, Heidelberg, Germany*

Background: Tebe is a bispecific consisting of an affinity-enhanced T cell receptor fused to an anti-CD3 effector that can redirect T cells to target gp100+ cells. In this Phase (Ph) 3, randomized trial of first line (1L) metastatic uveal melanoma (mUM) [NCT03070392], tebe significantly improved overall survival (OS) vs. investigator's choice (IC) in the intention-to-treat population (ITT). In previous trials, tebe-related skin adverse events (AEs), hypothesized to be on-target, off-tumor activity against gp100-expressing melanocytes, were associated with improved OS. This association was tested prospectively as a co-primary endpoint in the Ph3 study. **Methods:** 378 1L HLA-A*02:01+ mUM pts were randomized 2:1 to tebe (n = 252) or IC (n = 126). Co-primary endpoints were 1) OS in all randomized pts (ITT) and 2) OS in tebe-randomized pts who develop any grade rash in week (wk) 1 vs. all receiving IC. Rash was defined as composite of preferred AE terms. Melanocyte-related AEs (MRAEs) were defined as pigment change AEs in the skin or hair. Overall study-wide alpha was controlled at 0.05, with 90% assigned to ITT and 10% to rash. This analysis was conducted on the first interim analysis (data extracted Nov-2020). **Results:** In the 245 tebe treated pts, the characteristic skin related AEs included most frequently rash (at any time) in 201 pts (82%), pruritis in 167 pts (68%), MRAEs in 109 pts (45%) and erythema in 69 pts (28%). While rash, erythema and pruritis mostly occurred in the first 4 weeks, MRAEs occurred after a median of 2.7 mo. Rash captures most pts, 201/227 (89%), who have any of these skin related AEs. Rash occurred in 146 pts (60%) by wk 1; 179 pts (73%) by wk 2; and 195 pts (80%) by wk 3. Tebe pts with wk 1 rash had significantly longer OS vs. the IC arm, HR 0.35 (95% CI 0.23, 0.53), $p < 0.0001$. The estimated 1-yr OS rates were 83% vs 58%, respectively. When expanded to include tebe pts with rash through wk 3, the 1-yr OS rate of 75% was still numerically higher than IC. The 50 (20%) tebe pts who did not experience rash by week 3 had 1-yr OS rate of 55%. **Conclusions:** In 1L mUM pts, tebe significantly improved OS compared to IC in the ITT analysis. Week 1 rash, presumed due to tebe redirection of T cells to gp100+ skin melanocytes, was associated with a very strong OS benefit. Therefore, rash may be a marker that the immune system can be mobilized by tebe to target gp100+ cells. The vast majority of tebe pts will develop a rash at some point, and tebe pts without rash may still derive benefit. Clinical trial information: NCT03070392. Research Sponsor: Immunocore.

9528 **Poster Session**

Results of phase II randomized study of intermittent versus continuous schedule of vemurafenib plus cobimetinib in BRAF-mutated advanced melanoma. *First Author: Maria Gonzalez-Cao, Instituto Oncológico Dr. Rosell, Barcelona, Spain*

Background: Combination of vemurafenib plus cobimetinib is approved for the treatment of BRAF-mutated advanced melanoma. Although patients initially respond to treatment, resistance emerges before 18 months in most cases. One of the key pre-clinical observations that supported an intermittent schedule was that resistant tumors suffer a fitness deficit in the absence of the drug, so modulation of the drug pressure through an intermittent dosing could delay the emergence of resistance. **Methods:** GEM1501 is a randomized phase 2 study comparing the activity of the combination of vemurafenib 960 mg every 12 h/d plus cobimetinib 60 mg/d in a standard (arm A) versus intermittent schedule (arm B). Arm A: four-week (w) cycles of daily vemurafenib for 4w plus cobimetinib for 3w-on and 1w-off-treatment. Arm B: first three cycles according to the standard schedule, followed by 6w-cycle with 2w-off vemurafenib & 3w-off cobimetinib. Primary endpoint was progression free survival (PFS) and secondary were objective response (OR) and treatment-related adverse events (TAEs). **Results:** 70 treatment-naïve patients were included. Results in arms A and B: median PFS 16.2 (95%CI 9.5, 24.1) vs 6.9 months (95%CI 5.2, 9.3) (p = 0.079)**;** OR in 25 (71.4%) (8 complete -23%-) vs 21 (60%) patients (5 complete -14%-); G3-4 TAEs 42.8% vs 40.0%, respectively. Analysis of $BRAF^{V600}$ mutation in tumoral cell free DNA (cfDNA) was performed in serial plasma samples in 41 patients. Twenty-one (51%) patients had detectable $BRAF^{V600}$ mutation in pretreatment cfDNA (preBRAF+). Significant differences in PFS were found according to preBRAF^{V600}: 8.2 months (95%CI 5.2, 13.6) in preBRAF+ vs non-reached (NR) (95%CI 2.8, NR) in preBRAF- (p = 0.017). In arm A, median PFS was 13.3 months (95% CI 4.6, NR) in preBRAF+ vs NR (95% CI 2.3, NR) in preBRAF-. In arm B, median PFS was 6.2 months (95% CI 0.3-8.3) in preBRAF+ vs NR (95%CI 2.8, NR) in preBRAF- (p = 0.003).$BRAF^{V600}$ mutation became undetectable in cfDNA after treatment initiation in all preBRAF+ patients. Different kinetic of $BRAF^{V600}$ mutation in cfDNA was found according to treatment arm. At progression, $BRAF^{V600}$ reappeared in cfDNA in all (5/5) cases treated in arm B, but only in 50% (3/6) of cases in arm A. NGS analysis of cfDNA at progression suggested different resistance mechanisms. **Conclusions:** The results of this study do not support the use of an intermittent schedule of vemurafenib plus cobimetinib in advanced melanoma. $BRAF^{V600}$ detection in pretreatment cfDNA is a prognostic factor of poor survival that it is independent of treatment schedule, although most striking differences favoring continuous arm vs intermittent arm were found in patients with detectable $BRAF^{V600}$ mutation on pretreatment cfDNA. Further research is required to determine the clinical value of the analysis of resistance mechanisms in cfDNA. Clinical trial information: 2014-005277-36. Research Sponsor: Spanish Melanoma Group, Pharmaceutical/Biotech Company.

A phase 2 clinical trial on trametinib and low-dose dabrafenib in advanced pretreated $BRAF^{V600}/NRAS^{Q61R/K/L}$ wild-type melanoma (TraMel-WT): Interim efficacy and safety results. *First Author: Gil Awada, Department of Medical Oncology, Universitair Ziekenhuis Brussel, Brussels, Belgium*

Background: The mitogen-activated protein kinase (MAPK) pathway can be activated by alternative driver mutations in $BRAF^{V600}/NRAS^{Q61R/K/L}$ wild-type (wt) melanoma. MEK-inhibitor monotherapy has activity in $BRAF^{V600}/NRAS^{Q61R/K/L}$ wt melanoma, but is associated with considerate skin toxicity. Skin toxicity associated with the MEK-inhibitor trametinib (T) can be effectively mitigated by adding a low dose (50 mg BID) of the BRAF-inhibitor dabrafenib (LD-D) (Awada et al. Ann Oncol 2020). **Methods:** This two-stage, single-center phase 2 trial investigated T 2 mg QD in patients (pts) with advanced $BRAF^{V600}/NRAS^{Q61R/K/L}$ wt melanoma who previously progressed on treatment with checkpoint inhibitors. In case of dose-limiting T-related skin toxicity, LD-D (50 mg BID) was added to T (pre-amend). The trial was amended in June 2019 to administer T upfront with LD-D (post-amend). Objective response rate (ORR, by RECIST v1.1) served as the primary endpoint. A Simon's two-stage optimal design was used (p_0 0.10; p_1 0.30; alpha 0.05; power 0.80): in case of > 1 OR in the first 10 pts, 19 additional pts would be included in stage 2. The trial is considered positive if > 5 OR are observed. **Results:** As of February 9, 2021, 16 pts (3 pre-amend; 13 post-amend) were included (median age 56.5; male 56.3%; stage IIIB 6.3%, IV-M1a-c 68.8%, IV-M1d 25.0%; ECOG performance status 0-1 93.8%; normal lactate dehydrogenase 56.3%). Median duration of follow-up is 17.9 weeks (wks; range 1.9-90.1). The ORR in 14 evaluable pts is 42.9% (5 confirmed and 1 unconfirmed partial response), the disease control rate is 71.4%. Four OR are ongoing after a median follow-up of 8.0 wks (range 0.0-77.0), 2 responding pts progressed on therapy after respectively 16.6 and 24.0 wks. Four out of 6 OR are observed in pts with MAPK-pathway activating mutations (3 class II *BRAF* and 1 *GNAQ* mutation). Eight pts (50.0%) have progressed (median progression-free survival 16.4 wks [95% confidence interval [CI] 6.9-25.9]); 4 pts (25.0%) have died (median overall survival 54.7 wks [95% CI 37.6-71.8]). Adverse events (AE) are observed in all pts (grade [G] 3-4 9 [56.3%]). Two pre-amend pts added on LD-D due to dose-limiting T-related skin toxicity; no clinically relevant T-related skin toxicity was observed post-amend with the upfront addition of LD-D. The most frequent AE were creatine kinase increase (G1-2 11 [68.8%]; G3-4 1 [6.3%]), and anemia and acneiform rash (both G1-2 7 [43.8%]; G3-4 0). Therapy was temporarily interrupted due to AE in 11 pts (68.8%) and permanently interrupted in 1 pt (6.3%) due to recurrent pneumonitis. **Conclusions:** In this two-stage phase 2 trial, T plus LD-D was found to have promising antitumor activity and acceptable toxicity in pts with advanced pretreated $BRAF^{V600}/NRAS^{Q61R/K/L}$ wt melanoma, especially in the presence of identifiable somatic MAPK-pathway activating mutations. Clinical trial information: NCT04059224. Research Sponsor: Stichting tegen Kanker, Pharmaceutical/Biotech Company.

Discrepancies in response and immune-related adverse events (irAE) of anti-PD-1 monotherapy between races and primary sites in patients (pts) with advanced nonacral cutaneous melanoma (NACM). *First Author: Xue Bai, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Ultraviolet (UV)-induced high tumor mutation burden (TMB) of NACM is associated with response to anti-PD-1 monotherapy (aPD-1). Anatomic location of the primary lesion (reflecting UV exposure) and race (reflecting eumelanin level) may serve as surrogates for TMB and be associated with varying response and irAE patterns. **Methods:** Pts with advanced NACM receiving aPD-1 between 2009-2019 were retrospectively analyzed from 5 institutions in the US, Australia and China. Best response, survival (PFS and OS), and organ/system-specific irAEs were compared by race (Caucasian [C] vs non-Caucasian [NC]) and primary anatomic site. **Results:** Among 697 patients, 616 were C, 81 were NC. Complete response rate (CRR) was 24.8% (95%CI, 21.4-28.4) and 2.6% (95%CI, 0.3-9.1) and ORR was 54.9% (95%CI, 50.9-58.9) and 15.6% (95%CI, 8.3-25.6) in C and NC, respectively (both P<.001). Median PFS was 16.5 (95%CI, 12.0-23.1) and 5.2 (95%CI, 3.6-7.6) months, median OS was 60.5 (95%CI, 49.9-not reached [NR]) and 29.2 (95%CI, 17.9-NR) months, in C and NC, respectively (P<.001 and =.04). In multivariate analyses, C had significantly higher CRR (OR 13.4, 95%CI 3.1-57.4), ORR (OR 10.6, 95%CI 4.6-24.5), and longer PFS (HR 0.5, 95%CI 0.4-0.7) than NC. Compared to a head primary site, NACM from less UV-exposed regions had significantly lower CRR (upper trunk, OR 0.6, 95%CI 0.4-0.96; lower limb, OR 0.5, 95%CI 0.2-0.9), ORR (lower limb, OR 0.6, 95%CI 0.3-0.9) and poorer PFS (perineum/buttock, HR 2.1, 95%CI 1.2-3.5; lower limb, HR 1.6, 95%CI 1.2-2.2) and OS (perineum/buttock, HR 3.8, 95%CI 2.2-6.8; lower limb, HR 1.7, 95%CI 1.2-2.4). Overall irAE incidence was similar between C and NC but irAE subtypes varied. C had significantly higher incidence of GI (12.2%, 95%CI 9.5-15.3% vs 1.2%, 95%CI, 0.03-6.7%, P=.001), respiratory (10.3%, 95%CI 7.8-13.2% vs 0, P<.001) and grade 3/4 (15.4%, 95%CI 12.4-18.8% vs 6.2%, 95%CI 2.0-13.8%, P=.03) irAEs; and lower incidence of endocrine (13.8%, 95%CI 10.9-17.0% vs 32.1%, 95%CI 22.2-43.4%, P<.001) and liver (4.8%, 95%CI 3.2-7.1% vs 13.6%, 95%CI, 7.0-23.0%, P=.005) irAEs. IrAEs did not vary by primary NACM site. **Conclusions:** Race and primary site are independently correlated with distinct response and survival outcomes in pts with advanced NACM receiving aPD-1. IrAE subtypes vary by race although overall irAE incidence does not. Research Sponsor: None.

Characterization of cytokine release syndrome (CRS) following treatment with tebentafusp in patients (pts) with previously treated (2L+) metastatic uveal melanoma (mUM). *First Author: Richard D. Carvajal, Department of Medicine, Herbert Irving Comprehensive Cancer Center, Columbia University Medical Center, New York, NY*

Background: Cytokine-mediated adverse events (AEs) are commonly reported in pts treated with T cell engaging therapies. Tebentafusp (tebe), a bispecific consisting of an affinity-enhanced T cell receptor fused to an anti-CD3 effector that can redirect T cells to target gp100+ cells, has shown an overall survival benefit for pts with untreated mUM in a Ph3 trial (NCT03070392). Here we reviewed the incidence, kinetics, and outcome of CRS in tebe-treated pts on the IMCgp100-102 trial of 2L+ pts with mUM (NCT02570308). **Methods:** 127 HLA-A*02:01+ 2L+ mUM pts were treated with tebe at the RP2D of 68mcg following intra-patient dose escalation of 20 mcg dose 1 and 30 mcg dose 2. Pts were monitored overnight to allow management of hypotension and other cytokine-related AEs. Because the rate of severe CRS was low in Ph1, prophylactic corticosteroids, antihistamines or acetaminophen were not mandated. CRS was evaluated post-hoc according to ASTCT Consensus Grading criteria [1]. Circulating cytokines in serum were measured before and at 8hr and 12-24hr after dosing for the 1st, 3rd and 4th doses (n=105). This analysis was conducted on the primary analysis snapshot dated 04Jun20. **Results:** The most frequent treatment-related AEs that were likely cytokine-mediated included fever (80%), chills (64%), nausea (59%), hypotension (41%) and hypoxia (4%). In a post-hoc review using ASTCT criteria, 86% of pts (n=109) had any grade CRS. The majority of these 109 pts had either grade (G) 1 (n=42; 33%) or G2 (n=62; 49%), with few G3 (n=4; 3.1%), one G4 (0.8%), and no deaths. Onset of CRS began within 24 hours of administration and G≥2 hypotension or hypoxia typically resolved within 2 days of onset. Most CRS events occurred after the first 3 doses with a marked reduction in the frequency and severity of CRS thereafter; G3-4 CRS was limited to first two doses. Only 2 pts discontinued tebe due to CRS (1 G3 and 1 G4). Treatment of G≥2 CRS included iv fluids (n=45), iv steroids (n=18), oxygen (n=8), and vasopressor use (n=2). No pts received tocilizumab. Tebe induced a transient increase in peripheral cytokines, including IFNγ, IL-10, IL-6 and TNFα, within hours of tebe dosing, which were several fold higher in pts with CRS compared to pts without CRS. Higher levels of TNFα trended with severity of CRS. **Conclusions:** CRS, a common AE observed with all T cell engaging therapies, was frequently observed within 24 hours of initial tebe treatment. Most CRS events were mild or moderate in severity even without the use of prophylactic premedications, were reversible with standard management strategies, decreased in frequency and severity with subsequent doses, and rarely led to treatment discontinuation. Pts with CRS tended to have greater increases in serum cytokines, consistent with tebe's proposed mechanism of action. [1] Lee, DW et al. *Biol Blood Marrow Transplant* 2019. Triplet therapy with pembrolizumab (PEM), encorafenib (ENC) and binimetinib (BIN) in advanced, BRAF V600 mutant melanoma: Final results from the dose-finding phase I part of the IMMU-Target trial. *First Author: Lisa Zimmer, Department of Dermatology, University Hospital, University Duisburg-Essen; German Cancer Consortium (DKTK), Partner Site Essen, Essen, Germany*

Background: Survival of BRAF-mutated melanoma profoundly improved since the introduction of immune checkpoint inhibitors (ICI) and MAPK pathway inhibitors (MAPKi). Response kinetics of ICI and MAPKi are complementary, mechanistic evidence indicates that MAPKi may affect the tumor immune microenvironment. Combined use of both drug classes may further enhance clinical benefit. IMMU-Target was set-up as a prospective, open-label, phase I/II trial, with a safety phase I part followed by a randomized phase II part, to study the tolerability and clinical activity of PEM, ENC and BIN triplet therapy. **Methods:** Treatment naïve adult patients (pts) with stage IIIB-IV (AJCC 2017), BRAF V600 mutant melanoma with measurable disease but no active brain metastasis were eligible. The dose finding part used a 3+3 design, starting with a dose level (DL) 0 applying the clinically recommended doses of PEM (200 mg Q3W), ENC (450 mg QD) and BIN (45 mg BID). In case of ≥2 dose-limiting toxicities (DLT), a reduction of the ENC and BIN doses (300 mg QD and 30 mg BID at DL-1, 200 mg QD and 30 mg BID at DL -2) was foreseen. Primary endpoints of the phase I part were safety and tolerability. **Results:** From April 2018 until May 2020, 14 pts with BRAF V600 mutations were enrolled. 2 of 3 pts at DL 0 developed DLT (creatine phosphokinase (CPK) elevations grade 3 plus cytokine release syndrome grade 4; gamma glutamyl transferase (GGT) elevations grade 3), and had to stop therapy early. Therefore, 3+3 further pts at DL -1 were included with no DLT observed in these 6 pts. One (isolated GGT elevations grade 3) of the 2 DLT observed in the 3 pts of DL 0 enrolled initially was questionable as DLT, as the patient had further episodes of isolated GGT elevations without therapy. As a result, further 5 pts were enrolled at DL 0: here no DLT-matching treatment-related adverse event (TRAE) occurred. In total, 12 out of 14 pts (86%) experienced a TRAE and 7 (50%) experienced a grade ≥3 TRAE; there were no fatal AE or TRAE-related deaths. Increases in alanine and in aspartate aminotransferases, GGT and CPK elevations (6 of 14 pts) were the most common grade 3-4 TRAE. In median, pts at DL 0 (n=8) received triplet therapy for 18 weeks (IQR 7.5-29), at DL-1 (n=6) for 46 weeks (IQR 27-102). The overall response rate was 64% (95% CI=35-87). At a median follow-up of 10.0 months at DL 0 and 27.0 months at DL-1, progression-free survival at 12 months was 37.5% (95% CI 9- 67) and 60% (95% CI 13-88), respectively. **Conclusions:** Triplet therapy was feasible and safe at both dose levels leading to clinically meaningful disease control. The phase II part was not initiated, since the clinical efficacy of PEM plus ENC and BIN is currently investigated in STARBOARD (NCT04657991), a prospective, randomized, placebo-controlled (PEM mono), double-blinded phase III trial. Clinical trial information: NCT02902042. Research Sponsor: Funding in part by Merck Sharp & Dohme and Array/Pfizer.

Patterns and management of progression on first-line ipilimumab combined with anti-PD-1 (IPI+PD1) in metastatic melanoma (MM) patients. *First Author: Ines Pires Da Silva, Melanoma Institute Australia, Sydney, Australia*

Background: First line IPI+PD1 induces long-term response in 36% of MM patients (pts); however, the majority of pts will progress and may require further treatment, which is yet to be established. We studied the patterns of progressive disease (PD) on 1st line IPI+PD1, and the management and outcomes in MM pts. **Methods:** Demographics, disease characteristics, nature of PD, subsequent treatments and outcomes were examined in MM pts with PD on 1st line IPI+PD1. Multivariable analyses (MVA) identified factors associated with patterns of PD: innate resistance (IR) = PD as best response or stable disease (SD) < 6 mo; acquired resistance (AR) = PD after initial response or SD ≥ 6 mo. **Results:** 310 MM pts from 14 melanoma centres were included; 208 (67%) had PD during and 102 (33%) after ceasing IPI+PD1. Overall med. progression-free survival (mPFS) was 2.8 mo (CI 95% 2.7 – 3.0); 187 pts (60%) had IR (mPFS 2.2 [2.1 – 2.5]), 112 pts (36%) had AR (mPFS 8.5 [7.2 – 10.2]) and 11 pts (4%) had pseudoprogression, i.e. PD followed by response without changing treatment (mPFS 2.7 mo [1.4 – NA]). On MVA, pts with ECOG PS ≥ 1 were more likely to have IR vs AR; and within IR pts, those with head & neck primary melanomas and lung metastases were more likely to have PD < 1.5 mo. Most pts with IR (68%) had PD in multiple sites, while 61% AR pts had PD in a single site. Brain was most common site of single organ PD; 49% of IR and 41% of AR. Med. follow-up from PD was 32.7 mo (28.1 – 36.8). After PD, 61 pts (20%) had best supportive care (26% of IR and 11% of AR pts). 259 pts (80%) received further treatment: 39% IR pts had systemic treatment (ST) only and 27% had ST + local; 31% AR pts had ST only and 39% had ST + local. Of 200 pts (65%) who had ST(+/-local), 54% had 1 line of ST and 46% had ≥ 2; 1st line ST (ST1) was BRAF/MEKi in 36% of pts, PD1 in 32%, IPI+PD1 in 7%, investigational drugs in 11%, chemotherapy in 9% and others in 5%. ORR in IR pts was lower than in AR pts for every type of ST1 (see Table). Med. OS from PD was 11.4 mo (CI 95% 9.6 – 16.1); IR 6.4 mo (CI 95% 5.6 – 10.2) and AR 26.1 mo (CI 95% 17.1 – NA). **Conclusions:** These data suggest longer OS from PD for AR vs IR pts independent of ST type. BRAF/MEKi, rechallenge with PD1+/-IPI and investigational drugs showed activity after PD on IPI+PD1, while chemotherapy has no role in this context. Research Sponsor: None.

ST after PD on IPI+PD1	BRAF/MEKi	PD1	IPI+PD1	Investigational drugs	Chemotherapy
ORR 1st line, n/N (%)

Characteristics and probability of survival for patients with advanced melanoma who live five or more years after initial treatment with immune checkpoint blockade (ICB). *First Author: Kimberly Loo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A subset of melanoma patients treated with ICB (ipilimumab [ipi], nivolumab [nivo], pembrolizumab [pembro] or nivo+ipi) will experience durable responses. While five-year survival rates have been reported for patients treated with ICB on clinical trials, little is known about the clinical characteristics, survival past five years, and patterns of late relapse of long-term survivors. **Methods:** We retrospectively reviewed all patients treated at Memorial Sloan Kettering for unresectable stage III/IV melanoma who survived at least five years following their first dose of ICB (N = 151). Demographics, disease characteristics, and nature of progression were examined. Overall survival (OS) was calculated from 5 years post-ICB. Time to Treatment failure (TTF) was calculated conditionally from 5 years out until next therapy, progression, or death. **Results:** Of the 151 long-term survivors, median age at first ICB treatment was 62 years (range 22-83), with 101 (66.9%) male and 50 (33.1%) female patients. Stage at first ICB treatment was unresectable stage III (26, 17.2%), M1a (21,13.9%), M1b (39, 25.8%), M1c (52, 34.4%), M1d (13, 8.6%). Melanoma subtype was cutaneous (122, 80.8%), unknown primary (24, 15.9%), mucosal (3, 2%), and acral (2, 1.3%). First ICB was ipi (108, 71.5%), PD-1 (nivo or pembro) (5, 3.3%), and nivo+ipi (37, 24.5%). The best overall response to first ICB was CR (76, 50.3%), PR (27, 17.9%), SD (16, 10.6%) and PD (32, 21.2%). Of the patients who progressed after initial ICB, 38 received subsequent systemic treatment as follows: PD-(L)1 in 20 (53%), BRAF ± MEK in 9 (23.7%), ipi in 7 (18.4%), and chemotherapy in 2 (5.3%). Median duration of follow-up among survivors (N = 138) was 93 months (range 60-192). From 5 years post-ICB, 85% (95% CI: 73-92%) survived an additional 5 years. In those who made it to 5 years without treatment failure (N = 72), the probability of remaining failure-free was 92% (95% CI: 86-99%) at 7 years. Of the 151 patients, only 4 patients (2.6%) experienced disease progression after 5 years. Three patients had radiographic or pathologic disease progression in the lymph nodes and one in the subcutaneous tissue. No patients progressed in the lungs, visceral organs, or CNS after 5 years. At time of analysis, 13 (8.6%) patients died after 5 years post ICB, none died of progressive melanoma. 6 patients died of unknown causes, 2 died of other causes, and 5 died of other non-melanoma cancer-related causes. **Conclusions:** Patients who survive five years after their initial immunotherapy have excellent overall survival and treatment failure-free survival. Given the anxiety surrounding survivorship and late progression, long-term survivors should be reassured of their excellent prognosis. These data suggest that aggressive follow-up schedules and imaging of melanoma patients after 5 years of survival may not be required. Research Sponsor: None.

Clinical characteristics of SF3B1 mutant (mut) uveal melanoma (UM) and response to immune checkpoint inhibition (ICI). *First Author: Joe M Grimes, Columbia University Vagelos College of Physicians and Surgeons, New York, NY*

Background: Metastatic UM is associated with a median overall survival (OS) $<$ 1 year (yr) and overall response rate (RR) to ICI $<$ 18%. SF3B1 mut UM represent a clinically unique subset of UM, distinct from BAP1 mut disease, characterized by aberrant spliceosome machinery which may result in increased neoantigen presentation, increased immunogenicity, and sensitivity to ICI. To assess these hypotheses, we performed a multicenter retrospective analysis to assess the natural history and response to ICI in patients (pts) with SF3B1 mut UM. **Methods:** Patients were identified from institutional databases and the AACR Project GENIE Consortium. Data collected included: baseline and recurrent disease characteristics, molecular characteristics, treatments received, treatment response, and vital status. Efficacy endpoints included investigator assessed RECIST RR and OS. **Results:** 58 pts with deleterious SF3B1 mutations were identified: 56 R625; 1 D781G; 1 G742D. Median age at diagnosis (dx) was 52 (range, 14-87). 50% were female. 49 pts developed distant metastases. The median time from initial dx to metastasis was 6.1 years (yrs; range, 0.9 to 26.7). Initial metastatic sites (n = 48) were: liver-only (52%); non-liver-only (29%); mixed liver and non-liver disease (19%). The most common initial metastatic sites were: liver (71%), lung (29%), soft tissue (13%), lymph node (8%), and bone (4%). The median OS for all pts from time of metastasis was 3.9 years (95% confidence interval (CI), 2.3-6.2) with OS for pts with non-liver only disease at 6.2 yrs vs those with liver-only or mixed disease at 3.4 yrs (hazard ratio = 2.12, p = 0.14). 1-year OS rate from time of metastasis was 94% (95% CI, 0.86-0.99). 34 pts received ICI for metastatic disease at which time 27% had received a prior systemic therapy (median, 0; range, 0-3) and 35% had received a prior hepatic regional therapy (median, 0; range, 0-6). 15 pts received single-agent anti-PD1; 4 received ipilimumab alone; 15 received dual ICI. 10 pts received ICI with concurrent hepatic regional tx. Best response among 33 evaluable pts were: 9% partial response; 39% stable disease; 52% progressive disease. Median OS from ICI initiation was 20.2 months (95% CI, 13.1-27.4). 1-year OS from ICI initiation was 74% (95% CI, 0.59-0.90). **Conclusions:** SF3B1 mut UM is characterized by later development of metastases, more common involvement of extrahepatic sites, and longer OS when compared with historical datasets of molecularly unselected UM. Although a modest RR to ICI was observed, the median OS and 1-year survival rate post-ICI are numerically superior to historical controls. Given the more indolent course of SF3B1 mut UM, stratification by SF3B1 status should be included in future clinical trials. Research Sponsor: None.

Pembrolizumab and all-trans retinoic acid combination treatment of advanced melanoma. *First Author: Martin McCarter, University of Colorado Comprehensive Cancer Center, Aurora, CO*

Background: Myeloid-derived suppressor cells (MDSCs) are potent suppressors of antitumor immunity and are commonly associated with poor outcomes in melanoma patients treated with immune checkpoint inhibitors. Inducing the differentiation of MDSCs using all-trans retinoic acid (ATRA) reduces MDSC frequency. This analysis seeks to assess the safety and efficacy of combining ATRA and pembrolizumab in advanced melanoma patients. **Methods:** This single arm, single institution, phase I/II study (NCT03200847) enrolled 24 patients diagnosed with stage IV melanoma. Eligible patients were over the age of 18 and had not been previously treated anti-PD-1 therapy. Treatment consisted of 200mg Q3W pembrolizumab plus the supplemental treatment of 150 mg/m2 ATRA orally for 3 days surrounding each of the first four infusions of pembrolizumab, with patients continuing pembrolizumab for up to two years until confirmed disease progression or unacceptable toxicity. The primary endpoints were safety and reduction in circulating MDSCs. Secondary endpoints were overall response rate (ORR), disease control rate (DCR), progression free survival (PFS) according to RECIST v1.1. **Results:** At data cut off (Feb, 2021) 22 patients were evaluable for tumor response. Median follow-up was 1.0 years (0.3-2 years). In general, the combination of pembrolizumab and ATRA was well tolerated. The most common treatment-related adverse events (AEs) were grade 1 or 2, including headache (22 pts, 92%), fatigue (18 pts, 75%), rash (16 pts, 66%), and nausea (8 pts, 33%), most of which corresponded with the 3-day course of ATRA treatment. Ten patients had grade 3 or higher AEs with most being common ICI-related AEs. The ORR was 60% and DCR was 83%. Six-month PFS rate was 62%. Excluding patients diagnosed with uveal melanoma (n = 2) the ORR was 72%, DCR was 86%, and the six-month PFS rate was 68%. Paired analysis showed sustained decreases in absolute numbers (p = 0.002) and percentage (p = 0.007) of circulating MDSCs ($CD3^-CD19^-CD56^-CD11b^+CD33^+HLA\text{-}DR^{-/low}$) 4-6 weeks after stopping ATRA. The study is ongoing and further data will be presented in the future. **Conclusions:** This study demonstrates that the combination of ATRA and pembrolizumab is well tolerated and suggests that reducing MDSCs with ATRA may enhance the efficacy of pembrolizumab. This strategy of targeting MDSCs in combination with pembrolizumab warrants further development. Research Funding: Merck. Clinical trial information: NCT03200847. Research Sponsor: Merck Sharp & Dohme Corp.

Safety and efficacy of lifileucel (LN-144), an autologous, tumor infiltrating lymphocyte cell therapy in combination with pembrolizumab for immune checkpoint inhibitor naïve patients with advanced melanoma. *First Author: Sajeve Samuel Thomas, University of Florida Health Cancer Center at Orlando Health, Orlando, FL*

Background: Tumor infiltrating lymphocyte (TIL) cell therapy has demonstrated safety and efficacy in advanced melanoma, both in the pre-immune checkpoint inhibitor (ICI) setting (Goff, JCO 2016) and in patients who have failed anti-PD-1/PD-L1 therapy (Sarnaik, 2020). Combination of TIL and pembrolizumab (pembro) in ICI-naïve patients has demonstrated encouraging efficacy data with acceptable safety in head and neck squamous cell carcinoma (Jimeno, 2020). To improve treatment options in early lines, we explore a combination of LN-144 and pembro in patients with ICI-naïve advanced melanoma. **Methods:** IOV-COM-202 is a Phase 2 multicenter, multi-cohort, open-label study evaluating TIL cell therapy in multiple settings and indications. We report on Cohort 1A enrolling ICI-naïve advanced melanoma (unresectable or metastatic) patients for treatment with a combination of LN-144 and pembro. Key eligibility criteria include $\leq$ 3 lines of prior therapy, ECOG $<$ 2, one resectable lesion for lifileucel manufacturing, and $\geq$ 1 measurable lesion for response assessment. Primary endpoints are objective response rate (ORR) per RECIST 1.1 and safety as measured by incidence of Grade $\geq$3 treatment-emergent adverse events (TEAE). LN-144 is generated at centralized GMP facilities in a 22-day process. A nonmyeloablative lymphodepletion (NMA-LD) using cyclophosphamide and fludarabine is administered preceding a single LN-144 infusion, followed by $<$ 6 doses of IL-2 (600,000 IU/kg). Pembro is administered after tumor harvest but prior to NMA-LD and continues after lifileucel per label. **Results:** Seven patients have received lifileucel in combination with pembro as of data extraction date (Feb 14, 2021). Five of the 7 treated patients were treatment-naïve, 1 patient had prior BRAFi + MEKi and 1 had received prior chemotherapy; 71% had liver/brain lesions, 43% had LDH $>$ ULN. Mean SOD for the target lesions was 111 mm, with 86% of patients with $>$ 3 target lesions, representing advanced disease at baseline for this patient group. The TEAE profile was consistent with the underlying disease and known AE profiles of pembro, NMA-LD and IL-2. Six patients had a confirmed objective response with an ORR of 86% (1 CR, 5 PR) and 1 best response of SD. Three of the responding patients have remained off pembro due to pembro related AEs for 3, 4 and 13 months (mos), yet maintaining response. All responding patients remain in response with the longest duration of response being 16.8 mos. **Conclusions:** Lifileucel can be safely combined with pembro in patients with ICI-naïve advanced melanoma. The ORR of 86% is encouraging when compared to pembro alone in a similar patient population, especially considering the disease burden at baseline and persistence of responses in patients off therapy. Enrollment is ongoing and updated data to be presented. Clinical trial information: NCT03645928. Research Sponsor: Iovance Biotherapeutics, Inc.

The use of cryoablation to overcome resistance to PD-1 blockade in unresectable melanoma. *First Author: Meghan Mooradian, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Percutaneous image-guided cryoablation (cryo) is an established minimally invasive oncologic treatment that modulates the immune microenvironment. We hypothesized that cryo can augment anti-tumor responses in melanoma patients progressing on immune checkpoint inhibitors (ICI). **Methods:** In this non-randomized phase II single-center study, subjects with unresectable melanoma progressing on ICI underwent cryo of an enlarging lesion and ICI continuation for a minimum of 2 additional cycles. Computed tomography was performed at 6-8 weeks following cryo to determine tumor response in non-ablated lesions per RECIST1.1, with confirmatory scans at 8-12 weeks. The primary endpoint was safety and feasibility. Secondary endpoints were overall response rate (ORR) and disease control rate (DCR) with DCR defined as the percentage of pts who achieve complete response (CR), partial response (PR), and stable disease (SD). Correlative analyses on pre- and post-cryo tumor biopsy and blood samples were performed. **Results:** From May 2018 through July 2020, 20 pts were screened, 18 enrolled and 17 treated per protocol. All pts received prior PD-1/PD-L1 monotherapy and 12 (67%) experienced primary resistance to ICI. Median follow-up was 8.5 months. Ablated lesions included lymph nodes (n = 4), lung/pleura (n = 4), soft tissue/bone (n = 3), adrenal (n = 3), chest wall (n = 1), and kidney (n = 1). Peri-procedural events occurred in 3 cases (pneumothorax, diaphragm puncture, osteomyelitis). One pt. with underlying ICI-induced hypophysitis experienced an adrenal crisis post-procedure, which rapidly corrected with stress-dose steroid administration; there were no de novo immune-related adverse events post-ablation and there were no grade 4/5 events. In evaluable pts (n = 17), ORR was 18% and DCR was 47% (3 PR, 5 SD). To investigate the inflammatory state of the tumor microenvironment prior to cryo, PD-1, CD8+ TIL IHC, was performed and will be presented at the meeting. Additional exploratory analyses (serial ctDNA analysis, single cell RNA sequencing, HLA-subtyping) are ongoing. **Conclusions:** Cryoablation in patients with unresectable melanoma following progression on ICI is feasible with an acceptable side effect profile. Efficacy data of this potentially synergistic approach in metastatic melanoma is encouraging. Correlative analyses are underway to identify biomarkers of response to this novel strategy. Clinical trial information: NCT03290677. Research Sponsor: Philanthropy - donations to the MGH melanoma group.

Apatinib in combination with camrelizumab, a humanized immunoglobulin G4 monoclonal antibody against programmed cell death-1, in patients with metastatic acral melanoma. *First Author: Xuan Wang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Patients(pts) with metastatic acral melanoma respond poorly to anti–PD-1 monotherapy. Apatinib, a vascular endothelial growth factor (VEGF) inhibitor, is a kind of anti-angiogenic drugs which have shown synergistic therapeutic effects in combination with PD-1 blockade. We conducted this single-center, open label phase trial to evaluate the safety and efficacy of camrelizumab in combination with apatinib in advanced treatment-naïve acral melanoma pts. **Methods:** Eligible participants were adult pts (aged 18 to 75) with histologically confirmed unresectable stage or distant metastatic acral melanoma. Exclusion criterion included unknown primary melanoma, brain metastatic disease or previous use of anti PD-1 ab. Pts received camrelizumab at 200mg intravenous infusion every 2 weeks, in combination with apatinib 250 mg orally once a day. The primary endpoint was ORR according to RECIST 1.1 criteria, and the secondary endpoints were safety and RFS. **Results:** Thirty pts were enrolled from April 2019 to January 2021. Basic characteristics: the mean age was 56.7 years, 22 pts were at stage, 33.3% had an elevated LDH level. Median tumor burden was 45mm (10-187). Gene mutation: Nras 4, cKit 3, Braf 2. Up to January 2021, 27 pts could be evaluated, in which 2 pts got CR, 4 pts achieved PR, and 63% experienced tumor shrinkage. The ORR and DCR were 22.2% and 77.8%, respectively. With a median follow up time of 8.3 months, the median PFS was 8.0 months (95% CI, 3.68, 10.19), the one-year durable response rate was 83.3% and the duration of response time was still not reached. Univariate analysis showed high LDH level was negatively associated with PFS. Whole exome data of baseline tumor biopsies revealed a positive correlation between high copy number variation (CNV) plus high mutational load (TMB) and efficacy，and all of the 4pts with MDC1 gene mutation got tumor shrink and 2 got PR. 96.7% pts experienced treatment-related AEs (TRAEs), including hand foot syndrome in 40%, proteinuria in 40%, liver dysfunction in 36.7%, and hypothyroidism in 30%. The grade 3-4 TRAEs were 33.3%. AE-related permanent discontinuation occurred in only 13.3% pts. 6 pts had delays of treatment due to the COVID-19 epidemic. No dose-limiting toxicities and suspected unexpected AEs were observed in the combination. **Conclusions:** The combination of apatinib plus camrelizumab was tolerable and showed promising antitumor activities and PFS improvement in pts with treatment-naïve metastatic acral melanoma. The survival is still in follow up. Clinical trial information: NCT03955354. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co.

Predictors of overall survival (OS) in patients (pts) with melanoma brain metastasis (MBM) in the modern era. *First Author: Merve Hasanov, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The management and OS of pts with metastatic melanoma have improved due to new systemic therapies. However, relatively little is known about the use of these treatments (tx) and their association with OS in pts with MBMs. We reviewed a large cohort of MBM pts to assess how pt demographics, disease characteristics, and MBM tx impact OS in the current era. **Methods:** Under an institutional review board-approved protocol, retrospective data were curated and analyzed from pts diagnosed with, and received tx for, MBM from 2014 to 2018 at the MD Anderson Cancer Center (MDA). Pts diagnosed with uveal or mucosal melanoma or other cancers were excluded. Pt demographics; timing and features of initial melanoma dx; timing and features of initial MBM dx; prior, initial and subsequent tx; and OS were collected. OS was determined from MBM dx to last clinical follow-up (FU). Pts alive at last FU were censored. The Kaplan-Meier method and log-rank test were used to estimate OS and to assess univariate group differences, respectively. Multivariable (MV) associations of OS with variables of interest were investigated with Cox proportional hazards models. Initial treatment of MBM was assessed as a time-varying covariate. All statistical tests used a significance level of 5%. **Results:** A total of 401 MBM pts were identified. The median age at MBM dx was 61; 67% were male and 46% had a BRAF V600 mutation. At MBM diagnosis dx, most (70%) pts were asymptomatic; 70% had concurrent uncontrolled extracranial disease; 36% had elevated serum LDH. Prior tx included immunotherapy (IMT) for 39% and targeted therapy (TTX) for 17%. The median number of MBMs was 2; 31% had $>$ 3 MBMs. Median largest MBM diameter was 1.0 cm, 9% had MBM $>$ 3.0 cm, and 5% had concurrent leptomeningeal disease (LMD). Tx received after MBM dx included stereotactic radiosurgery (SRS; 53% as initial tx for MBM, 67% at any time after MBM dx), whole brain radiation therapy (WBRT; 16%, 35%), craniotomy (12%, 19%), IMT (37%, 74%), and/or TTX (22%, 40%). 31% received steroids during initial MBM tx. At a median FU of 13.4 (0.0 - 82.8) months (mos), the median OS was 15.1 mos, and 1- and 2-year OS rates were 56% and 40%. Notably, gender, time to MBM dx, and BRAF status were not associated with OS (univariate analysis). On MV analysis, clinical features associated with worse OS included increased age, increased primary tumor thickness, elevated LDH, $>$ 3 MBMs, +LMD, +symptoms, and prior tx with IMT. Among tx used at any time after MBM dx, WBRT (HR 1.9, 95% CI 1.5-2.5) was associated with worse OS; SRS (HR 0.7, 95% CI 0.5-0.8) and IMT (HR 0.6, 95% CI 0.5-0.8) were associated with improved OS. **Conclusions:** In one of the largest cohorts of MBM pts described to date, OS has improved in MBM pts in the current era. Prognostic factors for OS include pt age, primary tumor and MBM features, prior tx, and tx for MBM. Additional analyses to assess the interaction of tx, disease features, and OS will be presented. KEYNOTE-555 Cohort B: Efficacy, safety, and PK of pembrolizumab (pembro) 400 mg every 6 weeks (Q6W) as 1L therapy for advanced melanoma. *First Author: Conrad R. Jacobs, East Cape Onc, Cape Town, South Africa*

Background: In KEYNOTE-555, a model-based approach suggested expected drug exposure with pembro 400 mg Q6W is similar to that observed with approved doses of pembro 200 mg or 2 mg/kg Q3W. The pembro Q6W dose is now approved. We present interim efficacy, safety and PK of 1L pembro 400 mg Q6W for patients (pts) with advanced melanoma in KEYNOTE-555 Cohort B (NCT03665597). **Methods:** Eligible pts had unresectable stage III or IV melanoma, ECOG PS $\leq$1, and no prior systemic therapy for advanced disease.Pts received pembro 400 mg Q6W for up to 18 cycles ($\approx$2 years).The primary efficacy endpoint was ORR per RECIST v1.1 by blinded independent central review (BICR). Secondary endpoints included PFS by BICR per RECIST v1.1 and safety. PK profile and exposure were evaluated for cycle 1 and steady state (cycle 4). **Results:** Between May 2019 and Jan 2020, 101 pts were enrolled and received $\geq$1 dose of pembro. Baseline characteristics were generally similar to pt cohorts of historical pembro studies in advanced melanoma. As of the data cutoff date of August 6, 2020, all pts had $\geq$6 mo of follow-up and 40.6% of pts had discontinued study treatment. Median (range) duration of treatment and doses administered were 8.2 mo (1 day–13.9 mo) and 6 (1–11) doses, respectively. Observed exposure with pembro 400 mg Q6W had lower variability than model predictions and was within PK parameters from clinical experience with other pembro regimens (Table). ORR was 50.5% (95% CI 40.4–60.6). 12.9% of pts had CR and 37.6% had PR. Median PFS was 13.8 mo (95% CI 3.0–not reached). Estimated PFS rates were 56.5% at 6 mo and 54.3% at 12 mo. Treatment-related AEs of any grade occurred in 79.2% of pts (grade 3–4: 6.9% of pts; no deaths due to a treatment-related AE). The most common immune-mediated AEs were hyperthyroidism (6.9%) and hypothyroidism (6.9%). **Conclusions:** 1L treatment with pembro 400 mg Q6W yielded a clinically meaningful ORR in pts with advanced melanoma. PK, efficacy and safety results from KEYNOTE-555 Cohort B support prior findings from the model-based assessment and indicate that the benefit-risk profile for the more practical pembro 400 mg Q6W regimen is consistent with that of 200 mg or 2 mg/kg Q3W regimens. Clinical trial information: NCT03665597. Research Sponsor: Funding for this research was provided by Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Comparing the clinical efficacies of anti-PD-1 antibody monotherapy and anti-PD-1 and anti-CTLA-4 combination therapy as first-line immunotherapy in Japanese advanced acral melanoma: A retrospective, multicenter study (JAMP-neo study).

First Author: Yasuhiro Nakamura, Saitama Medical University International Medical Center, Saitama, Japan

Background: Anti-PD-1 antibody monotherapy (PD1) has been commonly used for patients with advanced acral melanoma (AM). However, recent studies have demonstrated the limited clinical efficacy of PD1 in AM compared to non-acral cutaneous melanoma, particularly in nail apparatus melanoma. Although advanced AM patients are strong candidates for first-line anti-PD-1 and anti-CTLA-4 combination therapy (PD1+CTLA4), data on the clinical efficacy of PD1+CTLA4 in AM are lacking. Thus, we aimed to compare the clinical efficacies of PD1+CTLA4 and PD1 in Japanese advanced AM patients. **Methods:** We retrospectively reviewed the clinical records of advanced AM patients treated with PD1+CTLA4 or PD1 as first-line immunotherapy at 23 Japanese institutions. Clinical response was assessed using the Response Evaluation Criteria in Solid Tumors (RECIST) criteria. Survival was estimated using Kaplan-Meier analysis. Toxicity was assessed according to CTCAE 4.0. **Results:** A total of 192 patients (median age, 72 years) with advanced AM (palm and sole melanoma, 135; nail apparatus melanoma, 57) were included in the study. PD1+CTLA4 and PD1 were used as first-line immunotherapy in 39 and 153 patients, respectively. The baseline demographics and characteristics were similar between the PD1+CTLA4 and PD1 groups, except for age (median age 67.3 vs. 73.2; $P = 0.005$). The objective response rate (ORR) in PD1+CTLA4 was significantly higher than that of the PD1 group (38.5% vs. 16.3%; $P = 0.047$). The median progression-free survival (PFS) and overall survival (OS) in the PD1+CTLA4 group tended to be longer than those of the PD1 group, but the differences were not significant (median PFS 7.3 months vs. 4.5 months; $P = 0.19$, median OS 43.6 months vs. 18.2 months; $P = 0.19$). In the subgroup analysis of the palm and sole melanoma cohorts, no significant differences in ORR, PFS, and OS were observed between the PD1+CTLA4 and PD1 groups (ORR 31% vs. 20.8%; $P = 0.67$, median PFS 5.3 months vs. 5.9 months; $P = 0.87$, median OS not reached vs. 22.3 months; $P = 0.66$). Meanwhile, the nail apparatus melanoma cohort in the PD1+CTLA4 group exhibited significantly higher ORR, and longer PFS and OS than the PD1 group (ORR 60% vs 6.1%; $P < 0.001$; median PFS 19.6 months vs 3.8 months; $P = 0.008$, median OS 43.6 months vs 13.5 months; $P = 0.049$). Due to immune-related adverse events in all cohorts, the treatment cessation rate was higher in the PD1+CTLA4 group than the PD1 group (59% vs. 11.8%). **Conclusions:** PD1+CTLA4 was clinically more efficacious than PD 1 in advanced AM patients. Notably, advanced nail apparatus melanoma patients were strong candidates for first-line PD1+CTLA4. Research Sponsor: None.

Durability of response to immune checkpoint inhibitors (ICI) in metastatic Merkel cell carcinoma (mMCC) after treatment cessation.

First Author: Alison Margaret Weppler, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: mMCC is a rare, aggressive neuroendocrine cancer which often occurs in older patients (pts) with multiple comorbidities. While initial response rates to ICI are high, optimal treatment duration, durability of response after treatment cessation and response to retreatment with ICI is unknown. **Methods:** mMCC pts from 12 international centres who received at least one dose of ICI and subsequently stopped treatment without progression for a minimum of 12 weeks were studied. Demographics, disease characteristics and treatment course were examined. **Results:** 40 pts with mMCC were included. Pt characteristics are summarised in Table. Median time on treatment was 13.5 months (range 1 to 35). Median time to best response was 4.5 months (range 1 to 17) and median time receiving treatment after best response was 8 months (range 0 to 29). 25 pts (63%) stopped primarily due to being in a complete or partial response (CR or PR), 9 (23%) due to toxicity and 6 (15%) due to other reasons, primarily pt choice or comorbidities. At time of discontinuation, 30 pts (75%) were in a CR, 8 (20%) in a PR and 2 pts (5%) had stable disease (SD). After a median follow up of 12 months from discontinuation, 14 pts (35%) have progressed (PD); 5 (36%) at a previous site, 5 (36%) at a new site and 4 (29%) at both. PD occurred after a median of 5.5 months (range 4 to 29) off treatment. 4 pts (29%) had a CNS recurrence, none of whom previously had CNS involvement. Pts in CR at time of discontinuation were less likely to progress (CR: 26% PD *vs* non-CR: 67% PD, p=0.044), but still had a considerable rate of PD (CR: 26%, PR: 57%, SD: 100%). Those who progressed had numerically less cycles of ICI prior to treatment cessation (17 *vs* 32, p>0.05). Baseline disease factors, time to best response and duration of treatment after best response were not associated with PD. ICI was restarted in 8 of 14 pts (57%) with PD, with response rate to retreatment of 75% (4 CR, 2 PR, 1 SD, 1 PD – pt with leptomeningeal disease). Median time to best response at retreatment was 3 months (range 2 to 7), with all responses ongoing after a median of 10 months back on treatment. 3 pts had an isolated site of PD successfully treated with radiation therapy and remain in remission off ICI. **Conclusions:** ICI responses in mMCC do not appear as durable off treatment as in other cancers, including in patients who achieve a CR. Ongoing treatment should be considered, though initial data on response to retreatment is promising. Research Sponsor: None.

Toxicity, response, and survival in older adults with metastatic melanoma treated with checkpoint inhibitors.

First Author: Nienke A De Glas, Leiden University Medical Center, Leiden, Netherlands

Background: Checkpoint inhibitors have strongly improved survival of patients with metastatic melanoma. Trials suggest no differences in outcomes between older and younger patients, but only relatively young patients with a good performance status were included in these trials. The aim of this study was to describe treatment patterns and outcomes of older adults with metastatic melanoma, and to identify predictors of outcome. **Methods:** We included all patients aged ≥65 years with metastatic melanoma between 2013 and 2020 from the Dutch Melanoma Treatment registry (DMTR), in which detailed information on patients, treatments and outcomes is available. We assessed predictors of grade ≥3 toxicity and 6-months response using logistic regression models, and melanoma-specific and overall survival using Cox regression models. Additionally, we described reasons for hospital admissions and treatment discontinuation. **Results:** A total of 2216 patients were included. Grade ≥3 toxicity did not increase with age, comorbidity or WHO performance status, in patients treated with monotherapy (anti-PD1 or ipilimumab) or combination treatment. However, patients aged ≥75 were admitted more frequently and discontinued treatment due to toxicity more often. Six months-response rates were similar to previous randomized trials (40.3% and 43.6% in patients aged 65-75 and ≥75 respectively for anti-PD1 treatment) and were not affected by age or comorbidity. Melanoma-specific survival was not affected by age or comorbidity, but age, comorbidity and WHO performance status were associated with overall survival in multivariate analyses. **Conclusions:** Toxicity, response and melanoma-specific survival were not associated with age or comorbidity status. Treatment with immunotherapy should therefore not be omitted solely based on age or comorbidity. However, the impact of grade I-II toxicity in older patients deserves further study as older patients discontinue treatment more frequently and receive less treatment cycles. Research Sponsor: Dutch Research Council (NWO).

Results from the phase Ib of the SENSITIZE trial combining domatinostat with pembrolizumab in advanced melanoma patients refractory to prior checkpoint inhibitor therapy.

First Author: Jessica Cecile Hassel, Department of Dermatology and National Center for Tumor Diseases (NCT), Heidelberg University Hospital, Heidelberg, Germany

Background: Anti-PD-1 +/- anti-CTLA4 antibodies are the current standard of care immunotherapy for advanced melanoma. However, a significant proportion of patients do not achieve disease control. Epigenetic modulation, particularly histone deacetylase (HDAC) inhibition, can overcome tumor escape mechanisms and thus might increase the susceptibility to immunotherapy. **Methods:** Advanced unresectable/metastatic cutaneous melanoma patients primary refractory or non-responding to prior checkpoint inhibitor (CI) therapy were treated with domatinostat at 5 different dose levels (DL) (100 mg (QD), 200 (QD), and 200 mg (BID) using two different schedules (D1-14 and D1-21 q3w) in combination with pembrolizumab (2 mg/kg) q3w to evaluate safety and tolerability. Tumor assessments were performed every 12 weeks and assessed using irRECIST. Sequential tumor biopsies were taken for gene expression analysis and peripheral blood for pharmacokinetic (PK) analysis. **Results:** We report on preliminary results from the phase Ib part of the ongoing study, data cut-off Feb 1st, 2021 a total of 40 patients have been enrolled. Patient characteristics show that the median number of pretreatments at stage IV was 3, 65 % of patients stage M1c (AJCC 7 or 8) and 35 % with elevated LDH at trial inclusion. Treatment emergent adverse events (AEs) related to domatinostat reported in ≥ 10% of patients were: diarrhea (23%), nausea (20%), fatigue (20%), rash (15%), pyrexia (13%), blood alkaline phosphatase increased (13%), vomiting (10%), dyspnea (10%), all grade 1 and 2 - except one maculo-papular rash grade 3. In total, 8 patients (20 %) developed ≥ grade 3 AEs, with no treatment-related deaths. Patterns of AEs resembled the known safety profiles of domatinostat and pembrolizumab with no increase of immune related AEs for the combination. Maximum tolerated dose was not reached. Four patients discontinued treatment per protocol due to AEs grade 3. We observed clinical activity with 1 complete response, 2 confirmed partial responses and 9 stable diseases (6 confirmed), resulting in a disease control rate of 30% in highly pretreated patients throughout all DLs. Notably, 3 out of 7 patients achieved disease control in DL 3 (domatinostat 200 mg BID D1-14, q3w) and were on treatment ≥ 1.5 years, indicating a trend of dose-dependent clinical activity. Domatinostat treatment resulted in a trend to higher intra-tumoral expression of MHC/APM genes and a more inflamed tumor microenvironment reflecting enhanced T cell infiltration. **Conclusions:** The combination of domatinostat and pembrolizumab was safe and well tolerated. The observed clinical activity in advanced melanoma patients refractory to previous checkpoint inhibition and the favorable translational findings warrant further development of domatinostat in combination with CI in melanoma and beyond. Clinical trial information: NCT03278665. Research Sponsor: 4SC AG.

KEYNOTE-629: Health-related quality of life (HRQoL) with pembrolizumab (pembro) in patients (pts) with locally advanced (LA) or recurrent or metastatic (R/M) cutaneous squamous cell carcinoma (cSCC).

First Author: Åse Bratland, Oslo University Hospital, Oslo, Norway

Background: KEYNOTE-629 is a single-arm phase 2 study of pembro for cSCC. At second interim analysis (IA), pembro had robust and durable antitumor activity and manageable safety in LA and R/M cohorts. At first IA, pembro maintained HRQoL in the R/M cohort; LA was not analyzed because of ongoing accrual. HRQoL of pts with LA or R/M cSCC at second IA (database cutoff July 29, 2020; additional 15-mo follow-up since IA1 for the R/M cohort) is shown. **Methods:** Pts with LA or R/M cSCC received pembro 200 mg IV Q3W for ≤35 cycles. HRQoL was a prespecified exploratory end point assessed using EORTC QLQ-30 and EuroQol EQ-5D-5L instruments administered at baseline, wk 3, and wk 6; then Q6W through y 1; then Q9W until treatment end/discontinuation; and at the 30-day safety follow-up. HRQoL was analyzed in pts who received ≥1 pembro dose and completed baseline and ≥1 postbaseline HRQoL assessments. Mean change from baseline in EORTC QLQ-C30 global health status (GHS)/quality of life (QoL), physical functioning (PF), and EQ-5D-5L visual analog scale (VAS) scores were evaluated at wk 12 to ensure adequate completion rate and through last pt visit at wk 75 for EORTC QLQ-C30 GHS/QoL and PF scores. HRQoL was categorized as improved or deteriorated based on ≥10-point change in EORTC QLQ-C30 scores (considered clinically meaningful). **Results:** The HRQoL analysis population for LA had 47 pts for EORTC QLQ-C30 and EQ-5D-5L; the R/M cohort had 99 pts for EORTC QLQ-C30 and 100 for EQ-5D-5L. At wk 12, compliance rates were >75% for LA and >80% for R/M cohorts for EORTC QLQ-C30 and EQ-5D-5L. Mean change from baseline to wk 12 was minimal for EORTC QLQ-C30 GHS/QoL, PF, and EQ-5D-5L VAS scores for both cohorts (Table). Mean change from baseline in EORTC QLQ-C30 GHS/QoL and PF scores remained stable over 48 wk in the LA cohort (75-wk data unavailable) and over 75 wk in the R/M cohort. Most pts had improved or stable EORTC QLQ-C30 GHS/QoL and PF scores relative to baseline during follow-up. **Conclusions:** HRQoL was generally maintained with pembro in LA and R/M cSCC cohorts and was not negatively impacted by tumor progression or AEs. Clinical trial information: NCT03284424. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Checkpoint inhibition in immunosuppressed or immunocompromised patients with advanced cutaneous squamous cell carcinoma (CSCC): Data from prospective CemiplimAb-rwlc Survivorship and Epidemiology (C.A.S.E.) study.

First Author: Guilherme Rabinowits, Department of Hematology/Oncology, Miami Cancer Institute/Baptist Health South Florida, Miami, FL

Background: Immunosuppressed and/or immunocompromised patients are at increased risk for solid tumors and cutaneous malignancies. Limited data exist on the safety and effectiveness of immune checkpoint inhibitors (ICIs) in these patients because they are frequently excluded from clinical trials. Here, we describe the safety and effectiveness results from the initial cohort of immunosuppressed and/or immunocompromised patients with advanced CSCC enrolled in the C.A.S.E. study (NCT03836105). **Methods:** C.A.S.E. is a prospective, real-world, multi-center, longitudinal study evaluating the effectiveness, safety, quality of life, and survivorship in patients with advanced CSCC treated with cemiplimab. Patients received cemiplimab 350 mg intravenously every 3 weeks per routine standard of care. Patient demographics, disease characteristics, immunosuppression, and relevant medical history were collected. Immunosuppressive regimens varied amongst patients. Investigator assessment of objective response rate (ORR), safety, and tolerability was conducted. Data from 26 immunosuppressed and/or immunocompromised patients with advanced CSCC treated with cemiplimab are presented. Recruitment is ongoing. **Results:** As of November 17, 2020, 121 patients were enrolled in the C.A.S.E. study, of which 26 patients (median age: 74 years [IQR: 71-84]; 85% male; 89% Caucasian) were designated as immunocompromised or immunosuppressed due to a history of solid organ transplant (n = 6), autoimmune disorder (n = 11), or hematologic malignancy (n = 9). Median duration of cemiplimab exposure was 14 months (IQR: 9.1–42, range: 0, 67). Among 19 immunocompromised or immunosuppressed patients who enrolled in C.A.S.E. prior to their third dose of cemiplimab, ORR per investigator assessment was 47% (95% CI: 24–71); 1 (5%) patient had complete response; 8 (42%) had partial response. One patient had a treatment-related serious adverse reaction of organ transplant rejection. One (3.8%) patient discontinued treatment due to increased alanine aminotransferase (not treatment-related). Immune-related AEs (irAEs) occurred in 23% of patients. No treatment-related AEs led to death. **Conclusions:** The safety, tolerability, and effectiveness of cemiplimab in this initial cohort of immunosuppressed and/or immunocompromised patients with advanced CSCC appear to be consistent with those observed in clinical trials that excluded these patients. Further follow-up and additional data would add to our general understanding of safety and effectiveness of anti-PD1 therapy in immunocompromised and/or immunosuppressed patient populations overall. Clinical trial information: NCT03836105. Research Sponsor: Regeneron Pharmaceuticals, Inc. and Sanofi.

The influence of harvest method on dendritic cell function and clinical outcomes in a randomized trial of a dendritic cell vaccine to prevent recurrences in high-risk melanoma.

First Author: Alexandra Marion Adams, Brooke Army Medical Center, Fort Sam Houston, TX

Background: A randomized, double-blind, placebo-controlled phase IIb trial of the tumor lysate, particle loaded, dendritic cell (TLPLDC) vaccine was conducted to prevent recurrence in patients (pts) with resected stage III/IV melanoma. Two methods for dendritic cell (DC) harvest were used for vaccine production, including no pretreatment or pretreatment with granulocyte-colony stimulating factor (G-CSF) in an attempt to reduce blood draw volumes. This analysis investigates differences in clinical outcomes and RNA gene expression between these DC harvest methods for TLPLDC vaccine creation. **Methods:** The TLPLDC vaccine is created by loading autologous tumor lysate into yeast cell wall particles (YCWPs) and exposing them to phagocytosis by DCs. By investigator/pt choice, pts had 120mL of blood drawn for DC harvest, or pts received 300μg of G-CSF for pre-DC mobilization and a 50-70 mL blood draw 24-48 hours later. Total vaccine production time was 72 hrs. Pts were randomized 2:1 to receive TLPLDC or placebo (DCs exposed to empty YCWPs). 1-1.5 x10^6 cells/dose were injected intradermally at 0, 1, 2, 6, 12, and 18 months. Differences in disease free survival (DFS) and overall survival (OS) were evaluated by Kaplan Meier analysis between pts who did not receive pretreatment (TLPLDC), pts who did receive pretreatment with G-CSF (TLPLDC+G), and pts receiving placebo. RNA-seq analysis was performed on the total RNA of pts' prepared TLPLDC vaccines to assess gene expression. Relative RNA expression (RRE) was compared between TLPLDC and TLPLDC+G. **Results:** As previously reported, 144 pts were randomized: 103 received TLPLDC (46 TLPLDC, 57 TLPLDC+G) and 41 received placebo. There were no significant clinicopathologic or treatment differences between the three treatment arms. Survival was significantly improved in TLPLDC compared to TLPLDC+G or placebo, including 36-month OS (92.9% vs 62.8% vs 72.3% respectively, p = 0.022) and DFS (51.8% vs 23.4% vs 27.1%, p = 0.027). When compared to TLPLDC+G (n = 3) vaccine, RNA-seq from TLPLDC vaccine (n = 3) showed upregulation of genes associated with DC maturation, including HLA-DMB (RRE: 3.60), IFIT1 (3.38), CD27 (3.26), IFI44L (3.24), MX1 (2.96), HLA-DQA1 (2.67), HLA-DRA (2.40), CD49D (2.34) and CD74 (2.09), while downregulated genes were associated with DC suppression or immaturity including SERPINA1 (RRE:7.8), TLR2 (6.65), CCR1 (5.11), IL10 (4.19), CD93 (3.84) and CD14 (3.25). **Conclusions:** Pts receiving TLPLDC vaccine had significantly improved OS and DFS, while outcomes remained similar between those who received TLPLDC+G vs placebo. Pts who did not receive G-CSF had higher expression of genes linked to DC maturation and antigen processing and presentation, likely explaining the improvement in clinical efficacy. A phase III trial to further assess the TLPLDC vaccine to prevent recurrence is planned. Clinical trial information: NCT02301611. Research Sponsor: Elios Therapeutics.

Survival outcomes associated with fewer combination ipilimumab/nivolumab doses in advanced-stage melanoma.

First Author: Vincent T Ma, University of Michigan, Ann Arbor, MI

Background: Standard combination ipilimumab/nivolumab (I/N) is given as 4 induction doses for advanced stage melanoma. While many patients receive less than 4 doses due to treatment-related toxicities, it is unclear if fewer doses of I/N may still provide long term clinical benefit. Our aim is to determine if response assessment after 1 or 2 doses of I/N can predict long-term survival and if fewer doses of I/N can achieve similar survival outcomes. **Methods:** We performed a single-center, retrospective analysis on a cohort of patients with metastatic or unresectable melanoma from 2012 to 2020 who were treated with standard I/N. Cox regression of progression free survival (PFS) and overall survival (OS) models were performed to assess the relationship between response assessment after 1 or 2 doses of I/N and risk of progression and/or death. Clinical benefit response (CBR) was assessed, defined as SD (stable disease) + PR (partial response) + CR (complete response) by imaging or physical examination. Among patients who achieved a CBR after 1 or 2 doses of I/N, a multivariable Cox regression of survival was used to compare 3 or 4 vs 1 or 2 doses of I/N adjusted by age, gender, pre-treatment LDH level, BRAF mutation status, primary melanoma site, time to initial assessment, brain metastasis, and liver metastasis. **Results:** 199 patients were identified and considered evaluable in our study. Median follow up was 28.8 months. Patients with CBR after 1 dose of I/N had improved PFS (HR: 0.23, 95% CI 0.14-0.39; p<0.001) and OS (HR: 0.19, 95% CI 0.10-0.38; p<0.001) compared to progressive disease (PD) [Table]. Patients with CBR (vs PD) after 2 doses of I/N also had improved PFS (HR: 0.17, 95% CI 0.11-0.26; p<0.001) and OS (HR: 0.13, 95% CI 0.07-0.23; p<0.001) [Table]. The survival risk comparing 3 or 4 vs 1 or 2 doses of I/N were HR 0.82 (95% CI 0.45-1.53; p=0.540) for PFS and HR 0.56 (95% CI 0.24-1.30; p=0.175) for OS. **Conclusions:** Clinical benefit response (CBR) after 1 or 2 doses of I/N may be predictive of long-term survival in advanced stage melanoma. Patients who have CBR after 1 or 2 doses of I/N may achieve a similar survival benefit with fewer doses of I/N. Longer follow up and prospective studies are warranted to validate our findings. Research Sponsor: None.

Complete responders to checkpoint inhibitors in advanced melanoma: Relapse risk factors, and patients' outcomes. *First Author: Amelie Dutheil, Dermatology Unit, Gustave Roussy Cancer Institute, Villejuif, France*

Background: Since the development of immune checkpoint inhibitors (ICI) for advanced melanoma, a small group of patients with an excellent and durable response has emerged. Complete response (CR) is achievable in about 10-20% of the patients and seem to have an excellent prognosis. However, 10 to 15% of them might relapse eventually. Our main objective was to determine factors associated with relapse after a CR to ICI in advanced melanoma. The second objective was to describe relapse modalities and tumor response to subsequent treatments. **Methods:** We performed a single-center, retrospective study, in 141 patients with a CR to ICI for advanced melanoma, treated at Gustave Roussy (France) from January 2010 to June 2020. CR was confirmed on two consecutive CT-scanner or PET-CT at least 3 months apart. Characteristics of the patients at diagnosis, during and after treatment were compared in both groups: CR with relapse and CR without relapse. The LASSO analysis, a statistical analysis using lambda penalization coefficient for prognostic studies, was performed regarding the many statistical variables analysed. **Results:** At data analysis, immunotherapy was interrupted in 94.3% of the patients and the median follow-up was 3.5 years since immunotherapy discontinuation. Eventually, 18 of 141 patients (12.8%) had relapsed and 126 (87.2%) had not. The statistical analysis identified three factors associated with melanoma recurrence: prior lines of therapy, the type of melanoma and the mutation status. Indeed, relapse risk was higher in patients with wild type melanoma (as opposed to BRAF or NRAS mutant melanoma), with a mucosal, acral or unknown primitive melanoma and who received prior lines of treatment. Other factors such as demographical characteristics, tumor burden, metastasis localization, type or grade of toxicity, pseudo progression, type of ICI, treatment duration, use of a complementary local treatment and pursuit/discontinuation of immunotherapy were not statistically associated with the duration of the complete response. In case of melanoma recurrence, reintroduction of immunotherapy provided tumor response in half of our patients: 13 of the 18 relapsing patients received immunotherapy after melanoma recurrence; allowing 3 CR, 2 partial responses and 1 stable disease. One third of the relapsing patients eventually died of disease progression. **Conclusions:** This study confirmed the excellent prognosis of CR to ICI in advanced melanoma, even after treatment discontinuation and identified 3 baseline factors associated with a risk of relapse: absence of BRAF or NRAS mutation, primary of acral, mucosal or unknown origin, and previous lines of therapy. Rechallenge with ICI was effective in 50% of the patients. Research Sponsor: None.

The risk and tropism of central nervous system metastases (CNS) in patients with stage II cutaneous melanoma. *First Author: Paul Johannet, NYU Grossman School of Medicine, New York, NY*

Background: Recent data suggest that patients with stage III melanoma are at high enough risk for developing CNS metastases to consider routine surveillance neuroimaging (Journal of Clinical Oncology; PMID: 31990608). Given that a subset of stage II patients have a worse prognosis than stage III patients, we investigated the risk of developing brain metastases in stage II disease and compared it to the risk in stage III disease. **Methods:** We studied a cohort of prospectively enrolled melanoma patients who had protocol driven follow-up at New York University (NYU) Langone Health. We investigated both the incidence and time to development of CNS metastases, and explored whether the frequency of CNS metastases as a first isolated site of distant disease varies among the different stages. **Results:** The study cohort included a total of 1,102 patients (stage II: n = 619 with median follow-up 56.5 months; stage III: n = 483 with median follow-up 40.9 months). 85/619 (14%) stage II and 91/483 (19%) stage III patients developed CNS metastases (p = 0.03). The estimated 5-year cumulative incidence was 9% in stage IIA, 14% in stage IIB, and 29% in stage IIC patients (p = 0.0001). It was 10% in stage IIIA, 32% in stage IIIB, 23% in stage IIIC, and 49% in stage IIID (p = 0.0001). The CNS was the site of first metastasis for 32/154 (21%) stage II patients who developed distant disease compared to 28/214 (13%) stage III patients (p = 0.06). **Conclusions:** A subset of stage II patients are at an elevated risk for developing CNS metastases within 5 years of their initial diagnosis, which is comparable to that seen in stage III patients. The frequency of the CNS as a first site of metastasis in stage II melanoma suggests a propensity for brain tropism that cannot only be explained by a generalized pro-metastatic phenotype. Surveillance strategies that incorporate serial neuroimaging should be considered for these individuals. Research Sponsor: U.S. National Institutes of Health.

Impact of systemic therapy sequencing on overall survival for patients with advanced BRAF-mutated melanoma. *First Author: B. Adi Kartolo, Division of Medical Oncology, Queen's University, Kingston, ON, Canada*

Background: Both immune checkpoint inhibitors (ICI) and BRAF targeted therapy (TT) are effective treatments for patients with advanced BRAF-mutated melanoma. However, the choice of first-line (1L) therapy is at the discretion of treating oncologists without clear guidance from current available data or established guidelines. Utilizing prospectively collected data from the Canadian Melanoma Research Network (CMRN) database, we provide real-world evidence to highlight the impact of sequencing these therapies. **Methods:** Prospective data from 9 cancer centres in Canada was retrieved from the CMRN database for patients with unresectable/metastatic melanoma, with BRAF targetable subtypes, who received at least one-cycle of 1L palliative-intent ICI or TT, and at least 1-year of follow-up. We categorized patients into 2 groups: 1L BRAF±MEK inhibitors with/without subsequent PD-1±CTLA-4 inhibitors (1L-TT), or vice versa (1L-ICI). The primary study outcome was overall survival (OS). Survival outcomes were analyzed through Kaplan-Meier methods, and multivariable Cox analysis was utilized to account for potential confounders. **Results:** Our study (N=235) included 152 and 83 patients in 1L-TT and 1L-ICI groups, respectively. Combined BRAF-MEK inhibitors accounted for 59% of the 1L-TT group, whereas single-agent IO accounted for 66% of the 1L-ICI group. There were 93 patients who received second-line (2L) therapy, with a non-significant trend of 1L-TT group receiving more 2L therapy compared to 1L-ICI group (65% vs. 43%, P=0.404). Neither treatment group showed significant differences in median time on 1L therapy (P=0.645) or 2L therapy (P=0.686). The 1L-ICI group was associated with a favourable median overall survival (OS) compared to 1L-TT group (19.3 vs. 10.0 months, P=0.031). Specifically, the ICI only group had the highest median OS, followed by TT-ICI sequence, ICI-TT sequence, and TT only groups respectively (not reached vs. 38.3 vs. 16.9 vs. 6.1 months, P<0.001). However, this OS benefit (HR 0.89, 95% 0.51-1.53, P=0.644) was non-significant upon controlling for confounders such as baseline metastatic sites >2 (HR 2.07, 95%CI 1.24-3.46, P=0.006) and ECOG ≥2 (HR 3.47, 95%CI 2.02-5.97, P<0.001) in multivariable Cox analysis. **Conclusions:** There was no significant difference in OS between 1L-TT and 1L-IO groups. Rather, OS is driven mostly by the patient's clinical status and tumour-associated features. Our study provides real-world evidence in an understudied area. Further studies are needed to validate our findings to inform guideline development. Research Sponsor: None.

IL-6 blockade for prophylaxis and management of immune-related adverse events (irAEs) with anti-PD-1 based immunotherapy. *First Author: Florentia Dimitriou, Melanoma Institute Australia, Sydney, Australia*

Background: Immune checkpoint inhibitors (ICIs) have activity across many tumor types, but activation of the immune system may also lead to significant, often steroid-refractory irAEs. We sought to determine the activity of tocilizumab, an anti-IL6R monoclonal antibody (mAb), in treatment or prevention of auto-immune irAE in ICI-treated patients (pts). **Methods:** Institutional databases from 2 melanoma centers were reviewed for pts treated with ICIs and tocilizumab. Treatment and melanoma outcomes were prospectively assessed. Longitudinal assessment of c-reactive protein (CRP) and assessment of clinical improvement (defined as irAE resolution to grade ≤1 CTCAEv5) or prophylaxis (absence of flare, defined as ≥ grade 2) were utilized to evaluate the benefit of tocilizumab. Paired Wilcoxon rank test was used to compare CRP levels prior to ICI administration, at the onset of irAEs and after tocilizumab administration. **Results:** 22 pts were identified. 2 pts were treated prophylactically (pre-existing dermatomyositis [n = 1] and giant cell arteritis [GCA, n = 1]) before the administration of PD1. 20 pts were treated for management of irAEs due to PD1 +/-CTLA4 (multiple concurrent irAEs [n = 3], steroid refractory irAES [hepatitis & pancreatitis, n = 2], steroid+anti-TNFα refractory colitis [n = 2], steroid+other immunosuppressive-refractory hepatitis [n = 1], cytokine release syndrome-related AEs [n = 6], musculoskeletal irAEs [n = 6]). 15 (68.2%) pts with irAEs required hospitalization and of those, 13 (86.7%) received tocilizumab whilst inpatient. Median time to irAE onset from ICI start was 48 days (range 8-786) and from irAE onset to tocilizumab administration 32 days (range 1-192). Median time to irAE resolution from tocilizumab administration was 7 days (range 1-799). Clinical improvement/benefit was demonstrated in 21/22 patients; one patient with ir-hepatitis did not respond. Median CRP prior to ICI administration was 32mg/L (range 0.3-99), at the onset of irAE 49.5mg/L (range 0.3-251, p = 0.055) and after the tocilizumab administration 18mg/L (range 0.3-18, p = 0.0015). Tocilizumab was well tolerated with self-limiting and transient toxicities in 17 (77.3%) patients. There were two grade 4 events; gastrointestinal tract perforation and Fournier gangrene, the latter unrelated to tocilizumab. Two (9%) patients died due to melanoma. From start of ICI, median progression-free survival (PFS) was 5.88 months and median overall survival (OS) was not reached. **Conclusions:** Tocilizumab was a well-tolerated and effective steroid-sparing treatment for both management of irAEs, as well as prevention of a flare of pre-existing auto-immune disorders during ICI administration. Prospective trials to evaluate its efficacy and impact on cancer outcomes compared with standard strategies are required. Research Sponsor: None.

Safety and efficacy of HX008: A humanized immunoglobulin G4 monoclonal antibody in patients with locally advanced or metastatic melanoma—A single-arm, multicenter, phase II study. *First Author: Bin Lian, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: HX008 is a new recombinant humanized anti-PD-1 monoclonal antibody, belonging to human IgG4 / kappa subtype, which can selectively block the binding of PD-1 with its ligands PD-L1 and PD-L2. **Methods:** In this single arm phase 2 trial, eligible patients (pts) were aged from18 to 75, who previously failed with conventional treatment for locally advanced or metastatic melanoma, with an ECOG performance status of 0 or 1 and had measurable lesions according to the RECIST criteria (V1.1). Ocular melanoma, brain metastasis or previous use of anti PD-1 ab were excluded. Pts received HX008 3mg/kg every 3 weeks, until disease progression, intolerable toxicity or treatment discontinuation for any other reasons. The primary endpoint was ORR according to RECIST criteria, and the secondary endpoints were OS, PFS, DCR and the toxicity. The iRECIST criteria would also be used in the evaluation of response and treatment discontinuation. Clinical trial information: NCT04749485. **Results:** From Oct 2018 to Jan 2021, 119 pts have been eligible and enrolled. Basic characteristics: median age 59 years; 57 males (42.9%) ; stage 22%, stage 78%; primary: acral 52.1%, mucosal 19.3%, cutaneous 18.5% and unknown 10.1%; Gene mutation status: Braf 10.9%, Nras 9.2%, cKit 4.2%; condition of previous treatments: 67.26%, 25.21%,7.56% pts had received 1st, 2nd and 3rd line or above treatments respectively (chemotherapy 69.7%, targeted therapy 15.1%, immunotherapy 43.7%). The ORR according to RECIST V1.1 and iRECIST was 18.49% (1CR, 21 PR , 95% CI 11.96-26.64) and 20.17% (1 iCR, 23 iPR ,95% CI 13.37-28.50), respectively. For PD-L1 positive pts the ORR was 15.09% (95%CI 6.75-27.60) and 12% for negative (95%CI 10.98-32.83). For different subtypes, the ORR was 36.36% for cutaneous melanoma, 14.52% for acral primary, 8.7% for mucosal primary, and 25% for unknown primary. The DCR and iDCR was 44.54% and 47.06% , respectively. With a median follow up time of 13.2 months, the median PFS was 3.25 months (95% CI 2.0, 4.1) and the PFS rate at 1 year was 25.8% (95%CI 17.19,35.33). The median OS was 17.91 months (95% CI 13.08,NR) and the OS rates at 1 year was 63.9% (95% CI 53.02, 73.00). Median DOR has not reached and the DOR and iDOR rates at 1 year were 80.64% and 87.39%, respectively. TRAEs occurred in 89.9% of the pts, with grade 3/4 AEs 31.9%, the followings were those incidences ≥1%, hyperglycemia (2.5%), elevated aspartate aminotransferase (1.7%), elevated serum bilirubin (1.7%), elevated serum creatine phosphokinase (1.7%), elevated lipase (1.7%), hypoalbuminemia (1.7%), hypokalemia (1.7%) and diabetic ketoacidosis (1.7%). **Conclusions:** HX008 shows its efficacy and safety in locally advanced or metastatic melanoma pts in the treatments of 2nd line or above. Randomized controlled studies are now on pending. Clinical trial information: NCT04749485. Research Sponsor: Taizhou Hanzhong biomedical co. LTD.

Encorafenib plus Binimetinib in patients with locally advanced, unresectable or metastatic BRAF^{V600}-mutant melanoma: First data of the multicenter, multinational, prospective, non-interventional longitudinal study BERING^{MELANOMA}. *First Author: Erika Richtig, Department of Dermatology, University of Graz, Graz, Austria*

Background: For the treatment of advanced BRAF^{V600}-mutated melanoma, targeted therapy (BRAF/MEK-inhibition) is a standard of care. Encorafenib + binimetinib (EB) were approved in the EU in Sep 2018 and in Switzerland in Nov 2019, based on positive results from COLUMBUS (NCT01909453), with a median progression-free survival (PFS) of 14.9 mo (4-year PFS: 26%) and overall survival (OS) of 33.6 mo (4-year OS: 39%). As data from controlled trials are based on selected populations, BERING^{MELANOMA} investigates the use of EB under real-world conditions in a broader population. **Methods:** BERING^{MELANOMA} is an ongoing, multi-national, multi-center, prospective, longitudinal, non-interventional study. It analyzes the effectiveness, quality of life and tolerability of EB-treatment under real-world conditions (primary endpoint: 1-year PFS-rate), focusing on the first- (1L) and second-line setting and including an evaluation of the impact of prognostic factors. The project aims to enroll up to 750 patients (pts) in a total of 80 German, Austrian and Swiss sites with a study duration of 8 yrs. So far, from Oct 2019 to Jan 2021, 153 pts have been included. Pts with prior BRAF-/MEK-inhibition (except adjuvant use completed > 6 mo) and > 1 prior treatment line were excluded. **Results:** Here we present the first planned interim analysis based on the initial 100 enrolled pts (91 treated / 89 evaluable; median follow-up: 8.1 mo). This analysis set shows a median age of 63.0 yrs (range 29.0-88.0), 52% of pts were female. 81% presented with distant metastases (brain: 31%), with an involvement of ≥3 organ systems in 51% and an elevated LDH in 42%. 54% of pts underwent prior systemic therapy (adjuvant: 28%; 1L: 24%, with ipilimumab + nivolumab as main 1L-treatment: 52%). EB was mainly administered in the 1L-setting (65%). Main reasons for EB-selection were: physician's preference (37%), efficacy (34%), quality of life (21%). Median estimated EB treatment duration was 12.7 mo (95%CI 8.3-NE), median relative dose intensity was 100% for both drugs. Treatment adaptations were required in 34% of pts. Adverse events (AE) were reported in 76% of pts (grade 3/4: 26%). Main AE (≥10%, all grades) were: nausea (18%), diarrhea (17%), CK increase (15%), fatigue (11%), gamma-GT increase (11%). No fatal toxicities were observed. **Conclusions:** This first interim analysis of BERING^{MELANOMA} shows an investigation of EB in a real-world population with advanced disease. Despite the poorer prognosis configuration as compared to the pivotal study, the observed treatment duration and tolerability profile are largely consistent with data derived from COLUMBUS without any new safety signals. The second interim analysis will be performed after enrollment of 200 pts and will include an initial analysis of effectiveness data. Clinical trial information: NCT04045691. Plasma thymidine kinase activity (TKa) as a novel prognostic biomarker in metastatic melanoma. *First Author: Hildur Helgadottir, Department of Oncology-Pathology, Stockholm, Sweden*

Background: In the recent decade, new effective immunotherapies and targeted therapies have emerged for the treatment of disseminated melanoma. However, a considerable fraction of patients does not respond or get lasting effects and the treatments also have significant side effects. Biomarkers can contribute with more knowledge on prognosis and the efficacy of these therapies in different patients. In other cancer types, the plasma activity of the enzyme thymidine kinase (TKa), has been demonstrated as a marker of tumor stage and prognosis. The TK enzyme is part of a reaction chain to introduce thymidine into the DNA strand. TK thereby has a key function in DNA-synthesis, -repair and cell division. Dividing cells release TK during mitotic exit and TK can thus be detected in the blood. This study is the first to investigate plasma TKa as a potential biomarker in melanoma patients. **Methods:** Plasma samples were collected within five days prior to treatment start in patients with unresectable metastatic cutaneous melanoma, treated with immunotherapy (anti-CTLA-4 and/or anti-PD-1) or targeted therapy (BRAF±MEK inhibitors). Plasma TKa levels were determined using the DiviTum TKa ELISA assay (Biovica, Sweden). TKa levels were correlated with the patients' baseline criteria, response rate (RR), progression free survival (PFS) and overall survival (OS). **Results:** Among the 124 study patients, the median TKa was 50 Du/L (range < 20-3491 Du/L). Significantly higher plasma TKa levels were found in patients with ECOG performance status ≥1 vs. 0-1 ($P<$ 0.001), M1c-d vs. M1a-b disease ($P<$ 0.001), ≥3 vs. 1-2 affected organs ($P=$ 0.002) or elevated vs. non-elevated LDH ($P<$ 0.001). In the patients treated with immunotherapy (n = 86) the RR was 63.2% vs. 37.9% in those with low (< 60 Du/L) vs. high TKa ($P=$ 0.024). The median PFS and OS was 19.9 and > 60 months in those with low TKa vs. 12.6 and 18.5 months in those with high TKa (HR for PFS: 1.73 (95% CI, 1.01-2.97), $P=$ 0.044 and HR for OS: 2.16 (95% CI, 1.17-3.98), $P=$ 0.011). In the patients treated with BRAF±MEK inhibitor (n = 38) a similar trend was observed, with shorter PFS and OS in those with high TKa, but the differences were not statistically significant. **Conclusions:** In this first study on plasma TKa in melanoma patients, high pretreatment TKa was significantly associated with poor baseline factors and poor response and survival in immunotherapy treated patients. Currently, plasma LDH is the only non-clinical factor that is routinely used as a prognostic marker in melanoma. Several other candidate markers have been described, such as PD-L1 tumor immunohistochemistry, tumor mutational burden, gut microbiome and circulating tumor DNA. Compared to these assays, TKa measured with DiviTum is a simpler, ELISA based test for a single plasma marker. TKa is hence a novel and interesting marker in melanoma and should be further studied to define its role as a prognostic and predictive marker in this disease. Research Sponsor: Swedish Cancer Society.

9557 **Poster Session**

Outcomes of non-treatment naive melanoma patients with central nervous system relapse. *First Author: Thiago Pimentel Muniz, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Melanoma has a high probability of central nervous system (CNS) spread. Although first line nivolumab and ipilimumab resulted in 56% response rate and 29.2 months median overall survival (OS) in patients with melanoma brain metastases (MBM), there is paucity of data for patients who develop MBM after prior systemic therapy. As this subgroup is often underrepresented in clinical trials, we aimed to evaluate the OS of non-treatment naïve patients who develop MBM and identify factors related to survival. **Methods:** In this single-center, retrospective study, consecutive melanoma patients with > 90 days from exposure to either immune checkpoint inhibitor (ICI), targeted therapy (TT), or chemotherapy, to CNS relapse were included. OS was defined as the time between CNS relapse and death by any cause. The Log-Rank method was used to calculate OS. Cox regression analysis was used to identify differences between subgroups. Variables with a p value < 0.1 were included in a multivariate model. A p value < 0.05 was considered statistically significant. **Results:** Between 2012 and 2018, 135 patients were identified. Median age was 57 (29-92) years, 92 (68%) were male, and median number of prior systemic therapies was 2 (1-6). One-hundred and nine (81%) patients had cutaneous melanoma; acral lentiginous melanoma (ALM) comprised 11 (8%) patients. Molecular studies were available for 123 patients, of whom 61 (50%) were *BRAF* V600 mutant. Eighty-nine (66%) patients had prior ICI, of whom 33 (37%) had prior exposure to both anti-PD1 and anti-CTLA-4, either as monotherapy or combination. Amongst the *BRAF* V600 mutant population, 48 (79%) had prior TT. Radiotherapy was given to 112 patients, of whom 55 (49%) had SRS. Median follow-up was 41 (95% CI 30-51) months. Median OS was 6.4 (95% CI 5.3-7.5) months. Patients with ALM, > 3 MBM, ECOG 2-4 and active treatment at CNS relapse (< 30 days from last dose of treatment to MBM diagnosis) were at increased risk of death, whilst subsequent treatment with ICI was related to better survival (Table). On multivariate analyses, age (p = 0.007), subtype (p = 0.04), number of MBM (p = 0.01), active treatment at CNS relapse (p < 0.001) and subsequent ICI (p = 0.002) remained statistically significant. Exploratory analyses suggested subsequent treatment with anti-PD1 + anti-CTLA-4 (n = 42) compared favourably to subsequent anti-CTLA-4 only (n = 21) (13 x 7 months, p = 0.004), and was independent of prior ICI. **Conclusions:** Previously treated melanoma patients who develop MBM have a poor prognosis, but subsequent ICI therapy seems to be associated with better OS. Further clinical investigation to identify optimal anti-PD1-based therapies is warranted for non-treatment naïve patients who develop MBM. Research Sponsor: None.

Variable	HR (IC 95%)	p value
ALM subtype (vs. other cutaneous)	2.3 (1.02-5.1)	0.04
> 3 MBM	1.7 (1.07-2.8)	0.02
ECOG 2-4	2.7 (1.4-5.0)	0.001
Active Treatment	2.3 (1.4-4.0)	0.001
Subsequent ICI	0.3 (0.2-0.5)	< 0.001

BRAF and _NRAS_ mutation status and response to checkpoint inhibition in advanced melanoma. *First Author: Olivier Jules van Not, University Medical Center Utrecht, Leiden, Netherlands*

Background: The ability to analyze tumor mutation profiles has altered the oncology treatment landscape over the past decades. However, little is known about the effect of specific gene mutations on the response to immune checkpoint inhibitors (ICIs) in patients with advanced melanoma. **Methods:** All unresectable stage IIIc and IV patients with *BRAF* V600, *NRAS* mutations and *BRAF* and *NRAS* wild-type patients treated with anti-PD-1 or ipilimumab-nivolumab between 2012 and 2020 were included from the Dutch Melanoma Treatment Registry, a nationwide population-based registry. Outcomes were objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). A Cox model was used to analyze the association of possible prognostic factors with PFS and OS. **Results:** In total 1358 first-line patients treated with anti-PD-1 and 524 treated with ipilimumab-nivolumab were included. Median follow-up was 25.6 months for anti-PD-1 treated patients and 16.3 months for ipilimumab-nivolumab treated patients. The highest ORR, in first-line, to anti-PD-1 was in patients who were *BRAF* and *NRAS* wildtype (50.2%), compared to *BRAF* V600 (43.8%) and *NRAS* mutated patients (49.8%). ORR to ipilimumab-nivolumab was highest in *NRAS* mutated patients (44.9%), while ORR was 39.5% for *BRAF* mutated patients and 40.3% for wild-type patients. Median PFS in the anti-PD-1 treatment regimen was significantly higher ($p = 0.049$) for double wild-type patients (16.7 months) patients than for *BRAF* mutated patients (9.9 months) and *NRAS* mutated patients (11.3 months). PFS was not significantly different ($p = 0.11$) in the ipilimumab-nivolumab treatment cohort, with a median PFS of 6.5 months for the wild-type group, 10.8 months for the *BRAF* group, and 9.1 months for the *NRAS* group. In the anti-PD-1 treated patients, median OS was significantly higher ($p < 0.001$) for *BRAF* mutated patients (32.8 months) compared to *NRAS* (21.0 months) and wild-type patients (23.0 months). For ipilimumab-nivolumab treated patients, median OS was also significantly higher ($p < 0.001$) for *BRAF* mutated patients (36.5 months) than for *NRAS* mutated patients (11.8 months) and wild-type patients (16.1 months). After adjustment for potential confounders, the presence of a *BRAF* mutation remained associated with lower PFS in the anti-PD-1 treatment cohort and better OS in both treatment cohorts. Higher age, higher ECOG score, elevated LDH levels, liver metastases and brain metastases were associated with worse survival. **Conclusions:** PFS in first-line PD-1 was significantly higher for double wild-type patients than for *BRAF* mutant and *NRAS* mutant patients. PFS in ipilimumab-nivolumab treated patients did not significantly differ between *BRAF* mutant, *NRAS* mutant and double wild-type patients. OS was significantly higher for *BRAF* mutant patients in both treatment strata, which is probably the result of the subsequent BRAF/MEK-inhibition treatment option in this group. Research Sponsor: None.

A phase 1b clinical trial of anti-PD-1 ab (Toripalimab) plus intralesional injection of OrienX010 in stage melanoma with liver metastases. *First Author: Jun Guo, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Liver metastasis was associated with reduced responses and PFS in melanoma patients (pts) treated with anti-PD-1 monotherapy, which is probably due to reduced marginal CD8+ T cell infiltration. Oncolytic virotherapy was found to increase CD8+ T cell infiltration in the injected lesions and improve the efficacy of anti-PD-1 ab in a phase 1b trial. We hypothesized that intratumoral oncolytic virus injection for liver metastasis in melanoma combined with systemic anti-PD-1 therapy might improve the efficacy, thus conducting this phase 1b trial with intratumoral OrienX010 - a HSV-1-derived oncolytic virotherapy with expression of GM-CSF combined toripalimab in liver metastatic melanoma pts. **Methods:** Eligible pts included those over 18 with injectable liver metastasis confirmed by biopsy with or without extra-hepatic metastasis; ocular melanoma and brain metastasis were excluded. Pts received intravenous toripalimab Q2W combined with ultrasound guided intratumoral injection of OrienX010 Q2W (8×10^7 pfu/ml, 10ml per injection) until intolerance or disease progression per iRECIST criteria. Liver biopsy would be performed at baseline and first tumor evaluation (8-12weeks). The primary endpoint was toxicity; secondary endpoints included ORR, DCR and PFS. Clinical trial information: NCT04206358. **Results:** From Jul 2019 to Dec 2020, 15 pts were eligible and enrolled. Baseline characteristics: median age 62 yrs; primary: mucosal 60%, cutaneous 20%, unknown primary 13.3%, acral 6.7%; gene mutation status: Braf 20%, Nras 6.7%; 73.3% got extra-hepatic metastasis: regional or distant lymph node 46.7%, lung 20.0%; LDH > ULN 20%; median size of injected lesions: 32mm(10-83mm); median number of liver metastasis: 4(1-10); median number of injection: 10 (3-36). AEs were all grade 1/2: pyrexia 86.7%, rigor 66.7%, elevated transaminase 53.3%, nausea/vomiting 40.0%, fatigue 26.7%. No grade 3-4 AEs. The ORR by investigator was 13.3% (2/15), DCR 46.7% (7/15); the response rate was 40%(6/15) for injected lesions, 28.5%(4/14) for non-injected lesions in liver, and 23% (3/13) for extra-hepatic metastasis. For biopsies of injected lesions at 8 to 12weeks, 30%(2 PR and 3 SD) showed no melanoma cells residual by immunohistochemistry, 46.7% got impressive TIL infiltration (Brisk n = 4 and Nonbrisk n = 3 according to the definition of AJCC 8th edition) compared with baseline in which all showed absence of TIL infiltration, also a large number of plasma cells, histiocyte and pigment were found with hyaline fibrosis. The PFS has reached 72 weeks for one PR pt. The median PFS was not reached. **Conclusions:** Systemic toripalimab combined with intrahepatic OrienX010 injection has shown remarkable pathological responses with good tolerance in melanoma liver metastases. Survival is still in follow-up. Clinical trial information: NCT04206358. Research Sponsor: Oriengene Biotechnology Ltd.

Pyrexia-related outcomes upon application of an adapted pyrexia management algorithm in patients (pts) with _BRAF_ V600: Mutant unresectable or metastatic melanoma treated with dabrafenib plus trametinib (DabTram) in the COMBI-i trial. *First Author: Paolo Antonio Ascierto, Melanoma, Cancer Immunotherapy and Development Therapeutics Unit, Istituto Nazionale Tumori-IRCCS Fondazione "G. Pascale", Naples, Italy*

Background: First-line DabTram has shown long-term efficacy in pts with *BRAF* V600–mutant unresectable or metastatic melanoma in the Phase III COMBI-d and COMBI-v trials. Data from the Phase III COMBI-i trial comparing spartalizumab plus DabTram vs placebo plus DabTram (pbo-DabTram) demonstrated efficacy in the pbo-DabTram arm, consistent with historical data. Pyrexia (single preferred term [PT]) is the most common adverse event (AE) reported with DabTram (pooled COMBI-d [data cutoff: Jan 12, 2015] and COMBI-v [data cutoff: Apr 17, 2014]: any grade, 54.2%; grade ≥ 3, 5.4%; serious pyrexia AEs leading to hospitalization, 11.8%). A new pyrexia management algorithm was implemented in the COMBI-i trial to improve pyrexia-related outcomes. We report pyrexia-related outcomes in pts treated with pbo-DabTram in the control arm of COMBI-i part 3. **Methods:** COMBI-i (NCT02967692) part 3 is a double-blind, Phase III trial in which pts with previously untreated *BRAF* V600–mutant unresectable or metastatic melanoma were randomized 1:1 to receive spartalizumab (400 mg intravenously every 4 weeks) plus Dab (150 mg orally twice daily) and Tram (2 mg orally once daily) vs pbo-DabTram. In the adapted pyrexia management algorithm, both Dab and Tram are interrupted promptly at the first symptom of pyrexia or its associated prodrome (ie, chills, rigors, night sweats, or influenza-like symptoms). Treatment at the same dose level is restarted upon the improvement of symptoms if pts are symptom free for ≥ 24 hours. Pyrexia incidence rates presented are for the single PT of pyrexia. **Results:** At data cutoff (July 1, 2020), median follow-up was 27.2 mo for all pts enrolled in COMBI-i part 3 (N = 532). In the DabTram control arm, 52.7% (139/264) and 3.0% (8/264) of pts had any-grade and grade ≥ 3 pyrexia, respectively. Serious pyrexia AEs were reported in 6.1% (16/264), which led to hospitalization in 5.3% (14/264). Pyrexia led to dose interruption of both Dab and Tram in 39.0% (103/264), with 1.5% (4/264) permanently discontinuing both agents. Median relative dose intensity was 97.8% for Dab and 97.7% for Tram. **Conclusions:** Pyrexia-related outcomes, including grade ≥ 3 pyrexia (3.0% vs 5.4%) and serious pyrexia AEs leading to hospitalization (5.3% vs 11.8%), were improved in pts treated with DabTram in COMBI-i part 3 compared with historical data from COMBI-d/v. The adapted algorithm offers a simplified approach for managing pyrexia, thereby reducing the incidence of severe pyrexia while maintaining consistent efficacy with DabTram. Clinical trial information: NCT02967692. Research Sponsor: Novartis.

Treatment outcomes in patients (pts) with melanoma brain metastases (MBM) treated with systemic therapy: A systematic literature review (SLR) and meta-analysis. *First Author: Hussein Abdul-Hassan Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The introduction of immunotherapy and targeted therapy has revolutionized the treatment landscape for metastatic melanoma. However, clinical trial data in pts with MBM are scarce; here we summarize the available clinical evidence. **Methods:** An SLR was conducted by searching EMBASE, MEDLINE, and the Cochrane Central Register of Controlled Trials databases through November 13, 2020. When available, KaplanMeier (KM) curves for overall survival (OS) were digitized and converted to pseudo-individual pt data using the Guyot algorithm. A meta-analysis of the pooled KM curves was performed for selected interventions, including immunotherapies and targeted therapies. Median OS was calculated either through the meta-analysis of KM curves or as a weighted average of median OS (table). When interventions were reported in only 1 study, the value reported was used instead of the weighted average and compared qualitatively with the other results. Results for treatment modalities other than systemic agents will also be presented. **Results:** The SLR included 70 publications that evaluated systemic therapies in pts with MBM for qualitative evidence synthesis: 12 pertaining to 7 randomized controlled trials, 55 pertaining to 46 single-arm studies, and 3 involving nonrandomized comparative studies. The pt population was highly heterogeneous with respect to prior therapies, pt characteristics, and neurological symptoms. For the meta-analysis, a total of 25 KM curves from 12 studies representing 6 interventions and 1043 pts were digitized. Based on the pooled KM curves, median OS was numerically longer with nivolumab plus ipilimumab (NIVO + IPI; 28.3 mo; 95% CI, 19.731.9) than with the other interventions (range 5.711.8 mo; table). Similar OS benefit was also observed with NIVO + IPI when the weighted average of the median was used (in a long-term study, median OS was 29.2 mo) compared with the other interventions. **Conclusions:** Given the lack of comparative clinical trial data in pts with MBM, there remains an unmet need to determine the best approach to treat these pts. This analysis suggested a clinical advantage with NIVO + IPI compared with other systemic agents analyzed. The heterogeneity of the available data added uncertainty to our treatment assessments. Therefore, these findings warrant further research into the best approach to improve outcomes in pts with MBM. Research Sponsor: Bristol Myers Squibb.

Efficacy of cetuximab after immunotherapy (IO) in advanced cutaneous squamous cell carcinoma (CSCC). *First Author: Julian Andres Marin-Acevedo, Moffitt Cancer center, Tampa, FL*

Background: Anti-PD1 (aPD1) monotherapy with cemiplimab-rwlc or pembrolizumab is now considered standard of care for first-line management of advanced CSCC not amenable to surgery or curative radiotherapy. Previously chemotherapy or anti-EGFR agents were commonly used for these patients albeit with modest efficacy and limited duration of response. In prospective evaluation, the overall response rate (ORR) to cetuximab was 28% with disease control rate (DCR) of 69% at 6 weeks. The efficacy of second-line treatment following primary or acquired resistance to aPD1 therapy is not known. We investigated the activity of cetuximab in patients who progressed on previous IO therapy. **Methods:** We performed a single institution retrospective review from 9/28/18 (US approval date of cemiplimab-rwlc for CSCC) through 11/30/20 of patients with locally advanced or metastatic CSCC who received cetuximab after prior IO therapy. We identified patients who received cetuximab either immediately following IO therapy (cohort A) or as a subsequent line not immediately following IO therapy (cohort B). Primary endpoint was ORR with secondary endpoints of DCR, survival and toxicity. Median follow-up and survival times were calculated using the Kaplan-Meier method. **Results:** Thirteen patients, median age 72 years (62-82), all Caucasian, and 11 males (85%) were included in this study. Eleven pts received cetuximab immediately post-IO progression; two had additional intervening therapy post-IO before receiving cetuximab. Three patients received concurrent radiotherapy (palliative or definitive) with cetuximab. The ORR to cetuximab was 54% (7/13) including 1 complete and 6 partial responses. The cumulative 6-month DCR was 77%. All responses were observed in cohort A; both patients in cohort B had progressive disease as best response. Six of 7 initial responses are ongoing, including 3 in whom cetuximab was discontinued. At a median follow-up of 9.1 months, the median PFS has not been reached for the entire cohort. There were no unanticipated toxicities to cetuximab with rash (77%) and hypomagnesemia (54%) being the most common adverse events. **Conclusions:** In advanced CSCC, cetuximab used immediately after progression on aPD1 therapy yields notably higher and durable overall response than previously reported in the pre-IO therapy era. If validated in a larger dataset, this should be the preferred therapy for second-line treatment in advanced CSCC. Further exploration into the mechanism of this high efficacy of anti-EGFR therapy post aPD1 therapy is warranted. Research Sponsor: None.

External validation of a Dutch predictive nomogram for complete response to T-VEC in an independent American patient cohort. *First Author: Emma H.A. Stahlie, Department of Surgical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Talimogene Laherparepvec (T-VEC) is a genetically modified herpes simplex type 1 virus and known as an effective oncolytic immunotherapy for injectable cutaneous, subcutaneous, and nodal melanoma lesions in stage IIIB-IVM1a patients. Recently, Stahlie et al. published (Cancer Immunol Immunother '21) a model for predicting a complete response (CR) to T-VEC based on 3 easily accessible tumor characteristics identified using univariable and multivariable logistic regression analysis. The aim of this study was to externally validate this model in an independent, American patient cohort. **Methods:** A total of 76 patients with stage IIIB-IVM1a melanoma treated with T-VEC at Moffitt Cancer Center were included. A second nomogram was built incorporating the same predictive factors: tumor size (diameter of largest metastasis in mm), type of metastases (cutaneous, subcutaneous and nodal) and number of metastases (cut-off: <20 and >20). Predictive accuracy was assessed through calculation of overall performance, discriminative ability, and calibration. Outcomes and previously published outcomes were compared. Statistical analyses were done using R software. **Results:** Overall performance of the validation dataset nomogram was calculated with the Brier score and found to be 0.195, demonstrating good overall performance and similar to the original model Brier score of 0.182. Discriminative power, assessed by calculating the area under the receiver operating characteristic (ROC) curve was similar for both models, 0.767 and 0.755 for the NKI and Moffitt, respectively, resulting in a fair discriminative ability. The calibration curve showed mostly slight underestimation for predicated probabilities >0.37 and slight overestimation <0.37. **Conclusions:** An independent dataset externally validated a recently published predictive nomogram for CR to T-VEC in stage IIIB-IVM1a melanoma, with both models resulting in overall performances that were comparable and good. The second model reinforces the conclusion that for the best response to T-VEC, it should be used early on in the course of the disease, when the patient's tumor burden is cutaneous with smaller diameter and fewer of metastases. Research Sponsor: None.

Outcomes of BRAF mutant metastatic melanoma (MM) patients (pts) after cessation of targeted therapy (TT) with BRAF or BRAF/MEK inhibitor(i). *First Author: Natalie Jackson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Since their introduction into the clinic a decade ago, BRAF and BRAF/MEKi have dramatically changed the outcomes of pts with BRAF mutant MM. While typically, these agents are administered until progression (PD), other reasons for stopping TT include unacceptable toxicity, complete response to treatment, or pt/physician decision or preference. The outcomes for MM pts that stop TT for reasons other than PD are largely unknown. Here we report the clinical features and outcomes of the largest cohort of MM pts who stopped TT for reasons other than PD to date. **Methods:** Under an institutionally approved database, we identified MM pts treated at the MD Anderson Cancer Center with BRAF±MEK inhibitors, and their records were reviewed to identify pts that stopped TT for reasons other than PD. Pts demographics, treatment information and clinical outcomes were recorded. Overall survival (OS) time was computed from three start dates (initial diagnosis, initial unresectable stage III melanoma, 1st dose of TT) to last known vital sign. Pts alive at the last follow-up date were censored. Time to recurrence was computed from date of 1st dose of TT to recurrence. Pts who did not experience disease recurrence were censored The Kaplan-Meier method was used to estimate OS and time to recurrence. **Results:** A total of 58 pts were identified, 32 (55%) were male. Most pts had a BRAF V600E (n = 49) or V600K (n = 6) mutation. At TT initiation median age was 59.5 years (range 29- 95), LDH was within normal range in 46 (85%), median number of prior systemic therapies was 1 (range 0-5), with 50% of pts receiving prior systemic therapy. Most (n = 33; 57%) pts were treated with single agent BRAFi (12 with dabrafenib, 11 vemurafenib). Among pts treated with combination TT (n = 25), most received dabrafenib with trametinib (n = 21; 84%). Median TT treatment duration was 9.5 months (range 0.03-80.5 months). Reasons for TT discontinuation were unacceptable toxicity (n = 29; 50%) and pt or physician decision/preference in responding patients (n = 23; 40%). At time of TT discontinuation, 48% of pts had achieved a complete response (CR), 28% a partial response (PR), and 22% stable disease (SD), 1 patient had unknown disease status. With standard follow-up, after stopping TT, 40 pts (69%) have recurred or experienced PD, with a median time to recurrence of 14.9 months (95% CI:7.8-26.3 months). At PD, 32 (76%) of pts had new metastatic sites. After PD 26 pts (63%) pts received BRAF/MEKi, 11 (44%) achieved a CR and 6 (24%) a PR, and 5 (20%) for a response rate of 88%; while 3 (12%) pt had PD as best response and 1 was unknown. For the full cohort, the median OS from time of 1st dose of TT was 6.4 years. **Conclusions:** Among MM pts who stopped TT for reasons other than PD, the majority of pts recurred, but most responded to re-introduction of TT. This information can help to inform discussion with pts regarding cessation of, or re-challenge with, TT. Research Sponsor: Cancer Center Support Grant.

Multicentre retrospective assessment of toxicity and response to immunotherapy in elderly patients with metastatic melanoma. *First Author: Shivanshan Pathmanathan, Department of Oncology, Gold Coast University Hospital, Gold Coast, QLD, Australia*

Background: The incidence of melanoma increases with age, however, elderly patients remain under-represented in landmark immunotherapy trials for metastatic melanoma. This study aims to investigate the impact of age on efficacy and toxicity of immunotherapy, and complications of immunosuppression to treat toxicity. **Methods:** A multicentre retrospective study involving centres in Australia [Gold Coast University Hospital, Cairns Base Hospital, Townsville University Hospital] was performed to compare the efficacy and toxicity of immunotherapy in metastatic melanoma in patients ≥70 years versus patients < 70 years treated between 2015 and 2019. Data collected included: baseline demographics, PFS, OS, Grade 3 or higher (Gr3+) adverse events as per CTCAEv5, adverse events leading to discontinuation, duration of steroids used to treat toxicity and complications secondary to steroids. Comparison of survival outcomes between the groups was calculated using Kaplan Meier, Log rank test and multivariate Cox regression analysis. Fisher exact test was used to determine differences in toxicity between the two groups. **Results:** A total of 229 patients were included with 106 patients ≥70years and 123 patients < 70 years. Baseline demographics were similar. Dual immunotherapy (ipilimumab + nivolumab) was less commonly used in patients ≥70years [13 v 38% p < 0.001]. Although the median PFS was numerically higher amongst ≥70years [10.8 v 6.9months p = 0.99], the landmark PFS was not [3yr PFS: 31 v 39%; 4yr PFS: 22 v 39%]. The median OS was similar in patients ≥70 years v < 70years [27.5 v 28.7 months p = 0.91], with similar landmark survival [3yr OS: 46 v 49%; 4yr OS: 42 v 49%]. Age was not associated with a difference in overall survival on multivariate analysis. There was no increase in Gr3+ adverse events in patients ≥70 years [22 v 21% p = 1.00] or discontinuation rates [26 v 20% p = 0.35]. There was one death in a patient < 70years secondary to colitis. There was a significantly higher rate Gr3+ adverse events in ≥70years patients receiving dual immunotherapy [71 v 35% p = 0.029] and a similar rate of Gr3+ adverse events with PDL1 inhibitors [13 v 11% p = 0.7]. Median duration of steroids was similar in both group [15 v 17wks], as was the median duration of high dose steroids defined as greater than 10mg of prednisone [5 v 6wks]. Complications of steroids was numerically higher in the elderly population [42 v 25% p = 0.15]. The most common adverse event to immunosuppression was infection. **Conclusions:** Patients ≥70years received similar benefit from immunotherapy in comparison to their younger counterparts. Toxicity related to PDL1 inhibitors was similar in both groups and was higher in patients ≥70years receiving dual immunotherapy. Patients ≥70 years had a clinically significant higher rate of complications secondary to steroids. Research Sponsor: None.

Health-related quality of life (HRQoL) in patients (pts) with locally advanced basal cell carcinoma (laBCC) treated with cemiplimab: Analysis of a phase II, open-label clinical trial. *First Author: Alexander J. Stratigos, University of Athens, A. Sygros Hospital, Athens, Greece*

Background: Cemiplimab-rwlc is the first immunotherapy to receive approval in the US, fully for pts with laBCC and accelerated for metastatic BCC, post hedgehog inhibitors or for whom hedgehog inhibitors are not appropriate. Cemiplimab resulted in clinically meaningful anti-tumor activity in pts with laBCC who progressed on or were intolerant to hedgehog inhibitor therapy (NCT03132636). This analysis evaluated HRQoL in these pts. **Methods:** Adults with laBCC and ECOG performance status ≤1 (n=84) received IV cemiplimab 350 mg Q3W for up to 9 treatment cycles. At baseline (BL) and day 1 of each cycle (C), pts completed EORTC QLQ-C30 and SKINDEX-16 questionnaires that assess Global Health Status (GHS)/QoL, functioning, and BCC-related symptoms. Mixed-effects repeated measures (MMRM) models were used to estimate least squares (LS) mean (standard error [SE]) change from BL during treatment (i.e., across C2 to C9); changes ≥|10| points were considered clinically meaningful. Responder analyses were conducted in pts with non-missing data from BL to determine the proportions with clinically meaningful improvement or deterioration, or stability on QLQ-C30 and SKINDEX-16 at C2 and C9; a 10-point threshold was considered meaningful for both instruments. **Results:** BL scores showed moderate to high levels of functioning and low symptom burden. In MMRM models, overall changes from BL on QLQ-C30 indicated stability for GHS/QoL and all scales except for clinically meaningful worsening of fatigue (LS mean [SE] change 12.5 [3.9]; $P<.05$). In responder analysis, the majority of pts reported clinically meaningful improvement or stability at C2 and C9 on all QLQ-C30 functioning scales and the key symptom of pain but not fatigue (**Table**). On SKINDEX-16, MMRM models showed clinically meaningful improvement on the emotional subscale (LS mean [SE] change −13.2 [3.9]; $P<.05$) and stability on the symptom and functional subscales. Responder analysis showed clinically meaningful improvements or stability across the SKINDEX-16 subscales in approximately 80% of pts at C2, and 70–80% of pts at C9. **Conclusions:** In laBCC pts treated with cemiplimab, the majority reported clinically meaningful improvement or stability in GHS/QoL and functional status while maintaining a low symptom burden except for fatigue. Clinical trial information: NCT03132636. Research Sponsor: Regeneron Pharmaceuticals, Inc. and Sanofi.

Pathology of durable stable disease in melanoma patients treated with ipilimumab, nivolumab, or ipilimumab, and nivolumab combination therapy. *First Author: Elizabeth Iannotti Buchbinder, Dana-Farber Cancer Institute, Boston, MA*

Background: As immunotherapy with checkpoint blockade becomes the backbone of melanoma treatment there is a need to better understand the biology associated with long term benefit. One particularly interesting set of patients are those with prolonged stable disease or response with residual findings on imaging. It is unknown if immunotherapy has led to scarring at the site of prior disease or if there are residual tumor cells being controlled by an ongoing immune response. Evaluating tissue from patients with prolonged responses provides a unique opportunity to determine the composition of residual lesions. Correlation with PET/CT helps determine if this is an accurate modality to reflect presence of residual viable tumor tissue. **Methods:** Metastatic melanoma patients that have attained long term stable disease after treatment with ipilimumab, nivolumab, or ipilimumab plus nivolumab were identified. Patients must have received ipilimumab, nivolumab or combination therapy 2+ years prior to enrollment and must have had stable disease for ≥ 6 months. Patients were consented and underwent PET/CT scans and biopsies of residual areas of stable disease. Pre- and post-treatment tissue samples underwent pathologic assessment to look at tumor cell content, fibrotic content, and inflammation. **Results:** Ten patients were consented for evaluation but only 7 met the screening criteria and underwent PET/CT and tissue biopsy. Six patients had FDG avid lesions on PET/CT which ranged in intensity from SUV 2.4-22. One patient had no FDG avidity in the areas of residual disease observed on CT. Biopsies from the residual stable lesions demonstrated predominantly necrosis and fibrosis with prominent pigment containing macrophages. One patient with an axillary nodal lesion with an SUV of 22 had active melanoma on pathology which was resected, and the patient has subsequently remained without progression of disease. **Conclusions:** Patients with durable stable disease after treatment with ipilimumab, nivolumab or ipilimumab and nivolumab combination therapy represent a unique population of melanoma patients treated with immune checkpoint inhibition. An examination of the residual lesions observed in these patients demonstrated predominantly necrosis and fibrosis consistent with resolving lesions. The presence of melanophages in these samples may suggest some ongoing immune surveillance. One patient did demonstrate residual melanoma suggesting the need for ongoing monitoring of this patient population. Research Sponsor: Bristol Myers. Squib.

Tumor PD-L1 expression and gene panel mutational profile as outcome predictors of PD-1-based checkpoint inhibition therapy in metastatic melanoma: A prospective multicenter DeCOG study. *First Author: Selma Ugurel, Department of Dermatology, University Hospital Erlangen and Department of Dermatology, University of Würzburg, Essen, Germany*

Background: PD-1 checkpoint inhibition (CPI) has recently advanced to one of the most effective treatment strategies in melanoma. However, since a considerable proportion of patients shows upfront therapy resistance, baseline predictive biomarkers of therapy outcome are needed. **Methods:** This prospective multicenter study included metastatic melanoma patients whose formalin-fixed paraffin-embedded tumor tissue samples taken prior to the start of a systemic non-adjuvant therapy of any line were analyzed for PD-L1 expression on tumor cells by immunohistochemistry (clone 28-8, DAKO) and for COSMIC-annotated oncogenic mutations by 29-gene panel sequencing (MiSeq, Illumina). Clinical baseline and follow-up data were collected within the DeCOG multicenter skin cancer registry ADOREG. **Results:** From 09/2015 until 10/2020, 706 enrolled patients from 15 centers were evaluable for the endpoints best overall response (BOR), progression-free (PFS) and overall survival (OS). Thereof, 540 patients received PD-1-based CPI as first systemic treatment after tumor tissue analysis. 197/540 patients tested positive for PD-L1 (cut-off = 5%) in pre-treatment tumors, and revealed a favourable BOR (objective response 34.4% versus 19.1%; $p < 0.0001$), PFS (median 10.4 versus 4.2 months; $p < 0.0001$) and OS (median 45.1 versus 18.8 months; $p = 0.001$) compared to patients with PD-L1 negative tumors. 47/540 patients presented oncogenic mutations of three or more genes in pre-treatment tumors, and revealed a favourable BOR (objective response 46.8% versus 32.1%; $p = 0.041$), PFS (median 15.1 versus 6.1 months; $p = 0.008$) and OS (median not reached versus 25.2 months; $p = 0.027$) compared to patients whose tumors showed mutations in two or less genes. Multivariable Cox regression including sex, primary site, non-adjuvant systemic pre-treatment, serum LDH, and ECOG performance state demonstrated tumor PD-L1 expression and gene panel mutational profile as independent predictors of survival upon treatment with PD-1-based CPI. In contrast, in 106/706 patients treated with BRAF/MEK inhibitors as first systemic treatment after tumor tissue analysis, no association was found between tumor PD-L1 expression or gene panel mutational profile and therapy outcome. **Conclusions:** PD-L1 expression quantification and gene panel mutational profiling provide useful outcome predictors of PD-1-based CPI therapy in metastatic melanoma patients. Analysis of patients (pts) with in-transit metastases treated with nivolumab (NIVO) or ipilimumab (IPI) in CheckMate 238. *First Author: James Larkin, The Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom*

Background: In the phase 3 CheckMate 238 study, NIVO has demonstrated improved recurrence-free survival (RFS) and distant metastasis-free survival (DMFS) vs IPI in pts with resected stage IIIB–C or IV melanoma, which was sustained at the 4-y analysis. Having in-transit metastases/satellites (ITM) is a poor prognostic factor, and pts with ITM are generally omitted from clinical trials. This study was the first and only adjuvant checkpoint inhibitor trial to include pts with ITM. Here, we present post hoc outcomes in this subgroup. **Methods:** Pts aged ≥15 y with completely resected stage IIIB–C or IV melanoma stratified by stage and tumor PD-L1 status were randomized 1:1 to NIVO (3 mg/kg Q2W; n = 453) or IPI (10 mg/kg Q3W for 4 doses, Q12W thereafter; n = 453) for a maximum of 1 y or until disease recurrence/unacceptable toxicity. Pts with ITM, with or without synchronous nodal involvement, were included. The primary study endpoint was RFS; overall survival (OS) was a secondary endpoint; and DMFS was exploratory. **Results:** Each of the 2 treatment groups had 164 pts with ITM. Baseline characteristics were generally similar between treatment groups in pts with or without ITM; in pts with ITM vs without ITM, tumor ulceration was less frequent in NIVO-treated pts, and fewer IPI-treated pts had PD-L1 expression ≥5%. RFS and DMFS favored NIVO vs IPI in all ITM subgroups (table). OS was similar to the intention-to-treat (ITT) population with no differences noted between treatment groups or between ITM subgroups. Among pts with or without ITM, dominant metastatic sites were lung and lymph nodes, followed by brain, liver, and soft tissue (in varying order). Similar metastasis patterns were observed in pts with ITM regardless of nodal involvement. Treatment-related adverse events (any grade and grade 3/4) in pts with ITM were similar to those of the ITT population. **Conclusions:** Results of this post hoc 4-y analysis of CheckMate 238 showed that safety and efficacy were similar in pts with or without ITM, supporting the use of adjuvant NIVO in pts with ITM, regardless of nodal involvement. Clinical trial information: NCT02388906. Research Sponsor: Bristol Myers Squibb, Pharmaceutical/Biotech Company.

A phase Ib clinical trial of neoadjuvant OrienX010, an oncolytic virus, in combination with toripalimab in patients with resectable stage IIIb to stage IVM1a acral melanoma. *First Author: Xuan Wang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/ Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Metastatic acral melanoma is very difficult to treat. Unlike cutaneous melanoma, acral melanoma responds poorly to checkpoint inhibitors in monotherapy. OrienX010 is a granulocyte-macrophage colony-stimulating factor expressing herpes simplex type-1 derived oncolytic virus. It has shown robust efficacy in metastatic acral melanoma, and may improve the response to checkpoint inhibitors. To evaluate the role of OrienX010 in combination with checkpoint inhibitors in acral melanoma, we conducted a Phase Ib neoadjuvant trial of OrienX010 in combination with the anti-PD-1 monoclonal antibody toripalimab in resectable stage IIIB-IVM1a acral melanoma (NCT04197882). **Methods:** Patients with resectable stage IIIB-IV M1a acral melanoma received neoadjuvant intratumoral OrienX010 up to 10 mL of 8 x 10^7 pfu/mL and intravenous toripalimab 3 mg/kg every 2 weeks for 4 – 6 doses prior to surgical resection. After resection, adjuvant toripalimab 3 mg/kg was administered every 3 weeks for up to 1 year. The primary endpoints were radiographic response rate per RECIST 1.1 and pathological response rate (pCR and pPR). The secondary endpoints were 1- and 2-year recurrence-free survival, and safety. **Results:** Between July 2019 and Jan 2021, 30 patients with regional metastatic acral melanoma were enrolled. Median age was 56.5 years, 14 (47%) were male, 19 (63%) had recurrent disease, and stage IIIB 12 (40%), IIIC 14 (47%), and IVM1a 4 (13%). Median tumor burden was 28mm (range, 10-80mm), and only 5 (17%) patients had melanoma mutations (2 cKIT, 1 NRAS, 2 BRAF). To date, of 24 patients who completed neoadjuvant treatment, 21 (88%) underwent surgery. Three (12%) patients did not undergo surgery due to disease progression prior to surgery and 6 patients are still receiving neoadjuvant treatment. Radiographic responses were seen in 10 (33%) patients. However, 17 of 21 (81%) patients showed pathologic responses in resected metastases, with 3 (14%) showing a pCR and 14 (67%) a pPR. Pathologic responses were associated with greater lymphoid infiltrate, hyaline fibrosis, and decrease in Ki-67 expression in the metastasis. At a median follow-up of 8.9 months, none of the patients who underwent resection have recurred. The neoadjuvant treatment was well tolerated, with all patients experiencing at least 1 treatment related adverse event (TRAE) and Grade 1 fever was most common . Three (10%) patients had a grade 3-4 TRAE, including 1 alanine aminotransferase increase and 2 wound infections. **Conclusions:** Neoadjuvant treatment with OrienX010 and toripalimab in resectable stage IIIB-IVM1a acral melanoma was well tolerated and produced a high pathologic response rate. To date, no patients have recurred, and recurrence-free survival evaluation is ongoing. This combination therapy warrants further evaluation in acral melanoma. Clinical trial information: NCT04197882. Research Sponsor: Oriengene Biotechnology Ltd.

Management of resected stage III/IV melanoma with adjuvant immunotherapy. *First Author: Rebecca Johnson, Melanoma Institute Australia, Sydney, Australia*

Background: Adjuvant anti-PD1 therapy reduces the risk of recurrence in resected stage III/IV melanoma and is now standard care. Limited data exist beyond registration trials. We sought to explore the use of adjuvant immunotherapy in routine clinical practice. **Methods:** Patients (pts) from 11 Australian centres who received adjuvant nivolumab (nivo) for resected stage III/IV melanoma were included in this study. Efficacy, toxicity, surveillance, recurrence characteristics, management and further treatment outcomes were examined. **Results:** 471 pts received adjuvant nivo between 8/2018 to 3/2020. 318 (68%) were male, median age 64y (range 17-94), 28 (6%) were AJCC v8 IIIA, 194 (41%) IIIB, 175 (37%) IIIC, 11 (2%) IIID, and 63 (13%) IV. 65 (14%) pts had in-transit only disease, 152 (37%) pts were sentinel lymph node biopsy (SLNB+) and only 9 (6%) of these had CLND. 128 (27%) had BRAF mutant (BRAFmt) melanoma. Median time from resection to start of adjuvant nivo was 1.8 months (mo) (range 0.2-4.0). Median FU was 17.5 mo. 256 (54%) pts completed 12 months of nivo, 86 (18%) ceased early for toxicity, 76 (16%) for disease recurrence, 25 (5%) other reasons (COVID-19 8, co-morbidities 7, pt choice 10); 28 (6%) pts were still receiving nivo at data cut. Median duration of treatment was 10.4 mo (range 0-16.8). 117 (25%) pts recurred; 76 (65%) while ON nivo and 41 (35%) OFF nivo ($>$ 1 month after last dose, including 20 pts who stopped early for toxicity). 24 mo RFS was 69%. Median time to recurrence was 6.0 mo (95% CI 5.1, 7.5). 56 (48%) had first recurrence with locoregional (LR) disease only and 61 (52%) had distant +/- LR recurrence. Of those who recurred with LR disease only, 46/56 (82%) underwent surgery, 15/46 (33%) then had adjuvant radiotherapy, and 15/46 (33%) had 'second adjuvant' therapy with BRAF/MEK inhibitors (15/21, 71% BRAFmt pts). 10/56 (37%) pts who recurred with LR disease subsequently recurred distantly. 58/80 (73%) pts received systemic therapy at either 1st or subsequent unresectable recurrence. For recurrences ON nivo, 18 pts received combination ipilimumab (ipi) and nivo (ORR 44%), 4 pts had ipi monotherapy (ORR 0%), 7 pts had anti-PD1 + investigational agent (ORR 57%), 11 pts had BRAF/MEK inhibitors (ORR 82%). 1 pt had PD with ongoing PD1 monotherapy. For recurrences OFF nivo, no patients responded to PD1 alone (n = 1) or with an investigational agent (n = 1), ipi+nivo (n = 3), ipi monotherapy (n = 4) or chemotherapy (n = 2); 6 pts received BRAF/MEK inhibitors (ORR 50%). 2-year OS was 92%. **Conclusions:** Despite higher rates of discontinuation due to toxicity compared with clinical trial cohorts, the efficacy data appear similar. Most early recurrences are distant, and many with LR recurrence soon recur distantly thereafter. Second line adjuvant BRAF/MEK inhibitors are frequently used for resected LR recurrence. Both ipi+nivo and BRAF/MEK inhibitors appear to have activity after distant recurrence. Research Sponsor: None.

Propensity weighted indirect treatment comparison of nivolumab (NIVO) versus placebo (PBO) as adjuvant therapy for resected melanoma: A number needed to treat and overall survival analysis. *First Author: Jeffrey S. Weber, Laura and Isaac Perlmutter Cancer Center, NYU Langone Health, New York, NY*

Background: The CheckMate 238 trial demonstrated that NIVO improved recurrence free survival (RFS) vs. ipilimumab (IPI). The EORTC 18071 trial demonstrated that IPI improved RFS and overall survival (OS) vs. PBO. The current study pooled data from these two trials to indirectly assess the RFS and OS of NIVO vs. PBO and the numbers needed to treat (NNTs) for one additional recurrence-free survivor and survivor over 4 years. **Methods:** Patients with resected AJCC 7th edition stage IIIB/C cutaneous melanoma from CheckMate 238 (NIVO vs. IPI) and EORTC 18071 (IPI vs. PBO) were pooled together with inverse probability weighting to balance between-trial differences in baseline characteristics. NNTs were calculated for RFS and OS comparing NIVO vs. IPI and PBO over 4 years. To account for improved post-recurrence survival over time, a sensitivity analysis that adjusted for post-recurrence survival in the PBO arm of EORTC 18071 was performed. **Results:** A total of 278, 643, and 365 patients treated with NIVO, IPI, and PBO, respectively, were included. In the weighted samples, patients treated with NIVO had consistently higher RFS rates than those treated with IPI (HR [95% CI]: 0.69 [0.56, 0.85]) and PBO (HR: 0.49 [0.39, 0.61]). NIVO was associated with similar OS as IPI (HR: 0.80 [0.60, 1.08]) and superior OS compared to PBO (HR: 0.45 [0.33, 0.60]). At 4 years, the weighted RFS rate was 53.1% for NIVO, 41.8% for IPI, and 29.1% for PBO. The NNT to achieve one additional recurrence-free survivor was 4.2 for NIVO vs. PBO and 8.9 for NIVO vs. IPI. The NNT to obtain one additional survivor was 4.8 for NIVO vs. PBO and 22.2 for NIVO vs. IPI. The OS rate for PBO after adjusting for differences in post-recurrence treatments at 4 years was 64.1%, and the corresponding NNT of OS comparing NIVO vs. adjusted PBO was 8.5. **Conclusions:** In patients with resected AJCC 7th edition stage IIIB/C cutaneous melanoma, this indirect comparison showed that NIVO improved RFS and OS vs placebo, with OS improvement maintained after adjustment for post-recurrence therapy. Research Sponsor: Bristol Myers Squibb.

NNT in patients with resected stage IIIB/C cutaneous melanoma.

Adjuvant anti-PD-1 ab (Toripalimab) versus high-dose IFN-a2b in resected mucosal melanoma: A phase randomized trial. *First Author: Chuanliang Cui, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Immunotherapies including anti PD-1 ab and high-dose IFN-a2b (HDI) have been approved for adjuvant therapies in resected cutaneous melanoma, but their roles in mucosal melanoma are still unknown. To determine the efficacies of toripalimab versus HDI as adjuvant therapy in patients (pts) with resected mucosal melanoma, this open-label, phase randomized trial was conducted. **Methods:** Mucosal melanoma pts who have undergone complete resections of localized with or without regional lymphatic disease were randomly (1:1) assigned to receive HDI ($15x10^6$ IU/m^2/d1-5/w/ 4weeks IH, followed by $9x10^6$ IU tiw IH) or toripalimab (3mg/kg intravenously q2w) for 52 weeks unless disease recurrence, unacceptable toxicity or consent withdrawal. Head and neck primary would receive adjuvant radiotherapy within 6-8weeks after enrollment. The primary end point was RFS in the intention-to-treat population. Data cutoff was December 10, 2020. Clinical trial information: NCT03178123. **Results:** From Jul 2017 to May 2019, 187 pts were screened, and 145 were randomized into HDI group (n = 72) and toripalimab group (n = 73). The median age was 58years; M:F 37.2%: 62.8%; localized disease 80.7%, regional lymphatic disease 19.3%; local excision ± CLND 37.2%, wide excision ± CLND 62.8%; head and neck primary 39.3%(87.5% received adjuvant radiotherapy); PDL-1positive 51.0%(CPS≥1%, 22C3), PDL-1 negative 49.0%. There was no difference in baseline characteristics between two groups. At a median follow-up of 31.5 months, there were 93 RFS events (43 in HDI group vs. 50 in toripalimab group), 76 DMFS events (35 vs. 41respectively) and 65 OS events (30 vs. 35 respectively). The median RFS, DMFS and OS were shown in the table. In the HDI group, 32.6% of pts received anti PD-1 ab in the following treatment. Grade 3/4 AEs were reported in 83.3% of pts in HDI group (most decrease of leukocytes or neutrophils) and 15.1% of pts in toripalimab group (mainly increase of amylase or liver enzymes). Discontinuations of treatment due to any AE occurred in 20. 8% of HDI group and 15.1% of toripalimab group. **Conclusions:** Both adjuvant toripalimab and HDI therapy improve RFS of mucosal melanoma. Toripalimab shows longer RFS in PDL1 (+) subgroup and better tolerance than HDI. Clinical trial information: NCT03178123. Research Sponsor: Shanghai Junshi biosciences Co.

Association of health-related quality of life (HRQoL) and treatment safety with nivolumab (NIVO) in patients (pts) with resected stage IIIB/C or IV melanoma: Analysis of CheckMate 238 four-year follow-up (FU) data.

First Author: Jeffrey S. Weber, Laura and Isaac Perlmutter Cancer Center, NYU Langone Health, New York, NY

Background: In CheckMate 238, NIVO 3 mg/kg vs ipilimumab 10 mg/kg showed significantly longer recurrence-free survival and a lower rate of grade 3–4 treatment-related adverse events (TRAEs) in pts with completely resected stage IIIB/C or IV melanoma. This analysis assessed the association of long-term HRQoL and TRAEs in NIVO-treated pts in this trial. **Methods:** HRQoL was assessed using EORTC QLQ-C30 (global health status [GHS] and physical/emotional functioning) and EQ-5D-3L visual analogue scale (VAS) questionnaires administered after randomization, during 1 y of treatment (wk 5, 7, 11, 17, 25, 37, and 49), at posttreatment FU visits 1 and 2 (FU1 and FU2; 30 and 114 days after last dose), and at survival FU visits up to 4 y after last dose (EQ-5D-3L only). NIVO-treated pts were grouped based on whether they had experienced a grade 3–4 TRAE, any-grade TRAE leading to NIVO discontinuation, or any-grade select (immune-related) TRAE on treatment or up to 100 days after last dose. Longitudinal change from baseline (BL) in scores was assessed for pts with and without TRAEs having patient-reported outcome data at BL and ≥1 post-BL assessment (HRQoL population) using descriptive statistics. QLQ-C30 subscale and VAS changes of 10 and 7, respectively, were considered clinically meaningful. **Results:** The HRQoL population comprised 446 of 453 pts randomized to NIVO. EQ-5D-3L assessments were completed by 81% of survivors (263/324) after 4 y post-randomization. Grade 3–4 TRAEs occurred in 17% of NIVO-treated pts (77/446). A slight trend toward deterioration of GHS from BL on treatment was noted, with clinically meaningful deterioration at posttreatment FU1 (mean [SD], −13.8 [25.0]) and FU2 (−10.3 [22.0]; last available time point). For the VAS, a similar trend on treatment was noted (−6.9 [28.3] at wk 11), with a clinically meaningful deterioration after NIVO discontinuation (−9.9 [27.0] at FU1) and a return to BL level by the start of survival FU. For pts without grade 3–4 TRAEs, mean change from BL scores remained stable (ie, no clinically meaningful deterioration on treatment or during FU). Any-grade TRAEs led to NIVO discontinuation in 9% of pts (42/446); HRQoL findings were similar to those for pts with grade 3–4 TRAEs. The most common any-grade TRAE was fatigue (35%). No clinically meaningful deterioration in VAS was noted for any select TRAE during FU except for hyperthyroidism (8%), with which deterioration occurred at FU1. EORTC QLQ-C30 physical and emotional functioning results will be presented. **Conclusions:** In CheckMate 238, pts with TRAEs showed early HRQoL deterioration after NIVO discontinuation, but HRQoL returned to BL levels with no sustained deterioration during survival FU. Overall, HRQoL was maintained on treatment and over a long-term FU period in pts with resected melanoma receiving adjuvant NIVO. Clinical trial information: NCT02388906. Postoperative radiotherapy in Merkel cell carcinoma (MCC).

First Author: Sonja Levy, Department of Medical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: MCC is a rare and aggressive neuroendocrine malignancy of the skin. Postoperative radiotherapy (PORT) is recommended by current guidelines to reduce recurrences and improve survival in patients with locoregional MCC. However, evidence supporting these recommendations is conflicting and deviations from the protocol occur frequently, due to the generally elderly and frail patient population. We aim to evaluate the influence of PORT on survival in stage I-III MCC patients treated in the Netherlands. **Methods:** All patients with stage I-III MCC treated in three referral centers between 2013 and 2018 were included retrospectively. Recurrence free survival (RFS) and disease specific survival (DSS, including death from unknown causes) were compared between patients with and without PORT. Prognostic factors for DSS were analyzed using Kaplan-Meier curves, logrank test and cox regression. Since sentinel node biopsies (SN) are frequently omitted in this patient population, analyses were performed in patients with clinical (SN not performed) stage I/II (c-I/II-MCC), pathologic (SN negative) stage I/II (p-I/II-MCC) and stage III MCC (III-MCC), separately. Propensity score matching (PSM) was performed to assess possible confounding by indication. **Results:** In total 219 patients were included, of whom 54 had p-I/II-MCC, 82 had c-I/II-MCC and 83 had III-MCC. Median follow up time was 53.4 (IQR 32.8-62.4), 28 (11.8-43.3) and 30.8 (19.5-50.0) months, respectively. PSM identified no confounding by indication, analyses were therefore performed in the unmatched cohort. Majority of recurrences were regional in p-I/II-MCC (77.8%) and c-I/II-MCC (74.2%), and distant in III-MCC (61.7%). RFS was significantly different across all stages ($p<0.001$), DSS was similar for patients with c-I/II-MCC and III-MCC, which was significantly worse compared to patients with p-I/II-MCC (p=0.003). Survival times are shown in table. PORT did not improve RFS and DSS in patients with p-I/II-MCC and c-I/II-MCC. In patients with III-MCC, PORT was associated with improved RFS, but not with DSS. Multivariable analysis identified male gender (hazard ratio (HR) 1.94, p=0.030), performance status (PS) of 3 (HR 3.87, p=0.014) and an unknown PS (HR 5.45, p=0.004), primary tumor on the trunk (HR 2.67, p=0.008), c-I/II-MCC (HR 5.38, p=0.001) and III-MCC (HR 6.44, $p<0.001$) as predictors for DSS. Effect of PORT was not significant. **Conclusions:** In this retrospective cohort PORT did not show a DSS benefit in patients with stage I-III MCC. RFS was improved by PORT in III-MCC. PSM showed no confounding by indication. Research Sponsor: None.

Isolated same-basin lymph node recurrence after precision lymph node excision for clinically evident melanoma metastasis.

First Author: Kevin Lynch, University of Virginia Health System, Charlottesville, VA

Background: While management of the nodal basin for melanoma has largely moved to observation for microscopic sentinel lymph node (SLN) metastasis, complete lymph node dissection (CLND) remains the current standard of care for melanoma patients with macroscopic, clinically detectable lymph node metastases (cLN). As CLND is associated with high surgical morbidity, we sought to study whether cLN may be safely managed by excision of only clinically abnormal nodes (precision lymph node dissection, PLND). Currently, a small subset of patients with cLN do not undergo CLND because of frailty or patient preference. We hypothesized that in these selected patients, PLND would provide acceptable regional control rates. **Methods:** Retrospective chart review was conducted at four academic tertiary care hospitals to identify melanoma patients who underwent PLND for cLN. cLN were defined as palpable or radiographically abnormal nodes. Recurrences were categorized as local/in-transit, same-basin lymph node, or distal lymph node/visceral. The primary outcome was isolated same-basin recurrence after PLND. **Results:** Twenty-one patients underwent PLND for cLN without synchronous distant metastases (characteristics of primary lesions summarized in Table). Reasons for forgoing CLND included patient preference (n=8), imaging indeterminate for distant metastases (n=2), comorbidities (n=4), loss to follow up (n=1), partial response to checkpoint blockade (n=1), or not reported (n=5). The inguinal node basin was the most common site (n=10), followed by the axillary (n=8) and cervical basins (n=3). A median of 2 nodes were resected at PLND, and 68% of resected nodes were positive for melanoma (median: 1, range: 1-3 nodes). Median follow-up was 23 months from PLND, and recurrence was observed in 28.6% of patients overall. Only 1 patient (4.8%) developed an isolated same-basin recurrence. The 3-year cumulative incidence of isolated same-basin recurrence was 5.3%, while risk of isolated local/in-transit recurrence or distant basin/visceral metastasis were 19.8% and 33.3%, respectively. Complications from PLND were reported in 1 patient (4.8%) and were limited to post-operative seroma and lymphedema. **Conclusions:** These pilot data suggest that PLND may offer acceptable regional disease control for cLN. Post-operative morbidity from PLND was also low, raising the possibility that PLND may provide adequate regional disease control without the morbidity associated with CLND. These data justify additional, prospective evaluation of PLND in selected patients. Research Sponsor: None.

Evaluation of patients with surgically resected high-risk melanoma receiving adjuvant therapy in routine clinical practice in the United States.

First Author: Michael B. Atkins, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC

Background: The management of patients with resected stage III melanoma has changed in recent years, and real-world data on recurrence patterns and adjuvant therapy responses are scarce. This study assessed adjuvant treatment patterns and outcomes in patients with advanced melanoma by *BRAF* status and relapse location. **Methods:** Patients diagnosed with stage III advanced melanoma between January 2011 and February 2020 in the nationwide Flatiron Health electronic health record–derived deidentified database were included if they were ≥18 years, received approved first-line (1L) adjuvant therapy after January 2018 with checkpoint inhibitors (CPIs; eg, nivolumab, pembrolizumab) or targeted therapies (TTs; eg, dabrafenib/trametinib), had 6 months' follow-up and had ≥1 visit after starting adjuvant therapy (Cohort 1). Patients from Cohort 1 were included in Cohort 2 if they had a recurrence following initiation of adjuvant therapy, and those from Cohort 2 were included in Cohort 3 if they had a distant recurrence and available documented *BRAF* status at any time. Time to next systemic treatment (TTNT), overall survival (OS) and relapse free survival (RFS) were estimated using Kaplan-Meier (KM) methods from adjuvant therapy start (Cohort 1), first recurrence date (Cohort 2) or first distant recurrence date (Cohort 3). **Results:** Cohort 1 included 447 patients receiving 1L adjuvant therapy; Cohort 2 included patients after first distant (n = 47) or local (n = 35) relapse; Cohort 3 included distant-recurrent patients with tumors that were *BRAF* wild type (WT) (n = 22) or *BRAF* mutant (n = 23). The majority of patients were aged < 65 years. Across cohorts, relative use of TTs vs CPIs was similar: Cohort 1 (4.5% vs 96%), Cohort 2 (2.4% vs 98%) and Cohort 3 (2.2% vs 98%). Nivolumab was the most frequent treatment used across cohorts (84%-88%). In Cohort 1, 1- and 2-year KM probabilities for OS, RFS and TTNT were 93.5%/83.8%, 83.2%/70.6% and 84.0%/62.4%, respectively. In Cohort 2, for patients with local recurrence, 6- and 12-month OS probabilities were 93.4% and 78.8%, respectively, which were substantially higher than those for patients with distant recurrence (64.5% and 46.9%). In Cohort 3, for patients with documented *BRAF* mutations, 6- and 12-month OS rates from disease recurrence were 79.1% and 49.4%, respectively, which were greater than for those with *BRAF*-WT tumors (54.1% and 46.3%). **Conclusions:** Early RFS and OS outcomes for patients with surgically resected Stage III melanoma appear comparable to those reported in randomized clinical studies. The majority of patients with advanced melanoma, including patients who experienced recurrence, initiated treatment with CPIs. OS rates were numerically greater for Cohort 3 patients with *BRAF*-mutant tumors. Outcomes for patients with distant recurrence after adjuvant therapy remain unfavorable and represent a continued unmet medical need. Research Sponsor: Genentech, Inc.

9578 **Poster Session**

Efficacy of adjuvant radiotherapy in recurrent melanoma after adjuvant immunotherapy.

First Author: Prachi Bhave, Westmead Hospital, Sydney, NSW, Australia

Background: Adjuvant (adj) radiotherapy (RT) halves the risk of locoregional (LR) recurrence in patients (pts) with high risk stage III melanoma after lymphadenectomy (CLND), however its role in the adj immunotherapy (IO) era without CLND is unknown. **Methods:** Pts with resected stage III melanoma who received adj IO and recurred with resectable LR only disease were studied. After resection of this 1st recurrence, adj RT may or may not have been administered. Disease characteristics, treatment at relapse and outcomes were examined. **Results:** 71 pts from 9 centres were included. Prior to adj IO, median age was 60y, 59% male, 56% BRAF mutant, 61% stage IIIC (AJCC V8), 52% underwent CLND and 17% had in-transit (IT) only disease. Adj IO included: 90% single agent anti-PD1, 8% ipilimumab-nivolumab (IN) and 1% nivolumab or IN (blinded on trial). Median duration of adj IO was 5 months. 21(30%) pts had high risk stage III disease at diagnosis, per previously established TROG criteria; 3 (4%) received upfront adj RT prior to recurrence. Median time to 1st recurrence was 7 months. 49 (69%) pts recurred during and 22 (31%) after cessation of adj IO. At 1st recurrence, 9 (13%) pts had stage IIIB disease, 55 (77%) IIIC, 7 (10%) IIID and 8 (11%) continued prior adj IO, 31 (44%) commenced therapy and 32 (45%) had no systemic therapy. 24 (34%) pts received adj RT after resection of 1st recurrence and 47 (66%) did not (Table). Adj RT was associated with a reduced risk of any 2nd recurrence (7/24, 29% vs 26/47, 55%, p=0.03) and LR 2nd recurrence (2/24, 8% vs 17/47, 36%, p=0.012). Whilst pts who received adj RT at 1st recurrence were more likely to have LN only disease, extra nodal extension and involved surgical margins, these factors did not significantly affect overall risk of 2nd recurrence on multivariate analysis. Of note, 70% of pts who did not receive adj RT at 1st recurrence had IT only disease, and though this did not significantly affect rate of 2nd recurrence (p=0.19), this likely reflects an inherent selection bias in this study. RT toxicity occurred in 16 (67%) pts, 10 with dermatitis only, and all grade 1 or 2. Median follow up was 22 months. Median recurrence free survival to 2nd recurrence was 23 months for all pts, not reached for those who had adj RT at 1st recurrence and 19 months for those who did not have adj RT (p=0.047). Median overall survival was not reached. **Conclusions:** Whilst adj RT appears to reduce 2nd recurrences, this may have been influenced by an unavoidable selection bias in the data, particularly an imbalance in the percentage of pts with IT disease. Prospective data with larger cohorts is needed to validate our results. Research Sponsor: None.

The prognostic value of the interferon-gamma (IFNγ) signature in patients with macroscopic stage III melanoma treated with and without adjuvant systemic therapy.

First Author: Judith M. Versluis, Department of Medical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Recently, trials have shown the benefit of adjuvant aPD-1 therapy in macroscopic stage III melanoma patients. This treatment has been incorporated in daily clinical practice, however, a substantial part of patients still does not benefit from this therapy, as they develop recurrences. The aim of this study is to evaluate the results of adjuvant aPD-1 therapy and the potency of the IFNγ signature as a prognostic or predictive marker, as it has proven to be predictive of response in neoadjuvant trials. **Methods:** Patients participating in an ongoing biobank study and naïve for systemic therapy were included, between 10-2017 and 06-2020, after complete resection of macroscopic stage III melanoma. Approval and reimbursement of adjuvant therapy in the Netherlands started in 12-2018, resulting in 2 cohorts of similar high risk patients: prior to availability of adjuvant aPD-1 (cohort A) and thereafter (cohort B). Data cut-off for clinical data was January 1st 2021. Transcriptome sequencing was performed on samples of stage III melanoma by CeGaT GmbH, IFNγ signature was determined on these data with the median as cut-off. Clinical data were compared between cohort A and B as intention-to-treat population, including patients with a recurrence before adjuvant therapy start (n=10). **Results:** In total, 99 patients were included: 50 in cohort A and 49 in cohort B. Majority of included patients had thick primary melanomas (Breslow >2mm in 59.6%) and stage IIIC/IIID disease (83.3%) according to AJCC 8th edition. At a median follow-up of 20.6 months (95% confidence interval [CI] 16.6-24.7), median recurrence-free survival (RFS) was 6.1 months (95%CI 3.9-8.4) versus 22.8 months (95%CI 8.7-36.9), significantly in favor of cohort B (p=0.011). Median overall survival (OS) was not reached in both patient groups, but was overall significantly different (p=0.040), favoring cohort B. RNA sequencing was performed in 25 patients who received adjuvant therapy and in 24 who did not, excluding patients with an early recurrence (<12 weeks). In both treatment groups median (p=0.003) and 12-months RFS (p<0.001) was significantly higher for IFNγ high patients, but both IFNγ low and high patients show higher RFS rates when receiving adjuvant aPD-1 therapy (Table). **Conclusions:** Our study confirms RFS and OS benefit of adjuvant aPD-1 for patients with macroscopic stage III melanoma. IFNγ has shown to be a prognostic marker in both patients who were and were not treated with adjuvant therapy, as both patients with IFNγ high and low signatures show benefit from adjuvant therapy. Research Sponsor: None.

		Median RFS (months)	12-months RFS
No adjuvant therapy	**IFN-γ low**	2.8 (95%CI 2.0-3.6)	6.9% (95%CI 0.0-20.3)
	IFN-γ high	13.0 (95%CI 3.1-23.0)	53.3% (95%CI 27.5-79.1)

Incidence, timing, and predictors of CNS metastasis in patients (Pts) with clinically localized cutaneous melanoma (CM).

First Author: Merve Hasanov, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Surveillance for CNS metastasis (mets) is not routinely performed in pts with clinically localized CM. Improved understanding of the incidence, timing and risk factors for the development of CNS metastasis in these pts may inform surveillance strategies. **Methods:** Under an IRB-approved protocol, demographics, tumor characteristics, and clinical events were collected for pts diagnosed from 1998 to 2019 with AJCC 8th edition stage I or II CM at MD Anderson Cancer Center. Dates of initial diagnosis, regional, distant non-CNS, and CNS mets were recorded. Symptoms and the extent of disease (brain, LMD, both) were recorded for pts with CNS mets. Cumulative incidence of distant mets (CNS and non-CNS) was determined using the competing risks method, including death; pts without CNS mets and alive at last follow-up were censored. Differences in cumulative incidence between groups were assessed using Gray's test. Associations between measures of interest and cumulative incidence were determined using proportional subdistribution hazards regression models. All statistical tests used a significance level of 5%. **Results:** 5,179 Stage I-II CM pts were identified. At a median follow up of 82 (0.0-268.8) months, 703 (13.6%) pts were diagnosed with distant mets, including 355 (6.9%) with CNS mets. Cumulative incidence of CNS mets was 0%, 2%, and 5% at 1, 2, and 5 years, respectively. Among pts with distant mets, the first site of distant mets was CNS only for 29 (4%), non-CNS only for 557 (79%), and both for 116 (17%) pts. At initial diagnosis of CNS mets, 195 (55%) pts were asymptomatic, and 46 (13%) had no active extracranial disease. Median time to any distant met was longer for pts who were diagnosed with CNS mets [40.0 (1.9-238.0) months] vs pts diagnosed with non-CNS mets only [31.4 (1.1-185.7) months, p < 0.001]. On multivariable analysis, risk of CNS mets was significantly associated with primary tumor location of scalp [Hazard Ratio (HR) 3.4, 95% Confidence interval (CI) 1.9-5.9], head/neck (HR 3.3, 95% CI 2.0-5.3), or trunk (HR 2.3, 95% CI 1.5-3.5) (vs upper extremity); acral lentiginous melanoma subtype (HR 2.0, 95% CI 1.2-3.6) (vs superficial spreading); increased T category (T2 HR 1.5, 95% CI 1.1-2.2; T3 HR 1.9, 95% CI 1.2-3.0; T4 HR 2.1, 95% CI 1.1-3.8; vs T1), Clark level (CL) (CL4 HR 2.1, 95% CI 1.2-3.7 vs CL2), and mitotic rate (MR) (MR 5-9/mm^2 HR 2.1, 95% CI 1.5-3.0; MR > 9/mm^2 HR 2.0, 95% CI 1.3-3.0; vs MR 0-4/mm^2). While high (> 9/mm^2) MR was associated with increased risk of CNS and non-CNS mets, intermediate (5-9/mm^2) was associated with CNS mets only. **Conclusions:** Primary tumor location, tumor thickness, and MR were strongly associated with risk of CNS mets. MR rate was more strongly associated with risk of CNS than non-CNS mets. Validation in independent cohorts may provide evidence to support CNS surveillance strategies in select pts with stage I-II CM who are deemed high risk for CNS mets. Research Sponsor: None.

Genome-wide association study to reveal novel germline markers of melanoma survival.

First Author: Vylyny Chat, New York University Medical Center, Manhattan, NY

Background: Cutaneous melanoma (CM) is the most invasive form of skin cancer accounting for ~80% of all skin cancer related deaths. While tumor staging (based on recent AJCC classification) is routinely used in prognostic assessment, a large fraction of the outcomes is not explained by AJCC staging system. This urges for the discovery of a more personalized prognostic surrogates. Growing evidence highlights the role of germline genetics in CM progression; yet, to date no systematic prognostic germline study has been conducted in melanoma. We performed the first genome-wide association analysis (GWAS) to identify germline variants associated with melanoma survival. **Methods:** A cases/case GWAS was performed using the Infinium global screening array (GSA v3.0) to genotype 1,117 stage 0-III melanoma patients with no history of immunotherapy treatments ascertained at New York University Langone Health (NYULH). We randomly divided the study cohort into a discovery (N=630) and a validation (N=487) sets and tested the association of > 5 million imputed germline variants with melanoma overall survival (OS) by fitting Cox-proportional hazard ratio (HR) regression in an additive genetic model adjusting for sex, age at diagnosis, AJCC 8th staging, tumor anatomic sites, and top 3 principal components. **Results:** We found 151 independent variants associated with melanoma OS ($p< 5\times10^{-5}$) in the discovery cohort. Two of these associations validated in the independent replication set (*Bonferroni* threshold for 151 tests: p < 0.003) with enhanced clinical and statistical significance in the pooled meta-analysis: rs4128212 [HR =2.47(1.75-3.48); $p=2.2\times 10^{-7}$], and rs13212644 [HR =2.59 (1.72-3.88); $p=4.2\times 10^{-6}$]. We further tested the combined effect of these two variants and found the presence of at least one risk allele of the variants associated with a substantially increased risk of death, surpassing GWAS level of significance (HR=3.74 (2.43-5.74); $p=1.5\times10^{-9}$). **Conclusions:** We present the results of first GWAS testing an association of germline variation with melanoma OS. Stemming from a unique patient population with extensive clinical follow-up data, we identified two prognostic germline loci with large HR effect size >2.5 that were independently validated. The observed association is independent of established histopathologic markers. While rs4128212 was mapped to a putative cancer prognostic gene locus (PLPP4: phospholipid phosphatase 4), rs13212644 was an eQTL (expression quantitative trait loci) for GCLC (Glutamate-Cysteine Ligase Catalytic Subunit), a key regulator in glutathione synthesis previously linked with favorable melanoma survival. The significantly enhanced combined effect of these two loci (HR >3.5; $p<5\times10^{-9}$) indicates a great promise for their clinical utility as independent personalized predictive markers of melanoma progression. Research Sponsor: U.S. National Institutes of Health.

Granulomatous and sarcoid-like immune related adverse events (irAEs) in melanoma patients following CTLA4 blockade adjuvant therapy: An analysis of 1670 high-risk patients. *First Author: Arish Noor, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Granulomatous and sarcoid-like lesions (GSL) affecting the skin, lungs, thoracic lymph nodes, eyes and other organs following treatment with immune checkpoint inhibitors (ICIs) have been described in sporadic reports in the literature but the true incidence is unknown. **Methods:** We sought to estimate the incidence of GSL in the context of prospectively conducted ECOG-ACRIN E1609 phase III adjuvant trial in high-risk resected melanoma (N=1670 patients) testing ipilimumab 3 mg/kg (ipi3) and 10 mg/kg (ipi10) versus high-dose interferon-α (HDI). Descriptive statistics were used to calculate the incidence. **Results:** Among 1670 total patients treated with ICIs or with HDI in E1609, 1034 were treated with ipilimumab and 636 with HDI. Six GSL cases were reported among 1670 total patients treated with ipilimumab or with HDI as summarized in the table along with the corresponding CTCAE grades. More cases were observed with ipi10, followed by ipi3 and HDI, respectively. Organs involved included skin and subcutaneous tissue (granuloma annulare, granulomatous dermatitis), eye (ocular sarcoidosis), lymph nodes (noncaseating granulomatous lymphadenitis), lung and mediastinal lymph nodes (sarcoidosis, granulomatous inflammation). **Conclusions:** The incidence of granulomatous and sarcoid-like lesions (GSL) with adjuvant ipilimumab therapy in high-risk melanoma is rare. Reported cases ranged in grade from 1-3 and appeared manageable. Since most cases are asymptomatic, it is possible that GSLs are under-recognized and therefore, under-reported. A larger analysis including patients treated with anti-PD1 antibodies is currently underway. Clinical trial information: NCT01274338. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Adjuvant nivolumab in high-risk stage IIb/IIc melanoma patients: Results from investigator initiated clinical trial. *First Author: Melissa Wilson, Sidney Kidney Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: Recent studies have shown 5-yr recurrence rates for Stage IIB and IIC melanoma of up to 46%. These high-risk patients currently have few options for adjuvant therapy to prevent this inevitable recurrence, with the only FDA approved therapy being high-dose interferon-alfa, which is quite toxic. However, there are now immunotherapies (anti-PD1) and targeted therapies (anti-BRAF and anti-MEK combinations) which are approved as adjuvants for Stage III patients, some of whom will have a lower baseline recurrence risk than those with Stage IIB/IIC melanoma. We sought to determine if adjuvant PD1 inhibition with nivolumab (N) would improve the recurrence free survival (RFS) compared to historical RFS rates. **Methods:** Our study (NCT03405155) is a single-arm, open label, multi-center, phase 2 clinical trial evaluating RFS at 24 months in patients with Stage IIB/IIC melanoma on treatment with N at 480 mg IV every 4 weeks for 12 cycles. Overall survival is a secondary endpoint. Associated translational research includes circulating tumor cell DNA and immune correlates. **Results:** Twenty three patients with Stage IIB and three patients with Stage IIC melanoma were enrolled onto the study and received at least one dose of N. At data cutoff, 22 patients remain in follow up, as four patients withdrew consent at different time points in the study – one patient after one dose who wished to discontinue, one due to concern for COVID and need for repeat visits, one due to insurance issues, and one due to recurrence and wish to discontinue (which was captured in study data and RFS calculations). Seventeen patients have been on the clinical trial for at least two years with nine patients having finished treatment but with less than two years follow-up; the median follow-up is currently 21.9 months. Two patients demonstrated melanoma recurrence, one after receiving cycle six of N and another one year after completing treatment, resulting in a 87.8% RFS (90% CI (64.2%-96.3%) at 2 years, compared to the historical RFS at 2 years of 70%. No N related serious adverse events (SAEs) were observed, with only 2% Grade 3 AEs observed (varied and unrelated to treatment) and all others were Grade 1-2, including 21% GI, 18% cutaneous, and 10% musculoskeletal, respiratory, and fatigue, each; overall, 2% of these Grade 1-2 AEs were treatment related. **Conclusions:** Our preliminary results show a trend towards improved RFS in patients with Stage IIB/IIC melanoma treated with nivolumab. The cohort has not reached a minimum follow up of at least 2 years for RFS; patients are continuing to be monitored. On study, we observed the expected adverse events, without evidence of new toxicities. Data maturation will reveal the full effect of adjuvant N on disease relapse and overall survival and distant metastasis-free survival in stage IIB/IIC melanoma patients. Clinical trial information: NCT03405155. Research Sponsor: BMS.

9584 **Poster Session**

Increased risk of immune-related hepatitis among adolescent and young adults (AYAs) with melanoma during immunotherapy with checkpoint inhibitors (ICIs). *First Author: Alicia Darwin, University of South Florida Morsani College of Medicine, Tampa, FL*

Background: Melanoma is the second most common malignancy affecting AYA patients after lymphoma. Nevertheless, AYA melanoma does constitute a minority of all melanoma cases. Additionally, the AYA population is not well represented in prospective clinical trials, including immunotherapy trials. While previous research has demonstrated the efficacy of ICIs across age groups, it remains unclear if toxicity profiles will be similar. In the general population, age-related changes in the immune milieu result in differential incidences of autoimmune diseases by age. This study aims to compare the toxicity profile between a cohort of AYA melanoma versus elderly melanoma patients receiving ICI therapy. **Methods:** In this single NCCN institutional study, electronic medical records of melanoma patients treated with ICIs between 01/2007-01/2019 were reviewed. Subjects receiving concurrent investigational agents or chemotherapy were excluded. The AYA cohort included those aged 15-40 years. The elderly cohort included those aged $\geq$65 years. Adverse events were coded according to CTC-AE version 5.0. Multivariable logistic regression analyses were performed. **Results:** Analyses included 184 treatment courses. In the AYA cohort (N = 57), median age at ICI initiation was 28.8 years (range: 17.9-39.3). In the Elderly cohort (N = 127), median age at ICI initiation was 72.3 years. More AYA patients (28.1% AYA vs. 7.9% Elderly) received ICI combination regimens. The most common adverse events amongst both cohorts were transaminitis (23.4%), rashes (49.5%), and diarrhea/colitis (20%). Incidences of pneumonitis, colitis, hypothyroidism, and hypophysitis did not differ significantly between cohorts. However, the AYA cohort experienced a higher incidence of transaminitis (38.6% AYA vs. 16.5% Elderly, p =0.001) and increased occurrence of treatment related hospitalization (26.3% AYA vs. 7.1% Elderly, p <0.001). Moreover, a higher proportion of severe grade $\geq$3 transaminitis occurred in the AYA group (27.3% AYA vs. 9.5% Elderly, p =0.004). While occurrence of transaminitis was significantly associated with combination ICIs, the association between AYA status and transaminitis remained significant after adjusting for ICI regimen (OR 2.75, 95% CI: 1.3-5.8). There was a trend toward shorter time to transaminitis onset among the AYA than Elderly cohort (median 53.0 vs. 74.5 days [nonparametric p= 0.28]). To date, median survival has not been reached in both groups (p= 0.09). **Conclusions:** In this large cohort of AYA melanoma patients treated with ICI, we found a significantly higher incidence of immune-related transaminitis than in the Elderly cohort. Other immune-related AEs were comparable between cohorts. This finding was independent of ICI regimen. Further investigation will be needed to understand these differences between the AYA and Elderly cohorts. Research Sponsor: None.

TPS9585 **Poster Session**

S1801: A randomized trial of adjuvant versus neoadjuvant pembrolizumab for melanoma. *First Author: Sapna Pradyuman Patel, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although long term outcomes for most patients with early-stage melanoma is excellent following surgery, patients who have high-risk features such as lymph node involvement have poorer outcomes. Adjuvant therapy (AT) is currently considered for patients with stage III melanoma and selected patients with resected stage IV melanoma. Currently, AT for melanoma is anti-PD-1 or targeted therapy in the presence of a *BRAF* mutation. At this time, we are not able to predict which patients will derive benefit from AT and experience cure. While curative intent is the goal of treatment for primary melanoma, patients with bulky nodal involvement are at high risk of local or distant recurrence despite upfront surgery. Neoadjuvant treatment (NAT) offers the benefit of an early on-treatment pathological sample that can be profiled for biomarkers and correlated with response and survival. Treating with anti-PD1 while tumor remains visible in the body may generate a stronger immune response against *in vivo* tumor antigens compared to the traditional adjuvant setting where antigen is presented by microscopic residual tumor burden. Pilot studies of NAT with anti-PD-1 therapy have been initiated in melanoma. Multidisciplinary coordination in these cases is paramount. In these studies, an improvement in relapse-free survival and overall survival has been observed; additionally, pathologic response rates to NAT have been estimated in small studies. **Methods:** S1801 is a randomized phase II study of AT versus NAT with pembrolizumab (PEM, NCT03698019). Patients with measurable, clinically detectable and resectable cutaneous, acral, and mucosal melanomas without brain metastasis are eligible. Patients with Stage IIIB to oligometastatic, resectable Stage IV are randomized 1:1 to AT or NAT. Patients getting AT undergo surgery first followed by 18 doses of PEM 200 mg IV every 3 weeks. Patients getting NAT receive 3 doses of pre-operative PEM followed by surgery and then 15 doses of adjuvant PEM. Radiation may be given on either arm after surgery, at the investigator's discretion. Primary endpoint is event-free survival measured from the date of randomization to the date of first documented progression that renders the patient unable to receive planned protocol surgery, failure to begin adjuvant therapy within 84 days of surgery, relapse after surgery, or death due to any cause. Secondary endpoints include RECIST and iRECIST response rates, as well as a number of surgical outcomes. Safety monitoring is conducted with disease progression and toxicity thresholds. The key Translational Medicine objective of this trial is to determine the pathologic response rate to NAT after 3 doses of PEM. Surgical pathology grossing instructions to ensure readout for pathologic response are provided in the form of training slides. Enrollment is at 40% of a planned 500 patients. Clinical trial information: NCT03698019. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS9586 **Poster Session**

Combination of radiomic and biomarker signatures as exploratory objective in a phase II trial with intratumoral BO-112 plus pembrolizumab for advanced melanoma. *First Author: Ivan Marquez-Rodas, Medical Oncology, General University Hospital Gregorio Marañón & CIBERONC, Madrid, Spain*

Background: Intratumoral immunotherapies are gaining interest in oncology, particularly in melanoma. These therapies, however, have faced some issues. For instance, standard response criteria do not accurately describe tumor burden, and responses may differ for injected/non injected lesions. Besides, target lesions may become non evaluable. Biomarkers provide interesting information for these therapies. In addition, some radiomic signatures have been associated with CD-8 infiltration. BO-112 is a double stranded synthetic RNA formulated with polyethyleneimine (PEI) that mimics a viral infection, mobilizing the immune system and changing tumor microenvironment. Clinical data are available from a first-in-human study, which showed ORR of 11% and DCR of 46% in patients who had developed progressive disease on immunotherapy. In patients with melanoma, this ORR was 20%. A phase 2 clinical study of BO-112 with pembrolizumab in patients with liver metastases from digestive tumors is ongoing. Both studies brought up data regarding how some biomarkers are increased after a single dose of BO-112 and correlated with responses. In this phase II study in patients with pretreated melanoma (NCT04570332), we will prospectively assess CD-8 and PD-L1 by immunohistochemistry, which will be compared with multi-parametric radiologic findings and correlated with clinical benefit. In addition, retrospective DNA sequencing will be performed. This kind of exploratory analysis in intratumoral immunotherapies might be key to identify predictive and prognostic factors. **Methods:** Phase 2, single arm, open label study of BO-112 with pembrolizumab in patients with advanced melanoma. BO-112 is administered once weekly (QW) in 1 to 8 tumor lesions, total dose 1-2 mg (depending on the number of injected lesions), for the first 7 weeks and then once every three weeks (Q3W); pembrolizumab 200 mg will be administered Q3W. Key eligibility criteria: advanced cutaneous or mucosal melanoma; patients must have progressed on or after treatment with an antiPD-1/L1 mAb; at least one measurable lesion amenable for weekly IT injection. Primary efficacy variable is ORR by RECIST 1.1, assessed by independent central radiologist (QUIBIM Precision platform). A 1-sided alpha of 4.19% and power of 81.8% are used. If less than 8 patients out of 40 have ORR, the study will not meet the statistical bar. Secondary endpoints include clinical activity by RECIST1.1 and iRECIST, overall survival, safety and PKs. Exploratory objectives include itRECIST and evaluation of CD-8 and PD-L1 expression by immunohistochemistry (Pangaea laboratory), which will be correlated with radiomic signatures (first order and second order) from standard-of-care computed tomography (CT) images. Enrollment is open and 1 of planned 40 patients has been enrolled. Nineteen sites are planned to participate. Clinical trial information: NCT04570332. Research Sponsor: Highlight Therapeutics, SL.

TPS9587 **Poster Session**

CAcTUS: A parallel arm, biomarker driven, phase II feasibility trial to determine the role of circulating tumor DNA in guiding a switch between targeted therapy and immune therapy in patients with advanced cutaneous melanoma. *First Author: Rebecca Lee, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Circulating tumor DNA (ctDNA; the tumour derived fraction of circulating free DNA in the blood) has been shown to be a biomarker of tumor burden/progression in many cancers. We recently accurately monitored treatment response and resistance in stage IV melanoma by ctDNA analysis in serial peripheral blood samples. Pre-clinical data has previously revealed that BRAF inhibition provokes a micro-environment with increased T cell infiltration, improved T cell recognition of melanoma associated antigens and reduced production of immunosuppressive cytokines that could enhance immune responses. We aimed to test the hypothesis that ctDNA could be implemented as a personalised, real-time liquid biopsy to identify when tumours are responding to targeted therapy in order optimise a switch to immunotherapy. **Methods:** We validated the ctDNA assays for BRAF mutation calling as a primary trial endpoint. We designed a phase II multicenter, parallel arm study across 6 UK sites, to assess primary objectives of i). Whether a ctDNA result can be turned around within 7 days and actioned in a clinically relevant timeframe ii). to assess whether a decrease in ctDNA levels of mutant *BRAF* by ≥80% from baseline on targeted therapy is an appropriate 'cut off' to instruct switching to immunotherapy. Secondary endpoints include Overall Response Rate (ORR) to immunotherapy, radiological/clinical and ctDNA determined progression free survival (PFS) on each treatment. Forty patients are planned based on inclusion criteria of stage IV or stage III unresectable cutaneous *BRAF* mutant melanoma, baseline ctDNA *BRAF* variant allele frequency (VAF) ≥1.5%, ECOG 0/1/2, no symptomatic brain metastases, no prior adjuvant nivolumab plus ipilimumab (N+I). Prior adjuvant dabrafinib + trametinib (D+T) is allowed as long as recurrence is >6 months from completion. Patients are randomised 1:1 to either standard Arm A; investigator choice of either D+T (150mg BD +2mg OD respectively) or N+I (1 mg/kg N +3 mg/kg I q3 wkly, then N 480mg q4 wkly) first line, then switch on progression to the other treatment. In the experimental Arm B; all patients start on D+T and have *BRAF* ctDNA monitored q2 wkly for 4 wks then q4 wkly. When ≥80% decrease vs. baseline in ctDNA *BRAF* VAF occurs, patients switch to N+I. If patients subsequently progress on N+I, they will resume D+T. The study is open with 9 patients enrolled at time of submission. Clinical trial information: NCT03808441. Research Sponsor: Bristol Myers Squibb, The Christie Charity and Cancer Research UK.

TPS9588 **Poster Session**

Clinical trial in progress: Phase II trial of defactinib (VS-6063) combined with VS-6766 (CH5126766) in patients with metastatic uveal melanoma. *First Author: Rino S. Seedor, Fox Chase Cancer Center, Philadelphia, PA*

Background: Despite successful treatment of primary uveal melanomas (UM), up to 50% of patients subsequently develop systemic metastasis, with the liver involved in up to 90% of patients. Currently there is no US FDA-approved treatment for metastatic uveal melanoma (MUM). Activating mutations in genes encoding alpha subunits of the heterotrimeric G proteins, GNAQ and GNA11, are found in 80-90% of UM. Recent information suggests that *GNAQ/GNA11*-oncogenic signaling involves a non-canonical pathway conferring the activation of YAP1, distinct from the activation of PLCβ and PKC-MEK-ERK, which may explain the failure of MEK inhibitors in MUM patients. Focal Adhesion Kinase (FAK) is a tyrosine kinase that provides a direct link between Gαq and tyrosine phosphorylation networks controlling YAP and UM growth. Interestingly, UM represents the human cancer harboring the highest level of FAK overexpression. Recent kinome-wide CRISPR-Cas9 screens revealed that FAK and RAF/MEK co-targeting may provide a new network-based precision therapeutic strategy for MUM treatment. **Methods:** This is an investigator-initiated, prospective, single arm, single-institution, phase II trial evaluating the combination of a FAK inhibitor (defactinib, VS-6063) with a RAF/MEK inhibitor (VS-6766, CH5126766) for the treatment of patients with metastatic uveal melanoma [NCT04720417]. The primary endpoint of the study is disease control rate (DCR) of 50% including complete response (CR), partial response (PR), and stable disease (SD) as determined by RECIST criteria version 1.1. Secondary endpoints include progression free survival, overall survival, and causality of adverse events. Exploratory endpoints include analysis of the pharmacodynamic profile, mechanism of resistance to the combination, and investigation of circulating free DNA as a biomarker. The efficacy of this combination treatment will be assessed using the Simon's two stage design. In stage I, a total number of 8 patients are accrued and if there are 2 or fewer overall responses among these 8 patients, further enrollment of patients may be stopped with the conclusion that DCR cannot be 50% or greater. Otherwise, an additional 10 patients will be accrued in stage II, resulting in a total sample size of 18 patients. Patients at 18 years or older with metastases from uveal melanoma will be eligible (any line of therapy). Defactinib (200 mg) will be administered orally twice a day in combination with VS-6766 (3.2 mg) administered orally twice a week for 3 weeks, in 28-day cycles. Dose modification will be considered based on toxicity. Treatment will be continued until maximum clinical benefit is obtained; disease progression or the development of intolerable side effects. Enrollment to stage 1 began in February 2021. Clinical trial information: NCT04720417. Research Sponsor: Verastem Oncology, Inc.

TPS9589 **Poster Session**

Ipilimumab, nivolumab and tocilizumab as first-line therapy for advanced melanoma. *First Author: Inderjit Mehmi, The Angeles Clinic & Research Institute, A Cedar-Sinai Affiliate, Los Angeles, CA*

Background: Interleukin 6 (IL-6) functions in the maintenance of hepatocytes, haemotopoietic progenitor cells, a variety of other tissues, and regulates the innate and adaptive immune system. IL-6 may play a role as a chronic inflammatory mediator in altering levels of acute phase proteins synthesized by the liver and circulating myeloid cells which have been shown to be associated with short survival with checkpoint inhibition and which are immune suppressive. The immunomodulatory properties of interleukin-6 may in part also be responsible for immune related adverse events, given the reversal of those toxicities observed with IL-6 receptor blockade in clinical practice. To assess if blockade of IL-6 binding is associated with a decrease in irAEs and/or an increase in efficacy defined as overall response rate (ORR) at week 24 in patients receiving ICB, we added tocilizumab to ipilimumab and nivolumab therapy. **Methods:** The current phase II trial is a two-stage design to assess the safety, tolerability, and grades 3-5 immune related toxicities of tocilizumab administered every 6 weeks up to week 24 in combination with ipilimumab at 1 mg/kg and nivolumab at 3 mg/kg every 3 weeks for 4 doses each during a 12 week induction period, then administered every 6 weeks with nivolumab at 240 mg flat dose every 2 weeks in maintenance for up to 24 weeks, and nivolumab alone will be given at 480 mg flat dose every 4 weeks thereafter for up to 2 years. Eligible patients include those age 18 or older with measurable and unresectable stages III/IV melanoma (cutaneous, acral, mucosal), without prior systemic treatment for metastatic disease. Adjuvant therapy (IFN-alpha, ipilimumab and/or nivolumab, or pembrolizumab) is allowed. Patients with metastatic melanoma of brain are allowed, if neurologically stable and off immunosuppressive steroids. A total of 18 patients will be treated in the first stage, and 49 additional patients in the second stage for a total of 67. The comparator data are from the N3I1 arm of Checkmate-511 trial, in which treatment-related grades 3-5 irAEs were 33.9% with a 45.6% response rate (1). Prespecified activity goal for the first stage of accrual has been met; second stage accrual began in January 2021. References: (1) Lebbé C, Meyer N, Mortier L, Marquez-Rodas I, et al. Evaluation of Two Dosing Regimens for Nivolumab in Combination With Ipilimumab in Patients With Advanced Melanoma: Results From the Phase IIIb/IV CheckMate 511 Trial. Journal of Clinical Oncology 2019 37:11, 867-875. Clinical trial information: NCT03999749. Research Sponsor: BMS and Genetech.

TPS9590 **Poster Session**

NCT04552223: A phase II study of nivolumab plus BMS-986016 (relatlimab) in patients with metastatic uveal melanoma (UM) (CA224-094). *First Author: Jose Lutzky, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Uveal melanoma (UM) is a rare disease but 50% of patients will eventually develop metastatic disease, for which not effective therapy is available. Liver-directed therapies, immunotherapy, targeted therapy and chemotherapy have limited activity [1]. Lymphocyte activation gene 3(LAG-3) is an immune checkpoint receptor associated with decreased T-cell effector function and tumor escape. Preclinical models have shown that dual inhibition of LAG-3 and PD-1 blockade generates synergistic anti-tumor activity [2]. Recent preclinical data indicates that uveal melanoma CD8+ T cells express the checkpoint receptor LAG3 to a greater extent than PD1 or CTLA4 [3,4]. Therefore, LAG3 is a potential candidate for checkpoint inhibitor immunotherapy in UM. Relatlimab is a human LAG-3-specific antibody isolated from immunized transgenic mice which binds to a defined epitope on LAG-3 with high affinity and specificity and potently blocks the interaction of LAG-3 with its ligand, MHC Class II. **Methods:** This is an open-label, single arm, single site investigator-initiated phase II study, NCT04552223. Based on Simon two-stage minimax design, 13 patients will be enrolled in Stage 1. If at least one response is noted, the study will proceed to Stage 2 and enroll an additional 14 patients. The null hypothesis will be rejected if 4 or more responses are observed among 27 patients. This design achieves 5% type I error and 80% power when the true ORR is 20%. The trial opened to accrual in December 2020. As of February 15, 2021 four patients had been enrolled the first stage of accrual. Main eligibility criteria include patients with biopsy proven metastatic uveal melanoma, previously untreated with PD-1, CTLA-4 and/or LAG-3 blocking antibodies and in good performance status. Enrolled patients are treated in the outpatient setting. Nivolumab 480 mg is mixed in the same bag with relatlimab 160 mg and administered intravenously over 60 minutes every 4 weeks until disease progression or intolerable toxicity for up to 24 months. The primary endpoint is best objective response rate (ORR). Secondary endpoints include disease control rate (DCR), progression-free survival (PFS), overall survival (OS), median duration of response (mDOR), and adverse events (AEs). Correlative studies will evaluate pre- and post-treatment characteristics of T cells in the tumor microenvironment and blood. Clinical trial information: NCT04552223. Research Sponsor: Bristol Myers Squibb, Sylvester Cancer Center trials grant.

TPS9591 **Poster Session**

Phase I/II trial of intratumoral administration of hu14.18-IL2, with local radiation, nivolumab, and ipilimumab in subjects with advanced melanoma. *First Author: Mark R. Albertini, University of Wisconsin, Madison, WI*

Background: We are studying an intratumoral (IT) in situ vaccine strategy using the GD2-reactive hu14.18-IL2 immunocytokine (hu-IC) to convert the injected tumor into a site of enhanced tumor antigen presentation, as has been shown in mice. Hu-IC is a humanized monoclonal antibody (mAb) covalently linked to two molecules of IL-2 at the Fc region. The hu14.18 mAb recognizes GD2, a disialoganglioside found in tumors of neuroectodermal origin. We previously studied intravenous (IV) hu-IC and reported immune activation and reversible toxicities (1). Surgery to resect recurrent stage III or stage IV melanoma combined with 3 courses of IV hu-IC resulted in prolonged tumor-free survival in some patients (2). Murine GD2+ tumor models showed enhanced antitumor activity and recruitment of T cells using hu-IC IT versus IV (3). In these models, the combination of radiation therapy (RT) followed by IT hu-IC dramatically potentiates the antitumor response and enhanced response to immune checkpoint blockade (4). Biological samples (blood and tumor) will be interrogated to identify biological mechanisms and develop biomarkers for future testing. **Methods:** This outpatient phase I/II trial uses a 3 + 3 design to determine maximum tolerated or maximum administered dose of IT hu-IC (planned dose level: 2 mg/m^2/day; de-escalation dose level: 1 mg/m^2/day) when given alone (Phase 1A: 3-12 patients), after RT (Phase 1B: 6-12 patients), after RT and in combination with nivolumab (Phase 1C: 6-12 patients), and after RT and in combination with nivolumab and ipilimumab (Phase 1D: 31-34 patients). The trial will evaluate safety, antitumor activity, and immunologic endpoints and includes an expanded Phase II cohort (Phase 1D). The IT injections (once daily x 3 days) are delivered every 21 days for 4 cycles and can then continue every 28 days for up to 13 cycles if there is response/stable disease and residual injectable tumor. Key inclusion criteria: 1) histologically proven, malignant melanoma that is advanced (Stage IV) or surgically incurable; 2) at least 1 (preferably 2) sites of disease amenable to safe repeated IT injections; and 3) must have received or declined at least one FDA approved therapy, either in the adjuvant setting or for metastatic disease, with an impact on survival. Two subjects have been accrued into Phase IA as of 2-4-2021. References: (1)King DM, et al. J Clin Oncol 22:4463-4473, 2004. (2)Albertini MR, et al. Can Imm Imm 67(10):1647-1658, 2018. TPS9592 **Poster Session**

A phase II, open-label study to investigate the efficacy and safety of domatinostat in combination with avelumab in patients with advanced unresectable/metastatic Merkel cell carcinoma progressing on anti-PD-(L)1 antibody therapy: The MERKLIN 2 study. *First Author: Alexander Christopher Jonathan Van Akkooi, Department of Surgical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Merkel cell carcinoma (MCC) is a rare but highly aggressive human skin cancer often caused by the Merkel cell polyomavirus or extended exposure to sunlight. Since the approvals of avelumab globally and subsequently pembrolizumab (US only), anti–PD–(L)1 antibody therapies have become the standard of care for advanced/metastatic MCC patients in recent years. Still, a significant proportion of MCC patients do not respond to or relapse on anti–PD–(L)1 antibody monotherapy. Recent preclinical data suggest that the small molecule, selective class I histone deacetylase inhibitor (HDACi) domatinostat can overcome critical mechanisms of MCC resistance to checkpoint inhibitors. These escape mechanisms include the epigenetic downregulation of the antigen processing and presentation machinery, hence treatment with domatinostat is thought to favorably modulate the tumor environment allowing a reintroduction of anti–PD–(L)1 therapy for an improved and sustained clinical benefit. **Methods:** The study is a phase II, multicenter, single arm clinical trial of the orally administered HDACi domatinostat in combination with the anti–PD–(L)1 antibody avelumab for patients with advanced unresectable/metastatic MCC that are progressing on previous anti–PD–(L)1 therapy. ClinicalTrials.gov Identifier: NCT04393753. Key Inclusion Criteria are: histologically confirmed MCC, an ECOG performance status $\leq$ 1, MCC in an advanced, unresectable stage III or metastatic stage IV, and progressing on previous anti–PD–(L)1 antibody monotherapy within the last 12 weeks before planned first administration of study medication. Key Exclusion Criteria are: history of serious anti–PD–(L)1 therapy related adverse reactions prohibiting further avelumab treatment, more than one line of previous systemic anti neoplastic therapy other than anti–PD–(L)1 antibody monotherapy (excluded: palliative radiation therapy of single lesions within 2 weeks before planned administration of study medication), significant active or chronic disease (infections, immunodeficiencies, cardiovascular, psychiatric disorders). A total of 40 patients will be enrolled in up to 46 clinical study sites in Europe and USA. Anti-tumor activity will be primarily assessed by the objective response rate according to RECIST v1.1 as an exploratory analysis. Secondary objectives include additional efficacy assessments, safety, quality of life and pharmacokinetics of domatinostat in combination with avelumab. Correlative aims include evaluating biomarkers for association with clinical benefit. The first patient was enrolled on Oct. 16, 2020, 21 of 46 clinical sites are active and 4 out of 40 planned patients have been enrolled as of Feb. 15, 2021. Clinical trial information: NCT04393753. Research Sponsor: 4SC AG.

TPS9593 **Poster Session**

Winship 4851-19: A pilot study of neoadjuvant and adjuvant cemiplimab for high-risk cutaneous squamous cell carcinoma. *First Author: Michael C. Lowe, Department of Surgery, Emory University, Atlanta, GA*

Background: The PD-1 inhibitor cemiplimab was approved in 2018 for treatment of locally advanced or metastatic cutaneous squamous cell carcinoma (cSCC) that is not curable with surgery or radiation. This approval was based on the results of the phase 2 EMPOWER-CSCC-1 trial, which demonstrated an objective response rate of 47% with a significant number of these patients experiencing a durable response. However, patients with high risk cSCC that are able to undergo curative intent surgery are not candidates for checkpoint inhibitor therapy but still experience high rates of recurrence and/or systemic progression even when offered adjuvant radiotherapy. In light of data using checkpoint inhibitor therapy in the neoadjuvant setting in other cutaneous malignancies, we hypothesized that cemiplimab therapy would improve surgical outcomes and reduce long-term recurrence rates in patients with high-risk resectable cSCC if used in the perioperative setting. **Methods:** Winship 4851-19 is a single arm pilot study of cemiplimab in the neoadjuvant and adjuvant setting for high-risk resectable cSCC (NCT04428671). In the neoadjuvant phase, patients receive three doses of cemiplimab every three weeks followed by standard of care surgery. Radiation may be offered when clinically appropriate at the discretion of the investigator. In the adjuvant phase (following surgery +/- radiation), patients receive cemiplimab every three weeks to complete one year total of treatment. Eligible patients must have surgically resectable histologically proven high risk cSCC defined as: nodal disease with extracapsular extension or one node $\geq$20mm; in transit metastases $>$ 2cm from primary lesion; T4 head and neck primary tumor; perineural invasion; or recurrent cSCC with concurrent $\geq$N2b nodal disease, size $\geq$4cm or bony invasion, or poorly differentiated histology. Patients cannot have received prior immunotherapy and must have a ECOG performance status of 0 or 1. Primary objective is to establish pathologic response rate. Secondary objectives include assessments of local and distant recurrence and overall survival rates. We also plan to evaluate the immune profile of fresh tumor and blood to assess the impact of neoadjuvant cemiplimab on the tumor microenvironment and circulating immune responses. To date 5 of 20 patients have been enrolled; this sample size was selected based on feasibility and ability enroll within a timely fashion. Clinical trial information: NCT04428671. Research Sponsor: Regeron.

TPS9594 **Poster Session**

Phase II study of binimetinib with imatinib in patients with unresectable KIT-mutant melanoma. *First Author: Katy K. Tsai, University of California, San Francisco, San Francisco, CA*

Background: Immune checkpoint inhibitors (ICI) have transformed treatment for patients (pts) with advanced melanoma, as have BRAF/MEK inhibitors for pts with BRAF V600-mutant melanoma. However, pts with acral or mucosal melanomas are in particular need of more options given a lower objective response rate (ORR) to ICI, and lower incidence of BRAF V600 driver mutation. Such BRAF mutations are found in only 5-10% of acral/mucosal melanomas, while KIT mutations/amplifications are found in 10-20%. Even when present, a KIT alteration does not guarantee response to KIT inhibition, with only about one-third responding as previously shown in 3 phase II studies. A significant number of KIT-mutant melanomas have been shown to demonstrate NF1 or SPRED1 loss, with recent preclinical work showing that such alterations are associated with the loss of negative suppression of RAS, resulting in RAS activation and MEK dependence. We hypothesize that NF1 or SPRED1 loss cooperates with KIT mutations to drive melanomagenesis and resistance to KIT inhibition, and propose to target this vulnerability with a combination approach to targeted therapy. This phase II study will be the first to evaluate the efficacy and safety of binimetinib plus imatinib in pts with KIT-mutant melanoma. **Methods:** This is an investigator-initiated phase II study of binimetinib in combination with imatinib in pts with BRAF V600 WT, KIT-mutant unresectable melanoma who have progressed on or who are ineligible for ICI (NCT04598009). Pts will be ≥18 yo with performance status ECOG 0-2, and have unresectable Stage IIIB/C/D or Stage IV melanoma that is BRAF V600 WT and KIT-mutant by CLIA-certified testing platform. Pts will have progressed on prior ICI or other standard-of-care (SOC) therapies, or be ineligible for or unable to tolerate SOC therapies. Pts with brain metastasis will be eligible if clinically stable and determination made that no CNS-specific treatment is required prior to study start. Pts previously treated with a MEK inhibitor will be excluded. A Simon 2-stage Minimax design will be used; the null hypothesis that the true response rate is 0.1 will be tested against a one-sided alternative. 15 pts will be accrued in the first stage. If there are £1 responses, the study will be stopped. Otherwise, 10 additional pts will be accrued for a total of 25. The null hypothesis that the true response rate is 0.1 will be rejected if ≥6 responses are observed. This yields a type I error rate of 0.05 and power of 0.8017 when the true response rate is 0.3.Primary endpoint: ORR (RECIST). Secondary endpoints: duration of response, progression-free survival, overall survival, clinical benefit rate (CR, PR, or SD ≥16 weeks), safety profile (CTCAE). Exploratory objectives to include investigations of association between clinical response and baseline NF1 and SPRED1 status, and of pathologic correlates of acquired resistance. Study began enrolling pts in December 2020 and is ongoing. Clinical trial information: NCT04598009. Research Sponsor: Array/Pfizer.

Phase Ib/randomized phase II study combining hepatic percutaneous perfusion with ipilimumab plus nivolumab in advanced uveal melanoma: The CHOPIN trial. *First Author: Thaïs M.L. Tong, Leiden University Medical Center, Department of Medical Oncology/Radiology, Leiden, Netherlands*

Background: Uveal Melanoma (UM), although rare, is the most common intraocular malignant tumor in adults. Despite successful treatment of the primary tumor, approximately half of all patients will develop metastatic disease, mainly in the liver. Prognosis of metastatic UM is poor and overall survival (OS) has not improved over the last 30 years. Effective systemic therapies are lacking but recent literature suggests an improved effect of the combination of immunotherapy with ipilimumab/nivolumab (IPI/NIVO) as opposed to monotherapy. Percutaneous hepatic perfusion (PHP) is a liver-directed therapy that allows delivery of a high dose of melphalan to the liver with limited systemic toxicity. Efficacy of PHP has been demonstrated in phase II trials including patients with liver-dominant or liver-only metastases. In this study we combine PHP with IPI/NIVO with the goal of inducing a synergistic effect and improving disease control. The aim of the phase 1b is to establish the maximum tolerated dose (MTD) of IPI/NIVO when combined with PHP. The following randomized phase II trial aims to determine the efficacy of IPI/NIVO combined with PHP, compared to PHP alone. **Methods:** We initiated a prospective, single center, phase Ib and randomized phase II trial with a maximum of 88 patients in total. Patients with confirmed measurable hepatic UM metastases according to RECIST 1.1 and WHO performance score of 0-1 are included. Exclusion criteria are age > 75 years, treatment with systemic immunosuppressive medication and prior systemic treatment for metastasic UM. Phase Ib is a dose-escalation study consisting of two cohorts. The dose of IPI and NIVO is increased from 1mg/kg and 1mg/kg in cohort 1, to 1mg/kg and 3mg/kg, in cohort 2, respectively. The melphalan dose for the PHP is 3mg/kg (maximum dose of 220mg) in both cohorts. Treatment duration is 12 weeks consisting of 4 courses of IPI/NIVO with 2 PHP's in week 1 and 7. In phase II, the same treatment scheme as phase Ib is used in the treatment arm combining IPI/NIVO with PHP at the established MTD. The second treatment arm consists of 2 PHP's performed at a 6 week interval. Follow-up includes laboratory tests, CT-chest/abdomen and MRI-liver. Safety and toxicity are assessed according to the CTCAE V5.0. Radiological response is assessed according to RECIST 1.1 and irRECIST. Primary objective of phase Ib is to determine safety of the combination of IPI/NIVO with PHP defined by the MTD. In phase II the primary objective is the efficacy of combination treatment of IPI/NIVO with PHP defined by progression-free survival at one year. Secondary objectives include OS and overall response rate. Cohort 1 and 2 of phase Ib have been completed without dose limiting toxicities and the MTD is defined as IPI 1 mg/kg and NIVO 3 mg/kg. Accrual to phase II started in December 2020. An update will be presented at ASCO 2021. Clinical trial information: NCT04283890. Research Sponsor: Bristol Myers-Squibb and Delcath System Inc.

TPS9596 **Poster Session**

Multicenter phase I/II trial of encorafenib with and without binimetinib in combination with nivolumab and low-dose ipilimumab in metastatic BRAF-mutant melanoma. *First Author: Max Jameson-Lee, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Targeted therapy (BRAF + MEK inhibitors) and immunotherapy (anti-PD1 + anti-CTLA4) have improved overall survival for metastatic or unresectable *BRAF*$^{V600E/K}$mutant melanoma. Whereas targeted therapy has a high response rate, immunotherapy may deliver longer term disease control for a larger number of patients. Despite these treatments, patients with high risk metastatic melanoma such as those with brain or liver metastases, elevated lactate dehydrogenase (LDH) and bulky disease have inferior treatment outcomes with current therapies. A BRAF+MEK+PDL1 regimen has recently emerged however the role for this treatment remains unclear. Several recent trials combining MEK inhibition and immunotherapy have failed possibly because MEK inhibition can compromise T cell activation. Meanwhile the addition of CTLA4 blockade to PD1 inhibition appears to disproportionately benefit patients with non-T cell-inflamed tumors and potentially high-risk disease. For patients with high risk BRAF-mutant metastatic melanoma, further investigation of BRAF/MEK targeted and PD-1/CTLA-4 directed immunotherapy combination strategies remains a priority. **Methods:** This is an open label, multi-site, Phase 1/2 study of encorafenib (Enco) +/- binimetinib (Bini) + nivolumab (Nivo) + ipilimumab (Ipi) for the treatment of patients with unresectable or metastatic *BRAF*-mutated melanoma in high-risk cohorts (NCT04655157). An initial regimen confirming Phase I approach will be pursued on two schedules concurrently, with patients accruing equally to each group. Group 1 will receive 3mg/kg Nivo, and 1 mg/kg Ipi and 300mg Enco (12 participants, triple therapy) and Group 2 will receive 3mg/kg Nivo and 1mg/kg Ipi and 450mg Enco and 45mg Bini, (12 participants, quadruple therapy). Dose limiting toxicity (DLT) will be evaluated weeks 1-6. A recommended Phase II regimen (RP2R) [either triple or quadruple therapy] will be carried forward into two high risk metastatic disease cohort expansions of 30 participants each. Cohort 1 will include patients with symptomatic brain metastases, while cohort 2 will include patients with elevated LDH as well as either liver metastases OR bulky visceral disease (sum of longest diameters > 44mm). Patients meeting criteria for cohorts 1 and 2 will be placed in cohort 1. Patients with symptomatic brain metastases will be included with an ECOG up to 2 and on ≤ 4mg of dexamethasone or equivalent. Continuous Bayesian toxicity monitoring will be used throughout to monitor DLT. Pre and on-treatment tumor biopsies will assess changes in the tumor microenvironment while peripheral blood ctDNA and T cell Ki67% changes will assess early response and immune activation during triplet and quadruplet therapy. Clinical trial information: NCT04655157. Research Sponsor: Bristol Myers Squibb.

The efficacy and safety of anti-CLL1 based CAR-T cells in children with relapsed or refractory acute myeloid leukemia: A multicenter interim analysis. *First Author: Hui Zhang, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Background: Chimeric antigen receptor (CAR)-T cell therapy has demonstrated remarkable success in treating a variety of blood cancers, such as CD19 CAR-T for B-cell malignancies and BCMA CAR-T for myeloid myeloma (MM). However, similar achievement has yet to be replicated in patients with relapsed and refractory acute myeloid leukemia (R/R AML), primarily due to the AML heterogeneity, making it difficult to find an ideal CAR-T target. Previous efforts have targeted single CD33, CD123, LeY, NKG2D, or CD70 receptors, but the overall response rate is very disappointed. To address these challenges, we aim to find an effective target for AML without the need for the hematopoietic stem cells transplant (HSCT). In our study, CLL1 is chosen as a promising target as it is not expressed on normal HSCs, but highly expressed on AML blasts cells and leukemia stem cells (LSCs). Here we report the interim analysis from a Phase I clinical trial using anti-CLL1 based CAR-T cells to treat children with R/R AML. The primary and secondary objectives were to evaluate the safety and anti-AML responses, respectively, with long-term prognosis within those patients who did not receive allogeneic HSCT (allo-HSCT) as an additional objective. **Methods:** We have generated a 2nd generation of CLL1 CAR-T, the extracellular scFv was derived from a murine CLL1 monoclonal antibody, which was generated by hybridoma technology. Autologous CAR-T cells were manufactured in a cGMP facility. Between Oct 2019 and Jan 2021, 11 pediatric R/R AML patients were infused. CLL1 or CLL1-CD33 dual CAR-T cells were given by a dose at $0.3\text{-}1x10^6$/kg with a single dose after lymphodepleting conditioning with cyclophosphamide/fludarabine(Cy/Flu). **Results:** Of the 11 patients infused, Grade 3-4 hematologic adverse events were observed before and during CAR-T cell infusion, and no dose-limiting toxicities were observed. Meanwhile, grade 1-3 cytokine release syndrome was observed but without any lethal events. All the adverse effects were resolved after guideline-directed intervention. Anti-CLL1 CAR-T cells efficiently expanded *in vivo,* the median expansion peaking time was at Day 8. For these 11 R/R-AML patients, 10 patients completely responded to anti-CLL1 based CAR-T cell therapy, with CLL1 positive AML blast eliminated within one month. Among the responded 10 patients, 5 patients reached CR/MRD-, 3 patients reached CR/MRD+, 1 patient reached PR and 1 patient showed SD, with only CLL1 negative AML cells. **Conclusions:** Our study demonstrated that 10/11 patients responded to CLL1 CAR-T cell therapy within one month. For patients showing MRD+ with CLL1 negative AML blast, chemotherapy like Azacitidine, and combined with HSCT may help those patients to reach complete response. These initial results suggested that anti-CLL1 base CAR-T cells can be a well-tolerated and candidate option for treating children with R/R-AML. Clinical trial information: ChiCTR1900027684. Research Sponsor: Guangzhou Bio-gene, Other Foundation.

Donor-derived CD7 CAR T cells for T-cell acute lymphoblastic leukemia. *First Author: Jing Pan, State Key Laboratory of Experimental Hematology, Department of Hematology, Beijing Boren Hospital, Beijing, China*

Background: Despite the success of chimeric antigen receptor T cell therapy in B cell malignances, there is currently no proved CAR T treatment for T cell neoplasms. We provide first evidence support the use of donor derived CAR T cells in T cell leukemia. **Methods:** In this phase 1 trial, CD7 CAR T cells were manufactured with T cells from prior SCT prior to a single infusion at doses of 5×10^5 or 1×10^6 (± 30%) cells per kilogram of body weight. donors, or from new donors who were HLA-matched or haploidentical, via leukopheresis and transduced with a lentiviral vector which carries a CD7 CAR construct. The primary endpoint was safety. Short-term efficacy was also assessed. **Results:** Results of 20 enrolled patients who received infusion are reported. Of 20 patients, 12 received previous HSCT-donor derived CAR T cells and 8 received fresh haplo-identical donor derived CAR T cells and plan to received transplantation as consolidation after remission.Adverse events included grade 3-4 hematologic toxicity in all (100%), grade 3-4 and grade 1-2 cytokine release syndrome in 2 (10%) and in 18 (90%), grade 1 neurotoxicity in 3 (15%), grade 1-2 graft-versus-host disease in 12 (60%), and grade 1 viral activation in 3 (15%) patients. Nineteen (95%) patients had a response, including 18 (90%) with complete remission and 1 (5%) with partial remission. Of 19 responders, 7 were bridged to SCT and remained minimal residual disease (MRD)-negative until last visit; 12 were followed up at a medium of 4.4 months, among whom 9 remained MRD-negative, 1 had a relapse, 1 discontinued for other treatment, and 1 died of pulmonary fungal infection at 5.5 months. CAR cells mostly persisted beyond 3 months. Patient CD7-positive healthy T cells were depleted, while CD7-negative T cells increased. **Conclusions:** We report the initial toxicity profile and anti-leukemia activity of a donor-derived CD7-targeted cellular immunotherapy for patients with relapsed or refractory T-ALL. (Funded by the National Key R&D program; ChiCTR.org number, ChiCTR2000034762). Clinical trial information: ChiCTR2000034762. Research Sponsor: the National Key R&D program.

Targeted gene expression classifier identifies pediatric T-cell acute lymphoblastic leukemia (T-ALL) patients at high risk for end induction minimal residual disease positivity. *First Author: Lauren K. Meyer, University of California, San Francisco, San Francisco, CA*

Background: The heterogeneity of T-ALL has hindered biomarker identification and limited biology-based risk stratification. Historically, minimal residual disease (MRD) has been the strongest predictor of poor outcomes. However, stratification by MRD does not allow for risk-adapted therapy early in treatment, which may induce deeper remissions and decrease risk of relapse. We hypothesized that gene expression profiling at diagnosis may have prognostic value in identifying high risk patients. **Methods:** We analyzed RNA-seq data from 189 diagnostic samples from the Children's Oncology Group (COG) AALL0434 trial. Using leave-one-out cross-validation, we identified a set of genes that optimally differentiated MRD+ and MRD- samples. We then derived a risk score (RS) that indicates a probability of being MRD+ for a given gene expression pattern. Finally, we validated this model in an independent cohort of COG AALL1231 samples. **Results:** The AALL0434 early T-cell precursor (ETP) samples (n = 19), which have high rates of MRD+, had the highest RS, with an average of 81.3 (SD 18.7), versus 24.9 (SD 22.7) for non-ETPs (n = 146). Intriguingly, non-ETPs with RS $>$ 50 had a gene expression pattern that mirrored ETPs and was distinct from the remaining non-ETPs. In this RS $>$ 50 non-ETP cohort, 80% were MRD+, versus 20% of the $<$ 50 cohort ($p < 0.0001$). When applied to 31 diagnostic non-ETP samples from COG AALL1231, 57% of the RS $>$ 50 cohort were MRD+, versus 17% of the RS $<$ 50 cohort ($p = 0.05$). Importantly, AALL0434 used prednisone during induction, while AALL1231 used dexamethasone, indicating that the predictive value is independent of the induction steroid. Finally, we converted our model to the customizable Nanostring nCounter platform by analyzing 96 AALL0434 samples on the Nanostring assay. The Nanostring data closely recapitulated the RNA-seq data, with a tight correlation between the resulting RS (concordance correlation coefficient = 0.91). **Conclusions:** We have developed a gene expression classifier that differentiates a subset of non-ETP T-ALLs with an ETP-like gene expression pattern and a high risk of MRD+, and have adapted the classifier to a clinically tractable targeted platform. Identification of this high-risk subset at diagnosis has the potential to facilitate risk-adapted trials to evaluate the utility of novel or more intensive therapies aimed at improving clinical outcomes. Prognostic Impact of CNS-2 status in T-ALL: A report from the Children's Oncology Group. *First Author: Nathan Gossai, Children's Minnesota, Minneapolis, MN*

Background: In B-acute lymphoblastic leukemia (B-ALL), CNS2 was associated with inferior 5-year (yr) event-free and overall survival (EFS/OS) in recent trials. Here, we report the impact of CNS2 in T-ALL on AALL0434 and AALL1231, recently completed consecutive randomized phase 3 trials for children and young adults with T-ALL and T Lymphoblastic Lymphoma. This report is limited to T-ALL. Both trials used augmented Berlin Frankfurt Münster regimens. AALL0434 compared Capizzi escalating methotrexate+pegaspargase (C-MTX) vs High Dose MTX (HDMTX) +/- six nelarabine (Nel) courses; outcomes improved with CMTX and Nel. CNS1/CNS2 patients, except those defined as low risk (LR) received 12Gy cranial radiation (CRT); CNS3 patients received 18Gy CRT. AALL1231 randomized patients to +/- bortezomib (Bort). AALL1231 changed the AALL0434 backbone, using dexamethasone instead of prednisone throughout. CRT was given only to patients with CNS3 disease (18Gy) and those defined as very high risk (VHR) (12Gy). CNS2 patients could not be classified as LR on AALL0434 or standard risk (SR) on AALL1231. CNS1/CNS2 patients received the same intrathecal therapy frequency on both studies. **Methods:** CNS status was assigned at diagnosis. CNS2 defined as: presence of $<$ 5/ μL WBCs and cytospin positive for blasts or $\geq$ 5/μLWBCs with negative Steinherz Bleyer algorithm. Outcomes by CNS status were compared between AALL0434 and AALL1231. **Results:** From 2007-2014, AALL0434 enrolled 1562 evaluable T-ALL patients, including 1128 (72.8%) CNS1, 306 (19.7%) CNS2 and 116 (7.5%) CNS3. 90.8% received CRT, including 90.4% of CNS1 patients. 5yr EFS rates for CNS1, 2, and 3 were 85.2±1.3%, 83.1±2.6%, and 71.4±5.2% ($p = 0.0007$); OS rates were 90.4±1.1%, 89.2±2.1%, and 83.1±4.3% ($p = 0.0438$). There were no differences in 5yr disease free survival (DFS) between CNS1 and CNS2 treated with CMTX (89.7% vs. 92.9%, $p = 0.17$) or CMTX+Nel (91.8% vs. 89.9%; $p = 0.62$). AALL1231 accrued 614 evaluable T-ALL patients [CNS1 437 (71.1%), CNS2 134 (21.8%), CNS3 43 (7.0%)] from 2014 to early closure in 2017. Of these, only 12% were scheduled to receive CRT. 3yr EFS rates for CNS1, 2 and 3 were 84.1±2.1%, 84.6±3.8% and 78.6±7.9% ($p = 0.50$). 3yr OS was: CNS1 87.5±1.9%, CNS2 92.2±2.8%, CNS3 78.5±7.9% ($p = 0.017$). 3yr EFS was not statistically distinct without Bort in CNS1, 2 or 3 (85.3±2.9%, 81.4±5.6%, 71.9±13.4%) ($p = 0.10$) or with Bort (82.9±3.0%, 88.3±4.9%, 83.3±9,4%; $p = 0.43$). Intermediate risk (IR) CNS1 and CNS2 patients received identical therapy and had similar 3yr EFS (88.8±2.8% vs 88.8±3.5%, $p = 0.98$). **Conclusions:** Unlike in B-ALL, EFS/OS was similar for CNS1 and CNS2 on AALL0434 (with CRT) and AALL1231 (without CRT). Further, IR CNS1 and CNS2 on AALL1231 had similar outcomes with identical therapy. Thus, CNS2 status is non-prognostic in T-ALL on these contemporary COG regimens. CNS3 patients have poor outcomes in T-ALL despite CRT and intensive chemotherapy, novel approaches are needed. Clinical trial information: NCT00408005, NCT02112916. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

10004 **Oral Abstract Session**

Minimal residual disease at end of induction and consolidation remain important prognostic indicators for newly diagnosed children and young adults with very high-risk (VHR) B-lymphoblastic leukemia (B-ALL): Children's Oncology Group AALL1131. *First Author: Wanda L. Salzer, Uniformed Services University, Bethesda, MD*

Background: Children and young adults with very high risk (VHR) B-acute lymphoblastic leukemia (B-ALL) [13-30 years of age with any features or 1-30 years of age with adverse prognostic features including *KMT2A* rearrangements, iAMP21, hypodiploidy (<44 chromosomes/DNA index < 0.81), central nervous system disease, end of induction (EOI) minimal residual disease (MRD) >0.01%, or induction failure] collectively have a predicted 4-year disease free survival (DFS) of approximately 70%. Whether patients with VHR B-ALL who are MRD positive at EOI and become MRD negative at the end of consolidation (EOC) will have improved survival versus patients remaining MRD positive at EOC is unknown. **Methods:** Patients with newly diagnosed NCI high risk B-ALL enrolled on AALL1131 or NCI standard risk B-ALL enrolled on AALL0932 and classified as VHR at EOI were treated on the VHR stratum of AALL1131 which sought to improve DFS with intensive post-Induction therapy using fractionated cyclophosphamide (CPM), etoposide (ETOP) and clofarabine (CLOF).Patients were randomly assigned post-Induction to Control Arm (CA) with modified augmented BFM CPM + fractionated cytarabine + mercaptopurine, Experimental Arm 1 (Exp1) with CPM + ETOP, or Experimental Arm 2 (Exp2) with CLOF + CPM + ETOP during Part 2 of Consolidation and Delayed Intensification. Doses of vincristine and pegaspargase were identical on all arms. Exp2 was permanently closed September 2014 due to excessive toxicities, and these patients are excluded from this report. MRD was measured by 6-color flow cytometry at EOI and for those who consented at the EOC. **Results:** 4-yr DFS for all patients (n=823) with VHR B-ALL was 76.8 ± 2.0%. As we reported previously, 4-year DFS was not significantly different between CA and Exp 1 (85.5 ± 6.8% versus 72.3 ± 6.3%; p=0.76; Burke, Haematologica 2019). 4-yr DFS for patients who were EOI MRD <0.01%, (n=325) versus >0.01 (n=498) was 83.3% ± 2.6% vs 72.0% ± 2.8%, p=0.0013. 4-Year DFS of Patients EOI MRD > 0.01%. **Conclusions:** MRD is a powerful prognostic indicator in VHR B-ALL with inferior outcomes in patients who are EOI MRD positive. Among patients who were EOI MRD positive treated on Exp1, outcomes were similar for EOC MRD negative and EOC MRD positive, though numbers were small. In contrast, patients who were EOI MRD positive treated on CA that were EOC MRD negative had significantly improved DFS compared to those that were EOC MRD positive. The CA remains the standard of care for COG ALL trials. With this therapy, patients with VHR B-ALL that are EOI MRD positive and EOC MRD negative have significantly improved DFS compared to those that remain MRD positive at EOC. Clinical trial information: NCT02883049. Research Sponsor: U.S. National Institutes of Health.

	EOC MRD < 0.01	EOC MRD >0.01	P value
CA	77.6 ± 5.2% (n=141)	55.7 ± 21.4% (n=41)	p=0.0002
Exp1	74.8 ± 3.8% (n=192)	69.1 ± 9.3% (n=44)	p=0.305

10005 **Oral Abstract Session**

Clinical impact of molecular tumor profiling in pediatric, adolescent, and young adult patients with extra-cranial solid malignancies: An interim report from the GAIN/iCat2 study. *First Author: Alanna J. Church, Department of Pathology, Boston Children's Hospital and Harvard Medical School, Boston, MA*

Background: Next generation sequencing (NGS) assays are now a standard part of clinical care for many adult solid cancers. The significance of molecular tumor profiling for the care of children with cancer is not well understood.We aimed to determine the clinical impact of identifying genomic alterations by NGS for young patients with relapsed, refractory, or high-risk extracranial solid tumors. **Methods:** We report on the first 389 participants in a prospective cohort study enrolling patients at 12 institutions with extracranial solid tumors diagnosed at age 30 years or less. Targeted DNA NGS was performed on one or more tumor samples from each patient. Selected patients also had tumors subjected to RNA sequencing. Test results were returned to the treating oncologist and follow-up treatment and response data were collected.Identified genomic alterations were classified according to evidence of impact on diagnosis, prognosis or response to targeted therapy matched to an identified alteration (matched targeted therapy, MTT) using established guidelines. Response to MTT was determined and reported as a response if either there was radiographic response according to RECIST or the duration of therapy was > 4 months. **Results:** Molecular tumor profiling (MTP) was successful in 345 (89%) patients (mean age 11 years at diagnosis; 65% with sarcoma). Two hundred and ninety-nine patients with MTP results (87%) had one or more alterations of clinical significance. Genomic alterations with diagnostic, prognostic or therapeutic significance were present in 208 (60%), 51 (15%) and 240 (70%) patients, respectively. Of the 240 patients with tumors harboring genomic alterations designated as having therapeutic impact, 23 (11%) had Tier 1 molecular findings. 205 patients were eligible to receive MTT based on having a molecular alteration with therapeutic significance and sufficient follow-up; 31 of these patients (15%) received MTT. Seven patients (23%) receiving MTT responded, 6 of these were kinase fusions. All of the responders received targeted therapy matched to a fusion and 78% of diagnostically significant alterations were fusions. **Conclusions:** Molecular tumor profiling has a significant impact on diagnosis and treatment recommendations for young patients with extracranial solid tumors. These results emphasize the importance of fusion detection for patients with sarcomas and rare tumors. Clinical trial information: NCT02520713. Research Sponsor: Private donor.

10006 **Oral Abstract Session**

Integrated whole-exome and transcriptome analysis of 250 treatment-refractory or relapsed (R/R) childhood solid tumors. *First Author: Sara A. Byron, Translational Genomics Research Institute, Phoenix, AZ*

Background: The major genomic profiling studies that have helped define the molecular landscapes of pediatric cancers have typically focused on untreated pediatric cancers at diagnosis. Despite improvements in overall survival for childhood cancers, patients with treatment-refractory or relapsed (R/R) solid tumors face a poor prognosis. The genomic underpinnings of R/R disease are less well-characterized. Here, we describe the integrated genomic and transcriptomic analysis of 250 R/R solid tumors from 202 children profiled within precision medicine studies (NCT01355679, NCT01802567, NCT02162732) conducted by the Beat Childhood Cancer Consortium. **Methods:** Tumor-normal whole-exome and tumor mRNA sequencing was performed by Ashion Analytics (Phoenix, Arizona), a CAP-accredited, CLIA-certified laboratory, or within the research setting at TGen. Longitudinal tumor samples were sequenced for 20 patients. Variant calling included single nucleotide variants, indels, copy number alterations, and fusions. Integrated genomic and transcriptomic research analysis included microsatellite instability assessment, immunogenomic profiling, and functional gene set enrichment analysis. **Results:** Forty-six tumor types were represented, grouped into four general categories: sarcomas (36.1%; n = 73), neuroblastomas (29.2%; n = 59), CNS tumors (23.3%; n = 47), and other rare tumors (11.4%; n = 23). For patients with whole exome sequencing data, 78.3% (n = 144/184) of tumors bore a somatic alteration in at least one known cancer gene. Over one-third (39.1%; 72/184) of the cohort bore oncogenic fusions and/or oncogenic/likely-oncogenic hotspot mutations in a known cancer gene. Pathognomonic fusions were identified in 25% (46/184) of tumors, occurring most frequently in sarcomas. Pathogenic or likely pathogenic germline variants were identified in 8.7% (16/184) of patients. Microsatellite instability was detected in five different tumor types. Despite nearly all tumors (94%, 173/184) having at least one predicted strong binding neoantigen, over a quarter of tumors lacked transcript expression of these neoantigens or exhibited low MHC class I expression. Further, a subset of tumors showed elevated expression of the co-inhibitory immune checkpoint molecule *PDL1*. Transcriptional analysis and functional gene set enrichment analysis identified cross-pathology tumor clusters associated with immune signaling, development, and cellular signaling pathways. Longitudinal analysis revealed temporal heterogeneity pointing to the importance of re-biopsy at relapse for targeted treatment planning. **Conclusions:** Together, these data suggest R/R childhood solid tumors exhibit shared molecular features that are reflective of underlying biology, demonstrating the importance of comprehensive profiling to inform molecularly-guided treatment of R/R disease. Research Sponsor: Dell Inc. Powering the Possible Program, Other Foundation, U.S. National Institutes of Health.

10007 **Oral Abstract Session**

Factors impacting enrollment on NCI-COG Pediatric MATCH trial treatment protocols. *First Author: Donald Williams Parsons, Texas Children's Cancer Center Baylor College of Medicine, Houston, TX*

Background: The NCI-Children's Oncology Group (COG) Pediatric Molecular Analysis for Therapy Choice (MATCH) trial assigns patients age 1 to 21 years with relapsed or refractory solid tumors, lymphomas, and histiocytic disorders to phase 2 treatment arms of molecularly-targeted therapies based on the genetic alterations detected in their tumor. Treatment arm assignments and enrollment decisions have now been made for 1000 study participants: we report here match and enrollment data and factors affecting treatment protocol enrollment. **Methods:** Patients enrolled in the Pediatric MATCH screening protocol were assigned to an open treatment protocol if an actionable mutation (aMOI) was detected by tumor DNA and RNA-based cancer gene panel sequencing. After a match, treatment protocol enrollment must occur within 8-12 weeks. Patient demographic data, reasons for not enrolling on treatment protocol (if applicable), and prior history of molecular testing were reported by study sites. The Fisher exact test was used to compare protocol enrollment rates between groups. **Results:** Results were analyzed for the first 1000 patients with testing completed (enrolled between July 2017 and October 2020). At least one tumor aMOI was detected in 310 (31%) patients and treatment protocol slots were available for 284 patients (28%). A total of 131 patients (46% of those matched) enrolled on a treatment arm. No difference in treatment protocol match or enrollment rate was observed for gender, race, or ethnicity. Both treatment protocol match rate (105/275, 38% vs 86/394, 22%) and enrollment rate (56/275, 20% vs 33/394, 8%) were significantly more frequent in patients with a reported history of prior molecular testing (p<0.0001). The most common reasons provided for not enrolling on a treatment protocol were: patient receiving other treatment (32% of responses), poor clinical status (16%), lack of measurable disease (11%), or ineligible diagnosis for that treatment arm (10%). Ineligibility due to history of excluded prior targeted therapy (6%) or inability to swallow capsules (4%) was less frequent. **Conclusions:** The rate of Pediatric MATCH treatment protocol enrollment has exceeded pre-study projections, due to more frequent actionable mutation detection and treatment assignment than anticipated (28% observed, 10% projected). This may in part reflect an increased number of targetable events in recurrent or refractory pediatric cancers. Correlative studies analyzing pre-treatment tumors from MATCH study patients are underway and will address this hypothesis. Prior history of molecular testing was associated with higher match and enrollment rate and poor clinical status was a common reason for not enrolling on a treatment protocol, suggesting that early molecular screening of children with solid malignancies may facilitate enrollment to biomarker-selected trials of targeted therapies. Clinical trial information: NCT03155620. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

10008 **Oral Abstract Session**

Selumetinib in patients with tumors with MAPK pathway alterations: Results from Arm E of the NCI-COG pediatric MATCH trial. *First Author: Carl E. Allen, Baylor College of Medicine Texas Children's Cancer Center, Houston, TX*

Background: The NCI-Children's Oncology Group (COG) Pediatric Molecular Analysis for Therapy Choice (MATCH) trial assigns patients age 1 to 21 years with relapsed or refractory solid tumors, lymphomas, and histiocytic disorders to phase 2 treatment arms of molecularly-targeted therapies based on genetic alterations detected in their tumor. Arm E evaluated the MEK inhibitor selumetinib (ARRY-142886) in patients whose tumors harbored activating alterations in the MAPK pathway (*ARAF*, *BRAF*, *HRAS*, *KRAS*, *NRAS*, *MAP2K1*, *GNA11*, *GNAQ* hotspot mutations; *NF1* inactivating mutations; *BRAF* fusions). **Methods:** Patients received selumetinib 25 mg/m2/dose (max 75 mg/dose) PO BID for 28-day cycles until disease progression or intolerable toxicity with response assessments obtained every 2-3 cycles. The primary endpoint was objective response rate (ORR); secondary endpoints included progression-free survival (PFS). Patients with low grade glioma were excluded. **Results:** A total of 21 patients (median age 14 years; range 5-21) were enrolled between 10/2017 and 8/2019, with 20 patients evaluable for response. Diagnoses were high grade glioma (HGG; n = 8), rhabdomyosarcoma (n = 7), adenocarcinoma (n = 2), and one each of MPNST, endodermal sinus/yolk sac tumor, plexiform neurofibroma (PN), and neuroblastoma. MAPK pathway alterations detected consisted of inactivating *NF1* mutations (n = 8), hotspot mutations in *KRAS* (n = 8), *NRAS* (n = 3), and *HRAS* (n = 1), and *BRAF* V600E (n = 2). No objective responses were observed. Three patients had a best response of stable disease (HGG with *NF1* mutation, 6 cycles; HGG with *KRAS* mutation, 12 cycles; PN with *NF1* mutation, 13 cycles prior to removal for dose-limiting toxicity). Six-month PFS was 15% (95% CI: 4%, 34%). Adverse events that were deemed possibly, probably, or definitely attributable to study drug included one case each of grade 3 uveitis, lymphopenia, and thromboembolic event; one grade 4 CPK elevation; and one grade 5 thromboembolic event. **Conclusions:** Selumetinib did not result in tumor regression in this cohort of children and young adults with treatment-refractory tumors with activating MAPK pathway alterations. Of note, two patients with HGG initially had stable disease, but ultimately progressed after 6 and 12 cycles, respectively. Selumetinib has previously demonstrated activity in low grade glioma and PN and is now FDA-approved for PN. The results of our study indicate that MAPK pathway mutation status alone is insufficient to predict response to selumetinib monotherapy. It is likely that selumetinib and other MEK inhibitors will require combination with targeted or cytotoxic agents for optimal efficacy in children with persistent or progressive cancers after front-line chemotherapy. Clinical trial information: NCT03213691. Clinical trial information: NCT03155620. Research Sponsor: U.S. National Institutes of Health.

10009 **Oral Abstract Session**

Oral selpercatinib in pediatric patients (pts) with advanced *RET*-altered solid or primary CNS tumors: Preliminary results from the phase 1/2 LIBRETTO-121 trial. *First Author: Daniel A. Morgenstern, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada*

Background: Activating *RET* alterations are oncogenic drivers of select pediatric and adult cancers. Selpercatinib is a first-in-class, highly selective and potent, CNS active *RET* kinase inhibitor. The manageable toxicity profile and durable anti-tumor activity in *RET*-altered cancers demonstrated in the LIBRETTO-001 phase 1/2 trial led to global approvals of selpercatinib in adults and adolescents with thyroid cancer and adults with NSCLC. **Methods:** LIBRETTO-121 (JZJJ) is a multicenter phase 1/2 trial in pts 0.5-21 years (yrs) of age with advanced, *RET*-altered solid or CNS tumors. Enrollment began in June 2019 and is ongoing. Selpercatinib is administered orally as capsule or liquid suspension BID continuously. Dosing started at the adult recommended phase 2 dose (RP2D) equivalent, 92mg/m^2 BID, to confirm RP2D in pts $\leq$2 yrs and $>$ 2 yrs. The phase 1 primary objective is to evaluate safety and dose limiting toxicities (DLTs). The phase 2 primary objective is to determine overall response rate by RECIST 1.1 or RANO by independent review. **Results:** As of 2-Oct-2020, 11 pts (6 male) aged 2–20 yrs (medullary thyroid cancer, n = 8; papillary thyroid cancer, n = 2; osteosarcoma, n = 1) had been treated (phase 1, n = 4; phase 2, n = 7). At baseline, 7 pts had measurable disease. *RET* alterations included fusions (n = 2), activating mutations (n = 8) and mutation with unknown clinical significance (n = 1). Prior therapies included surgery (n = 8), chemotherapy (n = 1), vandetanib (n = 1) and radiotherapy (n = 3), while 3 pts were previously untreated. Time on selpercatinib ranged from 0.9-13.4 months and 9 pts remain on treatment. One pt experienced a dose reduction and 2 pts experienced dose interruptions due to treatment-emergent adverse events (TEAEs) (elevated alanine aminotransferase [ALT] and bilirubin). There were no DLTs and no TEAEs that led to discontinuation of selpercatinib. TEAEs in $>$ 15% of pts included elevated alkaline phosphatase (ALP), constipation, headache, elevated aspartate aminotransferase (AST), diarrhea, hyperphosphatemia, hypoalbuminemia, hypothyroidism, nausea, pyrexia, urinary tract infection, vomiting and weight gain. Drug-related TEAEs in $>$ 15% of pts included elevated AST, elevated ALP, hyperphosphatemia and hypothyroidism. One pt reported TEAEs $\geq$ grade (G) 3 (elevated ALT, G3 and AST, G3) related to selpercatinib. Best response was unconfirmed partial responses in 4 pts, stable disease in 6 pts (two lasting $\geq$16 weeks) and progressive disease in 1 pt. **Conclusions:** These findings appear consistent with the adult trial results, showing preliminary evidence of safety and efficacy of selpercatinib in pediatric pts with *RET*-altered solid tumors. The phase 1 portion in pts $\leq$2 yrs and phase 2 portion at RP2D of 92mg/m^2 BID for pts $>$ 2 yrs are ongoing. Clinical trial information: NCT03899792. Research Sponsor: Eli Lilly and Company.

10010 **Oral Abstract Session**

Phase 2 trial of cabozantinib in children and young adults with refractory sarcomas, Wilms tumor, and rare tumors: Children's Oncology Group Study (ADVL1622). *First Author: Srivandana Akshintala, Pediatric Oncology Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: Cabozantinib is an inhibitor of multiple receptor tyrosine kinases (RTKs) including MET, VEGFR2, RET, and AXL. Preclinical and clinical data support these RTKs as potential therapeutic targets; Safety, tolerability, and responses were demonstrated in a COG phase 1 trial. We conducted a multi-center open label phase 2 trial to determine the activity of cabozantinib in select pediatric solid tumors (NCT02867592). **Methods:** Patients age 2-30 years old with selected relapsed or refractory cancer that was measurable (RECISTv.1.1) were eligible. Using a Simon minimax design, patients were enrolled to six strata: Osteosarcoma (OS), Ewing sarcoma (EWS), rhabdomyosarcoma (RMS), non-rhabdomyosarcoma soft tissue sarcoma (NRSTS), Wilms tumor (WT), and rare tumor (a non-statistical stratum including tumors of specific histologies or molecular features). Cabozantinib (40 mg/m^2/day) was administered on a continuous schedule (1 cycle = 28 days). For the OS stratum, activity was determined based on objective response rate (ORR, complete response (CR) + Partial response (PR)) or disease control success defined as at least stable disease (SD) for $\geq$ 4 months. For all other strata, the primary endpoint was ORR. Pharmacokinetics were performed in patients $<$ 19 years. **Results:** Between May 2017- Oct 2020, 109 patients enrolled (105 eligible, 104 evaluable for response and toxicity). Median age was 15.8 (range 5.6-27.1) years; 55 were male. In the OS stratum, 10/29 (34%) patients had central review confirmed disease control $\geq$ 4 months (2 PR, 8 SD), exceeding the protocol-defined criteria for activity of cabozantinib in OS. Median duration of therapy was 3 cycles (range 1-28+). In EWS, RMS, NRSTS, and WT strata (n = 13 evaluable patients each) no PR or CR were observed. In the rare tumor stratum (n = 23), 1/4 patients with renal cell carcinoma, 1/1 patients with RET fusion positive papillary thyroid cancer had a PR, and 1 patient with medullary thyroid cancer had a delayed PR. SD $\geq$ 6 cycles was seen in patients with EWS (n = 2), NRSTS (n = 5), WT (n = 3), and hepatocellular carcinoma (n = 1). At data cutoff (12/31/2020), 430 treatment cycles were administered; two patients remain on therapy. Cycle 1 and later cycle dose limiting toxicities (DLT) were seen in 20 (19%) and 39 (38%) patients, respectively. Common DLT were elevated liver enzymes, bilirubin, and lipase, hyponatremia, weight loss, anorexia, nausea, vomiting, wound dehiscence, palmar-plantar erythrodysesthesia, and pneumothorax. Day 1 pharmacokinetics (mean ± SD, n = 16) demonstrated a maximum plasma concentration of 556 ± 376 ng/ml, half-life 106 ± 102 hours, and area under the curve ($AUC_{0\text{-}24h}$) 8093 ± 4368 ng•h/mL. **Conclusions:** Cabozantinib is active in patients with relapsed refractory OS and deserves further study in this disease. PRs were also seen in select carcinomas. Activity is limited in other sarcomas and WT. Clinical trial information: NCT02867592. Research Sponsor: U.S. National Institutes of Health.

10011 **Oral Abstract Session**

Pilot study of nivolumab in pediatric patients with hypermutant cancers. *First Author: Daniel A. Morgenstern, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada*

Background: Responses to immune checkpoint inhibitors (ICI) in unselected pediatric solid tumors have been disappointing. We hypothesized that pediatric cancers with an increased tumor mutation burden (TMB) and/or replication repair deficiency (RRD) may be uniquely susceptible to ICI therapy. **Methods:** OZM-075 (NCT2992964) is a multicenter pilot study in patients (pts) aged 1-25 yrs with relapsed/refractory cancers (including CNS tumors). Pts were eligible only if tumor showed evidence of RRD (based on immunohistochemistry showing loss of expression of relevant RR protein) or elevated TMB $>$ 5mut/Mb determined by gene panel DNA sequencing. Pts with measurable or evaluable disease were eligible. Enrolment began in May 2017 and was completed in Nov 2020. Pts received programmed death-1 (PD-1) inhibitor nivolumab (NIVO) at a fixed dose of 3mg/kg every 2 weeks. Primary objective was objective response rate (ORR) by iRECIST or iRANO for those with measurable disease. Tumor tissue and serial blood samples were collected for analysis of biomarkers of response and survival. **Results:** As of 26Jan2021, 6 male and 5 female patients aged 9-18 yrs received treatment with NIVO (5 glioblastoma (GBM), 2 anaplastic astrocytoma (AA), 2 neuroblastoma, 1 colorectal adenocarcinoma (CRC), 1 adrenocortical carcinoma). 3pts had TMB 5-10mut/Mb, 5pts had TMB $>$ 10mut/Mb (range 14-837, median 64), 3 pts enrolled on basis of RRD. Time on treatment ranged from 0-21 months and 2 pts remain on therapy. Best OR was partial response (PR) in 2 pts (both GBM), with an additional patient with CRC achieving pathological CR. Remarkably one of the pts with PR showed early evidence of progression on imaging and elected to discontinue NIVO. Without further therapy, subsequent imaging 7 months later showed PR. Best response of stable disease was demonstrated in 5 further pts, lasting $\geq$5 months in 3 pts. Median overall survival (OS) not reached. Of 7 patients with relapsed GBM/AA, 5 were alive for $\geq$12 months following start of NIVO including 4 pts with confirmed TMB $>$ 10mut/Mb. **Conclusions:** This pilot study showed evidence of impressive clinical benefit particularly for relapsed GBM/AA patients for whom median survival is typically ~6 months (JCO 1995 13(1):112-). These data contrast previous pediatric data and suggest that in the context of RRD and hypermutation ICI therapy may provide profound long-term response and survival for these children. Analysis of other correlative biomarkers is ongoing. Clinical trial information: 2992964. Research Sponsor: BMS, Other Foundation.

10012 **Oral Abstract Session**

Changes in ctDNA levels after MIBG therapy in patients with relapsed or refractory neuroblastoma. *First Author: Kevin M. Campbell, Dana-Farber/ Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Circulating tumor DNA (ctDNA) is detectable in children with neuroblastoma. Less is known about how levels change during treatment and the implications of these changes. We evaluated ctDNA pre- and post- 131I-metaiodobenzylguanidine (MIBG) therapy. **Methods:** We utilized plasma samples from NANT11-01 (NCT02035137), a multi-center, open label, randomized phase II clinical trial evaluating MIBG with or without radiation sensitizers for patients with relapsed or refractory neuroblastoma. Plasma was collected at Baseline prior to MIBG, 72 hours (Hr72), 96 hours (Hr96), 15 days after MIBG (D15), and prior to a second course among patients without progression who received a second course (C2). Samples were analyzed for percent ctDNA levels using ultra-low passage whole genome sequencing. We evaluated associations between ctDNA findings with baseline disease measures of percent involvement in bone marrow, Curie score, and RECIST disease sum of diameters as well as overall response by NANT Response Criteria v1.2 (complete response or partial response coded as responders). **Results:** Eighty-four patients had a baseline sample and were included in this analysis. Of the 37 patients (44%) with detectable ctDNA at baseline, the median ctDNA level was 32% (range 3.9-91%). Baseline ctDNA levels showed a significant positive correlation with percent involvement in bone marrow (r=0.37; p= 0.0004) and Curie score (r=0.26; p = 0.018), but not RECIST sum of diameters for soft tissue sites (r=0.065; p=0.56).Following therapy, the proportions of patients with detectable ctDNA were: Hr72 47% (34/73; median level 28%); Hr96 50% (26/52; median 28%); D15 33% (7/21; median 4%); and C2 14% (3/21; median 50%). Rate of ctDNA detection was similar between responders and non-responders at baseline, Hr72, and Hr96, but lower among responders at D15 and C2 (Table). Among the 21 patients with C2 data, ctDNA levels were either undetectable (n=18) or lower than Cycle 1 Baseline (n=3). Among patients with detectable baseline ctDNA, the median relative ctDNA level at Hr72 (Hr72 ctDNA/baseline ctDNA) for non-responders was 0.87 (n= 24) vs. 1.16 for responders (n=7). In contrast, the median relative ctDNA level at C2 for non-responders was 0.56 (n=4) vs. 0 for responders (n=4). **Conclusions:** ctDNA is detectable in a substantial proportion of patients with relapsed / refractory neuroblastoma, with levels correlated with conventional measures of disease burden. Following MIBG therapy, early timepoints (Hr72 and Hr96) are less informative, whereas ctDNA becomes undetectable at D15 and C2 more commonly in patients with clinical response. Research Sponsor: None.

Proportion of patients with detectable ctDNA according to response to first course.

	Baseline	Hr72	Hr96	D15	C2
Responders	8/19 (42%)	9/17 (53%)	6/14 (43%)	0/2 (0%)	0/6 (0%)
Non-responders	29/65 (45%)	25/56 (45%)	20/38 (53%)	7/19 (37%)	3/15 (20%)

10013 **Oral Abstract Session**

Mortality among five-year survivors of childhood cancer: Results over five decades of follow-up in the Childhood Cancer Survivor Study. *First Author: Stephanie B Dixon, St Jude Children's Research Hospital, Memphis, TN*

Background: Adult survivors of childhood cancer are at greater risk for late mortality compared to the general population due to cancer and its treatment. Risk factors, patterns and specific causes of late mortality across the lifespan are not well established. **Methods:** All-cause, cause-specific, and health-related late mortality (HRM; excludes death from primary cancer and external causes) $>$ 5 years from diagnosis were evaluated in survivors diagnosed $<$ 21 years of age between 1970-1999. Cause of death was based on ICD codes from the National Death Index through December 2017. Cumulative mortality, mortality rates and standardized mortality ratios (SMRs) with 95% confidence intervals (CIs) were estimated, overall and in 5- and 10-year survival periods. **Results:** Among 34,230 survivors (median time from diagnosis 29.1 years, range 5.0 - 48.0) the 40-year cumulative mortality was 23.3% (95% CI 22.7 - 24.0). Of 5,916 deaths, 3,061 (51.2%) were attributable to health-related causes including subsequent neoplasm (n = 1,458), cardiac (n = 504), and pulmonary causes (n = 238). All-cause mortality by time from diagnosis demonstrated a U-shaped distribution: 10.1 deaths/ 1000 person-years at 5-9 years, largely due to recurrence of the primary cancer, decreasing to 4.1 at 15-19 years before increasing to 18.5 at 40-48 years, attributable to an increasing mortality rate from HRM (2.3 at 5-9 years; 17.0 at 40-48 years). For the interval 5-9 years from diagnosis, survivors had an 18.1-fold (95% CI 17.3-18.9) higher risk of death from any cause, and a 13.1-fold (11.9-13.4) higher risk for HRM when compared to the general population. Although the SMRs declined with duration of follow-up, survivors had a 4-fold higher risk of death overall, attributable to a more than 4-fold increased risk of HRM. HRM 40-48 years from diagnosis was largely attributable to an increased risk of death due to subsequent neoplasm (SMR 6.0, 95% CI 4.9-7.2), cardiac (3.9, 2.9-5.0) and pulmonary (5.6, 3.6-8.4) causes. Cause-specific mortality remained markedly elevated at 40-48 years from diagnosis: CNS malignancy (SMR 11.7, 95% CI 5.4-22.3), benign meningioma (171.3, 34.4-500.5), valvular heart disease (39.8, 21.2-68.1), cardiomyopathy (10.4, 4.5-20.5), stroke (7.9, 4.6-12.6), and renal failure (5.6, 1.8-13.2). HRM was significantly higher among the youngest group of survivors (0-4 years at diagnosis), non-Hispanic blacks and those who received radiation to the brain, chest or total body, or who were exposed to anthracycline, alkylating or platinum chemotherapy. **Conclusions:** After five decades, aging survivors consistently remain at higher risk of all-cause mortality compared to the general, aging population, primarily due to a persistent 4-fold increased risk of HRM. Continued late-effects surveillance and reduction of therapies associated with long-term morbidity and increased mortality is essential. Genetic and treatment risks for diabetes mellitus (DM) in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS) and St. Jude Lifetime (SJLIFE) cohorts. *First Author: Melissa A. Richard, Baylor College of Medicine, Houston, TX*

Background: Childhood cancer survivors face increased risk for DM, a polygenic trait also attributable to cancer treatment exposures, particularly abdominal radiation. We aimed to characterize the role of genetic and treatment risk factors for DM among two large cohorts of childhood cancer survivors. **Methods:** We performed a nested case-control genome-wide association study for DM managed with oral medications in the original CCSS cohort (diagnosed 1970-1986). Logistic regression was conducted in the total sample (N = 5083) and stratified by 1) European ancestry (EA) and 2) abdominal radiation. Replication of suggestive variants ($P < 1\times10^{-7}$) using Fisher's exact test was performed in independent cohorts: i) CCSS expansion diagnosed 1987-1999 (N = 2588) and ii) SJLIFE diagnosed 1962-2012 (N = 2182). To evaluate the effect of cancer treatment on the background genetic predisposition to DM, we estimated standardized effect sizes (Z') among EA survivors in each abdominal radiation group for 398 index variants from the largest population-based EA DM study. Radiation group Z' estimates were compared using linear regression. **Results:** In the original CCSS cohort we identified nine variants associated with DM and provide further support for four linked variants in the *ERCC6L2* locus. Among all survivors, the rs55849673-A allele was associated with increased odds for DM among survivors in the original CCSS cohort (minor allele frequency [MAF]-cases = 0.055; MAF-controls = 0.024; adjusted odds ratio [aOR] = 2.9, 95% CI: 2.0-4.2, $P = 3.7\times10^{-8}$). Allele frequencies were consistent in the CCSS expansion (MAF-cases = 0.075; MAF-controls = 0.028; P = 0.07) and SJLIFE (MAF-cases = 0.036; MAF-controls = 0.027; P = 0.5). Additionally, rs55849673-A estimates were consistent among EA survivors and stronger among survivors not treated with abdominal radiation (MAF-cases = 0.052; MAF-controls = 0.021; aOR = 3.6, $P = 1.6\times10^{-6}$). Notably, in the CCSS expansion all rs55849673-A EA carriers who developed DM did not receive abdominal radiation (MAF-cases = 0.1; MAF-controls = 0.026; P = 0.04). More broadly, the Z' of population-based DM index variants were 78% lower in survivors treated with abdominal radiation than survivors not treated with abdominal radiation (beta = 0.22; P = 0.01), indicating the background genetic risk for DM may be altered by treatment. **Conclusions:** We provide evidence for a novel locus of DM in childhood cancer survivors. This locus is a regulatory region associated with expression of *ERCC6L2*, a gene implicated in an East Asian population-based DM study. Taken together, our findings support the overwhelming effect of abdominal radiation on DM risk in childhood cancer survivors, relative to other risk factors, and provide insight on a genetic locus that may be useful for DM risk prediction in the context of cancer treatment. 10015 **Oral Abstract Session**

Exercise and QUality diet After Leukemia (The EQUAL Study): An intervention trial in the Childhood Cancer Survivor Study (CCSS). *First Author: Emily S. Tonorezos, National Institutes of Health, National Cancer Institute, Rockville, MD*

Background: Survivors of childhood acute lymphoblastic leukemia (ALL) are at risk for obesity and cardiovascular (CV) disease. Exposure to cranial radiotherapy (CRT) increases risks. We tested whether a weight loss intervention that was successful in the general population could result in weight loss or improvements CV risk factors for ALL survivors. **Methods:** Obese and overweight 5-year ALL survivors diagnosed $<$ age 21 from CCSS were randomized to a 24-month remotely delivered diet/physical activity intervention or self-directed weight loss (control), stratified by CRT. The intervention emphasized a low calorie DASH diet and physical activity via an app, a website, and weekly coach calls. The primary endpoint was difference in weight loss after 24 months, using an intent-to-treat analysis. Secondary endpoints: differences in changes in blood pressure, cholesterol, and triglycerides. Analyses were performed using linear mixed effects; the study was designed to detect a difference of 2.75 kg. **Results:** Of 358 survivors (59% female, 91% White non-Hispanic, median age 37, IQR: 33-43), 181 were randomized to the intervention and 177 to control. Baseline mean (SD) weight was 98.6 kg (24.0) for intervention and 94.9 kg (20.3) for controls. 55 (30%) of intervention participants were adherent beyond one year. At 12 months, after controlling for CRT, sex, race/ethnicity, and age, the adjusted mean (SE) change in weight from baseline was -1.83kg (0.7) for intervention and -0.16kg (0.64) for control participants. At 24 months, the adjusted mean (SE) change in weight was -0.36kg (0.78) for intervention and +0.18kg (0.66) for control participants with the average difference of -0.54 kg (95%CI: -2.5,1.5, p=0.59) between the arms. A small proportion had at least 5% weight loss at 24 months (intervention 24%; control 17%). No significant differences in CV risk factors were observed. **Conclusions:** A 24-month phone and app/web-based diet and physical activity intervention that was successful for weight loss in the general population did not result in greater weight loss or improvement in CV risk factors among adult survivors of childhood ALL. Reduced adherence to the intervention beyond 12 months, or lack of ALL survivor-specific tailoring, may account for these findings. Clinical trial information: NCT02244411. Research Sponsor: U.S. National Institutes of Health.

10016 **Oral Abstract Session**

Racial disparities in pediatric cancer care in the United States: An analysis of the Kids' Inpatient Database. *First Author: Sujith Baliga, Ohio State University-James Cancer Hospital Solove Research Institute, Columbus, OH*

Background: The impact of race and socioeconomic status (SES) on cancer mortality has been elucidated in adult patients, but is not well described in pediatric oncology. We hypothesize that racial and socioeconomic disparities exist in pediatric cancer patients, resulting in higher rates of hospitalization and mortality. **Methods:** We analyzed the Kids' Inpatient Database (KID) which shows national estimates of inpatient stays for pediatric patients. Inclusion criteria included patients who were ≤20 with a cancer diagnosis identified through the Clinical Classifications Software (CCS). Variables analyzed were discharge status, patient demographics, hospital characteristics, expected payment source, total visit charge, and length of stay. Initial comparisons between cancer and non-cancer related discharges were performed using a chi-square test. To estimate disparities by race, clinical comparisons were performed across five racial groups: White, Black, Hispanic, Asian/Pacific Islander, and Native American/Other. A multivariable logistic regression model was used to examine predictors of hospitalization and mortality. **Results:** From 2006-2012, there were 9,488,477 non-cancer related pediatric inpatient stays and 242,489 cancer related stays. Patients with cancer related visits were more likely to be white, male (54.9% vs 46.1%, $p < 0.0001$), older at admission, have private insurance (52.5% vs 41.7%), and were from a higher income quartile (76^{th}-100^{th} percentile, 25.2% vs 19.9%, $p < 0.001$). These patients also had a higher rate of death during admission (1.2% vs 0.5%, $p < 0.0001$), higher cost of visit charge ($25,097 vs $8,267, $p < 0.001$), longer length of stay (4 vs 2 days), and were less likely to be discharged (85.5% vs 92.0%, $p < 0.0001$).The four most frequent cancer diagnoses associated with hospital admission were leukemia (n = 75,807), Other and Unspecified Primary (n = 50,076), bone/connective tissue tumor (n = 42,477), and central nervous system tumor (n = 27,958). Patients who were non-white were more likely to die during their inpatient stay (1.5% Non-white versus 0.9% White, $p < 0.001$). On multivariate logistic regression, Black (OR: 1.61, 95% CI: 1.57-1.66, $p < 0.0001$) and Native American (OR: 1.39, 95% CI: 1.34-1.44, $p < 0.0001$) race, as well as lower income quartile (OR: 1.24, 95% CI: 1.19-1.28, $p < 0.001$) were associated with increased odds of death during admission. **Conclusions:** This is the largest observational study to date to identify the impact of race and SES on pediatric cancer hospitalization and mortality in the United States. Non-white race and lower SES was associated with significantly increased odds of death during admission. Given the significant difference in mortality by race, healthcare policy makers and insurance companies should investigate the specific drivers of increased admission and mortality and develop strategies to address inequity in cancer care. Research Sponsor: None.

Disparities in cardiovascular risk factors by race/ethnicity among adult survivors of childhood cancer: A report from the Childhood Cancer Survivorship Study (CCSS). *First Author: David H Noyd, Duke University Health System, Durham, NC*

Background: Racial, ethnic, and socioeconomic disparities are documented in outcomes for childhood cancer survivors. Understanding whether childhood cancer modifies established disparities in cardiovascular risk factors (CVRFs) in the general population would inform strategies to reduce health inequities among survivors. **Methods:** The CCSS is a retrospectively constructed cohort with prospective follow-up consisting of 25,579 five year survivors of childhood cancer diagnosed between 1970 and 1999. We estimated the incidence of self-reported Common Terminology Criteria for Adverse Events (CTCAE) grade >2 CVRFs (hypertension, diabetes, dyslipidemia, and obesity) and multiple (>2) CVRFs among survivors. Multivariable Poisson regression estimated the rate ratios (RR) of CVRFs by race/ethnicity, adjusted for key treatment exposures and sociodemographics. **Results:** Within the CCSS cohort, there were 20,416 non-Hispanic White (NHW), 1625 non-Hispanic Black (NHB), and 2043 Hispanic survivors with the cumulative incidence estimates of each CVRF at age 40 displayed in Table. Survivors who self-reported "Other" or mixed race were excluded for this analysis (n=1495). NHB survivors were more likely to report hypertension (unadjusted RR 1.3; 95% Confidence Interval [CI] 1.0-1.6), diabetes (RR 1.6; 95% CI 1.0-2.4), obesity (RR 1.6; 95% CI 1.4-1.9), and multiple CVRF (RR 1.3; 95% CI 1.2-1.5), whereas Hispanic survivors were more likely to report diabetes (RR 1.7; 95% CI 1.2-2.4), obesity (RR 1.4; 95% CI 1.2-1.5), and multiple CVRFs (RR 1.1; 95% CI 1.0-1.3) compared with NHW survivors. These observed disparities in risks of CVRFs remained nearly unchanged even after adjustment for sociodemographic factors (age, sex, household income, education, marital status, employment, and insurance) and treatment exposures (Yes/No for anthracyclines, alkylators, and chest radiation). **Conclusions:** NHB and Hispanic adult survivors demonstrate a higher burden of CVRF compared with NHW survivors, particularly diabetes and obesity. The associated morbidity of these conditions and established increase they incur in risk of more severe cardiovascular disease emphasizes the need for interventions to mitigate CVRFs to promote health equity among these survivors. Research Sponsor: U.S. National Institutes of Health.

Cumulative incidence of CVRFs (Percentage, 95% CI) at age 40.

Race/Ethnicity	Hypertension	Diabetes	Dyslipidemia	Obesity	>2 CVRFs
NHW (n=20,416)	14.7 (14.0-15.3)	5.2 (4.8-5.6)	10.2 (9.6-10.7)	32.5 (31.6-33.3)	12.6 (12.0-13.2)
NHB (n=1625)	20.7 (17.7-23.7)	9.2 (7.2-11.2)	6.6 (4.6-8.6)	50.0 (46.4-53.3)	18.6 (15.5-21.6)
Hispanic (n=2043)	14.1 (11.8-16.4)	10.1 (8.2-11.9)	11.1 (8.9-13.2)	50.1 (47.0-53.1)	16.4 (13.9-18.9)

10018 **Poster Discussion Session**

Feasibility of pevonedistat combined with azacitidine, fludarabine, cytarabine in pediatric relapsed/refractory AML: Results from COG ADVL1712. *First Author: Katherine Tarlock, Seattle Children's Hospital, Seattle, WA*

Background: Outcomes for children with relapsed/refractory (R/R) AML and MDS are poor and new therapies are needed. Pevonedistat is an inhibitor of the NEDD-8 activating enzyme, a key regulator of the ubiquitin proteasome system that is responsible for protein turnover, cell growth and survival. In preclinical models, pevonedistat was synergistic with cytarabine (AraC) and azacitidine (aza). The combination of pevonedistat + aza in adults with AML demonstrated improved responses compared to either single agent. We evaluated the feasibility, toxicity and pharmacokinetics (PK) of pevonedistat in combination with aza, fludarabine, AraC (Aza-FLA) in children with R/R AML and MDS. **Methods:** Pevonedistat 20 mg/m^2, IV days 1, 3, 5, the recommended adult dose, was administered in combination with aza (75 mg/m^2, days 1-5), fludarabine (30 mg/m^2, days 6-10), and AraC (2000 mg/m^2, days 6-10). Intrathecal AraC was administered at the start of therapy and additional doses given to patients with CNS leukemia. If < 33% of the initial 6 enrolled patients experienced dose limiting toxicity (DLT) during cycle 1 the regimen would be considered tolerable and 6 additional patients could enroll to further assess tolerability and PK. Pevonedistat PK was determined during cycle 1 following doses 1 and 5. Response was evaluated after cycle 1. **Results:** A total of 12 patients were enrolled, median age was 13 years (range 1-21). All patients received prior chemotherapy, median number of prior regimens was 2 (range 1-5) and 3 (25%) patients had prior hematopoietic stem cell transplant. Diagnoses were AML NOS (n = 10, 83%), acute monocytic leukemia (n = 1), and therapy related AML (n = 1). One of the initial 6 patients had DLTs (hypertension, GGT elevation, and proteinuria); pevonedistat 20 mg/m^2 + Aza-FLA was considered tolerable. Six additional patients were enrolled, two had DLTs (weight loss, hypoxia). Overall, 3/12 (25%) of patients experienced DLTs. As expected, using the intensive Aza-FLA backbone, myelosuppression, electrolyte abnormalities, and hepatic transaminase elevation were common. Day 1 PK parameters (n = 12, mean±SD) were: C_{max}= 223±91 ng/mL, $AUC_{0\text{-}24h}$= 892±216 ng/hr/mL, $T_{1/2}$=4.3±1.2 hours, CL = 23.2±6.9 L/hr/m^2. PK parameters were similar following doses 1 and 5, for patients < 12 (n = 6) and ≥ 12 (n = 6) years, and to adult PK profiles. Ten patients were evaluable for response. The overall response rate was 30% (95% CI: 7,75) with 3 patients achieving a CR with incomplete hematologic recovery (CRi). **Conclusions:** Pevonedistat 20 mg/m^2 combinedwith Aza-FLA was tolerable in children with R/R AML. The toxicity of the regimen was similar to other intensive AML regimens. PK parameters were similar among the two age groups and were comparable to adults. Within the confines of a phase I study, there was limited anti-leukemic activity of the combination of pevonedistat +Aza-FLA in R/R AML. Clinical trial information: NCT03813147. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

10019 **Poster Discussion Session**

Phase 1 study of pevonedistat (MLN4924) a NEDD8 activating enzyme inhibitor, in combination with temozolomide (TMZ) and irinotecan (IRN) in pediatric patients with recurrent or refractory solid tumors (ADVL1615). *First Author: Jennifer Foster, Texas Children's Hospital, Houston, TX*

Background: Pevonedistat (PEV), a first in class inhibitor of NEDD8 activating enzyme (NAE), prevents the activation of Cullin-RING ligases (CRL) necessary for proteasome mediated degradation of key regulatory proteins important in cell survival. In adults with solid tumors, the maximum tolerated dose (MTD) in combination with chemotherapy is 20-25 mg/m^2. Antitumor activity of PEV has been demonstrated in preclinical models of childhood cancer. *In vivo* additive activity has been demonstrated for PEV in combination with IRN and alkylating agents. The objectives of this study are to determine the MTD and recommended Phase 2 dose of PEV in combination with IRN and TMZ and describe the toxicities, pharmacokinetic (PK), and pharmacodynamics (PD) properties of this combination. **Methods:** We conducted a phase 1 trial of PEV in combination with IRN and TMZ in pediatric patients (pts) with recurrent or refractory solid tumors and brain tumors. During cycle 1, PEV was administered intravenously on days 1, 8, 10, and 12, with IRN (IV, 50mg/m^2) and TMZ (orally, 100mg/m^2), on days 8-12 of a 28 day cycle. In subsequent cycles, PEV was administered on days 1, 3, and 5, with IRN and TMZ on days 1-5 of a 21 day cycle. Dose escalation was determined using the Rolling 6 Design. **Results:** 30 pts enrolled. All pts were eligible and evaluable for cycle 1 dose limiting toxicity (DLT) assessment. Median (range) age was 13 (1-21) years; 19 (63%) were male. Eleven pts had brain tumors, and 19 pts had solid tumors. Six pts each enrolled on PEV dose levels (DL) 1 (15mg/m^2), 2 (20mg/m^2), 3 (25mg/m^2) and 4 (35mg/m^2) as well as an expanded PK cohort at DL4. Cycle 1 grade 3/4 toxicities include lymphopenia (n = 5), leukopenia (n = 4), neutropenia (n = 2), elevated ALT (n = 2), elevated AST (n = 1), diarrhea (n = 1), flu-like symptoms (n = 1). The most frequent non-dose limiting AEs in cycle 1 were anemia (87%), WBC decreased (77%), nausea (57%), diarrhea (53%), ALT increased (50%), AST increased (50%), and vomiting (50%). PK analyses showed the mean area under the curve at the 25 mg/m^2 dose level on day 8 (in combination with irinotecan and temozolomide) was 1300 hr•ng/mL, half-life (T $^1/_2$) was 5-6 hours, time to maximum concentration (Tmax) was 1 hour, and mean clearance was 20 L/hr/m^2. There were 3 DLTs, 2 of which were related to protocol therapy (diarrhea and thrombocytopenia), among 12 patients on DL4. Thus the MTD was not exceeded at any dose level. PK at the 25 mg/m^2 dose level are comparable to those in adult patients. PK from the 12 patients on DL4 (35mg/m^2) as well as responses of all patients are pending. **Conclusions:** PEV in combination with IRN and TMZ is well tolerated in children with solid or brain tumors. PEV PK was not altered by the addition of irinotecan and temozolomide. Further PK and PD analyses are ongoing to establish the recommended phase 2 dose. Clinical trial information: NCT03323034. Research Sponsor: U.S. National Institutes of Health.

10020 **Poster Discussion Session**

Low-dose metronomic topotecan and pazopanib in children with recurrent or refractory solid tumors: A C17 Canadian phase I trial (TOPAZ). *First Author: Arif Manji, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada*

Background: Low-dose metronomic topotecan (mTP) represents a novel approach to chemotherapy delivery which, in preclinical models, may work synergistically with pazopanib (PZ) in targeting angiogenesis. This study was designed to determine the recommended phase 2 dose (RP2D) of mTP/PZ in pediatric patients with solid tumors, while describing the safety and toxicity of this regimen. **Methods:** A phase I dose-escalation, pharmacokinetic (PK) and pharmacodynamic (PD) study of mTP/PZ was conducted at ten sites across Canada, enrolling pediatric patients aged 2-21 years with relapsed/refractory solid tumors. Patients were treated with oral mTP and PZ suspension daily without interruption in 28-day cycles, with dose escalation in accordance with the rolling-six design. Five dose levels (0.12/125, 0.16/125, 0.22/125, 0.22/160, and 0.3/160 mg/m^2/day of mTP/PZ) were evaluated. PK studies were performed on day 1 and at steady state, and PD studies included circulating angiogenic factors VEGFR1, VEGFR2, VEGF, endoglin and placental growth factor. **Results:** Thirty patients (pts) were enrolled, of whom 26 were evaluable for dose-limiting toxicity (DLT), with median age 12 years (3-20). The most common diagnoses included osteosarcoma (8), neuroblastoma (NB, 7), Ewing sarcoma/PNET (4), and rhabdomyosarcoma (4). The most common grade 3/4 adverse events (AEs) related to protocol therapy were neutropenia (18%), thrombocytopenia (11%), lymphocytopenia (11%), AST elevation (11%), and lipase elevation (11%). Only 2 cycle-1 DLTs were observed on study, both at the 0.3/160 mg/m^2 mTP/PZ dose level (2/5 pts) comprising persistent grade 3 thrombocytopenia and grade 3 ALT elevation. No AEs experienced beyond cycle-1 required treatment discontinuation. Best response was stable disease in 10/25 pts (40%) for a median duration of 6.4 months (1.7-45.1). One patient with refractory NB achieved stable disease for 45 months and continued on mTP/PZ via compassionate access after study closure. PK and PD results are pending at this time. **Conclusions:** The combination of oral mTP and PZ is safe and tolerable in pediatric patients with solid tumors, with a RP2D of mTP 0.22 mg/m^2/day and PZ suspension 160 mg/m^2/day. Ten patients achieved stable disease for a median of 6 months. The lack of objective responses suggests that this combination is likely of limited benefit for relapsed disease, but may play a role as maintenance therapy. Clinical trial information: NCT02303028. Research Sponsor: Novartis, C17 Research Grant.

10021 **Poster Discussion Session**

Naxitamab and GM-CSF for consolidation of high-risk neuroblastoma (HR-NB) patients in complete remission. *First Author: Jaume Mora, Pediatric Surgery Department, Hospital Sant Joan de Déu, Universitat de Barcelona, Barcelona, Spain*

Background: Naxitamab was recently approved in the US in combination with GM-CSF for the treatment of patients (pts) with relapse/refractory HR-NB in the bone/bone marrow who have demonstrated a partial response (PR), minor response (MR), or stable disease (SD) to prior therapy. Here we describe the use of 5 cycles of naxitamab and GM-CSF through compassionate use for consolidation of HR-NB pts in first or subsequent complete remission (CR). **Methods:** HR-NB pts in CR (first or subsequent) after initial multimodal induction treatment were eligible. Disease status was assessed at study entry by histology of BM biopsies/aspirates obtained from bilateral posterior and bilateral anterior iliac crests, I-MIBG SPECT scan, and whole body MRI. FDG-PET was used for MIBG non-avid cases at diagnosis. Quantitative reverse transcription-polymerase chain reaction was used to assess MRD in pooled heparinized BM aspirates. Disease response was defined according to the revised INRC. Four BM aspirates and ^{123}I-MIBG SPECT scan or FDG-PET scans were performed after cycles 2 and 5 and every 3 months thereafter for one year in all pts to assess response. Naxitamab was administered over ≥30 min in the outpatient setting on Days 1, 3 and 5 at 3.0 mg/kg/infusion (9.0 mg/kg/cycle) in combination with GM-CSF at 250 ug/m^2/day on Days -4 to 0 and at 500 ug/m^2/day on days 1 to 5. Treatment cycles were repeated every 4 weeks. Survival curves were built from the time of naxitamab treatment initiation by Kaplan-Meier methods and compared using the log-rank test. **Results:** From June 2017 to November 30 2020, 73 pts were treated: 55 (75%) in first CR and 18 (25%) in second or more CR. Majority of pts were MYCN non-amplified (n=56, 77%), all stage 4, median age at treatment initiation 4.5 years. 61 (84%) pts had received >5 cycles of induction chemotherapy; 22 (30%) high-dose chemotherapy and autologous stem cell transplant (ASCT); and 36 (49%) radiotherapy before receiving naxitamab. 58 (79.5%) pts completed naxitamab therapy, 53 (73%) in continued CR. 10 (14%) pts relapsed during treatment and 5 (7%) had grade 4 toxicities: 2 apnea related to naxitamab; and 2 non-related: 1 opioid related chest rigidity syndrome and 1 stroke. 3-y event-free-survival (EFS) for all pts is 58% [95% CI, 43.5; 78.4], 74% for first CR and 19% for second or more CR (p=0.0029). 3-y OS for the whole group is 82% [95% CI, 66.8; 100.0], 92% for first CR and 66% for second or more CR pts (p=0.18). Univariate Cox models for CR group, MYCN status, number of chemotherapies, ASCT, radiotherapy, MRD, and age showed significant p value only for prior relapse as predictor of EFS (p=0.047). **Conclusions:** Naxitamab for HR-NB pts in CR provided excellent 3-y OS rates regardless of previous management. The only predictor for relapse is prior history of recurrence. Research Sponsor: Ymabs Therapeutics, Other Foundation.

10022 **Poster Discussion Session**

Efficacy of naxitamab in patients with refractory/relapse (R/R) high-risk neuroblastoma (HR-NB) by bone/bone marrow (BM) evaluation, potential sites of residual disease. *First Author: Brian H. Kushner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NB is the most common extracranial solid tumor in children and half of patients present with high-risk disease. Bone and BM are frequent sites of metastatic disease and can serve as a reservoir for residual disease driving relapse. Naxitamab, a GD2-binding monoclonal antibody, was recently approved in the United States in combination with GM-CSF for the treatment of pediatric patients ≥1 year of age and adult patients with R/R HR-NB in the bone/BM who have demonstrated a partial response (PR), minor response (MR), or stable disease (SD) to prior therapy. Here we describe outcomes from the registrational Trial 201 (NCT03363373) detailed by bone/BM involvement. **Methods:** HR-NB patients with primary refractory disease or incomplete response to salvage treatment following relapse or progressive disease (PD) (in both cases including SD, MR and PR) with disease limited to bone and/or BM were eligible. Naxitamab was administered over ≥30 min in the outpatient setting on Days 1, 3 and 5 at 3 mg/kg/infusion (9 mg/kg/cycle) in combination with GM-CSF at 250 μg/m2/day on Days -4 to 0 and at 500 μg/m2/day on days 1 to 5. Treatment cycles were repeated every 4 weeks. Response was assessed after Cycle 2 and then every 2-3 months by revised International Neuroblastoma Response Criteria (INRC) using BM biopsies/aspirates and 123I-MIBG scintigraphy or FDG-PET. Effectiveness was concluded if the lower limit of the Clopper-Pearson exact 95% confidence interval (CI) of overall response rate (ORR) was >20%. We report efficacy data on 22 patients and safety data on the first 25 patients enrolled. **Results:** 13 (59%) patients had NB in bone, 2 (9%) had NB in BM, and 7 (32%) had NB in both bone and BM. Summary of overall response and response by compartment. **Conclusions:** Naxitamab provided clinically meaningful activity in both bone and BM with ORR of 68% and had a manageable AE profile. Clinical trial information: NCT03363373. Research Sponsor: Y-mAbs Therapeutics.

Response compartment; n (%) patients	Response[a]		n (%)	95% CI (%)
Overall; n = 22	Best response	CR	13 (59%)	36%, 79%
	ORR	CR+PR	15 (68%)	45%, 86%
Bone compartment; n = 20/22 (91%)	Best response*	CR	14 (70%)	46%, 88%
	ORR	CR+PR	16 (80%)	56%, 94%
BM compartment; n = 9/22 (41%)	Best response**	CR	7 (78%)	40%, 97%
	ORR	CR+PR	7 (78%)	40%, 97%

*2/20 (10%) patients had PR, 2/20 (10%) had SD, and 2/20 (10%) had PD. **1/9 (11%) patient had minimal disease and 1/9 (11%) was not evaluable. [a] INRC denotes that osseous lesions without soft tissue mass are considered non-measurable by RECIST and do not require confirmatory assessment of response Median time to first CR was 5.6 weeks (range 5.3-29.3). 5/25 (20%) patients reported 6 naxitamab-related serious adverse events (SAEs): 4 anaphylactic reaction, 1 pyrexia, 1 respiratory depression. 3/25 (12%) patients discontinued treatment due to naxitamab-related Grade 4 AE: 2 anaphylactic reaction, 1 respiratory depression. No fatal events were reported.

10023 **Poster Discussion Session**

Updated outcomes for patients with completely resected pulmonary recurrent osteosarcoma: A report from the Children's Oncology Group. *First Author: Alexander J. Chou, Weill Cornell Medical College, New York, NY*

Background: Amongst patients with recurrent osteosarcoma (OS), those with resectable pulmonary-only relapse appear to have the best outcomes. Prior analysis of patients with completely resected recurrent OS enrolled on a Children's Oncology Group (COG) Phase 2 trial AOST0221, which studied the efficacy of inhaled GMCSF, showed a 12-month disease control rate (DCR12) of only 20% (95% CI, 10 – 34%). DCR12 based on this analysis was used as the historical benchmark for efficacy analysis in two recently completed trials, AOST1321 (completely resected cohort only) and AOST1421. We analyzed the stability of the DCR12 benchmark using data from these contemporary studies. **Methods:** Patients were eligible for AOST1321 if they had undergone resection of all sites of recurrent or refractory OS within 30 days of enrollment and for AOST1421 if they had lung only recurrent OS completely resected within 4 weeks of enrollment. AOST1321 evaluated denosumab while AOST1421 evaluated dinutuximab. Patients with refractory disease, extrapulmonary recurrence or without histological confirmation of relapse were excluded from this analysis. DCR12 was defined as having at least stable disease 12 months after the start of protocol therapy. We report the DCR12 observed on AOST1321, AOST1421 and AOST0221. **Results:** One hundred and twenty-eight evaluable patients with completely resected recurrent OS were enrolled on AOST0221 (N=49), AOST1321 (N=38) and AOST1421 (N=41). One hundred and one patients were included in this analysis (AOST0221: 37, AOST 1321: 25, AOST1421:39). DCR12 was 14 % (95% CI, 5% – 26%) for AOST0221, 24% (95%CI 10-42%) for AOST1321, and 31% (95% CI, 17% - 45%) for AOST1421. Risk for disease progression did not differ across the 3 included studies. DCR12 for all three studies combined was 23% (95% CI, 15% – 31%). **Conclusions:** Prognosis for recurrent OS remains dismal, even for those with resectable pulmonary-only disease. Although not statistically significant, dinutuximab may have activity in a select group of relapsed OS patients; combination studies using dinutuximab are planned. The previously described benchmark of disease control at 12 months remained relatively consistent in recent studies for those patients who have resectable pulmonary-only relapse. Therefore, DCR12 remains a useful outcome measure in fully resected OS with lung only metastases. Analyses are ongoing to better define the appropriate threshold to define investigational agent activity in this specific patient population. Inflammatory myofibroblastic tumor: A multi-institutional study from the pediatric surgical oncology research collaborative. *First Author: Barrie S. Rich, Cohen Children's Medical Center, Queens, NY*

Background: Inflammatory myofibroblastic tumor (IMT) is a mesenchymal neoplasm of intermediate malignancy, predominantly seen in children and young adults. Given its rarity, data are limited. We describe the largest cohort of patients with IMT to date, with an aim to further characterize this poorly understood tumor. **Methods:** A multi-institutional review was performed at 18 North American hospitals participating in the Pediatric Surgical Oncology Research Collaborative to identify IMT patients ≤39 years, diagnosed from 2000-2018. Descriptive statistics are described as median and interquartile range. Multivariable analysis was used to identify predictors of event free survival (EFS). **Results:** 182 patients were identified with a median age of 11 years (5-17); 52% were female. 33% of tumors were thoracic, 26% abdominal/pelvic, 20% head/neck, and 14% genitourinary. Common presenting symptoms included pain (29%), respiratory symptoms (24%), weight loss (12%), and a palpable mass (10%). Median tumor size was 3.9 cm (1.9-6.5). Anaplastic lymphoma kinase (ALK) overexpression was identified via immunohistochemistry in 53% of patients tested. One third of patients had abnormal cytogenetics, with 12% of the entire cohort having an *ALK* mutation. 7% of patients had distant disease at diagnosis. 13% of patients received neoadjuvant therapy including chemotherapy (3%), ALK inhibitor (4%), radiation (0.5%), non-steroidal anti-inflammatories (NSAIDs) (7%), or steroids (2%). Of those who underwent resection with known margin status (n = 158), 66% had complete resection, 20% had microscopic positive margins, and 14% had gross residual disease. Just over 40% of patients had an en bloc resection of involved organs, most commonly lung (26%). 21% of patients received adjuvant therapy, including chemotherapy (3%), ALK inhibitor (9%), radiation (0.5%), NSAIDs (8%), or steroids (5%). 12% of all patients received an ALK inhibitor: 24% neoadjuvant, 62% adjuvant, and 14% without surgery. Median follow-up time was 36 months (14-69). Overall 5-year survival (OS) was 95% and 5-year EFS was 80%. Predictors of recurrence included respiratory symptoms, larger tumor size, or distant disease at diagnosis. Gender, race, age and primary site were not predictive of EFS. Likewise, there was no association of ALK overexpression or *ALK* mutation with EFS. The presence of gross or microscopic margins following resection was not associated with recurrence. **Conclusions:** IMT is a rare tumor with favorable OS. Five year recurrence rate was 20%. Presenting with respiratory symptoms, larger tumor size, or metastatic disease was associated with recurrence, while ALK positivity was not. Notably, a positive margin after resection was not associated with increased recurrence, indicating that aggressive attempts at surgical resection that would compromise form or function may not be warranted. Household material hardship and parental distress in a multicenter clinical trial for pediatric acute lymphoblastic leukemia. *First Author: Puja J. Umaretiya, Dana-Farber and Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Poverty is associated with inferior psychosocial function among parents of children with cancer. Severe parental distress during treatment predicts future poor mental health for both parents and children. It is also associated with impaired parental cognitive bandwidth and executive function, which may have implications for treatment adherence. Efforts to identify poverty-exposures amenable to intervention are essential to improving survivorship quality of life for the > 90% of children with acute lymphoblastic leukemia (ALL) who will be long-term survivors. Household material hardship (HMH) is a targetable poverty exposure defined as at least 1 of 3 unmet basic needs including food, housing, or utilities. Dana-Farber Cancer Institute (DFCI) ALL Consortium trial 16-001 is the first pediatric oncology clinical trial to systematically evaluate HMH. We investigated the hypothesis that HMH exposure independently predicts severe parent psychological distress during ALL therapy. **Methods:** Patients with newly diagnosed ALL ages 1-17 years were enrolled on the DFCI 16-001 embedded HMH cohort study at 8 U.S. and Canadian centers. Secondary interim analyses used baseline (within 32-days of trial enrollment) and 6-mos parent-reported sociodemographic data, the Kessler-6 (K6) Psychological Distress scale, and trial-collected child and disease data. Severe psychological distress was defined as a K6 > = 13. Multivariable cox regression evaluated baseline HMH-exposure and parent distress at baseline and 6-mos adjusting for child's initial ALL risk group (Very High Risk (VHR) vs other) and marital status (single vs dual parent). **Results:** Among 258 families with evaluable data, 34% reported baseline HMH. Families were predominantly English-speaking (54%) dual parent households (71%). Children were a median of 5.7 years (IQR 1.0-17.99) at diagnosis and predominantly non-Hispanic white (66%) with expected disease distribution by immunophenotype (84% B-cell). HMH (odds ratio (OR) 2.18, 95% confidence interval (CI) 1.0-4.31, p = 0.025) and VHR initial risk group (OR 2.32; 95% CI 1.06-5.06, p = 0.035) were independently associated with baseline severe psychological distress. Only HMH was independently associated with 6-mos severe psychological distress (OR 4.93, 95% CI 1.80-13.48, p = 0.002). Future analyses will investigate race and ethnicity associations with parental distress pending trial accrual for statistical power. **Conclusions:** HMH, a modifiable poverty exposure, is significantly associated with severe parent psychological distress at diagnosis that persists 6-months into pediatric ALL therapy. These findings identify a cohort at high risk of inferior mental health outcomes, and affirm the need for HMH-targeted interventions to support children and parents during cancer treatment to reduce poverty-associated outcome disparities in survivorship. Financial hardship in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Paul C. Nathan, Division of Haematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: The impact of childhood and adolescent cancer on the long-term financial outcomes of survivors is poorly understood. We compared financial hardship between survivors and siblings enrolled in the CCSS and identified survivors at elevated risk. **Methods:** Survivors treated for cancer at age < 21 years in 1970-1999 and siblings responded to a survey (23 binary-response questions) at age ≥26 years administered in 2017-2019. Principal component analysis with promax rotation extracted 3 factors with eigenvalues > 1 and KR-20 reliability coefficients > 0.7, retaining items with factor loadings > 0.4. These factors were behavioral hardship (8 items, e.g., forgone needed medical care), material hardship/financial sacrifices (8 items, e.g., problems paying medical bills) and psychological hardship (3 items, e.g., worry about having enough money to pay rent/mortgage). Factor scores were calculated by adding the item responses and dividing by their standard deviation. Multiple linear regression examined the association of sociodemographic and cancer treatment variables with factor scores. **Results:** Among 3349 survivors (49% male; median age [range] 40.2 [26.0-67.4] years) and 976 siblings (42% male, median age 46.5 [26.1-69.2] years), survivors were more likely to report being sent to debt collection (29.5 vs 21.4%), problems paying medical bills (20.0 vs 11.9%), foregoing needed medical care (13.3 vs 7.7%) and worry/stress about paying their mortgage (32.8 vs 23.2%) or having enough money to buy nutritious meals (25.0 vs 16.2%), all P < 0.001. Survivors reported greater hardship than siblings on all 3 factors: behavioral hardship (standardized mean score 0.51 vs 0.36), material hardship/financial sacrifices (0.63 vs 0.44), psychological hardship (0.69 vs 0.44), all P < 0.001. Behavioral hardship was increased by female gender (regression coefficient [▫] 0.17, 95% CI 0.10-0.25), < high school (▫ 0.45, CI 0.12-0.79) or < college (▫ 0.18, CI 0.09-0.26) education, no (▫ 1.14, CI 0.93-1.35) or public (▫ 0.23, CI 0.10-0.35) health insurance, being divorced/separated (▫ 0.28, CI 0.10-0.46) and ≥250mg/m^2 anthracycline chemotherapy (▫ 0.09, CI 0.00-0.19). The same variables were significantly associated with the other two hardship factors, but total body irradiation and cranial radiation also contributed to the risk of material hardship/financial sacrifices, and ≥8g/m^2 cyclophosphamide equivalent dose and cranial radiation contributed to psychological hardship. **Conclusions:** Survivors of childhood and adolescent cancer are at elevated risk for financial hardship as compared to sibling controls. Those at highest risk can be defined using a combination of sociodemographic and treatment variables. This information can be used to inform targeted intervention strategies to reduce the risk of poor financial outcomes in this vulnerable population. Research Sponsor: U.S. National Institutes of Health.

10027 **Poster Discussion Session**

Low-dose radiation to cardiac substructures and late-onset cardiac disease: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: James Edward Bates, Emory University, Atlanta, GA*

Background: Thoracic radiotherapy (RT) is a risk factor for cardiac disease among survivors of childhood cancer based on studies considering RT doses to the entire heart. Dose to specific cardiac substructures may provide more precise dose-response associations to guide RT planning. We report associations between RT dose to cardiac substructures and risk of specific cardiac outcomes. **Methods:** We determined the cumulative incidences of CTCAE grade 3 – 5 coronary artery disease (CAD), heart failure (HF), and valvular disease (VD) among 25,481 5-year childhood cancer survivors diagnosed 1970 – 1999 in the CCSS. Median age at diagnosis was 6.1 years (0 – 20 years) and at last follow-up 29.8 years (5.6 – 65.9 years). For the 12,228 individuals receiving RT, fields were reconstructed on an age scaled computational phantom. Mean doses to the entire heart, cardiac chambers, valves, and left main, anterior descending (LAD), circumflex, and right coronary (RCA) arteries were estimated. Adjusted piecewise exponential models (including cumulative anthracycline dose) evaluated associations between mean RT dose to each structure and outcomes. **Results:** At 30 years from diagnosis, the cumulative incidences of grades 3 – 5 CAD, HF, and VD were 2.3% (95% CI 2.0 – 2.5), 2.6% (95% CI 2.4 – 2.9), and 0.6% (95% CI 0.5 – 0.8) respectively. Low dose RT (mean 5 – 9.9 Gy) to the RCA (relative rate [RR] = 2.6, 95% CI 1.6 – 4.1, p < 0.001), LAD (RR = 1.9, 95% CI 1.1 – 3.3, p = 0.019), and left ventricle (RR = 2.2, 95% CI 1.3 – 3.7, p = 0.002) was associated with increased risk of CAD relative to those not exposed; mean dose of 5 – 9.9 Gy to the entire heart was not (RR = 1.1, 95% CI = 0.8 – 1.6, p = 0.59). Table shows the associated cumulative incidences of CAD for these structures. Mean RT doses of 5 – 9.9 Gy to the aortic valve (RR = 4.6, 95% CI 1.5 – 14.0, p = 0.008) and tricuspid valve (RR = 5.5, 95% CI 2.0 – 15.1, p = 0.001) were associated with risk of VD compared to those with no RT; mean heart dose 5 – 9.9 Gy was not (RR = 0.6, 95% CI = 0.2 – 1.3, p = 0.16). No cardiac structure was significantly associated with an increased risk of HF at a mean dose of 5 – 9.9 Gy. Mean RT doses below 5 Gy were not associated with increased risks of CAD, HF, or VD; doses ≥10 Gy to nearly all substructures and the entire heart were. **Conclusions:** Low dose RT to the coronary arteries and cardiac valves (5 – 9.9 Gy) from RT is associated with increased risk of CAD and VD, respectively. Sensitivity to low dose RT may vary across the heart and doses to specific structures may be more predictive of late cardiac disease than whole heart dose. These data can guide RT planning to prioritize substructures for avoidance. Research Sponsor: U.S. National Institutes of Health, American Lebanese Syrian Associated Charities.

30-year cumulative incidence for CAD with low dose RT to selected cardiac substructures.

Structure	Mean RT Dose	CI (95% CI)
Entire Heart	None	0.9% (0.6 – 1.2%)
Entire Heart	5 – 9.9 Gy	1.0% (0.2 – 1.8%)
RCA	5 – 9.9 Gy	2.6% (1.4 – 3.7%)
LAD	5 – 9.9 Gy	1.7% (0.8 – 2.7%)
Left ventricle	5 – 9.9 Gy	2.3% (1.1 – 3.5%)

10028 **Poster Discussion Session**

Efficacy of clinical breast examination in chest-irradiated female survivors of childhood Hodgkin lymphoma (HL). *First Author: Florence Lennie Wong, City of Hope, Duarte, CA*

Background: Female survivors of childhood HL treated with ≥10 Gy of chest radiation are at high risk for breast cancer (BC). The Children's Oncology Group (COG) guidelines recommend CBE annually starting at puberty and then semiannually from age 25, plus lifetime annual mammography (MAM) and breast Magnetic Resonance Imaging (MRI) starting 8y after chest radiation or age 25, whichever is later. While imaging-based screening recommendations are largely consistent with US guidelines for women at high BC risk, only the COG guidelines recommend CBE. The benefits of lifetime CBE starting from puberty for life in chest-irradiated HL survivors is unknown. **Methods:** Life-years (LYs) and lifetime BC mortality risk were estimated from a simulated cohort of 5-million HL survivors using the data from 5y female survivors of HL in the Childhood Cancer Survivor Study (CCSS) treated with ≥10 Gy of chest radiation. The simulated cohort underwent annual MAM+MRI from age 25 for life, with and without annual CBE from age 11 (presumed age of puberty) to age 24 and with and without semiannual CBE from age 25 for life with 100% adherence. BC included in-situ and invasive BC. Treatment-related BC incidence and non-BC mortality risks were estimated from the CCSS data. Risks at age <25 were extrapolated from the CCSS estimates while risks beyond age 50 were extrapolated additionally using the US population rates. CBE sensitivity (17.8%, in-situ and invasive BC) and specificity (98%) and MAM+MRI sensitivity (84.2-86.0%, in-situ; 96.7-97.1%, invasive) and specificity (75.3%) were obtained from the medical literature. **Results:** The CCSS cohort included 1057 female HL survivors. BC (all invasive) developed in three patients at age <25 (ages: 23, 24, 24). In the simulated cohort receiving no screening, lifetime BC risk was 40.8% and BC mortality was 17.5%. HL survivors around age 50 were at a 7.4-fold higher risk of developing BC and a 5.2-fold higher risk of non-BC mortality when compared with the general population. Compared to no annual CBE for ages 11-24y, undergoing annual CBE did not increase gains in LYs or reduce lifetime BC mortality relative to no screening (Table). Among those who survived to age ≥25, undergoing semiannual CBE from age 25 for life compared to no semiannual CBE also resulted in little gain in LYs or reduction in lifetime BC mortality relative to no screening. **Conclusions:** Lifetime CBE starting at puberty in conjunction with MAM+MRI appears to add little survival benefits compared with no CBE, suggesting that COG guidelines may be revised without adverse effect on long-term outcomes for chest-irradiated female survivors of childhood HL. Research Sponsor: American Cancer Society, U.S. National Institutes of Health.

Strategy	Annual CBE 11-24y	Semiannual CBE 25y-life	LY gained	BC mortality reduced (%)
No screening	NA	NA	REF	REF
Entire HL cohort undergoing MAM+MRI from age 25 for life	No	Yes	0.47	10.6
	Yes	Yes	0.47	10.6

10029 **Poster Discussion Session**

Neurocognitive outcomes in survivors of early adolescent and young adult (eAYA) hematologic cancers from the Childhood Cancer Survivor Study (CCSS). *First Author: Amy Yuan Wang, University of Chicago Medicine, Chicago, IL*

Background: Neurocognitive impairment in eAYA hematologic cancer survivors has not been well described, despite intensive neurotoxic therapies. We examined prevalence and risk for such impairment in hematologic cancer survivors diagnosed during eAYA compared to a younger age. **Methods:** We identified 1,213 eAYA (diagnosed at 15-21 years; median [range] follow-up age 40 [30-54]) and 4,538 childhood (diagnosed at <15 years; median age 30 [17-48]) survivors of ALL (n= 301 vs 3274), AML (n= 77 vs 424), and Hodgkin lymphoma (HL; n= 835 vs 840) from the CCSS (diagnosed 1970-1999) who completed the Neurocognitive Questionnaire. Impairment was defined as a score >90% of normative data in task efficiency (TE), organization (Org), memory (Mem), and emotional regulation (ER) domains. 1,014 age-matched siblings were controls. Treatment by diagnosis group, chronic health conditions, health status and health behaviors were examined as risk factors for neurocognitive impairment using multivariable logistic regression. Adjusted odds ratios (ORs) and corresponding 95% CI are reported. **Results:** Prevalence of neurocognitive impairment (≥1 impaired domain) was similar for eAYAs and childhood survivors of HL (31.0% vs 29.6%, p=0.54) and AML (36.4% vs 40.3%, p=0.51), although eAYA AML survivors were more likely to have impaired Mem (OR=2.3, 95% CI 1.0-5.4). eAYA ALL survivors were less likely to have neurocognitive impairment than childhood ALL survivors (28.2% vs 38.5%, p<.001) due to lower risk for impaired TE (OR=0.7, 95% CI 0.4-1.0) and Org (OR=0.5, 95% CI 0.4-0.9). No factors, including cranial radiation (RT), explained the rate differences. Treatment by diagnosis group (including cranial RT in ALL, chest RT in HL, and salvage therapy use) was not consistently associated with neurocognitive impairment in eAYA survivors. However, anthracycline dose ≥120mg/m^2 was a risk factor for impaired ER (OR=6.0, 95% CI 2.0-17.9) only in eAYA ALL survivors. Presence of a neurologic health condition was associated with impairment in all 4 domains in eAYA (ORs ranged 1.7-2.9) and childhood cancer survivors (ORs ranged 1.9-5.3). eAYA survivors with a respiratory condition were more likely to have impaired TE (OR=2.1, 95% CI 1.2-3.8). Being in good general health was associated with less impairment across all 4 domains for eAYA (ORs ranged 0.2-0.4) and childhood survivors (ORs ranged 0.3-0.5). eAYA survivors who never smoked were less likely to have impaired ER (OR=0.4, 95% CI 0.2-0.6) than those who smoke. **Conclusions:** Survivors of hematologic cancers diagnosed during eAYA are susceptible to neurocognitive impairment at rates similar to those diagnosed at younger ages. Having comorbidities and being in fair/poor general health are risk factors for impairment. Higher anthracycline exposure in ALL survivors diagnosed during eAYA was the only therapy associated with impairment rates. Research Sponsor: None.

Resolving driver events in MLL-r negative high-risk infant ALL. *First Author: Jennifer Seelisch, Children's Hospital London Health Sciences Centre, London, ON, Canada*

Background: Infant acute lymphoblastic leukemia (ALL) is the only subtype of childhood ALL whose outcome has not improved over the past two decades. The most important prognosticator is the presence of rearrangements in the *Mixed Lineage Leukemia* gene (MLL-r), however, many patients present with high-risk clinical features but without MLL-r. We recently identified two cases of infant ALL with high-risk clinical features resembling MLL-r, but were negative for MLL-r by conventional diagnostics. RNA sequencing revealed a partial tandem duplication in MLL (MLL-PTD). We thus aimed to determine if MLL-PTD, other MLL abnormalities, or other genetic or transcriptomic features were driving this subset of high-risk infant ALL without MLL-r. **Methods:** We obtained 19 banked patient samples from the Children's Oncology Group (COG) infant ALL trial (AALL0631) from MLL wildtype patients as determined by FISH and cytogenetics. Utilizing deep RNA-sequencing, we manually inspected the MLL gene for MLL-PTD, while also performing automated fusion detection and gene expression profiling in search of defining features of these tumors. **Results:** 3 additional MLL-PTDs were identified, all in patients with infant T-cell ALL, whereas both index cases were in patients with infant B-cell ALL. Gene expression profiling analysis revealed that all five MLL-PTD infants clustered together. Eight infants (7 with B-cell ALL) were found to have Ph-like expression. Five of these 8 infants were also found to have an IKZF1/JAK2 expression profile; one of these five had a PAX5-JAK2 fusion detected. Two infants (including the one noted above) had novel PAX5 fusions, known drivers of B-cell leukemia. Additional detected fusions included TCF3-PBX1 and TCF4-ZNF384. **Conclusions:** MLL-PTDs were found in both B- and T-cell infant ALL. Though Ph-like ALL has been described in adolescents and young adults, we found a substantial frequency of Ph-like expression among MLL-WT infants. Further characterization of these infants is ongoing. If replicated in other infant cohorts, these two findings may help explain the poor prognosis of MLL-WT ALL when compared to children with standard risk ALL, and offer the possibility of targeted therapy for select infants. Forecasting asparaginase quantity required to treat pediatric ALL in LMICs using ACCESS FORxECAST. *First Author: Terence M. Hughes, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Asparaginase (ASN) is a crucial component of pediatric acute lymphoblastic leukemia (ALL) protocols. ASN is available in three enzyme formulations: native from *Escherichia Coli* (*E. coli*), PEGylated from *E. coli* (PEG), and native erwinia from *Erwinia chrysanthemi* (Erwinase). PEG is typically preferred in high-income countries, while *E. coli* is more accessible in low and middle income countries (LMICs). Erwinase is reserved for patients who develop hypersensitivity. Short shelf lives, high prices, intermittent availability, and concern for substandard formulations in LMICs have created a need for proactive ASN demand estimates, particularly in LMICs. **Methods:** We modified FORxECAST, a publicly available tool that forecasts pediatric cancer drug quantity and cost, to estimate ASN quantity required to treat pediatric ALL in 2021 across all LMICs. Incidence data is based on the Global Childhood Cancer microsimulation model, which extrapolates country registries to estimate diagnosed pediatric ALL patients. We forecast ASN quantity for both a base regimen (BR), recommended by the International Pediatric Oncology Society (SIOP), and a more aggressive regimen (AR) used in some LMICs with more advanced supportive care capacity. For both BR and AR, we estimate ASN quantity across four scenarios, outlining how quantity would vary based on formulation and ability to switch in cases of hypersensitivity. **Results:** The estimated quantity of ASN required to treat all children diagnosed with ALL in LMICs in 2021, across scenarios and regimens, is provided (Table). If *E. coli* were used to treat all diagnosed pediatric ALL patients across LMICs, required quantity would range from 1,198 M IU (BR) to 1,661 M IU (AR) (Scenario 1). If PEG were used, required quantity would range 150 M IU (BR) to 473 M IU (AR) (Scenario 2). Accounting for hypersensitivity would require 77 M IU (BR) to 137 M IU (AR) Erwinase (Scenarios 3 and 4). **Conclusions:** We adapted FORxECAST to be ASN-specific and estimated demand in LMICs for a range of scenarios, including for second line Erwinase; accounting for hypersensitivity is particularly important because discontinuation typically results in lower cure rates. We also estimated how quantity of ASN required would increase with treatment intensity. These results provide the first quantification of ASN need for pediatric ALL in LMICs, creating a demand estimate that can inform private and public efforts to produce a reliable supply of high quality ASN for all children with ALL. Research Sponsor: Boston Children's Hospital, Dana Farber Cancer Institute, Dana Farber/Boston Children's Hospital Global Health Initiative, and the Division of Haematology/Oncology at The Hospital for Sick Children.

ASN Quantity for Diagnosed Pediatric ALL in LMICs (2021).

Scenario	BR	AR
1. *E. coli* [no hypersensitivity planning]	1,198	1,661
2. PEG [no hypersensitivity planning]	150	473
3. *E. coli* > Erwinase [hypersensitivity planning]	*E. coli*: 1,198 Erwinase: 77	*E. coli*: 1,661 Erwinase: 137
4. PEG > Erwinase [hypersensitivity planning]	PEG: 150 Erwinase: 77	PEG: 473 M Erwinase: 137

Quantities in millions of international units (M IU).

Correlation of ex vivo drug sensitivity with clinical response in pediatric AML. *First Author: Ryosuke Kita, Notable Labs, Foster City, CA*

Background: Pediatric acute myeloid leukemia (AML) is a rare disease with roughly 500 cases diagnosed in the United States each year and has had minimal improvement in clinical outcomes over recent decades. Novel treatment development to improve outcomes may be enhanced with an accompanying test for predicting treatment response. We previously demonstrated that an *ex vivo* drug sensitivity assay (DSA) can predict clinical response in myelodysplastic syndrome. Here we investigated the use of the DSA in pediatric AML patients, including a subset participating in a clinical trial of atovaquone. Atovaquone is an FDA-approved anti-parasitic drug that was associated with lower relapse rates in adult AML patients. Adding atovaquone and other standard of care combination treatments into the DSA, we investigated whether the assay, performed on pre-induction samples, correlated with measures of clinical response. **Methods:** We assayed pre-induction blood or bone marrow samples from 22 de novo pediatric AML patients diagnosed at Texas Children's between 5/2015 and 10/2020 who consented to research (82% enrolled in clinical trial identifier NCT03568994). We subsetted this analysis to patients who received ADE (Cytarabine, Daunorubicin, Etoposide) (n = 20) induction, with the majority additionally receiving atovaquone (n = 16). For the DSA, samples were incubated with up to 25 compounds, including the treatment drug combinations and each of the compounds individually. After incubation, changes in tumor blast populations were assessed by flow cytometry. For each drug condition, drug sensitivity was calculated based on the number of blasts remaining after treatment. After quality control, downstream analyses were limited to 13 samples. Clinical response data, including minimal residual disease (MRD) percentage by flow cytometry and one year relapse-free survival, were correlated with the drug sensitivity results. **Results:** For the de novo subset analysis, we observed correlations between *ex vivo* drug sensitivity with both MRD percentage (r = 0.63) and one year relapse-free survival (RFS1, AUC = 0.92). The 3 patients with lowest *ex vivo* sensitivity had the highest MRD percentages (mean 21%). 2 of the 3 patients who did not achieve one year relapse-free survival had the lowest *ex vivo* sensitivity. Drug combination sensitivity correlated more with MRD and RFS1 than the single agents alone (single agent mean MRD r = 0.39). **Conclusions:** In our cohort, *ex vivo* DSA for ADE and atovaquone in pediatric AML cases correlated with both MRD and one year relapse-free survival. This suggests that clinical response in pediatric AML may be assessed prior to treatment using a DSA. This study also suggests that the DSA can be used to test drug combinations, and thus may be used for investigating novel treatment combinations. Further development of the DSA may benefit treatment decisions and prioritization of drug development. Research Sponsor: Notable Labs.

Preclinical evaluation of the ETS inhibitor TK216 against relapsed and refractory childhood leukemia. *First Author: Ritul Sharma, University of Calgary, Calgary, AB, Canada*

Background: Although survival rates have improved in the recent past, relapse and refractory disease remain a significant cause of death in children with leukemia. This calls for an urgent need for the development of novel therapies that could effectively treat leukemias in children. The E26 transformation specific (ETS) family of transcription factors regulate various normal cellular functions but are abnormally expressed in various cancers, including leukemia. TK216 is an ETS inhibitor, that has shown pre-clinical activity and clinical efficacy in solid tumors. In this study, we explore the feasibility of using TK216 as a therapeutic agent for the treatment of high risk refractory pediatric leukemia. **Methods:** A panel of pediatric leukemia derived cell lines and primary blast cells representing a spectrum of molecular abnormalities seen in pediatric leukemia were treated *in vitro* with TK216 to determine cytotoxicity. Normal lymphocytes were used as controls and cell viability was determined 72 hours post-treatment by Alamar blue assay. The induction of tumor cell apoptosis and target modulation were detected by Western blotting. Alterations in the cell cycle were assessed by FACS analysis with PI staining. Drug combination studies were carried out with established anti-leukemic agents to identify synergy for greater therapeutic efficiency. **Results:** TK216 decreased cell viability in leukemia cells compared to normal lymphocyte controls in a dose-dependent manner with variations in sensitivity noted with inherent molecular abnormalities. The IC_{50} values observed ranged from 0.22 μM for the most sensitive cell line, MV4-11 to 0.95 μM for least sensitive cell line, SUP-B15. Apoptosis induction upon TK216 treatment was confirmed by PARP cleavage and caspase 3 activation. Cell cycle analysis demonstrated increased sub-G1 population of cells after TK216 treatment. A strong correlation between sub-G1 population and sensitivity of the cell line towards TK216 (47% in MV4-11 vs 3.72% in SUP-B15) was observed. Screening of a panel of 200 FDA approved anti-cancer agents in drug combination studies identified potential agents for drug synergy. Significant drug synergy was noted with TK216 in combination with the epigenetic modifier 5-azacytidine and the Bcl-2 inhibitor, Venetoclax. [Combination Index for Venetoclax and TK216, mean = 0.65 for MV4-11 and 0.33 for SUP-B15]. **Conclusions:** Data from our study demonstrate that the ETS inhibitor TK216 induces apoptosis and cell cycle arrest in pediatric leukemia cells at physiologically relevant concentrations. Our combination studies identified distinct anti-cancer agents that could be used for developing effective drug combination regimens with TK216. Overall, our findings provide essential preclinical data for the consideration of TK216 in early phase clinical trials for the treatment of selected high-risk and refractory childhood leukemia. Novel methods to assess cell-free circulating tumor DNA in acute lymphoblastic leukemia. *First Author: Meghan G. Haney, University of Kentucky, Lexington, KY*

Background: Acute lymphoblastic leukemia (ALL) is the most common pediatric cancer, with a relatively high relapse rate, which is associated with poor prognosis. Currently, minimal residual disease (MRD) at the end of induction and consolidation therapy is the best predictor of patient relapse, however obtaining bone marrow aspirate is invasive and not always accurate. Another major concern in ALL is the presence of central nervous system (CNS) disease, which is often present long before clinical diagnosis can be made by flow cytometry. To circumvent these clinical challenges, we developed a new assay quantifying cell-free, circulating tumor (cfDNA) as a biomarker of disease progression, which can be correlated with MRD status as a predictor of relapse. cfDNA is frequently used to monitor progression of solid tumors, but pediatric leukemias lack common mutations that can be used to distinguish leukemic cfDNA from normal cfDNA. **Methods:** We examined two possible methods for using ctDNA as a biomarker: leukemia cell clonality and DNA methylation profiling. We developed a novel workflow for identifying VDJ rearrangements in leukemia cells and tracking their presence in cfDNA. We collected bone marrow, blood, and CSF samples from newly diagnosed patients, and cfDNA was isolated from blood and CSF samples throughout treatment. Invivoscribe Lymphotrack PCR assays combined with MinION (Oxford Nanopore Technologies) sequencing were used to identify the VDJ sequence of the immunoglobulin (B-ALL) or T-cell receptor (T-ALL) rearrangements of leukemic clones in genomic DNA. The MinION assay relies on patient-specific sequencing. We are also in the process of developing a universal assay that utilizes recurrent methylation changes in ALL to identify leukemic cfDNA in patient samples. **Results:** The MinION workflow was used to follow leukemic cfDNA throughout the course of treatment, and accurately identified MRD and CNS disease in patients. This workflow performed equivalent or better at detecting leukemic clones compared to MiSeq and droplet digital polymerase chain reaction (ddPCR), and is faster and less expensive than traditional Illumina sequencing. Methylation analysis of 865 ALL and 79 healthy samples yielded 55 regions and 19 specific methylation sites that were uniquely present in ALL samples. We are validating these sites by ddPCR to establish a panel of biomarkers to track ALL over time via cfDNA. **Conclusions:** The end goal of our study is provide a more sensitive and less invasive method for tracking MRD and CNS disease than current approaches. Results will ultimately be correlated with patient response to therapy, the presence of relapse or CNS disease, and overall outcomes determined by standard clinical diagnostic procedures. Discovery and validation of a cross-platform 21-gene prognostic signature in neuroblastoma. *First Author: Mehul Gupta, Arnie Charbonneau Cancer Research Institute, University of Calgary, Calgary, AB, Canada*

Background: Neuroblastoma (NB) is the most common extracranial solid tumor in children. Despite the development of risk stratification tools to improve prognostication, prediction of patient survival outcomes in NB remains poor. In this study we used an unbiased machine-learning algorithm to develop and validate a transcriptomic signature capable of predicting 5-year overall (OS) and event-free survival (EFS) in these patients. **Methods:** The TARGET-Neuroblastoma dataset (n = 243) was used as the training set. Two independent NB cohorts, E-MTAB-179 (n = 478) and GSE85047 (n = 266) were used as validation sets. Elastic net regression was employed to identify transcripts associated with EFS. Association of the developed signature with EFS and OS was evaluated using univariate Cox proportional hazards (CoxPH), Kaplan-Meier, and 5-year receiver-operator characteristic curves in validation cohorts. Further, the independent prognostic value of the signature was assessed using multivariate CoxPH models with relevant clinicopathologic variables including age, INSS stage, and *N-Myc* amplification status in both validation sets. Finally, a nomogram was developed to integrate the signature with prognostic clinicopathologic variables to evaluate their combined efficacy for prediction of 5-year EFS and OS. **Results:** We identified a 21-gene signature that demonstrates significant association with EFS and OS in both E-MTAB-178 and GSE49710 validation cohorts. Moreover, the signature is independent of clinicopathological variables and can be effectively incorporated into a risk model, improving the prognostic performance. Several genes within the signature have been previously implicated in NB, including ECEL1, HOXC9 and ARAF1. **Conclusions:** To the best of our knowledge, we are the first to use an unbiased machine learning approach to generate a transcriptomic gene signature for neuroblastoma prognosis externally validated in multiple cohorts across platforms. This 21-gene transcriptomic signature significantly associated with EFS and OS in this disease. Combining this signature with current prognostic clinicopathologic variables will improve risk stratification of affected patients and may inform effective clinical decision-making. Research Sponsor: None.

	Signature alone		Signature with clinicopathologic variables	
	EFS	OS	EFS	OS
E-MTAB-179	HR: 5.869 (3.825-9.006), p < 0.0001 AUC: 0.827	HR 37.240 (11.760-117.900), p < 0.0001 AUC:0.904	HR 6.949 (4.320-11.180), p < 0.0001 AUC:0.837	No events in low-risk group, Log-Rank p < 0.0001 AUC:0.920
GSE85047	HR 3.736 (2.357-5.924) p < 0.0001 AUC:0.815	HR 4.941 (2.823-8.647) p < 0.0001 AUC:0.833	HR 5.460 (3.214-9.2274), p < 0.0001 AUC: 0.849	HR 11.891 (5.422-26.080), p < 0.0001 AUC:0.892

EFS = event-free survival; OS = overall survival, HR = hazard ratio, AUC = area under the curve.

Racial and ethnic disparities in risk and survival in children with neuroblastoma: An updated analysis. *First Author: Caileigh Pudela, University of Chicago, Chicago, IL*

Background: Biologic and socioeconomic factors contribute to health disparities among patients with pediatric cancer. In an analysis of Children's Oncology Group (COG) neuroblastoma (NBL) patients (pts) diagnosed between 2001-2009, non-Hispanic Black (Black) pts were previously shown to have a higher prevalence of high-risk disease and worse event-free survival (EFS) compared to non-Hispanic White (White) pts. Here, we analyzed data in the International Neuroblastoma Risk Group Data Commons (INRGdc) to validate these findings. **Methods:** Three-year EFS and overall survival (OS) of COG pts diagnosed between 2001-2009 (Cohort 1; n = 4,358) and 2010-2016 (Cohort 2; n = 3,689) in the INRGdc with known race and ethnicity were estimated by the Kaplan-Meier method. Cox proportional hazards regression models were used to evaluate differences in EFS and OS between racial/ethnic groups. The association of clinical characteristics and tumor biomarkers with racial/ethnic groups were analyzed using Chi-square tests. **Results:** The distribution of race/ethnicity for pts in Cohort 1 and Cohort 2 was as follows, respectively: White: 72% (n = 3,136) and 70% (n = 2,575); Black: 11.4% (n = 495) and 10.7% (n = 397); Hispanic: 12.2% (n = 532) and 14.1% (n = 522); Asian and Hawaiian: 4% (n = 178) and 4.6% (n = 172); Native American: 0.4% (n = 17) and 0.6% (n = 23). In both cohorts, a higher proportion of Black pts had INSS stage 4 disease, age $\geq$ 18mo, and unfavorable histology tumors when compared to White pts (Cohort 1: p = 0.003; $p < 0.001$; $p < 0.001$, respectively vs Cohort 2: p = 0.014; $p < 0.001$; $p < 0.001$, respectively). No significant differences in the proportion of pts with *MYCN* amplified or diploid tumors were detected between Black and White pts in either cohort. Black pts had a higher prevalence of high-risk disease compared to White pts in both Cohorts 1 and 2 ($p < 0.001$ and $p < 0.001$, respectively). Among all pts in Cohort 1, EFS was 73% and OS was 83%. In Cohort 1, Black pts had worse EFS (68% vs 73%; HR = 1.31, 95%CI 1.11-1.55, p = 0.002) and OS (78% vs 84%; HR = 1.41, 95% CI 1.16-1.70, p = 0.001) compared to White pts. Among all pts in Cohort 2, EFS was 81% and OS was 88%. Black pts in Cohort 2 also had worse EFS compared to White pts (76% vs 82%; HR = 1.35, 95% CI = 1.03-1.76, p = 0.027), although no significant difference in OS was observed (p = 0.21). In analyses restricted to high-risk pts, no statistically significant difference in EFS and OS in Black vs White pts was detected in either cohort. **Conclusions:** In the modern treatment era, Black NBL pts continue to have a higher prevalence of high-risk disease and inferior 3-year EFS compared to White pts. The lack of significant difference in survival among high-risk NBL pts by race suggests that Black and White pts are receiving comparable treatments and responding similarly. The socioeconomic and/or genomic factors contributing to the higher proportion of Black pts with high-risk disease requires further investigation. Research Sponsor: None.

Testing of B7-H3 targeting antibody-drug conjugate (ADC) MGC018 in models of pediatric solid tumors by the Pediatric Preclinical Testing Consortium (PPTC). *First Author: Raushan Kurmasheva, Univeristy of Texas Health Science Center San Antonio, San Antonio, TX*

Background: B7-H3 (encoded by the *CD276* gene) is an immunoregulatory molecule that is widely expressed in pediatric embryonal tumors and sarcomas, while expression is limited for normal tissues. Among PPTC models, osteosarcoma models showed highest CD276 transcript levels followed by Wilms tumor, neuroblastoma, rhabdomyosarcoma, and Ewing sarcoma. Protein expression by IHC generally followed expression at the RNA level, with high expression by IHC observed across a range of models. MGC018 is a duocarmycin-based humanized ADC targeting B7-H3 that shows selective cytotoxicity for B7-H3 expressing cancer cells, robust in vivo activity against a range of adult cancer preclinical models, a favorable pharmacokinetic and safety profile in cynomolgus monkeys, and has entered clinical testing for adults with cancer. Herein we report the in vivo antitumor activity of MGC018 against preclinical models of pediatric solid tumors. **Methods:** MGC018 was tested at 6 mg/kg administered intraperitoneally (IP) on Day 1. SYD988, an anti-CD20 ADC with the same linker and payload as MGC018, was used as a control arm at 6 mg/kg IP on Day 1. Osteosarcoma models, due to their slower growth kinetics and lower rates of tumor regression, were tested with n = 10 mice per arm, while the sarcoma and neuroblastoma models were tested with n of 1 or n of 2 designs, respectively. Activity was evaluated using response criteria mirroring clinical criteria (progressive disease (PD), stable disease (SD), partial response (PR), complete response (CR), and maintained CR (MCR)], by minimum relative tumor volume across all models, and by event-free survival (EFS) comparisons between treatment groups. **Results:** For neuroblastoma models (n = 9), 3 and 2 neuroblastoma models showed objective responses (PR/CR/MCR) or SD, respectively, to MGC018, while none showed an objective response or SD to SYD988. For osteosarcoma, results are mature for 1 of 5 models, with this model showing an MCR response to MGC018 and a PD response to SYD988. For Ewing sarcoma (n = 5), a PR and MCR were observed to MGC018 with the remaining models showing PD; for SYD988 a single CR was observed with the remaining 4 models showing PD. For rhabdomyosarcoma (n = 3) 2 MCR and 1 PD were noted for MGC018, while only PD was noted for SYD988. EFS duration exceeding 100 days to a single dose of MGC018 was observed for 2 rhabdomyosarcoma, 1 Ewing sarcoma, and 1 neuroblastoma model. Evaluation of the relationship between B7-H3 expression and response to MGC018 will be performed when results from all studies are completed. **Conclusions:** B7-H3 is an important target for immuno-oncology agents for childhood cancers. Our results provide proof-of-principle for the ability of MGC018 to produce profound antitumor activity in select pediatric solid tumor models in a B7-H3 specific manner. Research Sponsor: U.S. National Institutes of Health.

Late health outcomes in survivors of Wilms tumor: A report from the St. Jude Lifetime (SJLIFE) cohort study. *First Author: Kayla L. Foster, St Jude Children's Research Hospital, Memphis, TN*

Background: We aimed to characterize late health, neurocognitive, and physical performance outcomes among survivors of Wilms tumor. **Methods:** Wilms tumor survivors (n = 280), $\geq$ 5 years from diagnosis, participating in SJLIFE were clinically assessed along with a community control sample (n = 625). Health outcomes were graded per a modified Common Terminology Criteria for Adverse Events (grade 1 [mild] to grade 4 [life threatening]). Standardized neurocognitive testing was graded using age-adjusted z-scores. Aerobic function (six-minute walk), mobility (timed up and go) and flexibility (sit and reach) were assessed. Associations between treatment exposures and prevalent conditions were examined by multivariable logistic regression, adjusted for current age, sex and race. **Results:** Survivors (59% female, 73% white), median age 3 years (range 0-15) at diagnosis and 31 years (9-58) at evaluation, were comprehensively evaluated on the St. Jude campus. Two-thirds (67%) were treated with doxorubicin (median dose 175 mg/m^2 range 52-490), 167 (60%) received abdominal radiation (median dose 12 Gy range 8.8-61.2) and 25% received chest radiation (12 Gy range 9-44). By age 40 years, survivors averaged 12.7 (95% confidence interval [CI] 11.7-13.8) grade 1-4 and 7.5 (CI 6.7-8.2) grade 2-4 conditions, compared to 4.2 (CI 3.9-4.6) and 2.3 (CI 2.1-2.5), respectively, among controls. The most prevalent medical conditions (grade $\geq$ 2) are reported in the table. Abnormal glucose metabolism was associated with abdominal radiation (relative risk [RR] 5.1 CI 1.4-19.0); restrictive pulmonary defects with chest radiation (RR 24.0 CI 3.2-180); and cardiomyopathy (RR 15.6 CI 1.9-128), pulmonary diffusion (RR 4.5 CI 1.3-15.1), and chronic kidney disease (RR 4.5 CI 1.3-16.1) with doxorubicin exposure. Survivors had a three-fold higher risk (standardized incidence ratio 3.5, CI 2.2-6.6) for subsequent neoplasms. Impairments (grade $\geq$ 2) in executive function (20% vs. 12%), attention (17% vs. 9%), memory (21% vs. 10%), and processing speed (20% vs. 8%) were more frequent in survivors than controls ($p < 0.05$). Impairments in aerobic function (13.6%), mobility (13.6%), and flexibility (11.1%) were higher than expected ($p < 0.01$). Significant associations were not identified between treatment exposures and neurocognitive or physical performance outcomes. **Conclusions:** Systematic clinical assessment identified a significant burden of chronic health conditions and previously unrecognized neurocognitive and physical performance limitations in survivors of Wilms tumor. Research Sponsor: U.S. National Institutes of Health.

	Survivors	Controls	p-value
Cardiomyopathy	6.5%	2.6%	**0.01**
Dyslipidemia	7.1%	2.9%	**< 0.01**
Hypertension	19.3%	11.2%	**< 0.01**

Predicting response to chemotherapy in neuroblastoma using deep learning: A report from the International Neuroblastoma Risk Group. *First Author: Siddhi Ramesh, University of Chicago Pritzker School of Medicine (Chicago, IL), Chicago, IL*

Background: Metaiodobenzylguanidine (MIBG) scans are a radionucleotide imaging modality used to evaluate neuroblastoma stage at diagnosis and also determine disease response following therapy. Curie scoring is used to semi-quantitatively assess disease burden from an MIBG scan on a scale from none (0) to widespread throughout the body (30). While a Curie score $\leq$2 after six cycles of induction chemotherapy has been shown to be prognostic of outcome, there is no established correlation between diagnostic Curie score and outcome. Deep learning models, such as convolutional neural networks (CNN), have been shown to learn generalizable patterns within images for successful classification of metastases and detection of multiple adult cancers. We hypothesized a CNN could be developed to predict response to induction chemotherapy, a proxy for outcome, using diagnostic MIBG scans. **Methods:** DICOM MIBG scans and associated clinical data from a Children's Oncology Group (COG) pilot study for children diagnosed with high-risk neuroblastoma (ANBL12P1; NCT1798004) were deidentified and linked to clinical data by the Pediatric Cancer Data Commons and obtained from the International Neuroblastoma Risk Group Data Commons. Patients were defined as having a poor response to induction chemotherapy if their Curie score after four cycles of induction chemotherapy was $\geq$2. An independent external validation cohort was comprised of 29 images from 26 high-risk patients treated at the University of Chicago with clinically-annotated diagnostic and post-cycle six induction DICOM MIBG scans. The CNN was trained using 2D whole body MIBG scans obtained at diagnosis. We developed the CNN using a transfer learning approach using the Xception architecture as the base layer. Hyperparameter optimization was performed using an 80%-20% train-validation strategy. Model performance was evaluated using area under the receiver operating characteristic curve (AUROC). **Results:** Among 146 patients with high-risk neuroblastoma enrolled on ANBL12P1, 104 had available diagnostic and end-induction MIBG scans. There were no differences in clinical or biological characteristics between included and excluded patients. The base model CNN was able to predict which patients had a poor response to induction chemotherapy with an AUROC of 0.72 in the validation set from the ANBL12P1 cohort. Additionally, the CNN was able to predict patient response to therapy with an AUROC of 0.64 in an independent external dataset from University of Chicago. **Conclusions:** Our study suggests it is feasible to apply machine learning of diagnostic MIBG scans to predict response to chemotherapy for high-risk neuroblastoma patients. Given these promising results, further work to improve AUROC and performance within larger datasets is ongoing. Research Sponsor: U.S. National Institutes of Health.

Preclinical evaluation of an engineered oncolytic herpes simplex virus for pediatric osteosarcoma. *First Author: Sara Hutchins, University of Alabama at Birmingham, Birmingham, AL*

Background: Osteosarcoma is the most common primary bone tumor in children. For those with relapsed or metastatic disease, the five-year survival rate is approximately 20%, and survivors often suffer from long-term disability from current therapies. The high morbidity and mortality for these patients highlight a great need for improved therapies. One such novel therapeutic approach is oncolytic herpes simplex virus (oHSV) immunovirotherapy. We previously demonstrated that M002, an engineered oHSV that contains deletions of the neurovirulence gene preventing infection of normal cells, effectively infects and kills neuroblastoma and rhabdomyosarcoma. Currently, similar oHSVs are being evaluated in early phase clinical trials for children and adults with relapsed or refractory brain tumors. To date, there has been limited investigation of oncolytic virotherapy in osteosarcoma. Thus, we sought to examine the ability of oHSV, M002, to infect and kill osteosarcoma cells *in vitro*. **Methods:** We evaluated two long-term passaged human osteosarcoma cell lines, U2-OS and MG-63. Flow cytometry was used to assess baseline expression of oHSV viral entry-mediated receptors (CD111, CD112, syndecan, HVEM). Single and multi-step viral recovery experiments measured virus infectivity and replication. Cells were infected with increasing multiplicity of infection (MOI) of M002, and cell viability was measured 72 hours post-infection via alamarBlue assay. **Results:** Both MG-63 and U2-OS cells expressed HSV entry molecules (Table) including high levels of the primary HSV entry molecule CD111. Single step virus recovery experiments in MG-63 cells infected at a MOI of 10 plaque-forming units (PFU)/cell demonstrated a 3 log-fold increase in virus titer from 12 to 24 hours post-infection. For multi-step experiments, MG-63 cells were infected with a MOI of 0.1 PFU/cell; viral replication significantly increased from $1.1x10^3$ PFU at 6 hours post-infection to $3.8x10^{10}$ PFU at 72 hours post-infection. M002 successfully decreased osteosarcoma viability with a lethal dose in 50% of cells (LD_{50})of 2.82 and0.67 PFU/cell for MG-63 and U2-OS cells, respectively. Notably, at a virus MOI of 5 PFU/cell, viability was decreased by 64% ± 0.1% ($p<0.001$ vs control) in MG-63 cells and 96% ± 0.1% ($p<0.001$ vs control) in U2-OS cells. **Conclusions:** MG-63 and U2-OS osteosarcoma cells express high levels of HSV entry receptors. Virus recovery experiments demonstrated the ability of M002 to infect cells and replicate over time. The viability of osteosarcoma cells significantly decreased following infection with M002. These data suggest M002 may be a promising novel therapeutic option for patients with osteosarcoma and warrant further investigation for translation to the clinical setting. Nonhematologic neoplasia in biallelic BRCA2 mutated Fanconi anemia. *First Author: Vasant Chinnabhandar, University of Minnesota, Minneapolis, MN*

Background: Fanconi anemia (FA) is a cancer predisposition disorder. Affected individuals do not tolerate conventional doses of chemotherapy or radiation well. Biallelic BRCA2 mutations cause a rare (~3%) form of FA. Most patients with this subtype have a family history of breast cancer and die in early childhood. Optimal management remains uncertain. Herein, we report the world's largest single center cohort of biallelic BRCA2 patients, with a focus on non-hematologic malignancies. **Methods:** The University of Minnesota's prospectively maintained FA database was analyzed for data on biallelic BRCA2 mutated FA patients. IRB-approved consent was obtained for all subjects. **Results:** Twenty patients with biallelic BRCA2 were identified. Median age of FA diagnosis was 1.5 years (range: 0-16.2 years). All patients had a significant history of cancer in the family with breast cancer being particularly frequent (65%). Eight (40%) patients developed non-hematologic neoplasia before 18 years of age. These included 10 malignant tumors and 4 benign neoplastic lesions; 3 patients had more than one solid tumor (see Table). Surgical resection was attempted in all malignant tumors, dose reduced adjuvant chemotherapy was utilized in 5 cases and radiation in one case. Thirteen (65%) patients developed hematologic malignancies (AML=6, ALL=3, MDS=4), all without preceding marrow failure. Fourteen patients underwent allogeneic HCT. Eleven patients have died, 3 from solid tumors and 5 from leukemias. Nine patients are currently alive, of whom 3 are post-HCT. Only 4 (age range: 6.5-16.3 years) patients in the cohort remain free of any oncologic diagnoses. **Conclusions:** Patients with FA due to biallelic BRCA2 mutations have a unique phenotype with an extraordinarily high risk of early-onset de-novo acute leukemia and solid tumors, often both diagnosed in the same patient. They require extensive, lifelong cancer surveillance from an early age to optimize outcomes. Therapy for malignant diagnoses should aim to minimise exposure to genotoxic / crosslinking agents and radiation. BRCA2 mutation testing in family members and appropriate genetic counselling is essential. Additionally, a family history of BRCA2 mutated cancers should prompt FA testing in offspring with any relevant FA-related clinical findings. Nonhematologic neoplasia and therapy. Health-related quality of life (HRQoL) among pediatric patients with neurofibromatosis type 1 (NF1) and plexiform neurofibroma (PN) in the United States (U.S.). *First Author: Xiaoqin Yang, Merck & Co., Inc., Kenilworth, NJ*

Background: PNs occur in 30-50% of pediatric patients with NF1, often resulting in debilitating pain and dysfunction. Children with NF1 PN report significantly worse HRQoL than the general population, though real-world evidence is limited. Research is needed to better characterize HRQoL among this patient population in the US. **Methods:** Patients ages 8-18 years with NF1 PN in the US who were treatment naïve or new users of selumetinib (≤1 month of use) were recruited through the Children's Tumor Foundation to participate with their caregivers in an online cross-sectional survey in December 2020 and January 2021. Caregivers of similar patients ages 2-7 years also participated. Measures included the Pediatric Quality of Life Inventory (PedsQL; Acute version), EQ-5D-Y, Pain Interference Index (PII), Numeric Rating Scale (NRS-11), and the Patient-Reported Outcomes Measurement Information System (PROMIS) mobility and upper extremity functioning subscales. Patients provided self-reported responses; caregivers provided proxy responses and patient demographic and clinical characteristics. **Results:** 61 patients and 82 caregivers responded to the survey. Median (range) age of patients was 12.0 (8-14) years, and 53.7% were female. Most were treatment naïve (97.6%), white/Caucasian (85.4%), and had an NF1 and PN diagnosis for > 5 years (80.5% and 68.3%, respectively). On the PedsQL (range: 0-100; higher = better; mean scores typically > 80 among healthy patients), mean patient scores were 50.3 (school functioning), 56.1 (emotional functioning), 60.7 (social functioning), and 63.7 (physical functioning); the mean total score was 58.5.Caregiver-proxy mean scores were similar, ranging from 54.0 for school functioning to 65.0 for physical functioning, with a mean total score of 59.1. On the EQ-5D-Y, more than half of patients reported experiencing "some" or "a lot" of problems with pain or discomfort (65.6%) and with feeling worried, sad or unhappy (62.3%). Among patients with pain in the last 7 days, mean scores on the PII (range: 0-6; higher = more interference) were 3.0 for patients and 2.7 for caregiver proxies. Almost 75% of them reported moderate or severe pain on the NRS-11. Among patients with movement difficulty in the past 7 days, mean t-scores from the PROMIS scales (distribution mean = 50; higher = better) were 40.2 for mobility and 39.5 for upper extremity functioning among patients and 36.0 and 29.1, respectively, among caregivers. Within dyads, patients generally reported better functioning, on average, than their caregiver proxies. **Conclusions:** The humanistic burden of NF1 PN among this pediatric patient population is substantial, especially regarding pain, emotional functioning, and physical functioning. Results highlight an unmet need to be addressed for improving HRQoL in pediatric patients with NF1 and PN. Predicting decreased health-related quality of life (HRQL) in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Fiona Schulte, University of Calgary, Calgary, AB, Canada*

Background: This study examines temporal patterns in HRQL among adult survivors of childhood cancer, and socio-demographic, lifestyle and health status predictors of decline in HRQL. **Methods:** Adult survivors of childhood cancer (4755, 55.2% female, 86.9% non-Hispanic white) completed baseline (T0) and follow-up (T1 in 2003, T2 in 2014) surveys (median[SD] age 32.4[7.5] at T1, time since diagnosis to T1 23.0[4.5], T1-T2 interval 11.7[0.6] years). Socio-demographic (e.g., age, sex, educational attainment, annual family income), lifestyle (physical inactivity, smoking) and health status predictors were collected at T0 and T1. Chronic conditions graded ≥2 by CTCAE defined as presence, and mental and cognitive status with ≥1SD from norms defined as poor. SF-36 Physical and Mental Component Summary (PCS/MCS; mean 50/SD 10) at T1 and T2 classified HRQL as optimal (≥40) or suboptimal (< 40). Multivariable logistic regression identified risk factors (T0, T1 or status change T0-T1) of decreased HRQL (i.e., optimal to suboptimal) using a backward selection method ($p < 0.1$), adjusting for sex, race, age at T1 and years between T1-T2. The sample was randomly split into training (80%) and test (20%) datasets to develop and validate prediction models; Area Under the ROC Curve (AUC) evaluated model performance. **Results:** From T1-T2, 8.1% and 8.3% of survivors reported decreased PCS and MCS. AUCs of training/test models were 0.75/0.74 for decreased PCS and 0.72/0.68 for decreased MCS. Risk factors at T0 or T1 predicting decreased PCS included female sex (OR 1.67, 95%CI 1.25-2.24), younger age (OR 1.04, 95%CI 1.02-1.06), < college/vocational education (OR 1.59, 95%CI 1.02-2.46), family income < $20,000 (OR 2.00, 95%CI 1.21-3.30), obesity (OR 1.97, 95%CI 1.32-2.92), chronic health conditions (neurologic OR 2.47, 95%CI 1.69-3.60; musculoskeletal OR 2.27, 95%CI 1.42-3.64; endocrinological OR 2.25, 95%CI 1.44-3.52; gastrointestinal OR 1.89, 95%CI 1.32-2.69; pulmonary OR 1.66, 95%CI 1.06-2.59; cardiovascular OR 1.53, 95%CI 1.14-2.06) and depression (OR 1.79, 95%CI 1.20-2.67). Risk factors at T0 or T1 predicting decreased MCS included unemployment (OR 1.68, 95%CI 1.19-2.38), smoking (OR 2.03, 95%CI 1.37-3.00), physical inactivity (OR 1.48, 95%CI 1.05-2.09), poor mental health (depression OR 4.29, 95%CI 2.44-7.55; somatization OR 1.63, 95%CI 1.05-2.53) and poor cognitive status (task efficiency OR 1.90, 95%CI 1.34-2.68; organization OR 1.67, 95%CI 1.12-2.48). **Conclusions:** Nearly 10% of childhood cancer survivors have significant late-onset decline in HRQL. Chronic health conditions predict decreased physical HRQL, whereas smoking, physical inactivity and poor mental health predict decreased mental HRQL. Interventions targeting modifiable lifestyle and health conditions should be considered to prevent decreased HRQL for childhood cancer survivors. Research Sponsor: U.S. National Institutes of Health, American Lebanese Syrian Associated Charities (ALSAC).

Late morbidity and mortality among survivors of neuroblastoma treated with contemporary therapy: A report from the Childhood Cancer Survivor Study. *First Author: Danielle Novetsky Friedman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Survival rates for neuroblastoma vary widely based on risk group. Therapies have evolved over the past four decades to de-intensify treatment for individuals with low/intermediate risk disease and intensify therapy for those with high risk disease. Risk stratification is predicted to result in differential outcomes in late morbidity and mortality; the magnitude of these differences has not been well studied. **Methods:** We evaluated late mortality, subsequent malignant neoplasms (SMN) and chronic health conditions (CHC) graded according to CTCAE v4.03 among 491 5-year CCSS survivors of neuroblastoma diagnosed 1987-1999 at ≥1 year of age. Using age, stage at diagnosis, and treatment, survivors were classified into risk groups (low [n=182]; intermediate [n=70]; high [n=239]). Standardized mortality ratios (SMR) and standardized incidence ratios (SIR) of SMN were calculated using rates from NCHS and SEER, respectively. Cox regression models estimated hazard ratios (HR) and 95% confidence intervals (CI) for CHC compared to 1,029 CCSS siblings. **Results:** Among survivors (48% male; median age 22 years, range 7-42; median follow-up 19 years, range 5-29), 80.4% with low risk disease were treated with surgery alone, while 77.8% with high risk disease received surgery, radiation, chemotherapy ± transplant. The 15-year cumulative incidence of all-cause mortality was 9.2% (CI: 7.1-11.4), with a recurrence-related mortality of 7.3% (CI: 5.3-9.3) and SMN-related mortality of 0.3% (CI: 0-0.7). All-cause mortality was significantly higher in all risk groups: (low, SMR=5.8 [CI: 2.6-13.0]; intermediate, SMR=5.7 [CI: 1.4-23.5]; high, SMR=38.6 [CI: 27.9-53.5]). The risk of SMN was elevated among high risk survivors (SIR=25.1, CI: 16.7-37.6), but did not differ from the US population for survivors of low or intermediate risk disease. Table describes the HR of CHCs (grades 1-5 and 3-5) in survivors, by risk group, as compared with siblings, as well as categories of CHCs for which survivors were at increased risk. **Conclusions:** Long-term survivors of neuroblastoma have a high risk of late morbidity and mortality; risk is particularly pronounced among survivors of high risk disease. Vigilant lifelong medical surveillance will be required for this relatively young population as they age. Research Sponsor: U.S. National Institutes of Health.

CHCs in neuroblastoma survivors, by risk group, compared to siblings.

Low	Intermediate	*High*	HR (95% CI)
Any grade 1-5 CHC	2.0 (1.5-2.6)	2.9 (2.0-4.3)	6.9 (5.7-8.2)
Endocrine	3.9 (2.1-7.2)	5.9 (2.9-12.1)	27.7 (17.6-43.5)
Hearing	4.0 (1.7-9.0)	11.3 (4.8-26.3)	17.9 (9.7-32.9)
Gastrointestinal	-	-	21.3 (8.0-56.8)
Cardiac	2.5 (1.3-4.6)	4.7 (1.9-11.7)	10.9 (6.7-17.7)
Renal	-	4.1 (1.8-9.4)	10.8 (6.2-19.0)
Neurologic	2.4 (1.4-4.1)	4.5 (2.3-8.8)	6.1 (4.0-9.2)

Accelerated aging and mortality in long-term survivors of childhood cancer: A report from the St. Jude Lifetime Cohort (SJLIFE). *First Author: AnnaLynn M. Williams, St. Jude Children's Research Hospital, Memphis, TN*

Background: Survivors of childhood cancer have functional limitations and health-related morbidity consistent with an accelerated aging phenotype. We characterized aging using a Deficit Accumulation Index (DAI) which examines the accumulation of multiple aging-related deficits readily available from medical records and self-report. DAI's are used as surrogates of biologic aging and are validated to predict mortality in adult cancer patients. **Methods:** We included childhood cancer survivors (N = 3,758, mean age 30 [SD 8], 22 [9] years post diagnosis, 52% male) and community controls (N = 575, mean age 34 [10] 44% male) who completed clinical assessments and questionnaires and who were followed for mortality through December 31st, 2018 (mean follow-up 6.1 [3.1] years). Using the initial SJLIFE clinical assessment, a DAI score was generated as the proportion of deficits out of 44 items related to aging, including chronic conditions (e.g. hearing loss, hypertension), psychosocial and physical function, and activities of daily living. The total score ranged 0 to 1; scores $>$ 0.20 are robust, while moderate and large clinically meaningful differences are 0.02 and 0.06, respectively. Linear regression compared the DAI in survivors and controls with an age*survivor/control interaction and examined treatment associations in survivors. Cox-proportional hazards models estimated risk of death associated with DAI. All models were adjusted for age, sex, and race. **Results:** Mean [SD] of DAI was 0.17 [0.11] for survivors and 0.10 [0.08] for controls. 32% of survivors had a DAI above the 90th percentile of the control distribution ($p < 0.001$). After adjustment for covariates, survivors had a statistically and clinically meaningfully higher DAI score than controls (β = 0.072 95%CI 0.062, 0.081; $p < 0.001$). When plotted against age, the adjusted DAI at the average age of survivors (30 years) was 0.166 (95% CI 0.160,0.171), which corresponded to 60 years of age in controls, suggesting premature aging of 30 years. The mean difference in DAI between survivors and controls increased with age from 0.06 (95% CI 0.04, 0.07) at age 20 to 0.11 (95% CI 0.08, 0.13) at age 60, consistent with an accelerated aging phenotype ($p = 0.014$). Cranial radiation, abdominal radiation, cyclophosphamide, platinum agents, neurosurgery, and amputation were each associated with a higher DAI (all $p \leq 0.001$). Among survivors, a 0.06 increase in DAI was associated with a 41% increased risk of all-cause mortality (HR 1.41 95%CI 1.32, 1.50; $p < 0.001$). **Conclusions:** Survivors of childhood cancer experience significant age acceleration that is associated with an increased risk of mortality; longitudinal analyses are underway to validate these findings. Given the ease of estimating a DAI, this may be a feasible method to quickly identify survivors for novel and tailored interventions that can improve health and prevent premature mortality. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Determinants of symptom clusters and associations with health outcomes in childhood cancer survivors: A report from the St. Jude Lifetime Cohort (SJLIFE). *First Author: Hyewon Shin, Clemson University, Clemson, SC*

Background: Childhood cancer survivors experience concurrent symptoms, but associations with health outcomes are unknown. We characterize symptom clusters among adult survivors of childhood cancer in SJLIFE and tests associations with health-related quality of life (HRQL) and clinically assessed physical and neurocognitive performance. **Methods:** This cross-sectional study includes survivors diagnosed when $<$18 years of age, ≥10 years off-therapy, and ≥18 years of age at evaluation. Survivors rated 37 symptoms over 10 domains (cardiac, pulmonary, sensory, motor, nausea, pain, fatigue, memory, anxiety, depression), representing 3 broader symptom groups (physical, somatic, psychological). They also underwent a rating of HRQL (SF-36 PCS/MCS) and testing of physical performance (quantitative sensory, motor, endurance, mobility) and neurocognition (processing speed, executive function, attention, memory problems). Latent class analysis determined survivors with distinct symptom burden. Polytomous logistic regression identified risk factors of symptom clusters; multivariable regression tested associations of symptom clusters with health outcomes. **Results:** Among 3,085 survivors, mean [SD] age at evaluation was 31.9 [8.3] years, time from diagnosis was 28.1 [9.1] years, 49.7% were female, 37.1% were treated for leukemia and 33.0% for solid tumors. Four groups of survivors with distinct symptom burden were found: Cluster 1 (52%, low prevalence in all 3 symptom groups); Cluster 2 (16%, low in physical, moderate in somatic, high in psychological); Cluster 3 (18%; high in physical, moderate in somatic, low in physiological); and Cluster 4 (14%, high in all 3 symptom groups). Compared to the lowest symptom burden (Cluster 1), survivors with highest burden (Cluster 4) were significantly more likely to be female (OR 2.5; 95%CI 1.9, 3.4), have below a high school education (OR 7.7; 95%CI 4.5, 13.3), no insurance (OR 1.5; 95%CI 1.1, 2.3) and previous exposure to corticosteroids (OR 1.8; 95%CI 1.0, 3.0). High physical, moderate somatic and low psychological symptom burden (Cluster 3) was associated with below high school education (OR 2.7; 95%CI 1.4, 5.0), exposure to platinum agents (OR 2.2; 95%CI 1.4, 3.7) and brain radiation ≥30Gy (OR 4.0; 95%CI 2.3, 6.9) in contrast to Cluster 1. Survivors in Cluster 4 had the poorest PCS, MCS, physical and neurocognitive outcomes vs in Clusters 2 or 3, whereas those in Cluster 1 had the best outcomes (F-values for 4 clusters: 291.4 [PCS], 269.2 [MCS], 61.5 [physical], 36.9 [neurocognitive], p-values $<$0.001; effect sizes for Clusters 4 vs 1: 0.4-2.0 [4 outcomes]). **Conclusions:** Nearly 50% of survivors belong to symptom clusters with ≥1 moderate/high burden groups, associated with the socio-demographic and treatment exposures. Survivors in the highest symptom burden cluster had the poorest HRQL and functional outcomes. Research Sponsor: U.S. National Institutes of Health.

Development and validation of a prediction model for kidney failure in long-term survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Natalie Lucy Wu, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Kidney failure (need for dialysis or kidney transplantation, or death due to kidney disease) is a rare but serious late effect for survivors of childhood cancer. We aimed to develop a model using demographic and treatment characteristics to predict individual risk of kidney failure among five-year survivors of childhood cancer. **Methods:** CCSS survivors without kidney failure at five years after cancer diagnosis (n = 25,483) were assessed for subsequent kidney failure by age 40. Outcomes were self-reported and corroborated by the Organ Procurement and Transplantation Network and the National Death Index. A sibling cohort (n = 5045) served as a comparator. Piecewise exponential models with backward selection estimated the relationships between potential predictors and kidney failure and were converted to integer risk scores. Additional results from the St. Jude Lifetime Cohort Study (SJLIFE, n = 2490) and the National Wilms Tumor Study (NWTS, n = 6760) validated the models. **Results:** Among CCSS survivors, 204 developed late kidney failure. We developed a model with sex, race/ethnicity, age at cancer diagnosis, nephrectomy, exposure to specific chemotherapy, any abdominal radiation, presence of genitourinary anomalies, and early-onset hypertension (Table). Risk scores achieved an area under the curve (AUC) and concordance (C) statistic of 0.65 and 0.68 for kidney failure by age 40. Validation cohort AUC and C statistics were 0.83/0.86 for SJLIFE (8 cases) and 0.61/0.63 for NWTS (91 cases). An alternative model with specific chemotherapy doses and kidney-specific radiation dosimetry had similar AUC and C statistic (0.67/0.70). Integer risk scores were collapsed to form statistically distinct low (score $<$3; 87 cases of 17,326), moderate (score 3-5; 63 cases of 4667), and high (score 6+; 18 cases of 401) risk groups. These groups corresponded to cumulative incidences in CCSS of kidney failure by age 40 of 0.6% (95% CI 0.4-0.7%), 2.3% (95% CI 1.6-3.2%), and 9.4% (95% CI 4.4-16.7%), compared with 0.2% (95% CI 0.1-0.5%) among siblings. **Conclusions:** Using readily available information, we were able to identify low, moderate, and high risk groups for developing kidney failure following treatment for childhood cancer. These prediction models may help guide screening and interventional strategies for higher risk survivors. Research Sponsor: Childhood Cancer Survivor Study.

Risk scores by variable for kidney failure prediction model*.

Male sex (vs Female)	1
Black, non-Hispanic race/ethnicity (vs Other)	1
Age <10y at cancer diagnosis (vs 10+y)	1
Nephrectomy (vs None)	2
Ifosfamide (vs None)	2
Platinum (vs None)	1
Anthracycline (vs None)	1
Abdominal radiation (vs None)	1
Kidney/bladder/genital anomalies (vs None)	2
Hypertension within 5y of cancer diagnosis (vs None)	4

Health-related unemployment trends among survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Neel S. Bhatt, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The impact of treatment era and chronic health conditions on health-related unemployment among childhood cancer survivors has not been studied. **Methods:** Childhood cancer survivors (age ≥25 years) enrolled in the CCSS (3,420 diagnosed in the 1970s, 3,564 in the 1980s, and 2,853 in the 1990s) were matched 1:5 on sex, race/ethnicity, census bureau division, age, and year of survey to the Behavioral Risk Factor Surveillance System (BRFSS), a nationally representative population. Among survivors, health-related unemployment was defined as self-reported unemployment due to illness/disability and for BRFSS participants as self-reported inability to work. To standardize follow-up, health-related unemployment was assessed either in 2002-05 or 2014-16 for both cohorts. Sex stratified standardized prevalence ratio (SPR) and relative SPR (rSPR) with 95% confidence intervals (CI) for health-related unemployment were estimated using multivariable generalized linear models, with BRFSS background rates to assess the impact of treatment era and moderate to severe health conditions (per the Common Terminology Criteria for Adverse Events). **Results:** Prevalence of health-related unemployment in survivors (median age 9 years [range 0-20] at diagnosis and 33 years [25-54] at follow-up) was significantly higher compared to BRFSS participants (females: 11.3% vs 3.7%; SPR 3.0, 95% CI 2.7-3.3; males: 10.5% vs 3.0%; SPR 3.5, 95% CI 3.1-3.9). Health-related unemployment risks declined among survivors in more recent decades ($p_{trend} < 0.001$) for females: 1970s SPR 3.8, 95% CI 3.2-4.5, 1980s SPR 2.9, 95% CI 2.5-3.5, 1990s SPR 2.5, 95% CI 2.1-3.0; and males: 1970s SPR 3.6, 95% CI 2.9-4.4, 1980s SPR 3.8, 95% CI 3.1-4.7, 1990s SPR 3.0, 95% CI 2.5-3.7. Among survivors, multivariable models identified associations between presence of specific health conditions and elevated health-related unemployment (Table) adjusting for all statistically significant health conditions, race/ethnicity, treatment era, age at survey, and diagnosis. Among females, rSPR for endocrine conditions differed between 1970s and 1990s (interaction p = 0.04); fewer significant health conditions remained in the final model for males. **Conclusions:** While prevalence for health-related unemployment has declined over time, childhood cancer survivors remain at higher risk compared to the general population. These elevated risks are associated with chronic health conditions and affect female survivors more than male survivors. Research Sponsor: U.S. National Institutes of Health.

Accelerated cognitive decline in adult survivors of pediatric central nervous system (CNS) tumors: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Nicholas Steve Phillips, St. Jude Children's Research Hospital, Memphis, TN*

Background: Survivors of pediatric CNS tumors may be at elevated risk for accelerated cognitive decline as they age through adulthood relative to the general population, which may be an early risk factor for dementia. **Methods:** Longitudinal analysis of 512 CNS tumor survivors (52.3% female, mean [SD] 30.6 [7.1] years at T1) and 232 siblings (57.8% female, mean [SD] 34.2 [8.4] years at T1) from the CCSS was conducted using the Neurocognitive Questionnaire (NCQ) to assess task efficiency, emotional regulation, organization and memory at two timepoints separated by a mean of 11.6 [0.7] years. Impairment in each NCQ domain was defined as a score ≥ 90th percentile of the CCSS sibling distribution at each survey, with decline defined as moving from unimpaired at T1 to impaired at T2. Treatment exposures were abstracted from medical records. Chronic health conditions were self-reported at T1 and graded according to CTCAE v4.3. Relative risk of decline for group, treatment and chronic condition predictors was estimated using generalized linear models with robust variance estimates. Mediation analysis examined direct effects of treatments and mediating effects of chronic conditions. All models were adjusted for age, sex, and race. **Results:** At T1, survivors demonstrated higher frequency of impaired memory (24.5% vs. 6.5%, $p < 0.001$), emotional regulation (14.3 % vs. 5.6%, $p < 0.001$), task efficiency (43.3% vs. 13.8%, $p < 0.001$) and organization (17.7% vs. 10.8%, p = 0.015) than siblings. Among those unimpaired at T1, more survivors vs. siblings declined in memory (34.7% vs. 7.8; RR 4.2, 95% CI 2.6-6.9), emotional regulation (15.5% vs. 5.0%; RR 2.8, 95% CI 1.5-5.3), task efficiency (22.7% vs. 7.0%; RR 2.9, 95% CI 1.7-5.2), and organization (14.5% vs. 2.9%; RR 4.9, 95% CI 2.1-11.0) by T2. Decline in survivor memory was associated with exposure to craniospinal irradiation (RR 1.9, 95% CI 1.3-2.8) and focal irradiation (RR 1.6, 95% CI 1.1-2.3) compared with no radiation, and exposure to Ara-C (RR 1.7, 95% CI 1.0-2.8) and cyclophosphamide (RR 1.7, 95% CI 1.01-2.8). Independent of therapy, serious/disabling or life-threatening cardiopulmonary conditions at T1 predicted future decline in memory (RR 1.5, 95% CI 1.02-2.2) and organization (RR 2.0, 95% CI 1.1-3.6), with the presence of 2 or more cardiopulmonary conditions associated with even higher risk (memory RR 2.6, 95% CI 2.0-3.1; organization RR 3.4, 95% CI 1.1-10.5). Chronic conditions did not mediate associations between treatment exposures and cognitive decline. **Conclusions:** CNS tumor survivors are at elevated risk for impairment and accelerated cognitive decline compared to siblings. Cranial radiation, Ara-C, cyclophosphamide, and cardiopulmonary morbidity are risk factors for decline. Survivors with these exposures/conditions may benefit from interventions to prevent additional future cognitive decline. Research Sponsor: U.S. National Institutes of Health.

Psychosocial impacts of the COVID-19 pandemic on young adult cancer survivors and parents of children with cancer. *First Author: Stephanie M Smith, Division of Hematology/Oncology, Department of Pediatrics, Stanford University School of Medicine, Stanford, CA*

Background: The COVID-19 pandemic has affected oncology practice in a variety of ways. We sought to evaluate the impact on pediatric oncology parent and young adult (YA) patient experiences, concerns, and perceived stress. **Methods:** We conducted a cross-sectional Internet-based survey of parents and YA patients in the pediatric oncology and survivorship clinics at Stanford between June-December 2020. Patients were recruited in person by clinic staff or through the electronic patient health portal. Surveys (available in English and Spanish) included the NIH Perceived Stress Scale (PSS-10) and investigator-developed questions evaluating clinical practice changes, concerns about health and cancer care, and pandemic-related challenges. Bivariate analyses evaluated associations between demographic, clinical, and pandemic-related factors and (a) concern about the pandemic affecting health and cancer care, and (b) perceived stress. **Results:** Among 81 participants (66 parents, mean age 41.6 ± SD 9.6; 15 YAs, mean age 21.9 ± 8.4 years), 37% self-identified as Hispanic/Latino, 36% non-Hispanic white, and 21% Asian. Twenty-eight percent were on treatment and 47% had completed treatment (79% < 5 years prior). Thirty percent reported cancer-related appointment changes, largely rescheduling (75%) and/or switching to telehealth (42%). Nearly half (45%) of parents and 27% of YAs reported feeling 'very' or 'extremely' concerned about the pandemic affecting their child's/their health or cancer care. Race/ethnicity emerged as the only demographic feature that was significantly associated with high concern (p = 0.018), with 57% of Hispanic/Latino and only 21% of non-Hispanic white respondents reporting high levels of concern. Specific concerns included fear of severe infection, immunosuppression, and whether infection would change treatment and compromise effectiveness. Parents and YAs reported 'a lot' or 'a great deal' of challenges in their personal/family life (61%) and work/professional life (48%). Among these were having less support from friends/family (35%), reduced wages/work hours (31%), and job loss (20%) with 20% reporting ≥ 3 challenges. On the PSS-10, stress in the past month was high for parents (mean 30 ± 4) and YAs (mean 31 ± 5.1) on a scale of 0-40. Risk factors for higher stress included: male gender (p = 0.028), less support from family/friends (p = 0.002), and experiencing ≥ 3 pandemic-related challenges (p = 0.013). **Conclusions:** Our findings confirm the prevalent worry and stress that pediatric oncology patients and families are experiencing during the COVID-19 pandemic. Better communication about cancer care service changes may help to alleviate some concerns. Supportive care resources may also help patients and families cope with psychosocial stressors, particularly among at-risk groups. Research Sponsor: None.

Standardization of fertility preservation discussion amongst pediatric oncology and bone marrow transplant patients. *First Author: Chandni Dargan, Children's Mercy Hospital, Kansas City, MO*

Background: As treatment for pediatric malignancies improves long term survival, physicians are shifting focus to late effects of therapy such as infertility. Currently, options for fertility preservation include cryopreservation of mature oocytes, sperm, and gonadal tissue, although barriers remain present. Within our division, we lacked a standard approach to discussing fertility preservation options. **Methods:** Records from 474 pediatric patients with new oncologic diagnoses at CMH from 2014-2020 were retrospectively reviewed. We evaluated the frequency that reproductive health discussions were documented in pubertal males and females requiring chemotherapy or radiation treatment. We implemented a standard fertility preservation note and patient handouts, then surveyed our department to identify diagnoses that place patients at risk for infertility and barriers to formalized fertility consultations. We then provided educational sessions to address these barriers with pre- and post-evaluation to measure efficacy. Our longitudinal assessment, encompassing multiple points of intervention, was compared to results from previous chart review (2010-2013). **Results:** Of 474 patients diagnosed between 2014-2020, 175 (90 females, 85 males) warranted a fertility discussion per inclusion criteria. 61 (67.8%) females received a fertility discussion and of those 8 (8.9%) completed oocyte or gonadal tissue preservation, all between 2017-2020. 52 (61.2%) males received a fertility discussion and 20 (23.5%) completed sperm cryopreservation, with even distribution pattern between 2014-2020. Following implementation of an electronic fertility consult process and standardized fertility preservation documentation, there was an increase in documented fertility discussions from 30% in 2014 to 63.6% in 2020. Internal department survey responses identified a lack of comfort with knowing fertility preservation options available and diagnoses that should prompt this conversation. Education sessions with pre- and post-provider assessment demonstrated more comfort discussing fertility preservation (average score increase from 3.44 to 4.33) and knowledge regarding diagnoses at higher risk of infertility (average score increase from 3.67 to 4.33). **Conclusions:** Integration of a standardized fertility preservation process and addressing barriers identified within our division have led to a 33.6% increase in fertility discussions over the last 6 years. While the data shows a promising increase in oocyte and ovarian tissue preservation, sperm banking completion rates remained unchanged. Further steps include incorporation of an automated fertility consultation order into electronic chemotherapy orders, hospital-wide identification of other high-risk patient populations, and continued education of patient, families, and the health care team. Integration and feasibility of symptom burden assessment and early palliative care into an adolescent and young adult leukemia clinic. *First Author: Amy Yuan Wang, University of Chicago Medicine, Chicago, IL*

Background: Patients (pts) diagnosed with hematologic malignancies during adolescence & young adulthood (AYA) are a uniquely challenging population who are understood to have robust supportive care needs. Here, we describe their symptom burdens and the feasibility of integrating palliative care into an outpatient, multi-disciplinary AYA leukemia clinic at an academic medical center. **Methods:** Palliative care was introduced into the AYA clinic in 8/2020 to provide symptom-focused care. Pre-existing clinic services included psychologists, pharmacists, and social workers. All established pts receiving routine follow up were referred by the oncology team to the Supportive Care team, which provided same-day palliative care consultation in the same clinic space with a telehealth option and as needed follow-up. To describe baseline symptom burdens, a random cross-sectional sample of pts completed a multi-domain symptom assessment (SA) using validated self-report instruments including physical (Edmonton Symptom Assessment Scale [ESAS]); emotional (Brief Symptom Inventory-18 [BSI-18]); financial (FACIT-COST); cognitive (Childhood Cancer Survivor Study – Neurocognitive Questionnaire); spiritual (FACIT -Spiritual Well-being Scale); and quality of life (QOL) (FACT-General) measures. All pts have a diagnosis of acute or chronic leukemia and were on active treatment or in survivorship. **Results:** Over 6 months, 30 pts (median age 29 years at assessment, range 18-45 years) received symptom-focused palliative care over 16 combined clinics with 81 total encounters averaging 5 pts (range 1-8) per clinic. 47% were female. No pts declined palliative care. Pts received on average 2.7 follow up visits (range 1-6), with 50% of encounters resulting in adjustments to medical management. Common issues addressed included pain, muscle cramps, neuropathy, anxiety, insomnia, depression, nausea, and non-pharmacological symptom control remedies. Of 46 pts, 31 (67%) completed the SA (median age 30 years at assessment, range 18-43 years); 48% were female; 84% were on treatment. 100% of pts reported fatigue, and 48% reported $> = 1$ severe symptom (range 0-7) based on the ESAS with "poor feeling of well-being" as the most common (23%). 45% met criteria for BSI-18 emotional distress, and 45% reported some neurocognitive impairment. Emotional distress ($p < 0.01$), financial toxicity ($p = 0.03$), low spiritual well-being ($p < 0.01$), and presence of pain, nausea, or depression ($p < 0.05$) were all associated with lower QOL. **Conclusions:** AYA pts with leukemia undergoing treatment and in survivorship experience high symptom burden with poor QOL. It is feasible to both assess symptom burden and provide early palliative care focused on symptom management in an outpatient, multi-disciplinary clinic setting. Research Sponsor: None.

Assessment of physician perceptions of pediatric palliative care for children with cancer in Latin America. *First Author: Michael McNeil, St. Jude Children's Research Hospital, Memphis, TN*

Background: While great strides have transpired in pediatric cancer management in high-income countries (HICs), more than 80% of all children with cancer live in low- and middle-income countries (LMICs),where fewer than 20% will be cured. The World Health Organization (WHO) has stated that early integration of palliative care is an ethical responsibility in the management of children with life-limiting illness. While structural barriers impact the ability to deliver pediatric palliative care (PPC), underlying stigma also prevents early integration of PPC. **Methods:** The Assessing Doctor's Attitudes on Palliative Treatment (ADAPT) survey was created for physicians of all specialties who care for children with cancer, initially used in Eurasia. Survey questions evaluated provider perceptions on timing of palliative care integration, scope of palliative treatment, physician responsibility, and ethical issues. This survey was adapted for use in Latin America, including translation to Spanish and reviewed by regional palliative care specialists for syntax, comprehension, and cultural relevance. The survey was then distributed to physicians treating children with cancer in the region. To assess provider's perspectives on palliative care, we used fifteen statements from the WHO 2018 guidelines, describing general palliative care principles. Results are reported as percent of alignment with guidelines. **Results:** A total of 1,039 participants from 16 countries in Latin America completed the survey, with a median country response rate of 66% (range 26%-100%). Thirty-six specialties were represented with 34% general pediatricians and 23% pediatric hematologist/oncologists. The majority (59%) had received no PPC training and 37% had no access to PPC experts for consultation in their practice setting. On average, provider's perspectives on PPC were aligned with the WHO guidelines (81% alignment, range 53%-96%). However, almost half (42%) felt that the integration of pediatric palliative occurred too late in the course of treatment. Additionally, less than half (47%) of respondents felt comfortable addressing the physical symptoms of their patients, 33% felt comfortable addressing emotional symptoms, and only 26% felt comfortable addressing grief and bereavement for the patient's family. The most common barriers identified were a lack of home-based services (87%), a lack of physician knowledge on the role of PPC (84%), and physician discomfort in discussing palliative care with families (81%). Nearly all (95%) wanted more training in PPC. **Conclusions:** Most physicians who completed the survey were not confident in providing symptomatic and supportive care for their patients and families. This study will guide targeted interventions for education in PPC for physicians in Latin America as well as interventions to address barriers which impede earlier palliative care integration in the region. Research Sponsor: None.

Lessons from COVID-19, challenges of remote learning for childhood cancer survivors. *First Author: Kathy Ruble, Johns Hopkins University, Baltimore, MD*

Background: More than half of childhood cancer survivors (survivors) will have neurocognitive deficits that impact schooling, most commonly reflecting attention and executive dysfunction. Schools are legally bound (IDEA, 2004) to support eligible students with Individualized Education Program (IEP) informed instruction and related services (e.g. assistive technology, speech-language, physical, or occupational therapy) to foster academic success. However, these service provision were not designed under the constraints of remote learning. The COVID19 shift to remote learning is likely to extend beyond the pandemic especially for medically fragile students. This quality improvement project describes challenges for survivors during remote learning and recently developed related patient education materials. **Methods:** Interviews with families were used to identify themes around challenges during remote learning, which informed development of a 29-question survey disseminated via flyer in local oncology clinics and social media posts by local childhood cancer organizations in Fall 2020. **Results:** The survey was completed by 67 parents describing their affected child (mean age= 8.6 years; 60% male; 78% White, 12% Black, 95% non-Hispanic). Most children (74%) had completed therapy (43% for leukemia, 18% for brain tumor; 39% other). The majority (86%) attended public school and 37% received special education or related services: speech-language (26%), occupational (23%), and physical (14%) therapies, and vision services (3%). Fully remote learning was reported for 73%, in-person 4%, and hybrid learning for 14%. The majority (57%) reported observing greater difficulty with attention and focus during RL, indicating difficulty occurred about half of the time during related services therapies, class and/or small group video instruction. Technology-related challenges included difficulty navigating online instruction/equipment (28%), reading difficulty (16%), and difficulty seeing materials/lack of vision supports (18%). Findings did not differ based on treatment or IEP status ($p>0.50$). Few (14%) reported their school team discussed assistive technology options for online learning. Parents indicated the most helpful supports for addressing challenges included speech-to-text tools, screen readers, and audio books. Parents reported their oncology team was helpful in making referrals to neuropsychology and therapies and completing documentation necessary to secure supports. **Conclusions:** Childhood cancer survivors, irrespective of diagnosis or IEP status, report challenges with remote learning. Families find a lack of information or special accommodations as roadblocks to success. Oncology providers were identified as valued resources, so educational materials (https://tinyurl.com/nxbhj5or) were developed for oncology teams to share with families. Phase II study of nivolumab and ipilimumab in children and young adults with INI1-negative cancers. *First Author: Suzanne J. Forrest, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Several aggressive pediatric and young adult cancers are characterized by *SMARCB1* inactivation resulting in loss of INI1 expression, including rhabdoid tumors, epithelioid sarcoma and undifferentiated chordoma. These malignancies are associated with a poor prognosis and few effective treatment options for relapsed or refractory disease. Prior studies and emerging data suggest INI1-negative cancers may be uniquely susceptible to treatment with immune checkpoint inhibitors: Many INI1-negative pediatric tumors express PD-L1 and are infiltrated by immune cells, and there are reports of patients with advanced INI1-negative cancers with clinical responses to immune checkpoint blockade (Forrest et al. Clinical Cancer Research, 2020). We hypothesize that INI1 loss predicts tumor response to immune checkpoint inhibition (ICI). **Methods:** This is an ongoing multicenter, phase II, open-label clinical trial to evaluate the activity of nivolumab and ipilimumab in patients aged 6 months to 30 years with relapsed or refractory INI1-negative cancers (NCT04416568). The study enrolls patients in 2 strata: extracranial solid tumors in Stratum 1 and intracranial solid tumors in Stratum 2. Patients treated with prior ICI are excluded. Patients are treated with intravenous (IV) nivolumab 3mg/kg plus ipilimumab 1mg/kg IV every 3 weeks for 4 cycles followed by nivolumab 3mg/kg (max dose 240mg) IV every 2 weeks for up to 1-year. The primary objective is to evaluate the objective response rate (ORR) by Response Evaluation Criteria in Solid Tumors (RECIST) for Stratum 1 and by Response Assessment in Neuro-Oncology (RANO) criteria for Stratum 2. The trial has a 2-stage design targeting a 25% or greater response rate, with each stratum assessed independently. The analysis for Stage 1 in a given Stratum will be performed after 10 patients are enrolled. If a sufficient number of responders are observed, an additional 10 patients will be enrolled at Stage 2. Secondary endpoints include progression-free survival, overall survival, and disease control rate at 12 months. Correlative aims include assessing tissue and blood biomarkers associated with treatment response. Enrollment began 14 Aug 2020 and is ongoing. Clinical trial information: NCT04416568. Research Sponsor: Gateway for Cancer Research, Philanthropic funding.

FIREFLY-1: A phase 2 study of the pan-RAF inhibitor DAY101 in pediatric patients with low-grade glioma. *First Author: Lindsay Baker Kilburn, Children's National Hospital, Washington, DC*

Background: The mitogen-activated protein kinase (MAPK) signaling pathway is an essential pathway that regulates key cell functions such as growth, survival, and differentiation. Genomic alterations and dysregulation of the MAPK pathway including BRAF fusions, point mutations (e.g. BRAF V600) and in-frame deletions have been described in many different types of malignancies, including pediatric low-grade glioma (pLGG) and other pediatric cancers. The identification of the KIAA1549:BRAF fusion in 2008 led to deeper understanding of the genomic events driving growth of pLGG (Jones, Cancer Res 2008). Despite the low-grade histology and excellent long-term survival, pLGGs are often associated with tumor- and treatment-associated morbidity and significant late-effects that persist throughout the lifespan of the patient. DAY101 is an oral, highly selective, CNS-penetrant small-molecule, Type II pan-RAF kinase inhibitor that is being developed for patients with pLGG harboring an activating BRAF-alteration. DAY101 has demonstrated tumor inhibition in preclinical models and has achieved clinically meaningful and durable responses in 7/8 patients with RAF-altered LGG in a pediatric phase 1 trial, including 2 complete responses, 3 partial responses, 2 stable disease and 1 progressive disease with a median time to response of 10.5 weeks. Patients have been treated for up to two years with no discontinuations due to toxicity or disease progression (Wright, SNO 2020). **Methods:** FIREFLY-1 is an open-label, multi-center, international Phase 2 study with DAY101 in pediatric and young adult patients between the ages of 6 months and 25 years with LGG harboring a documented BRAF-alteration as determined by local laboratory testing. DAY101 is administered orally once a week on a continuous 28-day schedule. Patients who respond will be treated for a minimum of two years after which they may at any point, opt to enter a "drug holiday" discontinuation period. Dosing is based on body surface area. DAY101 is available in a pediatric-friendly oral liquid formulation and tablets. The primary endpoint is objective response rate based on Response Assessment for Neuro-Oncology (RANO) as determined by an independent review committee. Secondary endpoints include objective response rate based on Response Assessment in Pediatric Neuro-Oncology (RAPNO) working group criteria, duration of response and safety. Exploratory endpoints include quality-of-life measurements as well as functional outcomes. Molecular abnormalities will be characterized through the analysis of archival tissue. Enrollment began in February 2021 and is ongoing. Clinical trial information: NCT03429804. Research Sponsor: DOT-Therapeutics 1.

Breast cancer screening for carriers of ATM, CHEK2, and PALB2 pathogenic variants: A comparative modeling analysis. *First Author: Kathryn P. Lowry, University of Washington, Seattle Cancer Care Alliance, Seattle, WA*

Background: Inherited pathogenic variants in ATM, CHEK2, and PALB2 confer moderate to high risks of breast cancer. The optimal approach to screening in these women has not been established. **Methods:** We used two simulation models from the Cancer Intervention and Surveillance Modeling Network (CISNET) and data from the Cancer Risk Estimates Related to Susceptibility consortium (CARRIERS) to project lifetime breast cancer incidence and mortality in ATM, CHEK2, and PALB2 carriers. We simulated screening with annual mammography from ages 40-74 alone and with annual magnetic resonance imaging (MRI) starting at ages 40, 35, 30, and 25. Joint and separate mammography and MRI screening performance was based on published literature. Lifetime outcomes per 1,000 women were reported as means and ranges across both models. **Results:** Estimated risk of breast cancer by age 80 was 22% (21-23%) for ATM, 28% (26-30%) for CHEK2, and 40% (38-42%) for PALB2. Screening with MRI and mammography reduced breast cancer mortality by 52-60% across variants (Table). Compared to no screening, starting MRI at age 30 increased life years (LY)/1000 women by 501 (478-523) in ATM, 620 (587-652) in CHEK2, and 1,025 (998-1,051) in PALB2. Starting MRI at age 25 versus 30 gained 9-12 LY/1000 women with 517-518 additional false positive screens and 197-198 benign biopsies. **Conclusions:** For women with ATM, CHEK2, and PALB2 pathogenic variants, breast cancer screening with MRI and mammography halves breast cancer mortality. These mortality benefits are similar to those for MRI screening for BRCA1/2 mutation carriers and should inform practice guidelines. Research Sponsor: Breast Cancer Research Foundation, U.S. National Institutes of Health.

	Mortality Reduction Mean (Range)			Life Years Gained per 1000 Women Mean (Range)			False Positive Screens per 1000 Women Mean (Range)		
Strategy	ATM	CHEK2	PALB2	ATM	CHEK2	PALB2	ATM	CHEK2	PALB2

10501 **Oral Abstract Session**

Nearly half of *TP53* variants are misattributed to Li-Fraumeni syndrome: A clinical evaluation of individuals with *TP53* variants detected by hereditary cancer panel assays on blood or saliva. *First Author: Alison Schwartz, Cancer Genetics and Prevention, Dana-Farber Cancer Institute, Boston, MA*

Background: Multigene panel testing (MGPT) has identified *TP53* pathogenic or likely pathogenic (P/LP) variants in patients with diverse phenotypes from no cancer to classic Li-Fraumeni syndrome (LFS). There is increasing recognition of variants at low allelic fraction (VAF) for *TP53* in particular, which can be suggestive of post-zygotic mosaicism or aberrant clonal expansion (ACE), comprising clonal hematopoiesis of indeterminate potential (CHIP) or occult hematologic neoplasia. Distinguishing among these categories is essential because of widely different cancer risk and management implications for patients and their relatives. We report an evaluation of *TP53* positive probands to determine germline versus somatic status from a cancer genetics clinic. **Methods:** We reviewed probands with *TP53* P/LP variants by MGPT on blood (N = 83) or saliva (N = 1) samples from 2012-2019. Available VAFs were collected from commercial testing laboratories. Probands positive for a known familial variant, who met LFS testing criteria without indication of low VAF, or who carried the Brazil founder p.R337H variant were considered germline. For those with uncertain germline status, data was obtained from ancillary testing of family members, cultured skin fibroblasts, and other somatic benign or tumor tissues. *TP53* variants were further categorized based on all available data. **Results:** Of the 84 probands, 28 (33%) had germline *TP53* P/LP variants determined by above initial criteria; 18 (21%) were confirmed germline through ancillary testing. Seven (8%) individuals were classified as having constitutional mosaicism. In eleven (13%) individuals, the *TP53* variants were consistent with ACE, in 9 (11%) with CHIP and in 2 (2%) with a hematologic malignancy (1 CLL, 1 NHL). Five (6%) cases could not be categorized despite ancillary testing. Fifteen (18%) probands declined any further workup. **Conclusions:** A *TP53* P/LP variant found on peripheral blood or saliva MGPT does not always originate in the germline. In a clinical cancer genetics cohort, only 54% of patients had *TP53* P/LP germline variants; these patients plus those with constitutional mosaicism (8%) require intensified surveillance. Assessment of VAF, family member testing, and analysis of *TP53* in cultured fibroblasts or other tissue samples may distinguish germline and constitutional mosaicvariantsfrom the ACE spectrum. Expanding use of MGPT will increase this clinical challenge, which may motivate the modification of lab reports to include VAF and possible non-germline explanations. The findings of this study support a framework of multiple strategies to discern true constitutional status of a *TP53* P/LP variant. Research Sponsor: None.

10502 **Oral Abstract Session**

Ancestrally unbiased polygenic breast cancer (BC) risk assessment. *First Author: Elisha Hughes, Myriad Genetics, Inc., Salt Lake City, UT*

Background: BC risk is influenced by single-nucleotide polymorphisms (SNPs) with small effects that can be aggregated into polygenic risk scores (PRSs). PRSs have primarily been developed and validated for populations of European descent. To make a PRS available for all women, we developed and validated a novel global PRS (gPRS) that utilizes individual ancestral genetic composition. **Methods:** Ancestry-specific PRSs corresponding to 3 continental ancestries were developed from 149 SNPs (93 BC and 56 ancestry-informative): an African PRS was developed using a cohort of 31,126 self-reported African American patients referred for hereditary cancer testing; an East Asian PRS was developed based on published data from the Asia Breast Cancer Consortium; and a European PRS was developed using data from the Breast Cancer Association Consortium and 24,259 European hereditary cancer testing patients. For each patient, ancestry-informative SNPs were used to calculate the fractional ancestry attributable to each of the 3 continents. The gPRS was the sum of ancestry specific PRSs weighted according to genetic ancestral composition. In an independent validation cohort (N = 62,707), we evaluated discrimination and calibration of gPRS, and compared performance against a previously described 86-SNP PRS for women of European ancestry. Associations of SNPs and PRSs with BC were analyzed using logistic regression adjusted for personal and family cancer history, age, and ancestry. Odds ratios (ORs) are reported per standard deviation within the corresponding patient population. P-values are reported as two-sided. **Results:** The gPRS was strongly associated with BC in the full validation cohort and in sub-cohorts defined by self-reported ancestry (Table). 95% (88/93) of BC SNPs had $\geq$1% frequency of risk alleles within each of the self-reported populations. Compared to the aforementioned 86-SNP PRS, the gPRS showed improved discrimination overall, and within each sub-cohort, with the exception of the Asian population where the sample size was too small to show superiority of either score. The 86-SNP PRS was calibrated for white non-Hispanic women but mis-calibrated for non-European ancestries. The gPRS was properly calibrated for all women. **Conclusions:** The 149-SNP gPRS is validated and calibrated for women of all ancestries. Combined with clinical and biological risk factors, this approach may offer improved risk stratification for all women, regardless of ancestry. Research Sponsor: Myriad Genetics, Inc.

Validation Cohort	Total N	N w/ BC	OR (95% CI)	P-value
All	62,707	15,137	1.41 (1.38 – 1.44)	2.5×10^{-212}
Asian	1,325	396	1.25 (1.07 - 1.45)	3.7×10^{-03}
Black/African	6,743	1,754	1.23 (1.16 - 1.31)	8.5×10^{-11}
Hispanic	5,847	1,066	1.35 (1.24 - 1.46)	1.6×10^{-13}
Mixed Ancestry	2,681	400	1.59 (1.39 -1.82)	2.4×10^{-12}
Non-European	14,959	3,435	1.29 (1.23 –1.36)	2.5×10^{-25}
White and/or Ashkenazi	42,897	10,288	1.44 (1.40 – 1.48)	6.3×10^{-172}

Adrenal-permissive *HSD3B1* genetic inheritance and risk of estrogen-driven postmenopausal breast cancer. *First Author: Nima Sharifi, Cleveland Clinic, Cleveland, OH*

Background: Genetic factors that contribute to endogenous estrogen synthesis and postmenopausal breast cancer risk are unknown. We set out to test the hypothesis that homozygous inheritance of the common 1245A→C missense-encoding polymorphism in *HSD3B1*, which is common (8-10%) in White populations, functionally adrenal permissive and increases synthesis of the aromatase substrate, androstenedione, is associated with postmenopausal estrogen receptor-positive breast cancer. **Methods:** A prospective single institution study of postmenopausal estrogen receptor-driven breast cancer for determination of *HSD3B1* genotype, circulating steroid concentrations, and adrenal-permissive genotype frequency compared with the genotype frequency in the general population and in estrogen receptor-negative breast cancer. Validation was performed in 2 breast cancer genomic studies with estrogen receptor documentation. The primary outcome is the adrenal-permissive genotype frequency in postmenopausal estrogen receptor-positive breast cancer and the general population. Genotype comparisons were also done with postmenopausal estrogen receptor-negative breast cancer and the association with circulating adrenal androgen concentrations determined. **Results:** The prospective and validation studies had 199 and 1628 women, respectively. The adrenal-permissive genotype frequency in postmenopausal White women with estrogen-driven breast cancer in the prospective cohort was 17.5% (21/120) compared with 9.6% (429/4451) in the general population [p = 0.0077]. The adrenal-permissive genotype frequency for estrogen-driven postmenopausal breast cancer was validated using the Cambridge and TCGA genomic datasets together: 14.4% (56/389) compared with 6.0% (9/149) for estrogen receptor-negative breast cancer (p = 0.007) and the general population (p = 0.005). Circulating androstenedione concentration was significantly higher for women with the adrenal-permissive genotype compared with the other genotypes (p = 0.03). **Conclusions:** The adrenal-permissive genotype is associated with estrogen-driven postmenopausal breast cancer. These findings link genetic inheritance of endogenous estrogen exposure to estrogen-driven breast cancer and have broad implications for risk stratification, prevention, potential biomarkers for hormonal therapy response and possibly other clinical outcomes related to estrogen physiology in postmenopausal women. Underdiagnosis of germline genetic prostate cancer: Are genetic testing guidelines an aid or an impediment? *First Author: Edward D. Esplin, Invitae, San Francisco, CA*

Background: Pathogenic/likely pathogenic (P/LP) germline genetic variants are estimated to occur in 10-15% of all prostate cancer (PCa) patients. However, genetic testing for PCa patients is underutilized, partially due to complicated and restrictive testing guidelines developed at a time when the cost of testing was high. We conducted a study based in community urology clinics to determine the incidence of P/LP variants in PCa patients who met and did not meet the NCCN 2019 PCa germline genetic testing criteria. **Methods:** An IRB-approved, multicenter, prospective registry was initiated with 15 community and academic urologists nationwide. Eligibility criteria included patients with a PCa diagnosis unselected for personal or family history, stage or histology who had not been previously tested. Consecutive patients ages 18-90 were consented and underwent an 84-gene germline panel test. HIPAA-compliant electronic case report forms distributed to clinician collected information on patient diagnoses, NCCN testing criteria, and results-based recommendations. **Results**: To date, 640 enrolled patients have genetic testing results available. Overall, 69 (10.8%) patients had 72 P/LP variants detected, 15% of which were in *BRCA1/2*. Of the 532 patients for whom we have clinician-reported data, 293 (55%) met NCCN criteria and 239 (45%) did not. Median age was 70 (range 44-90). Overall, 11.1% (59/532) of patients with clinician-reported data had a P/LP variant. 36 (12.3%) of patients who met NCCN criteria and 23 (9.6%) of patients who did not meet criteria had a P/LP variant. The difference in P/LP rate between the two groups was not statistically significant (p=0.33). If only a conservative 12-gene PCa panel was considered, P/LP yield was 5.5% (29/532), with 8 (28%) of these patients missed by guidelines. Stratification by self-reported ethnicity was: 76% White/Caucasian (52 patients w/ P/LP), 18% Black/African American (2 patients w/ P/LP), and <5% each of Hispanic or Asian. **Conclusions**: There was no statistically significant difference in the yield of P/LP variants between patients who met and those who did not meet NCCN PCa guidelines, reinforcing that a significant number of P/LP variants are missed if NCCN guidelines are required for genetic testing. Expanded panel testing yields more medically actionable P/LP variants than testing *BRCA1/2* alone or PCa panels with 12 genes. While 18% of the cohort was Black/African American, there was a lower P/LP rate (2%) relative to other groups, indicating that more research is needed to understand genetic variation in underrepresented populations with PCa. Germline mutations in DNA damage repair genes and *HOXB13* among African American men diagnosed with early-onset prostate cancer. *First Author: Jennifer Lynn Beebe-Dimmer, Barbara Ann Karmanos Cancer Institute/Wayne State University, Detroit, MI*

Background: Inherited defects in DNA damage repair (DDR) genes (e.g. *ATM, BRCA1/2*) and the tumor suppresser gene *HOXB13* are rare in the general population, but have been observed at a higher rate among men with early-onset and advanced prostate cancer. However, most studies include few, if any, African American men, highlighting the need to understand the contribution of mutations in these genes in this high-risk population. **Methods:** A population-based cohort of 757 African American men diagnosed with prostate cancer at age 62 years or younger were identified and enrolled through the Metropolitan Detroit Cancer Surveillance System (MDCSS), one of NCI's founding members of the SEER program. Participants completed a short survey to collect information on family history, medical history (including cancer-related treatment), surveillance, and health behaviors. Each participant submitted a saliva or blood sample for genetic analyses and consent for tumor tissue if available. All clinical data were collected through linkage with the MDCSS registry. Full exome sequencing was performed and herein, we report the mutation patterns observed in a panel of DNA repair genes and *HOXB13*. All variants were ranked according to frequency (MAF < 1%); REVEL, SIFT and PolyPhen scores for pathogenic potential; evidence from existing literature; and prevalence in the cohort. **Results:** Among the 744 African American prostate cancer cases with adequate DNA for sequencing and thus included in this analysis, the mean age at diagnosis was 55.6 years, 29% reported a family history of prostate cancer in a first degree family member, and 40% were initially diagnosed with intermediate- to high-risk disease (stage T3/T4 and/or Gleason 4+3 and higher at diagnosis). We identified 20 variants that were either known or predicted to be pathogenic in 11 candidate genes (*ATM, ATR, BRCA1/2, BRIP1, CHEK2, FANCA, HOXB13, MSH2, PALB2, and PMS2*). These particular variants were more common among men diagnosed before age 55 and in men with high grade cancer in this cohort. **Conclusions:** Our results suggest that mutations in DDR genes and *HOXB13* may be important cancer risk factors for African American men diagnosed with early-onset and intermediate- to high-risk disease. Further study is necessary to describe the spectrum and prevalence of genetic mutations in this population including the characterization of variants of unknown significance. Research Sponsor: Department of Defense.

Completion of lung cancer screening after a baseline order for LDCT at five diverse health systems. *First Author: Christine Neslund-Dudas, Henry Ford Health System, Detroit, MI*

Background: In 2014 and 2015, the Affordable Care Act required coverage of, and CMS began reimbursing for lung cancer screening (LCS). Previous studies have shown that when new screening tests or treatments become available, disparities in disease outcomes often increase due to those with fewer resources having less access and greater barriers to care. African American men have historically had higher incidence of and death due to lung cancer than white males in the U.S., raising concerns regarding access to LCS and the potential for increases in disparities in lung cancer. We aimed to determine whether individual or neighborhood level factors were associated with completion of a baseline screening after an order for LCS low dose CT (LDCT) was placed. **Methods:** In a retrospective study conducted within the five health systems of the Lung Population-based Research to Optimize the Screening Process (PROSPR) Consortium, we determined adherence to baseline LDCT after a health care provider placed an order for LCS (January 2014 through June 2019). Follow-up was available through September 2019. Patients of interest for this analysis were current or former smokers, age 55 to 80 with a 30+ pack-year smoking history. Smoking history and other individual level variables were determined through electronic medical records. Neighborhood factors were derived from the 2010 Census and multivariable logistic regression was used. **Results:** Of the 13,920 patients that had at least one order for a baseline LCS exam, 14.1% were non-Hispanic Black, 70.3% were non-Hispanic White, and 15.7% were of other or unknown race. Overall, 61.2% of patients completed a LDCT within 90 days and 71.9% completed a scan by the end of follow-up. Completion of a baseline scan differed by health system (LDCT at 90-days, range 51% - 84%, p<0.0001) and increased in general across scan year (range 49.1%-66.0%, p <0.001). In multivariate logistic regression models, males (aOR=1.15, 95% CI 1.07-1.23, p=<0.0001), former smokers (aOR=1.31, 95% CI 1.21-1.40, p <0.0001), and those with a prior history of any cancer (aOR=1.16, 95% CI 1.02-1.32, p=0.03) were more likely to complete LDCT. Blacks were marginally less likely to have completed a baseline LDCT (aOR=0.90, 95% CI 0.81-1.00, p=0.06) within 90 days of an order. Sex modified the associations of race on completion of orders (p=0.08) (Black men aOR=0.81, 95% CI 0.70-0.94, p=0.006 ; Black women aOR=0.99, 95% CI 0.86-1.14, p=0.89). **Conclusions:** This multisite study indicates Black men in particular may have a lower likelihood of completing a baseline LCS after an order for screening is placed. As lung cancer screening programs move forward, attention should be given to factors associated with reduced uptake and adherence of screening to ensure disparities in lung cancer outcomes do not persist and increase. Provider and health system factors that may impact LCS uptake should be explored in future studies. Research Sponsor: U.S. National Institutes of Health.

10507 **Oral Abstract Session**

Second primary malignancies (SPM) in African American (AA) and white patients with multiple myeloma in the National Veterans Affairs (VA) healthcare system. *First Author: Sarah Premji, Baylor College of Medicine, Houston, TX*

Background: In the recent decade, novel therapies have led to significant improvements in overall survival (OS) in symptomatic multiple myeloma (MM). With this increase in OS, there is an increase in the incidence of second primary malignancies (SPM) in patients with MM. This is related to multiple factors; we hypothesize that racial disparities also play a role. There is a paucity of studies with large, high quality datasets evaluating racial disparities in SPMs in MM. Our goal is to explore patterns of incidence of SPMs in US Veterans with MM, focusing on racial disparities. **Methods:** We conducted a retrospective cohort study based on electronic health record (EHR) and cancer registry data recorded in the VA's Corporate Data Warehouse (CDW) between January 1, 1999 and January 1, 2018. We compared incidence of SPMs (defined as malignancies occurring after the diagnosis and treatment initiation of MM) using the standardized incidence rate ratio (IRR). Univariate and multivariable analyses were performed, using a Cox model adjusting for age, race, gender, treatment era, smoking status, and stage at MM diagnosis. **Results:** There were 8467 Veterans (97.4% male) with MM identified with self-reported race: White, 5029 (59.4%); AA, 2178 (25.7%); and other or unknown, 1260 (14.9%). At 7.5 years of follow up, 430 (5.1%) MM patients developed SPM while 8037 did not. 982 had received HSCT (Hematopoietic Stem cell transplant) of whom 65 (6.62%), a significantly higher proportion developed SPM versus those without HSCT (n = 7485) of whom 365 (4.87%) developed SPM (p = 0.024). Among those Veterans who had SPM 380 (88.3%) had solid tumors, 50 (11.6 %) had hematological malignancies. Of 88.3% with solid SPM the distribution was: prostate cancer, 113 (29.7%); digestive tract cancers, 63 (16.6%); lung cancer, 55 (14.4%); and GU (bladder/renal/testicular), 48(12.6%). The cumulative incidence of developing SPM increased steadily over time for the duration of this study period of 7.5 years from diagnosis. The median age of diagnosis for Whites was 68.2 years and for AA was 64.3 years, (p < 0.001) demonstrating that MM occurred earlier in AA. The hazard ratio for AA versus whites to develop SPMs was 1.21 (0.975-1.505) (p = 0.0823). However, the risk of prostate cancer was significantly higher in AA with an adjusted hazard ratio of 1.81 (1.196-2.739) (p = 0.005). No racial disparities were observed in the incidence of other types of SPMs. **Conclusions:** Our study suggests that the risk of SPMs does not plateau over a patient's lifetime. HSCT was found to be an independent predictor of SPM, while smoking and agent orange were not. Our cohort is one of the largest groups of AA with MM in published literature. AA did not have a higher incidence of SPMs overall; but had a significantly higher incidence of prostate cancer than whites. We hope to develop an individualized predictive model for SPM in patients with MM. Research Sponsor: Veterans Affairs.

Disparities in pan-cancer patients undergoing germline cancer risk assessment by self-reported race/ethnicity and ancestry. *First Author: Ying L Liu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Disparities in access to germline testing for cancer patients (pts) have been demonstrated; however, disparities in post-testing care are unknown. We sought to evaluate germline findings and subsequent genetic counseling/care in cancer pts undergoing tumor-germline sequencing to explore differences by self-reported ancestry. **Methods:** Pan-cancer pts were prospectively consented to tumor-normal sequencing via a custom NGS panel (MSK-IMPACT) from 1/2015-12/2019 inclusive of germline analysis up to 88 genes. Germline analysis was performed as a research non-billable test in 97.5% of cases. Referral to clinical genetics service (CGS) was recommended for all pts with a new positive (likely pathogenic/pathogenic) germline variant (PV). Ancestry was defined using self-reported Federal definitions of race/ethnicity and designations of Ashkenazi Jewish (AJ) ancestry. Pts were categorized into mutually exclusive groups: AJ, White, Non-White (Asian, Black/African American, Hispanic, Other), and unknown. All pts self-identifying as Hispanic were classified as such, regardless of race. Abstracted data on germline findings and downstream CGS follow-up were compared across groups using non-parametric statistical tests. **Results:** Among the 15,775 pts in this cohort (59.6% White, 15.7% AJ, 20.5% Non-White [6.9% Asian, 6.8% Black, 6.7% Hispanic, 0.1% Other], and 4.2% unknown), 2663 (17%) had a PV. AJ pts had the highest rates of PV (n = 683, 27.6%), and Non-White pts had a lower proportion of PV (n = 433, 13.6%) compared to Whites (n = 1451, 15.5%), $p < 0.01$, with differences mostly due to increased prevalence of moderate/low penetrance variants in White and AJ pts. These findings were consistent across multiple tumor types. Prior knowledge of the PV (424/2663, 16%) was more common in Non-White (19.9%) and AJ (19.2%) than White pts (13.4%), $p < 0.01$. Among 2239 pts with new PV, all were referred to CGS, and 1652 (73.8%) pts were seen. Non-White pts had lower rates of completing visits (67.7%) than White (73.7%) and AJ pts (78.8%), $p < 0.01$, with the lowest rates occurring in Black (63%) and Hispanic (68.1%) pts. All pts without a visit (n = 587) received a close out letter including 139 pts (6.2% of pts with new PV) who had no documentation of receipt of results in the medical record. Higher rates of non-disclosure were observed in Non-White (6.7%) compared to White (5.4%) and AJ (3.4%) pts with new PV, p = 0.032; non-disclosure did not vary by gene penetrance. There was a non-significant trend towards lower rates of cascade testing at CGS in Asian and Black pts with ongoing analysis. **Conclusions:** Even when traditional barriers to genetic testing were minimized, Non-White pts were less likely to receive recommended cancer genetics follow-up for subsequent cancer risk counseling, with potential implications for oncological care, cancer risk reduction, and at-risk family members. Research Sponsor: U.S. National Institutes of Health, This work was supported by the Robert and Kate Niehaus Center for Inherited Cancer Genomics. MSKCC is supported by the NCI Core grant P30 CA008748.

10510 **Poster Discussion Session**

Clinically sufficient vitamin D levels at breast cancer diagnosis and survival outcomes in a prospective cohort of 3,995 patients after a median follow-up of 10 years. *First Author: Song Yao, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: There have been suggestive findings for better cancer survival with vitamin D supplementation in the recent VITAL trial. The findings are consistent with meta-analyses based on earlier randomized trials testing daily supplement vitamin D intake. As there is no ongoing or planned randomized trial of vitamin D supplementation in sight for women after breast cancer diagnosis, we evaluated relationships between serum levels of vitamin D and breast cancer outcomes in a large prospective cohort of breast cancer survivors. **Methods:** We measured 25-hydroxyvitamin D (25OHD) levels in serum samples collected at the time of diagnosis from 3,995 women with incident breast cancer enrolled in the Pathways Study, a large prospective cohort established in 2006 at Kaiser Permanente Northern California with active follow-up (FU). Potential determinants of 25OHD levels, including a polygenic score, were examined. Vitamin D levels were categorized based on clinical cutoffs as deficient (< 20 ng/ml), insufficient (20 to < 30 ng/ml), or sufficient ($\geq$30 ng/ml). These levels were then evaluated in relation to overall survival (OS), breast cancer-specific survival (BCSS), recurrence-free survival (RFS), and invasive disease-free survival (IDFS). Cox proportional hazards models were adjusted for non-clinical, clinical, and treatment factors and were further stratified by stage, estrogen receptor (ER) status, and body mass index (BMI). **Results:** Vitamin D supplement use, lower BMI, and self-reported white race were the strongest determinants of higher 25OHD levels. The polygenic score was significantly associated with 25OHD levels but explained only 0.3% of the variance. The median FU was 9.6 years (range: 0.3-13). Compared to those with deficient vitamin D levels, patients with sufficient levels had significantly better survival outcomes, which remained after controlling for various covariates (OS: HR [95% CI] = 0.73 [0.58-0.91]; BCSS: HR = 0.78 [0.56-1.09]; RFS: HR = 0.79 [0.65-0.97]; IDFS: HR = 0.82 [0.68-0.99]). Associations were similar by ER status, but stronger among patients with more advanced stage disease and those with underweight or normal BMI. Black patients had the lowest 25OHD levels, which contributed to their poorer survival compared to white patients. Adding 25OHD levels to the Cox model of OS lowered the HR associated with Black vs. white race from 2.03 (1.57-2.62) to 1.79 (1.37-2.32). **Conclusions:** Sufficient vitamin D levels at the time of diagnosis were associated with improved breast cancer prognosis. Consistent with results from randomized trials, our findings from a large observational cohort of breast cancer survivors with long FU provide the strongest evidence to date for maintaining sufficient vitamin D levels in breast cancer patients, including among Black women and those with more advanced stage disease. Research Sponsor: U.S. National Institutes of Health.

10511 **Poster Discussion Session**

Dietary intervention influence on physical activity in the Women's Health Initiative randomized Dietary Modification trial. *First Author: Kathy Pan, Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center, Torrance, CA*

Background: In the Women's Health Initiative (WHI) Dietary Modification (DM) randomized trial, after 8.5 years dietary intervention and 19.5 years cumulative (median) follow-up, dietary intervention participation was associated with a statistically significantly 22% lower breast cancer mortality (P = 0.02). In observational studies, physical activity has been associated with lower breast cancer risk with emerging results now indicating, compared to inactivity, any increase in physical activity has health benefits. Currently, longitudinal data on whether an intervention targeting dietary change influences other health-related behaviors as a gateway effect is limited. To evaluate whether randomization to a dietary intervention was associated with self-directed change in physical activity. **Methods:** In the WHI DM trial, 48,835 postmenopausal women, ages 50-79 years, with no prior breast cancer and baseline normal mammogram were randomized at 40 US clinical centers to a dietary intervention (19,541) or a comparison group. Dietary goals were to reduce fat intake to 20% of energy and increase intake of vegetable, fruit, and grains addressed in 18 group sessions in year 1 then quarterly. Neither randomization group received specific or ongoing instructions to increase physical activity, but physical activity was referenced in written materials given to the intervention groups in 7 of the 56 sessions. Episodes per week of moderate or vigorous recreational physical activity (MVPA) were collected at baseline and serially through 15.9 years follow-up by self-report questionnaire. Marginal longitudinal logistic regression models were used to assess physically inactive (MVPA = 0) or physically active (MVPA $>$ 0) participants by randomization group. Marginal Poisson regression models estimated mean weekly MVPA by randomization group. **Results:** 45.6% of participants reported 0 MVPA at baseline which largely persisted throughout follow-up. During cumulative follow-up, relative to the comparison group, dietary intervention group participation was associated with 7% lower physical inactivity rate (odds ratio [OR] 0.93 95% confidence interval [CI] 0.91, 0.95, $P < 0.001$) and a 4% higher mean MVPA (ratio of means [RM] 1.04 95% CI 1.02, 1.06, $P < 0.001$). The association between dietary intervention participation with higher physical activity level was stronger with increasing BMI (P-interaction 0.01) and for women with waist circumference $\geq$ 88 cm (P-interaction 0.02). **Conclusions:** In conclusion, in a randomized trial setting, a low-fat dietary pattern intervention was associated with a significantly lower physical inactivity rate and significantly higher moderate and vigorous physical activity level which could be associated with health benefits. Clinical trial information: NCT00000611. Research Sponsor: U.S. National Institutes of Health.

10512 **Poster Discussion Session**

Analysis of real-world (RW) data for metastatic breast cancer (mBC) patients (pts) with somatic *BRCA1/2* (s*BRCA*) or other homologous recombination (HR)-pathway gene mutations (muts) treated with PARP inhibitors (PARPi). *First Author: Felipe Batalini, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA*

Background: PARPi are approved for treatment of pts w/ HER2-negative mBC and germline *BRCA1/2* (g*BRCA*) pathogenic or likely pathogenic variants (muts); however, clinical benefit has also been demonstrated in mBC pts w/ *sBRCA* or other HR-pathway gene muts. Using a RW Clinico-Genomic Database (CGDB), we assessed outcomes for pts w/ *gBRCA* muts compared to pts w/ either s*BRCA* or other HR-pathway muts treated w/ PARPi. **Methods:** 6,329 mBC pts from ~280 US cancer clinics were included in the Flatiron Health (FH) -Foundation Medicine (FM) CGDB, which includes comprehensive genomic profiling (CGP) linked to de-identified, electronic health record (EHR)-derived clinical data. Eligible pts had mBC, received care in the FH network from 1/1/2011-9/1/2020, and had tissue CGP by FM. Pts classified as *gBRCA*: positive germline result in EHR and *BRCA* mut predicted germline per FM's somatic, germline, zygosity algorithm (SGZ) (Sun et al PMID 29415044). Non-g*BRCA*: negative germline results in EHR and a somatic BRCA (s*BRCA*) mut per SGZ or *BRCA* wild-type w/ another HR mut per CGP result. Pts w/o a documented *gBRCA* result in EHR, unknown FM *BRCA* SGZ result, or conflicting results were excluded. RW overall survival (rwOS) and RW progression-free survival (rwPFS) from start of PARPi for pts w/ *gBRCA* and non-*gBRCA* mBC were compared using Kaplan-Meier analysis and Cox regression adjusted for mBC line number, prior platinum, age at PARPi initiation, race, and receptor status. **Results:** Among pts who received PARPi in the mBC setting, 44 had *gBRCA* and 18 had non-*gBRCA*: 9 s*BRCA* (5 *BRCA1*, 4 *BRCA2*), 4 *PALB2*, 2 *ATM*, and 1 each of *ATM+CDK12*, *BARD1+FANCF+RAD54L*, and *CHEK2*. Of HR muts 76% were confirmed biallelic: 33/44 *gBRCA* (11 unknown), 8/9 *sBRCA*, 3/4 *PALB2*, and 3/5 other (1 unknown). Neither median rwPFS nor rwOS from start of PARPi were significantly different between the non-g*BRCA* and g*BRCA* cohorts (rwPFS: 7.0 [4.6-11.3] vs 5.5 [4.3-7.2] months (mos), aHR: 1.19 [0.57 – 2.43]; rwOS: 15.0 [7.95-16.3] vs 11.5 [9.46-NA] mos, aHR: 0.85 [0.36-1.98]). For 9 pts w/ *sBRCA* mut, median rwPFS was 7.1 mos (range 1.4-12.4) and all pts had progressed by data cut off. **Conclusions:** Despite small pt numbers and limitations from RW data, our results suggest that pts w/ biallelic non-g*BRCA* mBC may derive similar benefit from PARPi when tumor CGP detects a s*BRCA* mut or germline or somatic mut in other HR-pathway genes. These findings are consistent w/ the results from TBCRC-048 (Tung et al PMID 33119476) and support further randomized trials exploring the efficacy of PARPi in this population. The marginal diagnostic benefit of pancreatic cancer molecular profiling after germline testing. *First Author: Evan Justin Walker, University of California San Francisco, San Francisco, CA*

Background: Germline genetic testing is now universally recommended for patients (pts) with pancreatic ductal adenocarcinoma (PDAC) for purposes of both familial screening and therapeutic guidance. Treatment selection can be further informed by tumor molecular profiling (TMP) to identify targetable somatic alterations in pts with advanced disease, but this is inconsistently applied. Determination of the rate of actionable findings identified with TMP after germline testing, which we term marginal diagnostic benefit, may inform practice patterns and workflow in this patient population. **Methods:** This retrospective analysis included all pts with PDAC who underwent germline testing and TMP at UCSF over a 4-yr period. Medical records were reviewed for demographics, disease-specific data, and germline testing/TMP clinical reports. Alterations classified as 'pathogenic' or 'likely pathogenic' were included, and were deemed 'actionable' if there was clinical or preclinical evidence of benefit from targeted therapy in any cancer, as previously described. **Results:** From 1/2016-1/2020, 144/738 (20%) UCSF pts with PDAC completed both germline testing and TMP. Germline testing identified actionable pathogenic alterations in 10 (7%). TMP confirmed 8/10 of these alterations and identified 3 additional therapeutic targets. Among the 134 pts without actionable germline findings, TMP identified 45 new therapeutic targets in 41 (31%) pts, increasing the overall rate of actionable findings from 7% to 35%. Most (35/58, 60%) actionable alterations involved genes associated with the Homologous Recombination DNA Damage Repair (HR-DDR) pathway (Table). 80% of pts with HR-DDR pathway alterations (9/10 germline, 19/25 somatic) received platinum-based chemotherapy. Four pts were treated with targeted therapy based on test results: PARP-inhibitor (n = 2, germline *BRCA1* and *PALB2* mutations), PARP-inhibitor + ATR inhibitor (n = 1, somatic *ARID1A* mutation) and mTOR inhibitor (n = 1, somatic *STK11* deletion). **Conclusions:** In this analysis, PDAC TMP after germline testing increased the detection of actionable alterations (the marginal diagnostic benefit) by five-fold. As more somatic tumor alterations become actionable with the development of targeted therapeutics, TMP is a necessary complement to germline testing to fully inform personalized treatment decisions for all pts with PDAC. Research Sponsor: None.

Clinical impact of medical policy supporting universal germline testing for patients with colorectal cancer. *First Author: Sarah M. Nielsen, Invitae, San Francisco, CA*

Background: Colorectal cancer (CRC) affects approximately 104,000 patients (pts) annually in the United States, up to 45% of which are estimated to be genetic and/or familial. Aligned with clinical guidelines, in 2020, a large U.S. insurer established Medical Policy allowing for and reimbursing germline genetic testing (GGT) for all CRC pts. This study reports overall uptake of GGT in CRC pts under this inclusive policy, actionable findings and treatment implications for pts tested, stratified by self-reported ancestry/ethnicity. **Methods:** Two independent de-identified datasets were reviewed, including administrative claims data of commercially insured and Medicare Advantage enrollees, aged 18+ with CRC (≥1 claim with ICD10 C18, C19 or C20 in the first position) who were continuously enrolled (CE) in the health plan from 1/2019-10/2020. Evidence of genetic testing based on CPT codes, was examined during 2020. A second de-identified dataset of CRC pts whose GGT was billed to the insurer under the Medical Policy, was also reviewed. Patient demographics, clinical information and GGT results were descriptively analyzed. **Results:** Of the >18,000,000 CE enrollees, 55,595 were identified as CRC pts, of whom 1,675 (3%) received GGT. From the GGT dataset, 788 pts had test results available for review. 143 (18%) pts had pathogenic/likely pathogenic (P/LP) variants in genes including *MSH2,MLH1, PMS2, MSH6, CHEK2, APC, BRCA2, ATM, MUTYH* (biallelic). Of pts with P/LP variants, 96 (67%) were potentially eligible for precision therapy and/or clinical treatment trials. Overall, 133 (93%) had P/LP variants in genes with precision therapy, clinical trial and/or published management implications. In a subset of pts (n=674) with ethnicity data; Asian, Black/African-American and Hispanic pts showed lower relative uptake of germline testing than Caucasians (Table). **Conclusions:** Despite Medical Policy allowing for GGT for all pts with CRC, only 3% of eligible pts received testing. If all CRC pts had been tested, these data suggest up to 6,705 pts with P/LP variants conferring potential eligibility for precision therapy (PD-1/PD-L1 inhibitors) or clinical treatment trials (PARP inhibitors), and an additional 2,602 pts with mutations in genes with published management recommendations, could have been identified, but were missed. Additional research is needed to identify obstacles to systematic implementation of this Medical Policy, the best timing of GGT to prevent CRC and improve access to underrepresented populations. CRC patients with germline genetic testing. Research Sponsor: None.

Limitations of direct-to-consumer (DTC) genetic testing for hereditary breast and ovarian cancer. *First Author: Neelam Vijay Desai, Beth Israel Deaconess Medical Center, Boston, MA*

Background: With the advent of DTC genetic testing, individuals have access to genetic testing without input from a healthcare professional. DTC testing now exists for the 3 Ashkenazi Jewish (AJ) *BRCA1/2* founder variants. DTC testing may provide false reassurance to individuals that they do not carry a pathogenic or likely pathogenic variant (PLPV) in *BRCA1/2* or other cancer-risk genes. **Methods:** Multi-panel genetic testing was performed in 348,692 individuals for a clinical indication of hereditary breast/ovarian cancer (Clinical cohort) and 7,636 self-referred ostensibly healthy individuals (Healthy cohort) by a clinical testing laboratory. The primary analysis evaluated PLPVs for Group 1 genes: *BRCA1/2* AJ founder variants and Group 2: full sequence *BRCA1/2*. Secondary analyses assessed PLPVs in Group 3: high-risk breast cancer genes (*BRCA1/2, CDH1, PALB2, PTEN, STK11, TP53*), Group 4: all breast or ovarian cancer-risk genes (Group 3 genes plus *ATM, BARD1, BRIP1*, truncating *CHEK2, EPCAM, MLH1, MSH2/6, NF1, PMS2, RAD51C/D*) and Group 5: 41 cancer-risk genes; these analyses were limited to participants who tested for all 41 genes. Potentially mosaic variants were excluded. **Results:** Table illustrates PLPVs found in both cohorts. The *BRCA1/2* AJ founder variants account for only ~11% (1513/13,987) and ~30% (19/64) of the *BRCA* PLPVs in the Clinical and Healthy cohorts, respectively. Even among AJ individuals, testing only for the 3 founder variants will miss ~10% (52/513) of all *BRCA1/2* PLPVs. Evaluating only the *BRCA*AJ founder variants missed a higher percentage of PLPVs in other cancer-risk genes. **Conclusions:** The 3 *BRCA1/2* AJ founder variants analyzed by DTC testing account for a small fraction of PLPVs in cancer-risk genes in the general population, and miss 10% of *BRCA* PLPVs even among AJ individuals. Greater public education is needed to dispel the misconception that DTC tests are equivalent to clinical assessment and comprehensive genetic testing. PLPVs identified in Clinical and Healthy Cohorts. Research Sponsor: None.

Early age of onset and broad cancer spectrum persist in *MSH6* and *PMS2*-associated Lynch syndrome. *First Author: Ying L Liu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recently updated NCCN guidelines for management of germline *MSH6* and *PMS2* pathogenic/likely pathogenic (P/LP) variant carriers suggest a more modest phenotype with later onset colorectal cancer (CRC) and limited extra-colonic cancers compared to other Lynch Syndrome (LS) genes. However, data are limited, and a comprehensive understanding of the risk spectrum and age of cancer onset is critical for cancer screening and risk-reduction. We sought to characterize *MSH6* and *PMS2*-associated cancers and age of diagnosis in those with mismatch repair deficient (MMRD)/ microsatellite instability-high (MSI-H) tumors, a hallmark of LS pan-cancer. **Methods:** Pts consented to IRB-approved protocols of tumor/germline sequencing or to a prospective registry of LS pts at a single institution from 2/2005-01/2021 were reviewed to identify those with germline heterozygous *MSH6*/*PMS2* P/LP variants; pts with constitutional MMRD (CMMRD) were excluded. In cancer-affected pts, tumors were evaluated for MSI and/or MMR protein expression via immunohistochemistry. Tumor types were tabulated, and clinical variables were correlated with MMR/MSI status using non-parametric tests. **Results:** We identified 243 pts (159 female, 94 male) with P/LP germline *MSH6/PMS2* variants, and 186 (77%) pts had a confirmed cancer [*MSH6* 111/148 (75%); *PMS2* 75/95 (79%)]. Overall, 51 (21%) pts had multiple primary cancers, 35 (24%) in *MSH6* and 16 (17%) in *PMS2* (p = 0.20), resulting in 261 total tumors, 160 in *MSH6* and 101 in *PMS2*. Of the 191 tumors with molecular assessment, 118 (62%) were MMRD/MSI-H, including CRC (n = 54), endometrial (EC, n = 34), small bowel (SBA, n = 6), ovarian (OC, n = 5), urothelial (n = 5), pancreato-biliary (n = 4), gastroesophageal (n = 3), non-melanoma skin (n = 3), prostate (n = 2), breast (n = 1), and brain (n = 1). While CRC and EC were more likely to be MMRD/MSI-H (79% each) compared to other cancers (37%) ($p < 0.001$ overall, $p = 0.001$ for *MSH6*, and $p < 0.001$ for *PMS2*), 25% of all MMRD/MSI-H tumors in both genes were comprised of non-CRC/EC cancers. Notably, there were 6 SBAs (5 in *PMS2*, 1 in *MSH6*), and all were MMRD/MSI-H. There were 17 OCs (12 in *PMS2*, 5 in *MSH6*), and of the 12 that underwent molecular assessment, 5 (41.7%) were MMRD/MSI-H (3 *PMS2*, 2 *MSH6*). Among MMRD/MSI-H CRC and EC, median age of diagnosis was 51.5 (range 27-80) and 55 (range 39-74) respectively, with 9/54 (17%) of CRC (4 in *MSH6*, 5 in *PMS2*) diagnosed < age 35, the suggested upper threshold for initiation of colonoscopy per NCCN. **Conclusions:** Despite being lower penetrance LS-associated genes, pts with *MSH6/PMS2* P/LP variants remain at risk for a broad-spectrum of cancers and very early-onset CRC, with 17% of MMRD/MSI-H CRC presenting prior to upper threshold of initiation of colonoscopic screening per NCCN. Cancer-specific mortality associated with germline genetic testing results among women with breast cancer or ovarian cancer treated with chemotherapy. *First Author: Allison W. Kurian, Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA*

Background: Breast and ovarian cancer patients increasingly undergo germline genetic testing. While studies suggest a greater chemotherapy benefit for carriers of *BRCA1/2* pathogenic variants, little is known about whether pathogenic variants in other genes are associated with cancer mortality. **Methods:** Georgia and California Surveillance, Epidemiology and End Results (SEER) registry records of women diagnosed with breast cancer or ovarian cancer from 2013-2017 were linked to results of clinical germline genetic testing from four participating laboratories. Patients were included if they linked to a genetic result, had stages I-III breast cancer or I-IV epithelial ovarian cancer and received chemotherapy. Multivariable Cox proportional hazard models were used to examine the association of genetic results, demographic and clinical factors with cancer-specific mortality. **Results:** 21,348 breast and 4,320 ovarian cancer patients were analyzed with median follow-up of 41 months. Pathogenic variants were present in 12% of patients with estrogen and progesterone receptor-positive, HER2-negative breast cancer, 9% with HER2-positive breast cancer, 17% with triple-negative breast cancer and 18% with ovarian cancer. Pathogenic variants were most common in *BRCA1/2, CHEK2, PALB2, ATM* and *BRIP1*. Among triple-negative breast cancer patients, mortality was lower with pathogenic variants in *BRCA1* (hazard ratio (HR) 0.27, 95% confidence interval (CI) 0.17-0.45) and genes other than *BRCA1/2* (HR 0.33, CI 0.13-0.81) versus no pathogenic variant. Genetic results were not associated with mortality in other breast cancer subtypes. Among ovarian cancer patients, mortality was lower with pathogenic variants in *BRCA2* (HR 0.36, CI 0.26-0.49) and in genes other than *BRCA1/2* (HR 0.48, CI 0.33-0.70). **Conclusions:** Among breast and ovarian cancer patients treated with chemotherapy, those with germline pathogenic variants in several cancer-associated genes had equivalent or lower short-term mortality than those testing negative. These results may guide patient counseling and clinical trial design. Research Sponsor: U.S. National Institutes of Health.

Chemoprotective effect of metformin against HR+/HER2- breast cancer among women with type-2 diabetes. *First Author: Soumya Chikermane, University of Houston, College of Pharmacy, Houston, TX*

Background: Type-2 diabetes mellitus (T2DM) increases the risk of breast cancer among postmenopausal women. Metformin has demonstrated a chemoprotective effect in breast cancer, however its role in HR+/HER2- breast cancer (HR+/HER2- BC), the most common subtype, has not been studied among older women with T2DM in the United States. This study evaluated if increased exposure to metformin is associated with a reduced risk of HR+/HER2- BC among postmenopausal women with T2DM. **Methods:** A case-control study was performed using the Surveillance, Epidemiology, and End Results (SEER)-Medicare data (2008-2015). Those diagnosed with HR+/HER2- BC as their first/only cancer after incident T2DM diagnosis were cases. The event date was the date of HR+/HER2- BC diagnosis in cases, and randomly assigned to non-cancer T2DM controls based on the distribution in cases. Cases were matched to up to 4 controls each using incidence density sampling with replacement. Metformin exposures were defined as cumulative dose, average intensity and adherence, measured during the 1-year lookback period prior to the event date. Dose (mg) was categorized as: 0, 0-30,000, 30,001-136,000, 136,001-293,000, and $>$ 293,000. Average intensity per day (mg/day) was categorized as: 0, 1-500, and $>$ 500. To evaluate adherence, those without metformin claims during the lookback period were excluded. Adherence measures were: binary proportion of days covered (PDC) ($\geq$0.80, $<$ 0.80) and adherence trajectories. Group based trajectory modeling was used to identify trajectories (adherent, slow decline, rapid decline, and early discontinuation). The Anderson Behavioral Model was used to guide selection of covariables: demographic and clinical variables (diabetes severity, metabolic syndrome, comedications, and health status). Conditional logistic regression was used to evaluate the association between exposure to metformin and the risk of HR+/HER2- BC. **Results:** The main cohort included 690 cases and 2747 controls. A decremental reduction in odds of HR+/HER2- BC in the highest cumulative dose (OR = 0.72, 95% CI: 0.55-0.95; OR = 0.60, 95% CI: 0.42-0.85) and intensity (OR = 0.61, 95% CI:0.46-0.82) categories of metformin was observed compared to the no-metformin group. Those non-adherent to metformin had 45% (OR = 1.45, 95% CI: 1.08-1.94) increased odds of HR+/HER2- BC compared to those adherent. The risk of HR+/HER2- BC in the adherent (OR = 0.67, 95% CI: 0.39-1.14), slow decline (OR = 0.75, 95% CI: 0.43-1.32) and rapid decline (OR = 0.73, 95% CI: 0.41-1.31) trajectories was not statistically significant compared to the early discontinuation trajectory. **Conclusions:** This retrospective study based on SEER-Medicare found an association between high dose and intensity of metformin use with reduced odds of incidence of HR+/HER2- BC among postmenopausal women with T2DM. Adherence to metformin also showed protective effect against HR+/HER2- BC. Research Sponsor: None.

Development of AI-powered imaging biomarker for breast cancer risk assessment on the basis of mammography alone. *First Author: Ki Hwan Kim, Lunit Inc., Seoul, South Korea*

Background: There is increasing interest in early detection of breast cancer by utilizing MRI in high-risk populations. However, it is still challenging to define and enrich the high-risk population. In this study, we developed an artificial intelligence (AI)-powered Imaging Biomarker in Mammography (IBM) to discover unique mammographic patterns, beyond simple density evaluations, that are related to breast cancer. **Methods:** A total of 49,577 mammography exams were collected to develop the AI-powered IBM, in which 6,218 were cancers. First, we evaluated the hypothesis that the unaffected breast of cancer patients would have a different pattern than that of non-cancer patients, by training AI (IBM-A) with unaffected breast in cancer patients and breasts of non-cancer patients. We then utilized further images of the cancer patients to train AI (IBM-B). This time we used both affected and unaffected breasts of cancer patients and breasts of non-cancer patients, allowing IBM-B to additionally learn patterns related to breast cancer. The IBMs were evaluated using the internal data (n = 2,058) that included 719 cancers. To demonstrate the feasibility of early detection by using IBM-B, it was tested with external data (n = 4,158) from an independent institution. This included pre-index exams (n = 292) taken prior to index exams acquired at the time of cancer diagnosis. **Results:** With the internal data, IBM-A showed AUC of 0.842, suggesting that AI could learn the difference between the normal breast of cancer patients and non-cancer patients. With IBM-B, which used additional cancer images to train, AUC was improved to 0.852. Based on the internal validation, IBM-B was chosen for the external validation, in which pre-index examinations were used only. IBM-B showed AUC of 0.777 in discriminating the pre-index exams of cancer patients and those of non-cancer patients. The radiologists excluded the apparent missed cancers (n = 87) by reviewing the pre-index exams retrospectively. After, the recalculated AUC of IBM-B was 0.770, suggesting that IBM-B can distinguish between mammograms of patients who will develop breast cancer in the future and those who will not. The mean IBM-B scores in pre-index exams of cancer group (0.580) were significantly higher than those in the normal (0.258, $P < 0.001$) and benign (0.258, $P < 0.001$) groups. **Conclusions:** AI-powered IBM could detect the unique parenchymal pattern associated with high breast cancer risks, and we show the potential of the AI-powered IBM to be used as an independent biomarker to select high-risk populations based on mammography alone. Research Sponsor: Lunit Inc.

Gene methylation and cytological atypia in random fine needle aspirates for assessment of breast cancer risk: 10-year follow up in average risk women. *First Author: Erica Wrubel, Northwestern University, Chicago, IL*

Background: Alterations in DNA methylation occur early in tumorigenesis, and are a potential breast cancer risk biomarker. We previously reported a study where healthy volunteers underwent random fine needle aspiration (rFNA) of the breasts; cumulative methylation index of eight preselected tumor suppressor genes (CMI) was associated with the presence of cytological atypia in rFNA samples. We now report 10-year follow-up of this population, to evaluate whether increased CMI is associated with subsequent breast cancer development. **Methods:** 380 women, unselected by breast cancer risk, were enrolled. Demographics, breast cancer risk factors, lifetime Gail model risk estimates (Gail-LR), and %breast density were obtained at baseline. rFNA samples were assessed for cytopathology (Masood Score, MS) and CMI. Patients were contacted annually for 10 years to ascertain development of invasive or non-invasive breast cancer. In univariate analysis, log-rank test was used to compare breast cancer incidence rates between individuals with high and low baseline measures (separated by median). Area under the ROC curve was used to evaluate the cancer prediction accuracy. In multivariate analysis, the effect of CMI (after log-transformation to reduce skewness) was further studied using Cox regression model adjusting for confounding baseline variables. **Results:** 362 women participated in follow up. At a median follow up time of 9.5 years after rFNA sampling, 16 women developed invasive or non-invasive breast cancer. There were no significant differences between women who developed cancer and those that did not in regard to demographic factors, %breast density, MS, or Gail-LR. On univariate analysis, Gail-LR was higher in women who developed cancer (13.0 vs. 16.5, p=0.08). The largest hazard ratios were observed from high breast density (2.30, 95% CI 0.8, 6.6) and high CMI (2.26, 95% CI 0.8, 6.6, p=0.07). In breast cancer prediction, the AUC for CMI was 0.64 (95% CI 0.51, 0.77). In separate bivariable models that adjusted for age, Gail-LR, MS, and %breast density, the HR for log CMI was consistently above unity, with a p value consistently below 0.1, except for the model that included MS (see Table). **Conclusions:** Elevated CMI has potential as a robust predictor of future breast cancer occurrence in average risk women, even when adjusted for breast density or cytologic atypia. Our prior analysis established that CMI is not susceptible to variation with menstrual cycle phase and menopausal status. These features support its further evaluation in larger trials. Clinical trial information: NCT00896636. Research Sponsor: Avon Foundation #02-2011-109 awarded to S. A. Khan, V. Stearns, and S. Sukumar, Other Foundation.

Models adjusting log CMI for covariates.

	Log CMI HR	log CMI p value	Covariate HR	Covariate p value
Log CMI + age	1.56	0.0990	0.93	0.0624

Mismatch repair gene alteration subtypes impact age of onset of mismatch repair-deficient cancers. *First Author: Aifen Wang, Zhangjiagang TCM Hospital Affiliated to Nanjing University of Chinese Medicine, Suzhou, China*

Background: This study investigated whether mismatch repair (MMR) gene alterations and alteration subtypes impacted age at onset of MMR-deficient cancers. **Methods:** A retrospective study of association of MMR-deficient alterations and age of onset of MMR-deficient lung, breast, prostate, bladder, colorectal, endometrial, and/or ovarian cancers was conducted by using cBIPORTAL dataset. **Results:** A total of 815 participants with MMR-deficient alterations were enrolled, 346 males and 469 females (median age 63 years; age range, 20-90 years). Males were diagnosed as colorectal and bladder cancer at later ages than females. When stratified by alteration type, individuals with *MSH6* or *PMS2* missense alterations had later ages of onset of colorectal cancer than those with no missense alterations. Participants with *MSH2* AMP alterations were older at the diagnosis of endometrial cancer than those without *MSH2* AMP alterations. Females with *MLH1* missense alterations had later ages of onset of ovarian cancer than those with no missense alterations. Individuals with *PMS2* AMP alterations were confirmed with lung cancer at later ages than those with no *PMS2* AMP alterations. Carriers with *MSH6*or *PMS2* missense alterations were older at the time of diagnosis of prostate cancer than those with no missense alterations. **Conclusions:** Gene alterations and subtype of alterations could stratify carriers with MMR-deficiency in bespoke surveillance. The mechanism of the association of MMR-deficient alterations and alteration subtypes and age at the diagnosis of MMR-deficient cancers needs to be further study. Research Sponsor: ZhongNan Hospital of Wuhan University Science Technology and Innovation Cultivating Fund.

The landscape of germline mutations and the relationship with tumor mutation burden in Chinese patients with lung cancer. *First Author: Jian Shi, Department of Medical Oncology, Fourth Hospital of Hebei Medical University, Shijiazhuang, China*

Background: Lung cancer is one of the most common types of cancer, ranking the first in the incidence and mortality of malignant tumors in the world and China. Although studies have been reported that genetic susceptibility to lung cancer is associated with certain germline mutations, the relationship between lung cancer risk and inherited genetic factors remains relatively elusive. However, the effect of germline mutation on TMB in lung cancer has not been explored. Herein, DNA genomic profiling was performed through NGS with a 539-gene panel to explore the germline mutations and the relationship with TMB in Chinese patients with lung cancer. **Methods:** We retrospectively analyzed the germline mutations through a comprehensive 539-gene profiling of 3541 Chinese patients with lung cancer. 539-gene panel contained germline mutations in 90 hereditary tumor-associated genes. We screened out the pathogenic and likely pathogenic germline mutations according to the standards and guidelines for the interpretation of sequence variants of The American College of Medical Genetics and Genomics (ACMG), and picked out there is no records in Clinvar database and no literature report. TMB of tissue or blood ctDNA in 3541 patients were further analyzed in with pathogenic mutations (P group), with likely pathogenic mutations (LP group), and no germline mutations group (Non-P group). The difference in TMB was analyzed via the Wilcoxon sign test. **Results:** In 3541 patients with lung cancer, 177 (4.999%) patients were identified harboring pathogenic or likely pathogenic germline mutations, in which 78 P group and 99 LP group, the rest 3364 were Non-P group. The highest prevalence of germline mutation was found in *BRCA2* (0.565%), *ATM* (0.339%), *MUTYH* (0.282%), and *BRCA1* (0.254%). In 177 patients with pathogenic or likely pathogenic germline mutations, 67 mutations were recorded as UNK (unknow) in Clinvar database and no literature report. The media TMB of tissue in P group, LP group and Non-P group were 5.149, 5.535 and 5.547 respectively. The media TMB of blood ctDNA in P group, LP group and Non-P group were 4.257, 3.945 and 4.483 respectively. There was no statistical difference in TMB between P and Non-P groups (tissue $p = 0.98$; ctDNA $p = 0.5$). **Conclusions:** In our study, we firstly identified 67 novel germline mutations and studied on the relationship between germline mutations and TMB in lung cancer, which expanded the understanding of germline mutations. Management impact of preoperative germline genetic testing in patients with breast cancer at the Lifespan Cancer Institute. *First Author: Kaitlyn P. Lew, Brown University, Providence, RI*

Background: Breast cancer is a heterogenous disease and management is complex. Advances in next generation sequencing has allowed genetic testing to be more accessible. However, conveying results to patients and care team can be challenging due to various variant classifications. Diagnostic results have the potential to guide management. Nondiagnostic results can be misinterpreted. The extent to which preoperative genetic testing affects management of newly diagnosed breast cancer is unknown. **Methods**: Newly diagnosed breast cancer patients were identified via review of breast tumor board between May 2019 and March 2019 followed by chart review to collect detailed information. **Results:** 408 newly diagnosed breast cancer cases were queried. Genetic evaluation was recommended and completed in 68%, not recommended (did not meet NCCN criteria) in 30% and declined in 2.7%. The genetic evaluation recommended cohort was associated with a higher mastectomy rate in comparison with when not recommended (31% vs. 9%, p=0.0001). Of those who completed genetic testing: 12% harbored a pathogenic/likely pathogenic variant (PV/LPV), 26% had a nondiagnostic variant of uncertain significance (VUS) and 61% had negative testing. Comparison between nondiagnostic test results (negative and VUS) and diagnostic test results revealed significantly increased number of women in the diagnostic group who chose mastectomy over breast conservation therapy (BCT, nondiagnostic 20% vs diagnostic 39%, p=0.018). When negative, VUS, and PV/LPV were each independently analyzed, diagnostic test results again revealed a significantly increased number of mastectomies over BCT ($p<0.05$). Comparison of surgical choices in nondiagnostic VUS vs. negative results was not significantly different (Table). Comparing the surgical timelines, completing a genetic evaluation did not affect surgery timing (mean 2.3 vs. 2.2 months, $p>0.5$). **Conclusions:** Germline genetic testing in patients with newly diagnosed breast cancer impacts clinical management. Those harboring a diagnostic result were more likely to choose mastectomy over BCT. Not surprisingly, mastectomy rate was higher among those where genetic evaluation was recommended, possibly due to concerning personal or family history. The mastectomy rate was higher among those with a diagnostic result, indicating an understanding of the genetic testing significance by patients and the care team. More importantly, those who harbored nondiagnostic VUS did not make significantly different surgical choices compared with negative genetic testing, highlighting the critical role of proper genetic counseling and being part of the care team. We conclude consideration of genetic evaluation is clinically useful and feasible without affecting the surgical timeline. Research Sponsor: None.

Uptake of genetic counseling and testing in a clinic based population of women with breast cancer. *First Author: Alexandra Wehbe, Wayne State University, Detroit, MI*

Background: Carriers of pathogenic variants in cancer susceptibility genes have an elevated risk of developing breast, ovarian, and other cancers.We conducted a medical record review to determine the uptake of genetic counseling and testing in a clinic-based population of women with breast cancer. **Methods:** Medical records of 150 women with breast cancer seen at the Karmanos Cancer Institute between January-December 2018 were reviewed to determine the proportion eligible for genetic testing according to National Comprehensive Cancer Network guidelines. We also assessed genetics referral rates, appointment completion and results of genetic testing. Using chi-square and ANOVA tests, we analyzed the association of demographic and clinical factors with eligibility and referral to genetic counseling. **Results:** The average age of diagnosis was 57.1 years old, with 68.7% of women diagnosed with stage I-III disease, and 31.3% diagnosed with stage IV disease. There were 91 (60.7%) women who met NCCN criteria for genetic testing, of which 46.2% ultimately underwent genetic testing. Eligible women were more likely to be younger (52.6 vs. 64.0 years old), White (75.0% vs. 54.5%), and have Medicaid (75.0%) or private insurance (72.9%) vs. Medicare (44.8%). Women who met NCCN criteria were 3.5 times more likely to be referred for genetic counseling than those that did not meet eligibility criteria. Women were also more likely to be referred if they had early-stage disease compared to stage IV (67.8% vs. 48.3%), and Medicaid or private insurance compared to Medicare (71.4%, 72.0% and 40.0%, respectively). Of eligible women, 59.3% had a genetic counseling appointment scheduled, and of those, 78.0% attended their appointment. There were no apparent differences in appointment completion based on race with similar percentages of Black and White women completing their appointments (74.0% and 77.0% respectively). Women with stage IV disease were more likely to complete their appointments (83.0%) compared to women with stages I-III (74.0%) and fewer women with Medicare completed their genetic counseling appointment (56.0%) compared to women with Medicaid (83.0%) and women with private insurance (83.0%). Among women who attended their appointment, 95.9% underwent genetic testing. Of women who had genetic testing, 8.5% had a pathogenic variant and 30.4% had a variant of unknown significance. **Conclusions:** The results of this study indicate that lack of genetic counseling referrals contribute to a gap between the need for and completion of genetic testing. By understanding barriers to genetic counseling and testing, future clinical initiatives could effectively improve accessibility to genetic counseling services. Research Sponsor: None.

Closing the gap: Trends in inconclusive rates on hereditary cancer testing across racial/ethnic groups. *First Author: Foluso Olabisi Ademuyiwa, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Several groups have described disparities in genetic test results for inherited breast cancer predisposition, with a disproportionate number of variants of unknown significance (VUS) reported in non-Caucasian individuals. These disparities are due in part to the underrepresentation of non-Caucasians in reference databases and clinical genetic testing cohorts. Over the past few years, diversification efforts have been made however, little data exists on how ethnicity- and gene-specific VUS rates have changed over time and whether such disparities have improved or worsened. **Methods:** We retrospectively reviewed demographic information and test results for individuals who underwent hereditary cancer multigene panel testing between March 2012 and September 2020 at a single laboratory. Individuals who self-reported as African American, Asian, Caucasian, or Hispanic on the test requisition form and whose testing included *ATM, BRCA1, BRCA2, CHEK2* and *PALB2* (five commonly tested breast cancer predisposition genes with management guidelines) were included in the study (n = 284,130). The frequency of germline variants of unknown significance (VUS) in the five geneswas assessed in September 2015 and September 2020. **Results:** Amongst patients tested between March 2012 and September 2015, 82.8% of the study cohort self-reported as Caucasian and 17.2% were not Caucasian (6.5% African American, 6.0% Hispanic, and 4.6% Asian). The proportion of non-Caucasian individuals in the study cohort increased slightly by September 2020 to 22.8% (77.2% Caucasian, 9.2% African American, 8.4% Hispanic, and 5.3% Asian). Consistent with previous reports, Caucasians had the lowest VUS rate overall in both 2015 and 2020. This was also true at the individual gene level, with the exception of *CHEK2*. Over time, we observed a relative decrease in VUS rates across all ethnicities. Between 2015 and 2020, the overall VUS rate for the five included genes in non-Caucasian individuals was reduced by 32.0% in non-Caucasians compared to 23.6% in Caucasians. The absolute difference in VUS rate between non-Caucasians and Caucasians decreased from 7.9% in 2015 to 4.5% in 2020. **Conclusions:** While VUS rates for commonly tested breast cancer predisposition genes remain higher in non-Caucasians relative to Caucasians, our results demonstrate that this gap has been reduced over a five-year time period. These findings may be indicative of efforts by clinicians and laboratories to reduce these disparities. Further studies are necessary to improve the clinical utility of genetic testing in under-represented populations. Research Sponsor: Ambry Genetics.

Breast cancer ER, PR, and HER2 expression variance by germline cancer predisposition genes. *First Author: Grace Wei, USF Health Morsani College of Medicine, Tampa, FL*

Background: The association between breast cancer characteristics and survival with estrogen receptor (ER) and progesterone receptor (PR) expression has been primarily studied via binomial categories, ER-positive and ER-negative. In order to better characterize germline genetic influences on these markers, we investigated their IHC expression semi-quantitatively in cancer predisposition germline pathogenic variant (PV) carriers of the following genes: *BRCA1,BRCA2, PALB2, TP53, PTEN, CDH1, ATM, CHEK2*, and Lynch syndrome genes. The HER2 expression was also analyzed. **Methods:** We conducted a retrospective chart review of patients with germline panel genetic testing for cancer predisposition genes at Moffitt Cancer Center's GeneHome clinic. Inclusion criteria included 1) women ≥18 years old, 2) breast cancer diagnosis, 3) cancer predisposition germline panel genetic test results, 4) available ER and PR expression levels, and 5) available HER expression and/or amplification status. ER, PR, and HER2 status were compared between PV carriers and non-PV carriers via Mann-Whitney U at $p>0.05$. **Results:** A total of 847 cases were reviewed for the study. Among 658 patients with a breast cancer diagnosis and complete ER PR data, 365 cases (55.5%) were non-PV carriers and 293 cases (44.5%) carried a PV in at least one of the genes listed above. Among 635 cases with available HER2 expression/amplification status, 355 (55.9%) cases were non-PV carriers and 288 (45.4%) cases were PV-carriers. When compared with non-PV carrier controls, *BRCA1* PV carriers' breast tumors had significantly lower ER and/or PR expression. Further, *BRCA2* and *TP53* PV tumors also displayed moderately lower ER expression. Contrarily, *CHEK2* tumors displayed higher ER and PR expression compared to controls. Further, *BRCA1* and *BRCA2* PV carriers were more likely to have HER2- breast cancers. **Conclusions:** Differences in ER, PR, HER2 expression levels were observed in germline PV carrier breast cancers, signaling differential impacts by germline PVs on the tumor evolution process. It is likely that tumor differences in PV carriers influence responses to therapies, including hormone therapy, anti-HER2 therapy, and subsequent survival. Research Sponsor: None.

Use of comprehensive next-generation sequencing to identify pathogenic germline variants with therapeutic relevance in metastatic breast cancer. *First Author: Nicole Margo Grogan, University of Michigan Rogel Cancer Center, Ann Arbor, MI*

Background: Among patients with early-stage breast cancer, approximately 6-10% have a pathogenic germline variant (PGV) conferring inherited cancer predisposition. In contrast, few studies have explored the frequency and types of PGVs identified in patients with metastatic breast cancer (MBC); therefore, additional data is needed. **Methods:** From 2011-2020, 278 patients with MBC underwent fresh tumor biopsy and blood sample collection for paired tumor/normal DNA (targeted exome capture with analysis of 1700 genes) and RNA (tumor transcriptome) sequencing through the Michigan Oncology Sequencing (Mi-ONCOSEQ) program. Somatic and germline alterations were annotated and classified according to degree of clinical actionability with results returned to treating oncologists. Retrospective chart review was performed to determine if: 1) a PGV was identified prior to Mi-ONCOSEQ testing, 2) patients met National Comprehensive Cancer Network (NCCN) guideline criteria for genetic testing on the basis of personal or family cancer history and 3) patients received subsequent therapy informed by a PGV. **Results:** Forty-eight of the 278 patients (17.3%) had at least one PGV identified, with a total of 50 PGVs identified in this cohort. Only twelve of these PGVs (24%) had been identified prior to Mi-ONCOSEQ testing. The most frequent PGVs identified were in CHEK 2 (n = 9, 18%), MUTYH (n = 6, 12%), BRCA 1 (n = 5, 10%), BRCA2 (n = 5, 10%), ATM (n = 4, 8%) and PALB2 (n = 4, 8%). Somatic loss of heterozygosity events (LOH) occurred in 30 of the 50 cases with PGVs identified (60%). LOH events were observed in 83.3% of BRCA1, BRCA2, ATM and PALB2 PGVs, but were less frequently observed with CHEK2 (33.3%) and MUTYH (66.7%). Two hundred sixteen out of 278 patients (77.7%) in this cohort met NCCN criteria for genetic testing, although six patients with a PGV identified (CHEK2: n = 5; MUTYH: n = 1) did not meet NCCN criteria. Twenty-nine PGVs identified (58%) had potential therapeutic relevance and 11 patients (22.9%) received targeted therapy based on the PGV. **Conclusions:** The frequency of PGVs identified in this cohort is nearly double the frequency reported for patients with early-stage disease, suggesting that certain PGVs may confer worse prognosis. CHEK2, the most frequently identified PGV, was less likely to have an identifiable LOH event. The direct role of CHEK2 PGVs in tumor pathogenesis is uncertain, but other mechanisms of silencing the wild type allele must be considered. Despite the majority of patients meeting NCCN criteria for genetic testing, those with PGVs in CHEK2 were less reliably identified by this mechanism. The majority of PGVs identified were of potential therapeutic relevance, supporting the recommendation for genetic testing in all patients with MBC. Research Sponsor: U.S. National Institutes of Health.

Identification and management of pathogenic mutations in *BRCA1, BRCA2,* and *PALB2* in a tumor-only genomic testing program. *First Author: Brittany L. Bychkovsky, Cancer Genetics and Prevention, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Tumor-genomic testing is increasingly used to guide treatment decisions in cancer patients. Although tumor-only testing cannot definitively distinguish between germline versus somatic alterations, the identification of pathogenic or likely pathogenic (P/LP) variants in certain genes should prompt consideration of germline testing. Germline P/LPs in *BRCA1*, *BRCA2* and *PALB2* (*B1B2PAL*) are associated with hereditary cancer syndromes. **Methods:** We reviewed tumor-only genomic data (Dana-Farber Oncopanel) between 10/2016 and 6/2018 to examine the prevalence of P/LPs in *BRCA1, BRCA2,PALB2* among adult cancer patients at Dana-Farber Cancer Institute/Brigham and Women's Hospital. We characterized the frequency of P/LPs by primary tumor type, confirmation by germline testing before or within 12 months after Oncopanel testing or not, and factors associated with germline testing. **Results:** Among 7,575 patients, the median age was 62 (range 18-99); 53.9% were female. A total of 272 (3.6%) had P/LPs in *BRCA1* (n = 90), *BRCA2* (n = 162) and/or *PALB2* (n = 29). P/LPs in *B1B2PAL* were detected in 5.3% (38/712) of breast, 11.9% (34/285) of ovarian, 6.6% (18/272) of pancreatic, and 5.1% (12/234) of prostate cancers. P/LPs in *B1B2PAL* were also detected in other neoplasms (12.9% (8/62) of non-melanoma skin, 5.0% (43/855) of colorectal, 7.6% (20/264) of endometrial, and 4.6% (10/216) of head and neck cancers). Of 169 patients who had not had prior germline testing, 29/169 (17.2%) completed germline testing within 12 months after Oncopanel; 13 (7.7%) referred for testing declined or did not complete testing within 12 months, 14 (8.3%) died before or within 3 months of the Oncopanel results, and 113 (66.9%) had no documented germline testing within 12 months. Among 132 patients who had germline testing, 117 (88.6%) had a clinical indication based on personal or family history compared to 66/140 (47.1%) who did not undergo germline testing. Among 132/272 (48.5%) germline-tested patients, 70.5% were positive for a germline mutation in *B1B2PAL*; the remainder had somatic *B1B2PAL* mutations only. Germline testing was more often performed in patients with *B1B2PAL*-associated tumors (breast, ovarian, pancreatic and prostate cancers) or other clinical indications for germline testing. **Conclusions:** A low but clinically meaningful rate of P/LPs in *BRCA1, BRCA2* and *PALB2* was detected by tumor-only genomic testing in diverse malignancies. Given the implications of *B1B2PAL* alterations on treatment and familial cancer risk, our data support current NCCN guidelines recommending germline testing among patients with cancer and P/LPs in *B1B2PAL* detected on tumor-genomic testing and highlights the need for systems to ensure germline testing when indicated. Research Sponsor: None.

Genetic counseling and testing rates among community cancer programs for patients with breast cancer following site-directed quality improvement. *First Author: Leigh Boehmer, Association of Community Cancer Centers, Rockville, MD*

Background: National Comprehensive Cancer Network (NCCN) guidelines recommend testing for highly penetrant breast/ovarian cancer genes in several scenarios, including women with early-onset (≤ 45 years) or metastatic HER-2 negative breast cancer regardless of family history. A 2018 Association of Community Cancer Centers (ACCC) survey (N = 95) showed that > 80% of respondents reported ≤ 50% testing rate of patients with breast cancer who met guidelines. To improve rates of genetic counseling(GC)/testing, ACCC partnered with 15 community cancer programs to support site-directed quality improvement (QI) interventions. **Methods:** Pre- and post-intervention data from 9/15 partner programs for genetically at-risk women with early-onset or HER-2 negative metastatic breast cancer (MBC) were analyzed. Pre-intervention data were collected between 01/01/2017 and 06/30/2019 while post-intervention data were collected as early as 07/01/2019 and as late as 10/01/2020. QI project scope ranged from creation of testing eligibility education to implementation of a virtual GC clinic. De-identified data collected included: family history documentation; GC appointment; test results; and timing of results relative to surgical date. **Results:** The pre-intervention cohort included 2691 women and the post- cohort included 3104 women who were eligible for GC. Early-onset patients in the post-intervention group attended a GC appointment 83% (331/401) of the time and 74% (296/401) had genetic test results, with 92% (271/296) receiving results before surgery. Sixty-one percent (1387/2267) of women with HER-2 negative MBC in the post-intervention group received GC, compared to 36% (658/1845) in the pre-intervention group. There was an overall increase in the number of MBC patients with documented test results following GC in the post-intervention cohort (55% (1243/2267) versus 15% (273/1845); $p < 0.0001$). Rates of GC appointments improved overall, regardless of family history documentation. Rates among those with a documented high-risk family history improved from 57% (729/1284) to 85% (1485/1741) following QI interventions ($p < 0.0001$). There was also a significantly higher rate of GC provided in the post-intervention group among women with negative family histories (40% (462/1155) versus 23% (181/778); $p < 0.0001$). GC also increased from 6% (35/629) to 45% (94/208) of women in the post-intervention cohort with no documentation of family history ($p < 0.0001$). **Conclusions:** Genetic testing is underutilized in women with breast cancer. Significant improvement was achieved with QI initiatives specifically designed to target easily identified populations meeting guidelines for GC/testing. This project demonstrates the importance of attention to practice-directed strategies aimed at improving identification of risk as well as follow through to GC/testing. Cancer surveillance in adults with germline *TP53* pathogenic variants: A single-center observational study. *First Author: Thomas Meyskens, Department of General Medical Oncology, Leuven Cancer Institute, University Hospitals Leuven, Leuven, Belgium*

Background: Germline pathogenic variants (PV) in the tumor suppressor gene *TP53* are associated with a high risk of developing diverse malignancies, often at young age, and predispose to Li-Fraumeni syndrome (LFS). Surveillance programs for presymptomatic PV carriers have shown survival benefit in a non-randomized trial. Here we describe the surveillance findings and clinical outcomes of adults with *TP53* PV undergoing a standardized screening protocol. **Methods:** We identified adults with germline PV in *TP53* who underwent surveillance at the University Hospitals Leuven, Belgium, between 04/2013 and 08/2020. Patients with prior cancer were allowed, while patients with an active malignancy requiring treatment at diagnosis of the *TP53* PV were excluded. Surveillance was performed per modified Toronto protocol, including annual whole body diffusion-weighted MRI (WB-DWI/MRI), brain MRI, abdominal ultrasound (US), endoscopic surveillance, laboratory tests, dermatological examination and breast MRI/US in females. The primary aim was to evaluate the number and type of malignancies and premalignant lesions diagnosed during screening and to assess the proportion of malignancies detected by surveillance. Secondary outcomes were the cancer detection rate during the first year of screening, the proportion of carriers with false-positive findings, and overall survival. **Results:** We included 42 adults from 20 apparently unrelated families. Median age was 38y (range, 17-70y) and 23 had a history of prior cancer. After a median follow-up of 41.5mo, we diagnosed 18 cancers in 12/42 participants (29%). Overall survival was 95% in all participants, including 2 carriers who opted to discontinue surveillance. Surveillance detected 10/18 cancers (56%), the majority of whom through WB-DWI/MRI (6/10; 60%). No malignancies were identified with brain MRI. In 5/42 individuals (12%), surveillance detected a malignancy during the first year of screening. Only 2/10 cancers discovered with surveillance (1 soft tissue and 1 bone sarcoma) belong to the LFS core tumors. Cancers not detected with surveillance (8/18) were 6 non-melanoma skin cancers and 2 interval cancers (sarcoma post radiation, secondary acute leukemia). Additionally, we detected 27 premalignant lesions in 11/42 patients (26%), of whom 78% were diagnosed by colonoscopy. False-positive findings occurred in 7/42 patients (17%) and were mostly seen with WB-DWI/MRI. **Conclusions:** Adults with germline PV in *TP53* that undergo surveillance have high cancer detection rates. The majority of malignancies were asymptomatic at diagnosis and detected with WB-DWI/MRI. Despite the high cancer incidence, few LFS core cancers were diagnosed and survival was encouraging. Increased genetic testing changes the clinical picture of germline *TP53* carrier populations, justifying the transition from LFS to a wider concept of heritable *TP53*-related cancer syndrome. Twenty-one-gene recurrence score (RS) in germline (g)*CHEK2* mutation-associated versus sporadic breast cancers (BC): A multi-site case-control study. *First Author: Anosheh Afghahi, University of Colorado, Aurora, CO*

Background: Genomic assays, such as RS, are used to determine chemotherapy benefit in early-stage, estrogen receptor (ER)- and/or progesterone receptor (PR)-positive, HER2 negative BC patients (pts). Currently, guidelines to use pts' germline genetic testing results to guide adjuvant therapy are lacking. Several reports have indicated worse outcomes for BC pts with g*CHEK2* pathogenic variants (PV). We investigated whether PV in *CHEK2* were associated with increased RS. **Methods:** Patient-level clinical data and RS were derived from electronic medical records of seven medical centers between years 2013-17. Confirmation of RS using the Genomic Health provider portal was performed. 38 pts with germline PV in *CHEK2* (15 pts/39.5% with c.1100delC mutation) and RS score (cases) were matched with BC pts whose genetic testing did not identify PV (controls) using a 1:2 matching schema. Pts were matched based on age at diagnosis and lymph node (LN) status. LN negative pts were further matched based on T-stage. A multivariate random intercept linear mixed model of *CHEK2* mutation status on RS was performed, adjusting for PR. A secondary ordinal univariate analysis was conducted that categorized RS into low, intermediate and high risk (< 18, 18-30, and > 30, respectively). P-values were reported based on a null hypothesis of no effect against a two-sided alternative. **Results:** The median RS for cases was 19.5 (interquartile range [IQR]: 15 to 25) and the median RS for controls was 18 (IQR: 12 to 22). A greater proportion of cases were categorized as high risk (10.5%) compared to controls (5.6%), and a smaller proportion of cases were categorized as low risk (36.8%) compared to controls (49.3%). Cases had higher grade and increased proportion of PR-negative BC as compared with controls (grade 1: 12.1% of cases versus 32.4% of controls; PR-negative: 7.9% of cases versus 5.6% of controls). The variables used to match cases and controls (age, lymph node status, and T-stage) had similar summary statistics. The RS was 1.97-point higher in pts with g*CHEK2* PV compared to controls, after adjusting for PR (95% confidence interval [CI]: 1.02-point lower to 4.96-point higher; $p = 0.194$). The secondary analysis of *CHEK2* mutation status on an ordinal RS risk group yielded comparable results; on average, the odds of being high risk compared to the combined intermediate/low risk groups was 1.72 times higher in cases compared to controls (95% CI: 0.77 to 3.80; $p = 0.181$), but these differences were not significant. **Conclusions:** Our case-control study did not show a statistically higher RS for BC that develops in pts with g*CHEK2* PV. Further studies are warranted to evaluate the association between type of *CHEK2* PV (frameshift versus missense) and other modifying genetic variables and RS. Research Sponsor: None.

Identifying individuals with primary central nervous system tumors at risk for hereditary cancer syndromes using the Utah Population Database. *First Author: Nicholas Shawn Whipple, Division of Pediatric Oncology, Department of Pediatrics, University of Utah, Salt Lake City, UT*

Background: CNS tumors are the most common solid tumors and the deadliest cancers in children. Approximately 10% of children with a CNS tumor harbor a hereditary cancer syndrome (HCS), but many will not be tested for a HCS. The Utah Population Database (UPDB) contains comprehensive cancer registry data for Utah families and can determine multigenerational cancer pedigrees across an archive of 5.8 million individuals. Early identification of HCSs results in improved cancer surveillance and outcomes, reducing the impact of CNS tumors in children. We hypothesize that the UPDB can identify children and families with HCSs not previously identified. **Methods:** We queried the UPDB for individuals ages 0-39 diagnosed with a primary CNS tumor (malignant and benign) between 1966-2017 and generated cancer pedigrees of 3 generations or more for probands, extending to at least third-degree relatives. Specialized software calculated a familial standardized incidence ratio (FSIR) to determine families with excess clustering of CNS tumors. Clinical cancer genetics experts reviewed pedigrees to confirm patterns of HCS. **Results:** We identified 4,634 CNS tumors in 4,550 individuals, of whom 2,233 (49%) reside in high-quality pedigrees containing ≥2 grandparents, at least 1 from both maternal and paternal sides. To identify families with excess clustering of CNS tumors, we selected pedigrees with an FSIR $P < 0.05$ and ≥2 affected patients, resulting in 161 high-risk families with a mean of 170 (median 96) relatives per pedigree of 3-6 generations. Among these 161 families, there were 2,017 unique relatives (first-third degree) of CNS probands with 2,355 tumors (any site), for a per pedigree average of 14.7 tumors in 12.5 relatives. Review of the 10 highest risk pedigrees indicated that 4 meet HCS criteria, including Li-Fraumeni (n = 2), von Hippel-Lindau (n = 1), and rhabdoid tumor predisposition (n = 1). **Conclusions:** The UPDB can produce multigenerational cancer pedigrees that identify individuals and families at risk of harboring a HCS who warrant germline testing. These findings should encourage clinicians to perform thorough family history screening and to always consider workup for associated HCSs. Rare *BAP1* variant of unknown significance (VUS) and analysis of *BAP1* codon 146 genomics: Potential germline and therapeutic implications. *First Author: Jo-Ellen Murphy, Foundation Medicine, Cambridge, MA*

Background: The *BAP1* gene (*BRCA1*-Associated Protein) encodes a protein ubiquitin carboxyl-terminal hydrolase (BAP1), which removes ubiquitin moieties and regulates various cellular functions including DNA repair. This association has driven interest in defining if *BAP1* variants confer susceptibility to PARP inhibitors (PARPi). Germline and somatic *BAP1* alterations are both rare, mostly unique, often classified as VUS's, and associated with a broad range of overlapping tumor types. Based on the identification of a *BAP1* R146K VUS variant in tumor, also previously identified as germline, an analysis of *BAP1* codon 146 alterations was initiated to explore potential genetic and therapeutic implications. **Methods:** 394,756 tumor specimens were tested using hybrid capture-based genomic profiling (Foundation Medicine) for all variant types and Tumor Mutational Burden (TMB). *BAP1* codon 146 cases were analyzed for clinicogenomic features and germline results when available. **Results:** *BAP1* codon 146 variants were identified in 23 unique patients across the following tumor types: cholangiocarcinoma (CCA) (4), mesothelioma (4), NSCLC (3), RCC (2), ocular melanoma (2), and carcinoma of unknown primary (CUP) (3); many of which overlap with known and suspected germline associated *BAP1* syndromic tumor types. *BAP1* R146 mutations were classified as VUS in 16 patients and 7 were likely or known pathogenic. In 20 of the 23 cases where zygosity could be determined 16 (80%) were homozygous and 4 (20%) were heterozygous. In 2 of the 3 NSCLC cases, the *BAP1* variant appeared likely somatic and/or associated with a high TMB. A previously reported germline *BAP1* variant in a RCC patient, R146K, occurred 5 times in our tumor database. One case which was homozygous in tumor and confirmed in germline occurred in a patient who had both breast and CCA. She also had a sibling with RCC who shared the germline *BAP1* R146K variant along with multiple 1st and 2nd degree relatives with RCC, mesothelioma, melanoma, liver cancer, colon cancer, and a cancer of unknown primary. **Conclusions:** Codon 146 of *BAP1* localizes to the UCH (ubiquitin carboxyl hydrolase) domain, which includes the BARD1 interaction region. Loss of BAP1 activity as a consequence of germline or somatic mutation likely impacts ubiquitination status and activity of downstream proteins, such as those involved in DNA repair. For patients with suspected *BAP1* inactivating alterations, often seen in non-homologous recombination deficiency related tumor types, PARPi therapy may be relevant. As demonstrated here, variants identified through tumor testing may also aid in re-classification of germline VUS's. These results support the further investigation and validation of *BAP1* alterations for germline risk stratification and therapeutic strategies with either PARPi and/or other therapies specific to tumors with impaired chromatin remodeling. Germline alterations among Hispanic men with prostate cancer. *First Author: Justin Shaya, University of California San Diego, Moores Cancer Center, La Jolla, CA*

Background: With the growing indications for germline testing in prostate cancer (PCa), there is accumulating evidence that African American and Hispanic men with PCa are significantly under-tested compared to non-Hispanic white (NHW) men. Given this, little is known about the pathogenic germline variant landscape in Hispanic men with PCa. **Methods:** This was a retrospective cohort analysis of 17,256 men with PCa who underwent diagnostic germline testing through a commercial laboratory (Invitae) from 2015-2020. Self-identified Hispanic and NHW men were selected for comparative analysis. The primary endpoint was the rate of pathogenic/likely pathogenic (PLP) germline alterations in Hispanic men among 25 genes associated with PCa. Secondary endpoints included comparison of PLP rates in Hispanic vs NHW men, the rate of specific PLP alterations, and the rate of variants of uncertain significance (VUS). Fisher's exact test was used to compare germline alteration rates for significance. **Results:** We identified 508 Hispanic and 12,542 NHW men with PCa who underwent testing during the study period. Median age at the time of testing was 69 vs 67 years in Hispanic vs NHW cohorts. A family history of PCa was reported in 21.1% (N=108) vs 27.3% (N=3428) in the Hispanic vs NHW cohorts, respectively (p=0.002). The PLP alteration rate was 7.1% in the Hispanic cohort and this rate was numerically lower but not significantly different when compared to the NHW cohort (9.7%) (p=0.058). A significantly higher rate of VUS was seen in the Hispanic cohort (Table). The four most frequently detected genes with PLP alterations in both cohorts were *ATM, BRCA1, BRCA2,* and *CHEK2*. Only the rate of *CHEK2* alterations was significantly different between cohorts among all 25 genes analyzed (Table). **Conclusions**: In this analysis, the PLP alteration rate among Hispanic men was 7.1%, a much higher rate than has been previously reported, and the germline genomic landscape was similar to that of NHW men. The VUS rate was significantly higher among Hispanic men, a known consequence of under-testing among minority populations.These data support germline testing in Hispanic men with prostate cancer and emphasize the importance of improving testing rates. Research Sponsor: None.

Germline characteristics.

Germline Characteristic	Hispanic	Non-Hispanic White	p-value
PLP alteration rate*	7.1%	9.7%	0.058
ATM	1.2%	1.6%	0.71
BRCA1	0.6%	0.6%	1.00

Pan-cancer evaluation of homologous repair deficiency somatic mutations and response to first-line anti-neoplastic therapy. *First Author: Jessica A. Lavery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Homologous recombination is a major mechanism of defective DNA repair, but it remains uncertain whether homologous repair deficient (HRD) tumors have favorable prognosis or are more/less likely to respond to treatment than tumors lacking such mutations. **Objective:** To determine whether lung (NSCLC) and colorectal (CRC) HRD+ tumors have better survival or response to chemotherapy than HRD- tumors. **Methods:** Patients with de novo stage IV NSCLC or CRC who had next generation sequencing (NGS) between 2015-2018 from one of four cancer centers were identified. Records were curated using the PRISSMM framework to ascertain treatment, overall survival (OS) and progression free survival based on imaging (PFS-I) and oncologists' notes (PFS-M). Each NSCLC or CRC tumor was categorized as HRD+ if NGS revealed an oncogenic/likely oncogenic mutation in: *ATM, BAP1, BARD1, BLM, BRCA1, BRCA2, BRIP1, CHEK2, FAM175A, FANCA, FANCC, NBN, PALB2, RAD50, RAD51, RAD51C, RTEL1,* or *MRE11A* based on the OncoKB database. The tumor was categorized as HRD- if no oncogenic mutation in any of these genes was evident and HRD indeterminate (HRD?) if no mutation was identified but the panel did not include all genes. OS, PFS-I and PFS-M from start of first line therapy were reported by HRD status. The percentage with a good response to first line therapy (≥2x the median) and exceptional response (≥3x the median) was estimated for each endpoint. **Results:** For NSCLC 4% were HRD+, 59% HRD- and 37% HRD?. For CRC there were 5% HRD+, 60% HRD- and 35% HRD?. There were no significant differences for any survival endpoint between patients who were HRD+ vs HRD- in univariable analyses. The proportion of good and exceptional responders to first line systemic chemotherapy also did not vary by HRD status, though patients with HRD+ CRC were potentially more likely to be exceptional responders. Similarly, no differences between HRD+ and HRD- tumors were apparent for the subgroup receiving platinum containing therapy. **Conclusions:** NSCLC and CRC patients with somatic mutations in HRD oncogenic genes did not differ from patients lacking such a mutation with respect to OS or PFS. CRC patients with HRD+ tumors may be more likely to be exceptional responders, but sample sizes are limited. By May, the analysis will include breast and pancreatic cancer cases. Research Sponsor: American Association for Cancer Research GENIE BPC.

Genetic ancestry and clinical outcomes to immune checkpoint inhibitors among seven common cancers. *First Author: Amin Nassar, Brigham and Women's Hospital, Boston, MA*

Background: Prior studies and clinical trials report associations between self-reported race and clinical outcomes to Immune Checkpoint Inhibitors (ICIs). However, comprehensive studies of ancestry-associated differences in clinical outcomes have not been performed. We derived genetic ancestry scores and assessed clinical outcomes in 1341 patients with cancer treated with ICIs. **Methods:** Patients at the Dana-Farber Cancer Institute treated with ICIs only and with relevant cancer types and targeted exome sequencing data (Oncopanel) were included. Relevant cancer types included colorectal adenocarcinoma (CRC), esophagogastric adenocarcinoma (EGC), head and neck squamous cell carcinoma (HNSCC), melanoma, non-small cell lung cancer (NSCLC), renal cell carcinoma (RCC), and urothelial carcinoma (UC). We developed a bioinformatics pipeline to infer fine-scale genetic ancestry for each patient (n=1341) directly from tumor sequencing data by leveraging off and on-target sequenced reads and external ancestry reference panels. Three ancestry scores were determined (African, East Asian, European). Overall survival (OS) and time-to-treatment failure (TTF) were compared by Cox logistic regression between ancestral populations. Hazard ratio (HR) was derived using multivariable analysis, adjusted for single versus combination therapy, prior lines of therapy, and tumor mutational burden (TMB, as percentiles). **Results:** Median follow-up was 37.8 months (m; interquartile range: 35.7-39.5m). Common cancer types included CRC (n=52), EGC (n=114), HNSCC (n=88), melanoma (n=274), NSCLC (n=571), RCC (n=99), and UC (n=143). A higher East Asian ancestry (EAS) was significantly associated with worse OS (p=0.03) and TTF (p=0.002) in patients with RCC, independent of the histologic subtype (Table). There was no significant association between any of the three ancestral populations and clinical outcomes in the other 6 cancer types. **Conclusions:** We described clinical outcomes to ICIs across three global populations in 7 cancers. As the medical field re-evaluates the use of self-reported race in clinical decision-making, we utilize a novel ancestry pipeline that can be readily applied to tumor-only sequencing panels and better characterize non-white populations. We find no ancestry differences in clinical outcomes except in patients with RCC treated with ICIs which will require future validation. We plan to analyze genomic correlates of response by ancestry in each of the cancer types to better understand these diverge clinical behaviors. Research Sponsor: None.

The protean phenotype of MSH6 pathogenic variants (PV) in Lynch syndrome (LS) patients (pts). *First Author: Michelle J McSweeny, Fox Chase Cancer Center, Philadelphia, PA*

Background: LS is among the most common hereditary cancer (CA) syndromes. PVs in MSH6 are 2-4 fold more common in the population (1/758) than those in MLH1 (1/1946) or MSH2 (1/2841), and are increasingly regarded as lower penetrance for CRC due to published data supporting later mean age of CRC onset and lower CRC risk. Unlike for MLH1/MSH2, NCCN 2020 CA risk estimates recognize only endometrial CA (EC) and CRC risks in MSH6+ carriers as clearly above SEER population estimates. Further, risks of other LS manifestations such as skin disease/Muir-Torre, ovarian CA (OC), and possible rare tumors in LS like sarcoma, have been minimally characterized in MSH6+ carriers. **Methods:** Pedigree data for 44 MSH6+ index (first-evaluated family member by our program) pts consecutively ascertained since 2009 at Fox Chase (FCCC) were reviewed. 1 pt w/a rare MSH6 uncertain variant w/personal history (PHx) of MSH6-expression deficient EC (age 50) and MSH6-deficient sebaceous skin CA (age 50) and a strong family history (FHx) c/w LS is also included here. 34% (15/44) index pts were referred to FCCC for cascade testing due to a known MSH6 PV in the family. Of the remaining 29 index pts, ascertainment included: 14% w/positive universal LS tumor screening, 21% w/early-onset or synchronous LS CA, 14% w/multi-gene panel for PHx of OC, 10% w/incidental MSH6+ result (2 had testing for PHx breast CA, 1 tumor genomic profiling), and 28% w/PHx and/or FHx of LS CA warranting genetic testing. Age of CA onset and path data were verified in $>$ 90% index pts. **Results:** Index pts had a mean age of 55.5 yrs, and 77% were female. Overall, 11% (5/44) of MSH6+ index pts were found to have LS at diagnosis of synchronous primary CAs (3 EC/OC, 1 CRC/CRC, 1 CRC/EC), and 4/5 of these occurred $<$50 yrs. An additional 20% (9/44) index pts reported PHx of $>$2 metachronous LS CAs. OC was the presenting CA in 14% (6/44) female index pts; 2 additional index pts had rarer OC variants (Mullerian duct @ 41, primary peritoneal CA @ 50). Skin manifestations of LS were documented in 9.1% (4/44) index pts (3 sebaceous, 1 SCC in-situ/Bowen's disease); 1 other family had documented sebaceous CAs in an FDR (father) but the 2 daughters seen @FCCC (both 30s) had yet to develop skin lesions. 2 index pts were found to have LS after developing early-onset breast CA (age 39) and contralateral breast CA (ages 50 and 54). Finally, 7% (3/44) index pts had a PHx of sarcoma: 2 were liposarcomas (ages 57 and 67), and 1 was a dermatofibrosarcoma. 2 other index pts had siblings w/childhood sarcomas. **Conclusions:** Our data, encompassing 44 MSH6+ pts evaluated in our clinic and consecutively ascertained, suggest MSH6 PV carriers develop synchronous primaries (11%), common and rare OC histologic types (18%), sarcomas (7%) and skin disease/Muir-Torre (9%). While common in the population and lower penetrance for CRC, MSH6 PV can behave in uncommon ways and may have significant extra-colonic CA risks such as OC, sarcoma and skin manifestations. Identification and characterization of de novo TP53 mutation carriers in Li-Fraumeni syndrome families: A single institution experience. *First Author: Carlos Christian Vera Recio, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Li-Fraumeni syndrome (LFS) is an inherited cancer syndrome mainly caused by a deleterious mutation in TP53. An estimated 48% of LFS patients present due to a deleterious de novo mutation (DNM) in TP53. The knowledge of DNM status, DNM or familial mutation (FM), of an LFS patient requires genetic testing of both parents which is often inaccessible, making de novo LFS patients an understudied population. Famdenovo.TP53 is a Mendelian Risk prediction model used to predict DNM status of TP53 mutation carriers based on the cancer-family history and several input genetic parameters, including disease-gene penetrance. The good predictive performance of Famdenovo.TP53 was demonstrated using data collected from four historical US cohorts. We hypothesize that by incorporating penetrance estimates that are specific for different types of cancers diagnosed in family members, we can develop a model with further improved calibration, accuracy and prediction. **Methods:** We present Famdenovo.CS, which uses cancer-specific penetrance estimates that were derived previously using a Bayesian semi-parametric competing risk model, to calculate the DNM probability. We use our model to analyze 101 families recently collected from the Clinical Cancer Genetic program at MD Anderson Cancer Center (CCG-TP53) that includes 20 families with known DNM status and 81 families with unknown DNM status. We used the concordance index (AUC), observed:expected ratios (OE) and Brier score (BS) to measure our model's discrimination, calibration and accuracy, respectively. We estimate the proportion of probands that present a DNM and compare DNM to FM carriers in several areas including: cancer types diagnosed, age at diagnosis, number of primary cancers diagnosed, sex, amino acid change caused by mutation in TP53. **Results:** Famdenovo.CS showed equally good discrimination and calibration performance to Famdenovo.TP53, while improving the overall accuracy, demonstrated by a decrease in the Brier score of -0.09 (95% CI: [-0.02, -0.19]). Of the 101 probands in the CCG-TP53 cohort, we predict 39 to be DNMs and 62 to be FMs. The cancer types and ages of diagnosis observed in FMs and DNMs are similarly distributed. **Conclusions:** Famdenovo.CS shows improved model accuracy in the CCG cohort. DNMs in TP53 are a prevalent cause of LFS and we did not find differences in the clinical characteristics of DNM and FM carriers. Our model allows for a systematic identification and characterization of TP53 DNM carriers. Research Sponsor: U.S. National Institutes of Health, Cancer Prevention and Research Institute of Texas.

Differential effects of the 2015 American Cancer Society guidelines on screening mammography exams based on socioeconomic status. *First Author: Kathleen M. Capaccione, Department of Radiology, Columbia University Irving Medical Center, New York, NY*

Background: Guidelines for screening mammography have changed several times since initiation of regular screening mammography in the 1970's. Most recently, in 2015, the American Cancer Society (ACS) revised their screening guidelines, recommending that a patient discuss screening mammography with her primary care doctor (PCP) between the ages of 40-44 and should begin yearly screening at age 45; after age 54, ACS recommended screening every other year. Prior to this, from 2003-2015, ACS had recommended screening mammography every year beginning at the age of 40. We hypothesized that these guidelines were adopted to varying degrees in different patient populations and may have disproportionately reduced screening mammography utilization in socioeconomically disadvantaged populations. **Methods:** Here, we analyzed monthly screening mammography rates over time in two large New York City hospitals, one in a socioeconomically advantaged area and the other in a socioeconomically disadvantaged area. Using our radiology records query system, we searched for monthly screening mammography numbers for women by decade from 2012 to 2018. We performed statistical analysis to evaluate changes in number of exams over time. Student's t-tests were used to evaluate for significant differences. **Results:** In both groups of 40-49 year old patients, monthly mammograms increased from 2012-2016. In the socioeconomically advantaged group, this increase continued until 2018 resulting in an overall 400% increase in screening mammograms over time. The change in ACS screening guidelines had no effect on the rate of screening mammography in this group. Conversely, after the revision of the ACS guidelines in 2015, there was a marked decline in screening mammography in the 40-49 year old group in the socioeconomically disadvantaged population. By 2018, there was a statistically significant difference in women screened in all age groups (40-49, $p<.0001$; 50-59, $p<.0001$; 60-69, $p<.01$; 70-79, $p<.0001$; 80+, $p<.0001$) between these two patient populations. **Conclusions:** These data suggest that implementation of the 2015 ACS screening guidelines had a disproportionate effect on patients from socioeconomically disadvantaged areas and that these effects have led to significant disparities in screening mammography trends over time. We postulate that lower levels of health literacy may have contributed to misunderstanding of the screening guidelines. More research is needed to elucidate the underlying etiology of these disparities and ensure that women from all socioeconomic backgrounds receive appropriate screening mammography. Over time, this may result in disproportionate breast cancer morbidity and mortality in populations not receiving appropriate screening. Research Sponsor: None.

Community-based lung cancer screening adherence to Lung-RADS recommendations. *First Author: Roger Y. Kim, University of Pennsylvania, Philadelphia, PA*

Background: In the NLST and NELSON trials, most low-dose CT (LDCT) screen-detected lung cancers were not diagnosed during the first round of screening, suggesting that longitudinal adherence to lung cancer screening (LCS) recommendations is key. Adherence was as high as 95% in clinical trials, but limited data exist regarding LCS adherence in clinical practice. We aimed to determine adherence to Lung-RADS recommendations among community-based patients undergoing LCS. **Methods:** We performed a multicenter retrospective cohort study of patients screened for lung cancer at healthcare systems within the Lung Population-based Research to Optimize the Screening Process (PROSPR) Consortium. We included 55-80 year-old current or former smokers who received a baseline (T0) LDCT with a Lung-RADS score between January 1, 2015 and September 30, 2017 and excluded patients who were diagnosed with lung cancer prior to the T0 scan. Over a 24-month period, we calculated the proportion of patients adherent to Lung-RADS recommendations and evaluated associations with patient-level (age, sex, race, ethnicity, smoking status, body mass index, Elixhauser comorbidities, year of T0 scan, and Lung-RADS score) and census tract (median family income, level of education) data, using multivariable logistic regression with mixed effects to account for site variability. **Results:** Of the 6,723 patients in our cohort (median age 65 years [IQR 60-69]; 45.1% female; 73.0% white; 59.0% current smokers), 5,583 (83.0%) had Lung-RADS 1 or 2 T0 scans, 733 (10.9%) Lung-RADS 3, 274 (4.1%) Lung-RADS 4A, and 133 (2.0%) Lung-RADS 4B or 4X. Overall, 55.2% (3,709/6,723) of patients were adherent (Table). In the final multivariable model, Black patients had reduced adherence compared to white patients (adjusted odds ratio [aOR] 0.79, 95% CI 0.66-0.94), while greater adherence was observed in former smokers compared to current smokers (aOR 1.33, 95% 1.19-1.49). Compared to individuals with a negative T0 scan (Lung-RADS 1 or 2), those with Lung-RADS 3 (aOR 1.56, 95% CI 1.31-1.86), 4A (aOR 1.63, 95% CI 1.24-2.15), or 4B/4X (aOR 3.59, 95% CI 2.30-5.60) T0 scans had greater odds of adherence. **Conclusions:** In the largest study of real-world patients receiving LCS to date, adherence to Lung-RADS recommendations is lower than previously observed in clinical trials. Our results highlight the need for further study of system-level mechanisms to improve longitudinal LCS adherence rates. Research Sponsor: U.S. National Institutes of Health.

Lung-RADS Score	Lung-RADS Recommendation	Definition of Adherence	Adherence, %
1	12 month LDCT	9-15 month LDCT or CT chest	52.5% (2,931/5,583)
2			
3	6 month LDCT	3-9 month LDCT or CT chest	67.1% (492/733)
4A	3 month LDCT or PET/CT	2-6 month LDCT, CT chest, or PET/CT	66.4% (182/274)
4B	Chest CT, PET/CT, and/or	<3 month LDCT, CT chest, PET/CT, or procedure (bronchoscopy,	78.2% (104/133)

Global tissue stiffness on breast MR elastography: High-risk dense breast patients have higher stiffness compared to average-risk dense breast patients. *First Author: Bhavika K. Patel, Mayo Clinic, Phoenix, AZ*

Background: Biomechanical tissue properties may vary in the breasts of patients at elevated risk for breast cancer. We aim to quantify *in vivo* biomechanical tissue properties in various breast densities and in both normal risk and high risk women using Magnetic Resonance Imaging (MRI)/MRE and examine the association of biomechanical properties of the breast with cancer risk. **Methods:** In this IRB–approved prospective single-institution study, we recruited two groups of women differing by breast cancer risk to undergo a 3.0 T dynamic contrast enhanced MRI/MRE of the breast. Low-average risk women were defined as having no personal or significant family history of breast cancer, no prior high risk breast biopsies and a negative mammography within 12 months. High-risk breast cancer patients were recruited from those patients who underwent standard of care breast MR. Within each breast density group (non-dense versus dense), two-sample *t*-tests were used to compare breast stiffness, elasticity, and viscosity across risk groups (low-average vs high). **Results:** There were 50 low-average risk and 86 high-risk patients recruited to the study. The risk groups were similar on age (mean age = 55.6 and 53.6 years), density (68% vs. 64% dense breasts) and menopausal status (66.0% vs. 69.8%). Among patients with dense breasts, mean stiffness, elasticity, and viscosity were significantly higher in high risk patients ($N = 55$) compared to low-average risk patients ($N = 34$; all $p < 0.001$). In the multivariate logistic regression model, breast stiffness remained a significant predictor of risk status (OR=4.26, 95% CI [1.96, 9.25]) even after controlling for breast density, MRI BPE, age, and menopausal status. Similar results were seen for breast elasticity (OR=4.88, 95% CI [2.08, 11.43]) and viscosity (OR=11.49, 95% CI [1.15, 114.89]). **Conclusions:** Structurally-based, quantitative biomarker of tissue stiffness obtained from global 3D breast MRE is associated with differences in breast cancer risk in dense breasts. As such, tissue stiffness could provide a novel prognostic marker to help identify the subset of high-risk women with dense breasts who would benefit from increased surveillance. Risk factors for early-onset colorectal cancer in China. *First Author: Zhe Pan, Department of Gastrointestinal Surgery, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China*

Background: The incidence of colorectal cancer among persons aged < 50 years (early-onset colorectal cancer, EOCRC) has increased since the early 1990s. However, the risk factors contributing to this trend remain largely unknown. **Methods:** We conducted a retrospective study of participants who were aged < 50 years and without a previous cancer history, using the China Kadoorie Biobank cohort study. We analyzed data related to demographics, lifestyle habits, family history, and comorbidities of EOCRC cases with participants without colorectal cancer in this age group (controls). Univariate and multivariate-adjusted cox regression models were used to estimate the associations with risk factors. **Results:** We identified 225 EOCRC cases and 88842 controls that include the final analyses. Of the 225 EOCRC patients, 105 (46.7%) were colon cancers and 120 (53.3%) were rectum cancers. EOCRC cases were older, have more intake of fish and eggs, have higher BMIs, diabetes, and family history of cancer compared with controls ($P < 0.05$). After adjustment for potential confounding factors, increasing age (HR 2.18, 95%CI 2.05-2.31), BMI (HR 1.06, 95%CI 1.01-1.11), family history of cancer (HR 1.41, 95%CI 1.00-1.98), and more intake of fish (HR 1.54, 95%CI 1.09-2.19) were significantly associated with a higher risk of EOCRC. In sensitivity analyses stratified by cancer site (colon and rectum), the results remained consistent. **Conclusions:** Based on the large Chinese cohort study, we found increasing age, higher BMI or obesity, family history of cancer, and more intake of fish were independent risk factors for EOCRC. Further studies are needed to identify factors that cause the increasing incidence of EOCRC in China and other countries, and explore the potential mechanism behind. Analysis of breast cancer screening results in urban areas of Henan Province. *First Author: Guo Lan-Wei, The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China*

Background: Breast cancer is the most common female cancer in China. Reasonable and effective screening is an important means to reduce the mortality of breast cancer. This study was to evaluate the compliance and efficacy of breast cancer screening in urban areas of Henan province from 2013 to 2019. **Methods:** A cluster sampling method was used to select the residents of 40-74 years old in Henan province to investigate the risk factors and breast cancer risk assessment. For subjects with high risk of breast cancer, those aged 40-44 conduct breast ultrasound examination; those aged over 45 conduct breast ultrasound combined with mammography examination. BI-RADs classification was used as the evaluation standard in both examinations. BI-RADS 3 class was defined as suspicious and BI-RADS≥4 class was defined as positive. Chi-square test was used to analyze the compliance rate and breast cancer detection rate among different groups. **Results:** A total of 29 111 residents at high risk for breast cancer were recruited in this study. They were 55.03 ± 7.91 years old, of which 13 760 took the following breast ultrasound or mammography examination, yielding a participation rate of 47.27% (13 760/29 111). The detection rates of suspected positive patients, positive patients and breast cancer patients were 23.40% (3 220/13 760), 2.55% (351/13 760) and 0.30% (41/13 760), respectively. Among the screening population, the highest detection rate of suspected positive patients was found in the 45-49 age group [27.79% (935/3 365)], the highest detection rate of positive patients was found in the 50-54 age group [2.98% (97/3 257)], and the highest detection rate of breast cancer was found in the 65-69 age group [0.49% (5/1 012)]. The detection rate of breast cancer positive patients by breast ultrasound combined with mammography examination was 2.95% (316/10 728), which was significantly higher than that of breast ultrasound alone [1.99% (213/10 728)] or mammography examination alone [1.25% (134/10 728)]. **Conclusions:** Breast ultrasound combined with mammography examination as a means of screening for breast cancer can significantly increase the detection rate of breast cancer positive patients. The next step should be to improve the compliance of the population, as well as the organization's implementation and service capabilities of the screening provider, to improve screening effectiveness. An ultrasensitive method for noninvasive pan-cancer early detection based on targeted methylation sequencing of cell-free DNA. *First Author: Tiancheng Han, Genecast Precision Medicine Technology Institute, Beijing, China*

Background: Screening the biomarkers from the cell-free DNA (cfDNA) of peripheral blood is a non-invasive and promising method for cancer diagnosis. Among diverse types of biomarkers, epigenetic biomarkers have been reported to be one of the most promising ones. Epigenetic modifications are widespread on the human genome and generally have strong signals due to the similar methylation patterns shared by adjacent CpG sites. Although some epigenetic diagnostic methods have been developed based on cfDNAs, few of them could be applied to pan-cancer and their sensitivities are barely satisfactory for early cancer detection. **Methods:** Targeted methylation sequencing was performed using our in-house-designed panel targeting regions with abundant cancer-specific methylation CpGs. The cfDNA samples from 80 healthy individuals and 549 cancer patients of 14 cancer types were separately sequenced. The dataset was randomly split into one discovery dataset and one validation dataset. Moreover, cfDNA samples from four cancer patients were diluted with the healthy cfDNAs to generate 12 *in vitro* simulated samples with low circulating tumor DNA (ctDNA) fraction. Additionally, DNAs extracted from 130 unmatched tumor formalin fixation and paraffin embedding (FFPE) samples of 10 cancer types were sequenced to screen the diagnostic biomarkers. Adjacent CpG sites were first merged into methylation-correlated blocks (MCB) according to their correlations of methylation levels in tumor DNAs. The MCBs with higher methylation levels in tumor DNAs than that of healthy cfDNAs (from the discovery dataset) were defined as our hypermethylation biomarkers. For each cfDNA sample, a hypermethylation score (HM-score) was computed to measure the overall methylation level difference of selected biomarkers. The performance of our method was evaluated with the real-world dataset, while the limit of detection was estimated using the simulated low-ctDNA samples. **Results:** Our model based on 37 hypermethylation MCB biomarkers achieved an area under the curve (AUC) of 0.89 and 0.86 in the real-world pan-cancer discovery and validation cfDNA datasets, respectively. Furthermore, the overall specificity and sensitivity are 100% and 76.19% in the discovery dataset, and 96.67% and 72.86% in the validation dataset. In the validation dataset, 28/40 (70%) of early-stage colorectal cancer patients and 10/20 (50%) of non-small-cell lung cancer patients were successfully diagnosed. Additionally, all the simulated samples with theoretical ctDNA factions over 0.5% were predicted as diseased, demonstrating the ability of our method to detect tumor signals at early stages. **Conclusions:** Our cfDNA-based epigenetic method outperforms currently available methods in various cancer types, and is promising to be applied to early-stage cancer detection and samples with low ctDNA fractions. Impact of the sessile serrated polyp pathway on predicted colorectal cancer outcomes in the CRC-AIM model. *First Author: John B. Kisiel, Mayo Clinic, Rochester, MN*

Background: Approximately 20–30% of colorectal cancers (CRC) arise from the serrated polyp pathway. The multitarget stool DNA (mt-sDNA) test has greater sensitivity to detect sessile serrated polyps (SSPs) than a leading fecal immunochemical test (FIT). However, most modeling analyses do not account for the contribution of the SSP pathway to risk of CRC. We used the CRC-AIM model to assess the impact of the SSP pathway on predicted CRC outcomes with mt-sDNA or FIT screening. **Methods:** A simulated cohort of average-risk US patients underwent triennial mt-sDNA or annual FIT screening from ages 50–75. The percentage of CRCs arising from the SSP pathway were modeled at 0% (base case), 20%, and 30%, with stool screening adherence based on theoretical (100%) or previously reported (mt-sDNA 71%; FIT 43%) rates. Published SSP sensitivities for mt-sDNA and FIT were used. All other model inputs were identical to CISNET models. Sensitivity analyses used screening adherence rates of 40–70%. Key outcomes were life-years gained (LYG), CRC incidence and CRC mortality per 1000 patients. **Results:** Including SSPs in the model demonstrated a greater loss of LYG with FIT than mt-sDNA (Table). At 100% adherence, compared with base case, modeling 20% or 30% SSP pathway CRCs resulted in a decrease of 9–15 LYG with FIT and 2–4 LYG with mt-sDNA, a decrease in CRC incidence reduction of 3.9–6.1% with FIT and 0.7–1.1% with mt-sDNA, and a decrease in CRC mortality reduction of 2.6–4.0% with FIT and 0.4–0.8% with mt-sDNA. Using previously reported adherence, compared with base case, modeling 20% or 30% SSP pathway CRCs resulted in a decrease of 13–20 LYG with FIT and 2–5 LYG with mt-sDNA, a decrease in CRC incidence reduction of 4.4–6.9% with FIT and 0.6–1.1% with mt-sDNA, and a decrease in CRC mortality reduction of 3.5–5.4% with FIT and 0.4–0.9% with mt-sDNA. Assuming reported adherence and 30% SSP pathway CRCs, mt-sDNA had 48 more LYG, 14.6% greater CRC incidence reduction, and 12.4% greater CRC mortality reduction than FIT. Assuming 30% SSP pathway CRCs, outcomes favored mt-sDNA vs FIT even after modeling equivalent adherence rates ranging from 40–70%. **Conclusions:** After incorporating the SSP pathway into the model, outcomes with mt-sDNA neared those of FIT at 100% screening adherence rates and surpassed FIT at more realistic reported screening adherence rates. Research Sponsor: Exact Sciences Corporation.

CRC outcomes for triennial mt-sDNA and annual FIT after assuming 0%, 20%, or 30% SSP pathway CRCs and assuming either 100% or reported screening adherence rates.

Contribution of family history of melanoma to associated risk factors: Analysis of an Internet-based risk assessment tool. *First Author: Ryan M O'Keefe, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Risk factors for melanoma (ML) include UV exposure, sunburns, multiple nevi, and fair skin. Smoking and alcohol use may also play a role. Demographics associated with increased UV exposure include male gender, white race, age 18-29, and high-income. Those with family history (FH) of ML have increased risk of developing ML themselves yet are often unaware or do not engage in preventive behaviors. We sought to understand the association between FH of ML and other personal risk factors for cancer. **Methods:** Since 2009, voluntary participants could receive personalized information regarding their cancer risk via the OncoLink.org *Reduce My Risk* tool. Survey data was collected on demographics, FH, risk-factors, and risk-associated behaviors. Use of data was IRB approved. Differences between respondents with v. without FH of ML were analyzed using chi-square test and adjusted via logistic regression. **Results:** 25255 responses were analyzed; 1928 (7.6%) had FH of ML. Of these, median age was 26 (range 18-75), 73.1% were female, 88.6% from North America, 91.4% White, 78.2% had at least some college, and 62.0% household income > $45,000. Comparing those with FH of ML to those without, no significant differences were observed in education, income, or home setting. Those with a FH of ML were less likely to be "light" smokers (< 1 pack per day) but were more likely to be both "light" drinkers and "heavy" drinkers (Table). There were no significant differences in BMI or exercise habits. Those with FH of ML were more likely to sunbathe, to have had "blistering" sunburns, have 50+ moles, show signs of sun damage on their skin, and have dysplastic nevi (Table). There were no differences in use of indoor tanning beds (Table). **Conclusions:** Those with a FH of ML were more likely to sunbathe and to report skin damage and history of blistering sunburns; they were more likely to use tanning beds, though not statistically significant. These behaviors are modifiable and may suggest parental influence on sun-protective behaviors. Those with FH also reported increased non-modifiable risks. Future work should continue to explore targeted intervention for those with a FH of ML to educate on risk and promote sun-protective behaviors. Research Sponsor: OncoLink - Hospital of the University of Pennsylvania.

Red blood cell folate, high-risk human papillomavirus risk and cervical intraepithelial neoplasia development: A large Chinese community-based cohort study of cervical screening. *First Author: Wei Wang, The Second Hospital of Shanxi Medical University, Taiyuan, China*

Background: Although low folate status has been implicated in cervical carcinogenesis, large-scale population-based prospective cohort studies controlling for high-risk types of human papillomavirus (hrHPV) infection are lacking. The aim of this study is to evaluate the associations of red blood cell (RBC) folate, hrHPV infection risk and cervical intraepithelial neoplasia (CIN) development. **Methods:** In this prospective, population-based cohort study, we analyzed the cross-sectional data of 2304 women from a large cervical cancer screening program of 40,000 women aged 19-65 years in the Chinese rural area from 2014-2015. We conducted a nested case-control study including 35 CIN1 progression cases and 105 CIN1 regression controls. A logistic regression model was used to evaluate the associations of RBC folate and hrHPV infection risk and CIN1 development. **Results:** The median RBC folate concentration decreased gradually with cervical lesion severity. The risks of CIN 1 and CIN2 or worse (CIN 2+) in the 1st quartile of RBC folate concentration were significantly higher than those in the 4th quartile (Odds Ratio [OR], 2.27; 95% confidence interval [CI], 1.71-3.01 and OR, 2.33; 95% CI,1.52-3.56; respectively). We did not observe a significant relationship between hrHPV infection and CIN1 risk in the unadjusted and adjusted models, however, a statistically significant association was observed for CIN2+. Interestingly, RBC folate concentration was not associated with hrHPV infection among women with CIN1 or CIN2+. After full adjustment for potential confounders, a highly significant inverse linear relation between RBC folate concentration and CIN2+ was observed (P-overall < 0.001, P-nonlinearity $= 0.969$). We further observed a positive additive interaction between RBC folate concentration and hrHPV infection on the risk of CIN2+ (P-interaction < 0.01). Moreover, during the 21-month follow-up, CIN1 progression risk was significantly higher in the lowest RBC folate quartile (1st quartile compared with 4th quartile: OR, 3.86; 95% CI,1.01-14.76). **Conclusions:** Our findings indicates that RBC folate is inversely associated with the risk of higher-grade CIN and CIN1 progression in the Chinese rural population, either with or without hrHPV infection. Therefore, improving folate status has the potential to prevent higher-grade CIN and cervical cancer among women in the areas without mandatory folic acid food fortification. Clinical trial information: ChiCTR-ROC-15006479. Research Sponsor: This project was supported by the Special Public Welfare Industry Research of National Health and Family Planning Commission of China (grant number: 201402010).

Risk-reducing salpingo-oophorectomy and breast cancer incidence among BRCA-mutation carriers. *First Author: Tamar Perri, Gynecologic Oncology Department, Sheba Medical Center, Ramat Gan, Israel*

Background: Uncertainty exists with regard to the role of bilateral salpingo-oophorectomy in altering the risk of breast cancer in BRCA-mutation carriers. **Methods:** Included were 1645 healthy Jewish Israeli BRCA1/2 -mutation carriers from a single center without prophylactic mastectomy. Carriers with and without risk-reducing bilateral salpingo-oophorectomy (RRBSO) were matched according to BRCA-mutation type (BRCA1 vs. BRCA2) and year of birth (±1 year). Hormonal and reproductive variables were compared and incidence of breast cancer recorded. Association between RRBSO and breast cancer was studied. **Results:** Seventy-seven and 50 matched-pairs had BRCA1 and BRCA2 mutation respectively. Fifty-two carriers had breast cancer, 21 in RRBSO-group and 31 in no- RRBSO group, with no statistically significant difference. When analysing each mutation group separately, stratified by age at surgery, no association between RRBSO and breast cancer incidence was found among BRCA1-mutation carriers. However, in BRCA2 mutation carriers, RRBSO was associated with a statistically significant decreased overall incidence of breast cancer, HR = 0.2 (confidence interval 0.44-0.913, p = 0.038). Breast cancer incidence was lower after 5, 10,15 and 20 years in BRCA2-mutation carriers with RRBSO compared to no-RRBSO. Age at menarche, age at surgery, parity and oral contraceptive use were not significant risk factors for breast cancer. Hormone replacement therapy was used by 62 mutation carriers, 52 in the RRBSO group and 10 in the no-RRBSO group, and its use did not alter breast cancer risk (p = 0.463). **Conclusions:** According to our findings, RRBSO is associated with a reduced risk of breast cancer only in BRCA2 mutation carriers, regardless of HRT use. Research Sponsor: None.

Attention to diet, exercise, and weight in the oncology clinic: Results of a national patient survey. *First Author: Jennifer A. Ligibel, Dana-Farber Cancer Institute, Boston, MA*

Background: Obesity and related factors are increasingly associated with increased risk of developing and dying from cancer. The American Society of Clinical Oncology (ASCO) conducted a survey of cancer patients to assess their experience in receiving recommendations and referrals related to weight, diet and exercise as a part of their cancer care. **Methods:** An online survey was distributed to potential participants between March and June 2020 via ASCO channels and patient advocacy organizations, with an estimated reach of over 25,000 individuals. Eligibility criteria included being 18 years, living in the US, and having been diagnosed with cancer. Logistic regression was used to determine factors associated with recommendation and referral patterns. **Results:** In total, 2419 individuals responded to the survey. Most respondents were female (75.5%), 61.8% had an early-stage malignancy, 38.2% had advanced disease, and 49.0% were currently receiving treatment. Breast cancer was the most common cancer type (36.0%). Average BMI was 25.8 kg/m^2. The majority of respondents consumed £2 servings of fruits and vegetables per day (50.9%) and exercised £2 times per week (50.4%). Exercise was addressed at most or some oncology visits in 57.5% of respondents, diet in 50.7%, and weight in 28.4%. Referrals were less common: 14.9% of respondents were referred to an exercise program, 25.6% to a dietitian and 4.5% to a weight management program. In multiple regression analyses, racial and ethnicity minority respondents were more likely to receive advice about diet (Odds Ratio [OR] 1.92, 95% CI 1.56-2.38) and weight (OR 1.64, 95% CI 1.23-2.17) compared to non-Hispanic whites, individuals diagnosed with cancer in the past 5 yrs (vs $>$ 5 yrs) were more likely to receive advice about exercise (OR 1.48, 95% CI 1.23-1.79), and breast cancer patients were more likely to receive advice about exercise (OR 1.37, 95% CI 1.11-1.68) and weight (OR 1.46, 95% CI 1.03-2.07) than other cancer patients. Overall, 74% of survey respondents had changed their diet or exercise after cancer diagnosis. Respondents reporting that their oncologist spoke to them about increasing exercise or eating healthier foods were more likely to report a change in behavior than those whose oncologists did not (exercise: 79.6% vs 69.0%, $P < 0.001$; diet 81.1% vs 71.4%, $P < 0.001$). Respondents whose oncologist had spoken to them about exercise were more likely to exercise $>$ 2 times per week compared to respondents whose oncologists did not address exercise (53.5% vs 44.1%, $P < 0.001$). **Conclusions:** In a national survey of oncology patients, slightly more than half of respondents reported attention to diet and exercise during oncology visits. Provider recommendations for diet and exercise were associated with positive changes in these behaviors. Additional attention to diet and exercise as part of oncology visits is needed to help support healthy lifestyle change in cancer patients. Research Sponsor: None.

Reductions in cancer screening: The consequence of changes in routine care during the COVID-19 pandemic. *First Author: Ashley Kim, GRAIL, Inc., Menlo Park, CA*

Background: The COVID-19 pandemic imposes significant impact on daily activities with regard to public health orders and individual responses to the pandemic. Much of the direct or indirect impact is potentially in reductions in healthcare encounters for services such as preventive care. Here, we quantified changes in cancer screening rates to better understand the impact of the evolving COVID-19 implications and shifts in health-seeking behaviors. **Methods:** We conducted a retrospective analysis of cancer screening rates during March-June 2019 (pre-COVID-19) and March-June 2020 (post-COVID-19 restrictions), using Optum's de-identified Clinformatics Data Mart Database which includes Medicare and commercially insured members. Members meeting age and/or sex criteria as detailed in the United States Preventive Services Task Force recommendations for breast, colorectal, lung, prostate, and cervical cancer screening represented the eligible membership for screening. Procedure and laboratory services were used to identify those who received cancer screening. Analyses were conducted cross-sectionally by cancer screening type. **Results:** Eligible cohorts were identified from insured members within March-June 2019 and 2020 (2019: 17,931,318; 2020: 17,521,411). The percent of eligible members screened in March-June 2019 was 19.3%, 9.4%, 16.7%, 0.4%, and 7.8% for breast, cervical, prostate, lung, and colorectal cancer, respectively. Changes in screening rates from 2019 to 2020 are summarized in Table, with the sharpest decline in April. The percent change from 2019 to 2020 during the combined March-June period for each cancer screening type was statistically significant ($p<0.0001$). **Conclusions:** Routine cancer screening rates from March-June 2020 showed meaningful reductions when compared to the same period in 2019, with substantial declines during the initial peak of the pandemic in April. These declines may be impacted by variations in regional restrictions with tighter restrictions leading to larger screening declines and loosening restrictions reflecting catch-up screening. Efforts to promote cancer screening in a safe and timely manner are crucial given individual risk factors, to reduce later stage cancer diagnoses and improve clinical outcomes. Research Sponsor: GRAIL, Inc.

Percent change in eligible members screened for cancer (March-June 2019/2020).

	Breast	Cervical	Prostate	Lung	Colorectal
Population Included	Females aged 50-74 years, no history of breast cancer	Females aged 21-65 years, no history of cervical cancer	Males aged 55-69 years, no history of prostate cancer	Males and Females aged 55-80 years, no history of lung cancer	Males and Females aged 50-75 years, no history of colorectal cancer
March-June	-42.8%	-42.8%	-28.7%	-31.5%	-42.3%
March	-34.5%	-35.3%	-24.8%	-14.6%	-29.2%

Trends in cancer screening volumes at an urban health center during the COVID-19 pandemic. *First Author: Mahir Khan, University of Illinois at Chicago, Chicago, IL*

Background: The Coronavirus-19 (COVID-19) pandemic has disrupted cancer screening for reasons including healthcare resource preservation, infection control efforts, and patient factors. There is limited literature quantifying this interruption of care, particularly in vulnerable and racial/ethnic minorities. **Methods:** We compared the volume of cancer screening at the University of Illinois Hospital & Health Sciences System before and during the COVID-19 pandemic using data obtained from the electronic medical record. Modalities included mammogram, ultrasound, and MRI for breast; Pap test for cervical; colonoscopy, CT colonography, and flexible sigmoidoscopy for colorectal; low-dose CT for lung; and prostate-specific antigen test for prostate. Of note, screening and diagnostic tests could not be distinguished for colorectal cancer. We examined percent changes in cancer screening counts for each month from February 2020-August 2020, using January 2020 as a reference. Results were stratified by gender, race, and ethnicity. **Results:** Screening volume declined rapidly after January 2020, with the nadir for each cancer site occurring in April 2020: breast (n = 0, -100%), cervical (n = 169, -84%), colorectal (n = 35, -89%), lung (n = 0, -100%), and prostate (n = 108, -72%). Values recovered by August 2020 for most cancer sites except cervical cancer, which remained decreased (-23%). There were no differences in screening trends by gender. With respect to race, breast screening volume in Black patients decreased earlier and exhibited slower recovery compared to White patients. White patients had poorer cervical screening recovery than Black patients by August 2020 (-60% vs. -23%). Hispanics had poorer recovery of breast screening compared to non-Hispanics by August 2020 (-23% vs. 6%). **Conclusions:** We observed widely decreased cancer screening attributable to COVID-19. Breast cancer screening data specifically showed persistent disparities affecting Black and Hispanic patients. Despite the reassuring recovery of multiple screening methods by August 2020, an increase above baseline is needed to compensate for initial declines. Further studies will likely reveal long-term consequences of this unprecedented situation. Research Sponsor: None.

Efficacy of HPV vaccination among seropositive, DNA negative cohorts. *First Author: Colm Mac Eochagain, St James' Hospital, Dublin, Ireland*

Background: Prophylactic HPV vaccination of naïve cohorts is known to be highly effective in the prevention of incident HPV infection and HPV-associated cervical premalignancy. Conversely, vaccination of women with active (DNA+) HPV infections has been demonstrated to be ineffective. Vaccine efficacy among previously exposed, but currently uninfected women, i.e. those who have serological evidence of a prior HPV infection without corresponding detectable HPV DNA, remains incompletely defined. This meta-analysis assessed the serotype-specific efficacy of prophylactic HPV vaccination against HPV16/18 persistent infection (PI) and cervical intraepithelial neoplasia (CIN) among seropositive, DNA negative (SPDN) women enrolled to RCTs of HPV L1-based vaccines. **Methods:** The study protocol was prospectively registered on PROSPERO (CRD42020206888). Searches were conducted on 08/16/20 on MEDLINE, EMBASE, SCOPUS and CENTRAL. RCTs of L1-based prophylactic bivalent or quadrivalent HPV vaccines, reporting serotype-specific clinical efficacy endpoints in the HPV16/18 seropositive, DNA-negative populations were included. Two authors independently screened studies, extracted data and assessed for bias. Data for SPDN women were extracted from subgroup analyses within primary and secondary publications, publication supplements, and manufacturers' clinical study reports. Relative risks (RR) of 6-month persistent infection (6mPI), 12-month persistent infection (12mPI), CIN1+ and CIN2+ were pooled using a random-effects model. **Results:** A total of 1727 citations were reviewed. 8 studies, with a total of 9569 SPDN participants, met all eligibility criteria. The relative risk of 6mPI (RR: 0.22, 95% CI 0.08-0.61, p = 0.018), 12mPI (RR: 0.20, 95% CI 0.05-0.80, p = 0.035), CIN1+ (RR:0.13, 95% CI 0.05-0.30, p = 0.003) and CIN2+ (RR: 0.15, 95% CI 0.04-0.59, p = 0.022) was significantly reduced in the vaccinated compared to the unvaccinated group. The number needed to vaccinate (NNV) to prevent one case of CIN1+ and CIN2+ was 152 and 208 respectively. **Conclusions:** Our findings suggest high serotype-specific efficacy for HPV vaccination among cohorts of women with evidence of prior HPV 16/18 infections. Women without DNA evidence of active infection may be seronegative, implying naïve status and $>$ 99% efficacy; or seropositive, implying SPDN status and 87% efficacy against CIN1+ for HPV 16/18. Women without DNA evidence of HPV 16/18 infection should be offered prophylactic HPV vaccination regardless of prior exposure history. Research Sponsor: None.

Sociodemographics, lifestyle determinants, and viral infections in patients with head and neck cancer undergoing radiotherapy in Taiwan: A prospective cohort study. *First Author: Kevin Sheng-Kai Ma, Department of Life Science, National Taiwan University, Taipei City, Taiwan*

Background: Human papillomavirus (HPV) screening has been implemented to monitor both cervical cancer and head and neck cancer. In this prospective cohort study, we determined sociodemographic, behavioral, and infectious etiology for head and neck squamous cell carcinoma (HNSCC) in Taiwan using data collected from an anonymous sexually transmitted infections screening program. **Methods:** An anonymous sexually transmitted infections screening program was conducted at a medical center during 2016, in which sociodemographic characteristics including gender, age, marital status, education level, and occupation; medical history regarding underlying comorbidities and history of receiving HPV and other vaccines; lifestyle determinants including betel quid chewing, drug using, and sexual behaviors, were inquired. Blood, anal swab, and penile swab samples were collected to determine viral infections using polymerase chain reaction (PCR). With PCR, 37 HPV genotypes were detected. Regular follow-ups were made for patients enrolled in the screening program until end of 2020, during which all suspected malignancies were recorded upon referrals to oncologists. From this prospective cohort, odds ratios (ORs) of HNSCC for sociodemographic, lifestyle, and infectious variables were derived with logistic regression (R version 4.0.1). $P < 0.05$ was considered statistically significant. **Results:** A total of 376 patients were enrolled. Most patients were men (n = 372), with a median age of 27 years. There were 124 (32.98%) HPV-positive patients and 78 (20.74%) HIV-positive patients. Among HPV-positive patients, 20 (25.64%) were of high-risk genotypes. During the follow-up, 44 patients developed HNSCC and all received radiotherapy. Multivariate analysis revealed that patients who were single (OR = 1.43, 95% CI = 1.12-1.83, P = 0.01) or widowed (OR = 2.47, 95% CI = 1.88-3.25, $P < 0.001$) had higher risk of HNSCC than patients who were married. Patients aged 51-60 (OR = 2.93, 95% CI = 2.10-4.09, $P < 0.001$) and over 60 (OR = 1.89, 95% CI = 1.45-2.47, $P < 0.001$) presented higher risks of HNSCC, compared with those aged below 20. Patients addicted to betel quid chewing had high HNSCC risk (OR = 1.29, 95% CI = 1.11 – 1.50, $P < 0.001$). However, patients with HPV infections did not present with higher HNSCC risks (OR = 0.925, 95% CI = 0.852 – 1.003, P = 0.058). **Conclusions:** In this prospective cohort study, the elderly, unmarried patients, and patients addicted to betel quid chewing, presented with high HNSCC incidence. On the contrary, the association between HPV infection and HNSCC was insignificant. As both betel nut-chewing and HPV infection could be prevented, we advocate for comprehensive screening and patient education for HNSCC prevention. Research Sponsor: None.

One-stop-shop for cancer screening: A model for the future. *First Author: Ezra Bernstein, Integrated Cancer Prevention Center, Tel-Aviv Medical Center, Tel-Aviv, Israel*

Background: Cancer is the second leading cause of death globally. Early detection will often greatly reduce mortality for many cancers, increase treatment effectiveness, and improve the quality of life for cancer patients, and, by implementing evidence-based prevention strategies, 30–50% of cancers can be prevented. Screening for different cancer types separately is inefficient. A solution is the Integrated Cancer Prevention Center (ICPC), a program with specialists in each discipline who test for multiple cancers during one visit. **Methods:** This is a prospective cohort study of 17,104 self-referred, asymptomatic patients who visited the Integrative Cancer Prevention Center (ICPC) between January 1, 2006, and December 31, 2019. Clinical, laboratory, and epidemiological data were recorded by multiple specialists. Patients were given follow-up recommendations and diagnoses when appropriate. The primary measure was the detection and staging of new malignant lesions. Secondary measures included cost-benefit and mortality benefit. **Results:** We screened 8618 men and 8486 women with an average age of 47.11 ± 11.71 years. Of 259 cancers detected through the ICPC, 49 (18.9%) were stage 0, 115 (44.4%) were stage I, 31 (12%) were stage II, 25 (9.7%) were stage III, and 32 (12.4%) were stage IV. Seventeen cancers were missed, only six of which were within the scope of the ICPC, and 189 cancers developed > one year after the last visit to the ICPC. Compared to the stage of detection for cancers in the US, all cancers except for colon were detected at an earlier stage at the ICPC. Lung was the most significant with 86.7% of cancers detected at stage 0, I, or II at the ICPC compared to only 49.3% caught at those stages in the US. **Conclusions:** This is a proof of concept for a one-stop-shop approach to asymptomatic cancer screening in a multidisciplinary outpatient clinic. It offers evidence that this screening framework can and should be replicated in other healthcare settings and on a national policy level as it saves lives and money. The encouraging results presented here should further the conversation about the utility of screening and add momentum to the movement for increased screening. Research Sponsor: None.

Adverse consequences of the COVID-19 pandemic on breast cancer stage distribution and breast cancer disparities. *First Author: Genevieve A. Fasano, Weill Cornell Medicine/New York Presbyterian, New York, NY*

Background: The COVID-19 surge in March 2020 resulted in a hiatus placed on screening mammography programs in support of shelter-in-place mandates and diversion of medical resources to pandemic management. The COVID-related economic recession and ongoing social distancing policies continued to influence screening practices after the hiatus was lifted. We evaluated the effect of the hiatus on breast cancer stage distribution on the diverse patient population of a health care system in New York City, the first pandemic epicenter in the United States. **Methods:** Breast cancer patients diagnosed January 1, 2019 to December 31, 2020 were analyzed, with comparisons of stage distribution and mammography screen-detection for three intervals: Pre-Hiatus, During Hiatus (March 15, 2020 to June 15, 2020), and Post-Hiatus. Results were stratified by African American (AA), White American (WA), Asian (As) and Hispanic/Latina (Hisp) self-reported racial/ethnic identity. **Results:** A total of 894 patients were identified; of these, 549 WA, 100 AA, 104 As, and 93 Hisp comprised the final race/ethnicity-stratified study population. Overall, 588 patients were diagnosed Pre-Hiatus, 61 During-Hiatus, and 245 Post-Hiatus. Nearly two-thirds (65.5%) of the Pre-Hiatus cases were screen-detected versus 49.2% During-Hiatus and 54.7% Post-Hiatus (p = 0.002). Frequency of tumors diagnosed < 1 cm declined from 41.9% Pre-Hiatus to 31.7% Post-Hiatus (p = 0.035). WA patients were more likely to have screen-detected disease compared to AA in the Pre-Hiatus period (69.1% vs. 56.1%; p = 0.05) but non-significantly more likely to have screen-detected disease compared to As and Hisp patients (66.2% vs. 56.9%; p = 0.08). In the Post-Hiatus period, the frequency of screen-detected disease was highest among WA patients (63.0%) compared to all other racial/ethnic groups (AA; 48.1%, As-33.3%, and Hisp-40%; p = 0.007). Similar patterns were observed for frequency of tumors diagnosed ≤1cm Pre-Hiatus (WA-44.3% vs AA-26%, p = 0.02; and vs. As-41.3%, Hisp-48%; p = 0.09), and Post-Hiatus (WA-37.7% vs. AA-18.2%, As-30.8%, Hisp-23.5%; p = 0.25). **Conclusions:** The 3-month pandemic-related mammography screening hiatus resulted in a more advanced stage distribution for New York City breast cancer patients, and worsened pre-existing race/ethnicity-associated disparities, especially for AA pts. Impact of a sustainable breast and cervical cancer screening program in spite of COVID-19 pandemic: The AMPATH experience in Kenya. *First Author: Stephen Kiptoo, AMPATH Oncology, Eldoret, Kenya*

Background: Cancer is the third leading cause of death with about 48,000 new yearly diagnoses in Kenya. Breast and cervical cancers are the major leading cancers in females, both of which are curable with access to timely and effective care. To meet population health goals, early abnormalities of the cervix and breast must be treated promptly to maximize the chance for cure. The AMPATH Breast and Cervical Cancer Control Program (ABCCCP) was initiated to improve access to screening and diagnostic services for breast and cervical cancer in Kenya by addressing the barriers of cancer care through a population health approach, working with communities and the Ministry of Health in Kenya with a potential for scaling these efforts to other parts of the region. **Methods:** We performed an interim analysis 3 years into a 5-year program, to assess the impact of COVID-19 on our screening program. Statistical descriptive summaries were used to show the trend of screening using visual inspection with acetic acid and breast clinical examination. The screening was conducted facility-based along with community screening upon requests across nine counties. Also, we conducted capacity building through mentoring of health care providers and initiating a telemedicine program to improve patient care and management plans. **Results:** From 2018-2021, we conducted training, connected 12 centers with telemedicine capacity and screened a total of 100,973 persons were for breast and cervical cancer. The yearly trends demonstrate that the facility routine screenings were maintained: 23,421 (2018); 27,997 (2019); and 28,045 (2020). The total women seen through organized mass screenings however declined (10,304 (2018); 10,107 (2019); and 1,099 (2020), respectively) as this type of screening was stopped after the onset of COVID-19 pandemic. Of all women screened, 3,019 (2.98%) had clinical abnormalities requiring follow-up per standard of care including 1,781(1.8%) who were eventually histologically confirmed to have cancer. During our first and second year of the program, 83 physicians were trained on cancer management and treatment, 341 nurses were trained on breast and cervical cancer screening procedures, and 247 community health workers (CHW) were trained on the importance of screening to enlighten the community on awareness. However, this training was suspended in our year three due to COVID-19. **Conclusions:** An integrated training program utilizing CHW, nurses and physicians are an effective means for breast and cervical cancer screening in LMC, such as Kenya. This capacity building allows flexibility and sustainability even in the midst of the global COVID-19 pandemic. We also demonstrated successful integration with the county government for program sustainability. The use of telemedicine has greatly enhanced our screening and patient care across several facilities in western Kenya. Research Sponsor: Lily Foundation.

Cancer screening utilization in patients diagnosed with cancer types with and without recommended screening modalities. *First Author: Ariella Cohain, Thrive, An Exact Sciences Company, Cambridge, MA*

Background: Several studies have shown screening methods can detect cancer at earlier stages and improve cancer prognosis; however, only four cancer types (breast, colorectal, cervical, and lung) currently have screening methods recommended by the United States Preventive Services Taskforce (USPSTF). In 2021, these four cancers are expected to make up roughly 40% of new cases and cancer deaths, meaning that the majority of cancer deaths will be associated with cancer types lacking recommended screening. We sought to characterize patients who were diagnosed with cancer types with and without recommended screening modalities to demonstrate the gaps in screening faced by the majority of cancers today. **Methods:** The Geisinger Health System (GHS) Phenomics Initiative Database (PIDB) provides deidentified data from electronic health, billing, and imaging records, and a tumor registry. PIDB was used to identify patients aged 50 to 76 who had cancers diagnosed between 2008 and 2020 and a record of USPSTF-recommended cancer screenings within GHS prior to diagnosis. Analysis focused on patients who received care at GHS during their screening-eligible intervals. **Results:** Between 2008 and 2020, 13,347 incident invasive cancers were identified in the GHS tumor registry. Of these, 40% (N = 5,331) were cancer types with a recommended screening modality. 57% of these cases (N = 3,039; 23% of all incident cancers) occurred in patients who underwent screening in the interval preceding diagnosis. Screening adherence was significantly associated with stage at diagnosis; patients who were not screened for their diagnosed cancer were more than twice as likely to have a late-stage diagnosis as compared with patients who received screening (multivariate ordinal logistic regression, OR = 2.16, $p < 0.001$). Patterns of screening adherence in this population are complex; however, 57% of these patients had received screening for a different cancer type. The majority of incident cancers were of those types with no recommended screening modality (N = 8,016; 60% of all incident cancers). Of these, most (N = 6,252; 78%) had been screened for at least one of breast, lung, colon, or cervical cancer and nearly half (N = 3,607; 45%) were current for all guideline-recommended screenings. Not surprisingly, stage at diagnosis was not associated with adherence to any or all screening modalities (multivariate ordinal logistic regression, p = 0.11 and p = 0.45). **Conclusions:** The majority (79%) of individuals diagnosed with cancer had a history of adherence to at least one screening recommendation. Out of all cancer patients, only 23% were screened specifically for the cancer with which they were subsequently diagnosed, a group that is associated with a lower odds of a late-stage diagnosis. This suggests that the majority of cancer patients who underwent any cancer screening did not benefit from earlier stage diagnosis. Research Sponsor: None.

TNF-alpha immunosuppressive use and future malignancy risk. *First Author: Conor Driscoll, Northwestern Medicine, Chicago, IL*

Background: Tumor Necrosis Factor Alpha (TNF-a) inhibitors suppress the immune system in patients with systemic inflammatory conditions. Long term data assessing future cancer risk for these patients is not known. We assessed long term risk of malignancy in patients with Rheumatoid Arthritis [RA], Inflammatory Bowel Disease [IBD], Psoriasis [PS], and Ankylosing Spondylitis [AS], who were or were not exposed to a TNF-a inhibitor. **Methods:** This was a retrospective, cohort study conducted using electronic medical record data for patients with complete demographic and treatment data at Northwestern Medicine from years 1998 to 2020 (RA: n = 10763; IBD: n = 12106; PS: n = 1920; AS: n = 5103). Inverse Probability of Treatment Weighting (IPTW) was used to balance the distributions of age, race, gender, smoking status, and follow-up time across exposure groups within each inflammatory condition type. Relative risk (RR) of malignancy based on TNF-a exposure was assessed using logistic regression. **Results:** 2583 (24.0%) of RA, 2185 (18.0%) of IBD, 1811 (94.3%) of PS, 572 (11.2%) of AS patients had TNF-a exposure. Median follow-up for patients was 43 months. The RR for any cancer was higher for patients exposed to a TNF-a agent with rheumatoid arthritis (RR 1.121 (95% CI 1.02-1.23, p = 0.015) and psoriasis (RR 1.763 (95% CI 1.32-2.37, $p < 0.001$). The relative risk of any cancer was lower in patients exposed to a TNF-a agent with IBD (RR 0.858 (95% CI 0.78-0.94, p = 0.001). No significant difference in relative risk associated with TNF-a exposure was detected with ankylosing spondylitis (RR 0.929 (95% CI 0.8-1.08, p = 0.344). **Conclusions:** Patients with RA or PS and TNF-a exposure had higher RR of overall malignancy. Patients with IBD and TNF-a exposure had lower risk of overall malignancy. TNF-a immunosuppression may alter cancer risk differently based on the disease states for which it is being used. This information is critical when counseling patients on long term risk and screening strategies when considering TNF-a inhibition. Research Sponsor: None.

Understanding factors associated with uptake of lung cancer screening among individuals at higher risk. *First Author: Abdi Gudina, University of Rochester Medical Center, Rochester, NY*

Background: Lung cancer is the leading cause of cancer death in the U.S, accounting for about 25% of all cancer mortality. The U.S Preventive Services Task Force has recommended annual screening for lung cancer using low-dose computed tomography (LDCT) scanning for individuals at higher risk (aged 55-80 years with a >30 pack-year smoking history). Early detection using LDCT scanning reduces lung cancer specific mortality by 20%. Despite its efficacy, the uptake of annual lung cancer screening among high-risk individuals remains low (< 18%). The purpose of this study was to identify factors associated with the uptake of lung cancer screening in high-risk individuals in the U.S population. **Methods**: Data for this study were obtained from the 2017-2019 Behavioral Risk Factor Surveillance System (BRFSS), a population-based survey conducted annually by the Centers for Disease Control and Prevention (CDC) in collaboration with health departments in all 50 states, Washington, DC, and the U.S territories. We restricted our sample to high-risk individuals aged 55-80 years with a >30 pack-year smoking history. Only subjects with complete data on all predictor variables (age, gender, race/ethnicity, marital status, education, income, insurance, COPD, current smoking status, primary care provider) and the outcome variable (uptake of lung cancer screening) (n = 11, 714) were included in the final analysis. Chi-square tests were used to compare the uptake of lung cancer screening by demographic and socioeconomic factors. Multivariable logistic regression models were used to model the association between the predictors and the outcome variable. **Results**: Individuals with no health insurance (OR: 0.64; 95%CI: 0.46-0.90), no primary healthcare provider (OR: 0.40; 95%CI: 0.31-0.52), no chronic obstructive pulmonary disease (COPD) (OR: 0.35; 95%CI: 0.31-0.0.40) and who were females (OR: 0.86; 95%CI: 0.76-0.96) were less likely to participate in annual lung cancer screening. Individuals aged 65–69 years (OR: 1.65; 95%CI: 1.38-1.97), 70–74 years (OR: 1.77; 95%CI: 1.46-2.14) or 75–80 years (OR: 1.42; 95%CI: 1.16-1.76) were more likely to receive annual lung cancer screening compared with those aged 55-59 years. Race/ethnicity, level of education, level of income, marital status, and current smoking status had no significant association with the uptake of annual lung cancer screening. **Conclusions**: Our study identifies factors associated with lower uptake of annual lung cancer screening (no health insurance coverage, no primary healthcare provider, no COPD, and female gender). The findings from this study have important implications for the design of more effective interventions to target specific subgroups for the uptake of annual lung cancer screening. Young patients with cancer related to modifiable behaviors in the United States: What can we learn from them? *First Author: John Chan, Palo Alto Medical Foundation, Palo Alto, CA*

Background: We proposed to examine trends in modifiable behaviorally related cancers among younger men and women in the United States. **Methods:** Alcohol-associated cancers, HPV-associated, obesity-associated, physical inactivity-associated, and tobacco-associated were defined using ICD-O-3 site codes. From 2001 and 2017, registry data were obtained from the United States Cancer Statistics database. SEER*Stat 8.3.8 and Joinpoint regression program 4.8.0.1 were used to calculate the trends of associated cancers expressed per 100,000. **Results:** Of the young women (ages 20-49 years) the incidence of cancers in 2017 associated with alcohol, smoking and obesity were 89/100,000, 43/100,000 and 64/100,000 respectively. Based on analysis of trends of women from 2001 to 2017, obesity, physical inactivity and alcohol related cancers increased with an annual percent change (APC 2.31%, 1.67%, 0.46%, $p < 0.001$). Using a projection model, in Hispanic women, obesity related cancers will become the highest incidence cancers by 2035, surpassing alcohol and physical inactivity. Of the young men (ages 20-49 years) the incidence of cancers in 2017 associated with alcohol, obesity, and tobacco were 23/100,000, 36/100,000 and 44/100,000 respectively. On trends analysis, obesity, physical inactivity, and alcohol related cancers have increased (APC 2.0%, 1.65%, 0.17%, $p < 0.001$, $p < 0.001$, p = 0.044), whereas tobacco-related cancers are decreasing with an APC of -0.44% ($p < 0.001$). When examining different regions, the highest APC for obesity and physical inactivity related cancers was 2.43% in the Midwest ($p < 0.001$). Using a prediction model, obesity is predicted to surpass alcohol and physical inactivity related cancers for men 20-49 years old by 2035. **Conclusions:** In women, most modifiable factors associated with cancer are increasing except in HPV related cancers. In men, these rates of cancer are increasing except in tobacco related cancers. However, rates of obesity related cancers are on the rise in Hispanic women and younger men in southern U.S. regions. Obesity is projected to become the major modifiable factor for many associated cancers. Research Sponsor: Fisher Foundation and Denise Cobb Hale.

Validation of a high performing blood test for multiple major cancer screenings. *First Author: Linhao Xu, AnchorDx Medical Co., Ltd, Guangzhou, China*

Background: Early detection at the localized stage is pivotal for the successful treatment of various cancer types. Although several cancers already have routine screening approaches, the comprehensive utilities are impeded for various reasons, e.g., low accuracy, high cost, limited availability of required facilities, especially in the developing countries. Therefore, an accurate, cost-effective, and non-invasive test for multiple major cancer screening is in high demand. We previously reported a cfDNA methylation test, which can detect five major cancer types with high specificity and sensitivity, especially at the early stage (stage I). These five major cancers, including lung cancer (LC), breast cancer (BC), colorectal cancer (CRC), gastric cancer (GC), and esophageal cancer (EC), account for 56% of new cancer cases and 60% of cancer-related deaths yearly in China. Here, we report the result in an independent cohort as a further validation of this multi-cancer screening test. **Methods:** The high-throughput targeted methylation profiling platform, Aurora, was used to analyze the plasma samples from an independent retrospective cohort containing 505 healthy controls and ~200 cases for each cancer type. A locked model based on our previous pilot study (reported in AACR 2020 and 2021) was applied to this data set to assess the overall performance. **Results:** The Area Under Curves (AUC) of the classifier for LC, BC, CRC, GC and EC are 97.3%, 96.2%, 92.0%, 94.0% and 93.5%, respectively. At a fixed specificity of 99%, the sensitivities for LC, BC, CRC, GC and EC are 84%, 75%, 82%, 85% and 78%, respectively. **Conclusions:** A methylation blood test for five major cancer screening has been validated in a large retrospective cohort. Its high sensitivity for each cancer type, especially at the early stage (stage I), and easy to use suggests it can be implemented in real clinical world. A large prospective clinical trial is undergoing to further validate this test in asymptomatic populations. Research Sponsor: AnchorDx Medical Co., Ltd.

Factors associated with breast self-examination in Mexican young women with breast cancer. *First Author: Andrea Becerril Gaitan, Centro de Cancer de Mama, Hospital Zambrano Hellion TecSalud, Tecnologico de Monterrey, San Pedro Garza Garcia, NL, Mexico*

Background: Breast cancer (BC) is the most common cause of cancer-related death and morbidity among young women in Latin America. This group has a higher prevalence of advanced disease stages at diagnosis compared to their older counterparts. Thus, strategies aimed at detecting BC at early stages are imperative. Breast self-examination (BSE) remains a useful strategy for BC detection, especially in women who do not routinely undergo screening with imaging studies. This study aims to evaluate factors related with BSE practice in Mexican young women with BC and assess its association with earlier disease stages. **Methods:** Women aged ≤40 newly diagnosed with BC from 2014 to 2020 at three cancer referral centers in Mexico accrued in the Joven & Fuerte cohort were included and asked to complete a socio-demographic survey. Fisher's exact and Mann-Whitney U tests were used to evaluate associations between BSE and socio-demographic characteristics, as well as disease stages. **Results:** A total of 554 patients with a median age at diagnosis of 36 years (range: 19-40) were analyzed. Most patients (65%) were married or in a domestic partnership, and the majority were housewives (63%). Regarding educational background, 64% had completed at least high school, and up to 84% had a monthly income < 11,600 Mexican pesos (US$ 581). Overall, 85% of patients had public insurance, 6% had private insurance, and 9% were uninsured. The distribution of clinical stages at diagnosis was: 0 (2%), I (11%), II (45%), III (32%), and IV (10%). BC detection methods were: 85% by self/partner exam, 11% by an imaging study, and 4% by a healthcare professional. A total of 443 (80%) patients practiced BSE, of which 50% did it on a monthly basis, 18% every 2-3 months, and the remaining 12% every 4-12 months. Notably, a higher educational level (≥ high school *v* ≤ middle school) was positively associated with BSE practice (RR: 1.28; 95%CI 1.06-1.54; $p = 0.005$). No significant association was found between BSE and age (≤35 *v* > 35), marital status (in a relationship *v* no), occupation (housewive *v* other), monthly income (< 11,600 *v* ≥11,600) or medical coverage (public/uninsured *v* private). Patients that performed BSE were more likely to be diagnosed with early BC (stages 0-II) compared to those that did not (61% *v* 45%; $p = 0.003$). No association was found between BSE frequency and stage at diagnosis. Noteworthy, patients with private insurance were more likely to be diagnosed with stages 0-II compared to those with public or no insurance (80% *v* 56%; $p = 0.007$). **Conclusions:** The significant association between BSE and earlier stages at diagnosis found in this study highlights the need to raise awareness and promote this practice among young women with the objective of downstaging BC diagnoses. Public health interventions such as educational and social media campaigns that aim to improve the correct practice of BSE might be particularly useful in settings with inadequate screening programs. Young-onset colorectal cancer: A call for action. *First Author: Iosune Baraibar, Vall d'Hebron Institute of Oncology (VHIO), Medical Oncology, Vall d'Hebron University Hospital (HUVH), Barcelona, Spain*

Background: Young-onset colorectal cancer (YOCR) is defined as diagnosis below the age of 50. Over the past decades, the incidence of YOCRC has increased at an alarming rate, but causes and pathogenesis still remain unknown. Early detection of colorectal cancer (CRC) has demonstrated to improve survival. Despite these facts, adults < 50 years old are not yet included in screening programs and YOCRC is not well characterized. We aimed to characterize the clinical and molecular characteristics of YOCRC in patients (pts) diagnosed at our institution. **Methods:** Consecutive pts with a diagnosis of CRC below the age of 50 visited for the first time at Vall d'Hebron University Hospital in Spain between January 2017 and October 2020 were included in the analysis. Data of clinicopathologic features and treatment were collected retrospectively from medical records. **Results:** 205 pts met the inclusion criteria, 111 (54%) were females, 8 (4%) presented a personal history of cancer at diagnosis and 109 (53%) a family history of cancer. Age at diagnosis was: < 30: 10 (5%), {30 – 40): 52 (25%), {40-45): 51 (25%), {45-50): 92 (45%). Site of primary tumor was: right colon: 50 (24%), left colon: 107 (52%): rectum: 48 (24%). Stage at diagnosis was I: 3 (1%), II: 14 (7%), III: 60 (29%), IV: 128 (63%). 6 of 14 (43%) and 44 of 60 patients (73%) with stage II and III CRC presented disease progression after initial treatment, respectively. Molecular status was: *KRAS* mutation: 74 (36%), *NRAS* mutation: 7 (3%), *BRAF* mutation: 12 (6%), MSI-H: 12 (6%). 43 pts (21%) had documentation of genetic counseling. Median (range) number of lines of treatment for metastatic disease was 3 (1-7), 53 pts (30%) received at least 4 lines of treatment. Median (range) number of metastatic sites was: 2 (1-6). 114 patients (55.6%) had died at the cut-off timepoint. **Conclusions:** YOCR is usually diagnosed with a more advanced stage than standard-onset CRC, with a poorer course of the disease. Further studies in young adults with CRC should address this phenomenon to understand the underlying causes, and prioritize genetic counseling. Our results support the unmet need of initiating screening programs in adults younger than 50 years, the urgency for a global consensus and a call for action. Research Sponsor: None.

Interactive online skin cancer training game "Whack-a-Mole" assesses training strategies and real-time feedback on melanoma identification among U.S. adults. *First Author: Margaret I Sanchez, Sylvester Comprehensice Cancer Center-University of Miami Miller School of Medicine, Miami, FL*

Background: Cutaneous melanoma is a deadly form of skin cancer. Several studies have shown that early melanoma detection is associated with decreased mortality through self-examination and dermatology full-body skin exams. ABCD rule and the ugly duckling sign (UDS) are used to identify melanomas, but little research has explored the comparative efficacy of these approaches. This investigation compares the effectiveness of different mole identification training strategies and explores the effect of real-time feedback on decision-making. **Methods:** We developed an online melanoma identification game that tests differences between training types and expert feedback on mole identification. This online RCT tests a 4 (training: ABCD, UDS, both, control) X 3 (feedback: standard, motivational, control) factorial design on melanoma identification, skin cancer beliefs (perceived susceptibility and self-efficacy), and skin cancer prevention intentions. Standard feedback included expert evaluations of moles, whereas motivational feedback added statements grounded in fear appeals theory to encourage skin self-examination. An online research panel service was used to recruit 1025 US adults. Participants were randomly assigned to condition, completed a pretest, participated in the game intervention, and completed a posttest. Gameplay incorporates the same mechanics as *Tinder* (swipe left on benign moles and swipe right on malignant moles). **Results:** In total, participants reviewed 48 moles, 12 of which were melanomas. We used two-way ANCOVA for the analysis. ABCD training resulted in significantly higher melanoma identification than the control ($p = .011$). Every training type resulted in significantly higher self-efficacy than the control ($p = .007$). Additionally, there was a significant main effect of feedback on self-efficacy ($p = .001$), where both standard and motivational feedback elicited significantly higher levels of self-efficacy than the control condition. Around 88% of participants intend to conduct skin self-exams and wear sunscreen. **Conclusions:** Our data suggests that "Whack a Mole" is an efficacious tool for melanoma training. ABCD and UDS training with interactive feedback are important to improve accuracy and ability for melanoma identification. Research Sponsor: None.

The impact of socioeconomic status on stage at presentation, receipt of diagnostic imaging, receipt of treatment, and overall survival in colorectal cancer patients. *First Author: Rajan Shah, University of Toronto, Faculty of Medicine, Mississauga, ON, Canada*

Background: Socioeconomic factors have been identified to influence patterns of care in colorectal cancer yet current literature findings are sparse, conflicting, and often incomplete. As such, this study investigates the impact of socioeconomic status (SES) on stage at presentation, receipt of diagnostic imaging, receipt of treatment, and overall survival (OS) in a universal healthcare system. **Methods:** The Ontario Cancer Registry was accessed to identify a cohort of patients diagnosed with colorectal adenocarcinoma from 2007-2016 in Ontario, Canada. Linkage to administrative datasets allowed study of the impact of SES, measured by mean neighbourhood household income divided into quintiles (Q1-Q5; Q1 = lowest income), on stage, imaging, treatments, and OS. Multivariable regression analyses of all endpoints were adjusted for age, sex, comorbidity, and rurality with OS models also adjusting for imaging and treatment. **Results:** 39,802 colon and 13,164 rectal patients were identified. Lower SES patients were more likely to present at a higher stage in both cohorts. Lower SES colon patients were less likely to receive magnetic resonance imaging (MRI) of the abdomen, liver resection, adjuvant oxaliplatin, and all palliative systemic therapies studied. In rectal patients, lower SES was associated with decreased receipt of MRI pelvis, rectal cancer resection in early stages, adjuvant oxaliplatin, and most palliative chemotherapies studied. All OS models found that lower SES was associated with poorer OS. **Conclusions:** These findings suggest disparities across the continuum of cancer care persist even within a universal healthcare system. Further efforts should be directed towards temporal research, identifying barriers, and subsequently applying this information to actionable policies. Research Sponsor: None.

Impact of COVID-19 pandemic in 2020 on the diagnosis and management of breast cancer in Korea: A multi-institutional study. *First Author: Young-Joon Kang, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea*

Background: Since the COVID-19 pandemic began in early 2020, there have been many reports that it has had a significant impact on screening, case identification and referral in cancer diagnosis. We investigated the diagnostic and therapeutic status of breast malignancy before and after the COVID-19 pandemic at the multi-institution level. **Methods:** We have reviewed the records of patients with breast cancer from February 2019 to July 2020 in six university hospitals in Korea. The patients were divided into two groups according to the initial date of cancer diagnosis: Period A, from February to April and Period B, from May to July in 2020. The two groups were compared for the same periods in 2019. The goals were to determine whether breast cancer screening and diagnosis have been delayed and thus resulted in stage migration. We also examined the difference in the number of surgeries in patients diagnosed with breast cancer during those periods. **Results:** The total of 1,669 breast malignancy diagnosis was made in the grouped periods of 2019, and 1,369 diagnoses in 2020. All patients were screened by PCR test for COVID-19 prior to hospitalization, and none of them tested positive. Overall, there was a 9.9% reduction in the number of diagnoses than in 2019 and the decrease was more significant in Period A (11.1% vs. 8.7%). According to the age, there was no difference until the 30s but decreased from those in their 40s and above. The decline was more pronounced in the elderly. The COVID-19 pandemic has affected breast cancer screening (decreased by 27.4%) and more diminished in Period A (41.0% vs. 19.0%). Invasive breast cancer stage was not statistically different in Period A compare with 2019 ($p = 0.170$). But the stage in Period B was different ($p = 0.032$), and more patients were observed in advanced stages in 2020. The decrease in surgery was noticeably observed in Period A (4.6%, from 480 to 438 surgeries) and not in Period B. The analysis of reconstruction surgery was similar. **Conclusions:** Patients with COVID-19 increased exponentially from late February in Korea. However, the number of patients per day decreased to less than 100 on March 15 and then flattened. The health care system for cancer was not overloaded and restrictions on visiting hospital were minimal. Analysis in the pandemic period of the 6-month showed that the number of breast cancer screening, diagnosis and surgeries decreased compared with the previous year. Those decreases were prominent in Period A when the COVID-19 patient surged. The upstage migration of breast cancer was generally insignificant but slightly occurred in Period B. The outbreak of infectious disease makes patients reluctant to come to the hospital, especially in the elderly. We need to discuss the potential long-lasting deleterious effect of the COVID-19 pandemic on cancer diagnosis and management. And we should prepare for how to deal with the backlog caused by the COVID-19 pandemic. Research Sponsor: None.

10567 **Poster Session**

Outcomes for cancer patients on systemic anti-cancer therapies during the COVID-19 pandemic from the CAPITOL (COVID-19 Cancer PatIenT Outcomes in North London) cohort study. *First Author: Valerie Crolley, Barts Cancer Institute, London, United Kingdom*

Background: One of the major challenges with COVID-19 has been the changes to cancer services, including changes to the type of systemic anti-cancer treatment being delivered to patients. There needs to be a better understanding of which cancer patients are at the greatest amount of risk to make informed decisions on how cancer treatment can be altered to protect patients from COVID-19 infection. The CAPITOL (COVID-19 CAncer PatIenT Outcomes in North London) study investigated the outcomes of patients receiving systemic anti-cancer therapies (SACT) with regards to COVID-19 infection, as patients with cancer are hypothesised to be at higher risk. **Methods:** CAPITOL collected data from all patients receiving SACT at two cancer centres. The effect of clinical characteristics on the incidence and severity of COVID-19 infection in patients on SACT was the primary outcome, and we used univariable and multivariable models in our analysis, adjusting for age, gender and comorbidities. **Results:** 2871 patients were analysed from 2nd March to 31st May 2020, all of whom received SACT; during this time period 68 (2.4%) were diagnosed with COVID-19. Receiving SACT increased the risk of death when contracting COVID-19 (adjusted (adj.) OR 9.84; 95% CI 5.73 – 16.9). The risk of contracting COVID-19 was increased by receiving chemotherapy (adj. OR 2.99; 95% CI = 1.72 - 5.21), with the risk significantly increased by high dose chemotherapy (adj. OR 2.36, 95% CI 1.35 – 6.48). Patients with comorbidities (adjusted OR 2.29; 95% CI 1.19 - 4.38), or with a respiratory or intrathoracic neoplasm (adj. OR 2.12; 95% CI 1.04 - 4.36) were also at increased risk of contracting COVID-19. Cancer patients who received targeted treatment had a reduced risk of contracting COVID-19 (adj. OR 0.53; 95% CI 0.30 – 0.95), while there was no significant change in risk caused by treatment intent (curative versus palliative), hormonal- or immunotherapy and solid versus haematological cancers. **Conclusions:** To the best of our knowledge, this is one of the first investigations into the risk of contracting COVID-19 in a cohort of all cancer patients on SACT. We found that patients on SACT are more likely to die if they contract COVID-19. The type of SACT received by cancer patients can affect their likelihood of contacting COVID-19, with chemotherapy increasing risk, targeted therapy decreasing risk and a potential protective effect for hormonal and immunotherapy. Research Sponsor: None.

10568 **Poster Session**

Prior tonsillectomy and subsequent risk of breast cancer in females: Systematic review and meta-analysis. *First Author: Salah Eddine Oussama Kacimi, Faculty of Medicine, University of Tlemcen, Tlemcen, Algeria*

Background: Exposure to recurrent infections in childhood was linked to an increased risk of cancer in adulthood. There is also evidence that a history of tonsillectomy, a procedure often performed in children with recurrent infections, is linked to an increased risk of leukemia, and Hodgkin lymphoma. Tonsillectomy could be directly associated with cancer risk or it could be a proxy for another risk factor such as recurrent infections and chronic inflammation. Nevertheless, the role of recurrent childhood infections and tonsillectomy on the one hand, and the risk of breast cancer (BC) in adulthood remain understudied. Our study aims to verify whether a history of tonsillectomy increases the risk of BC in women. **Methods:** A systematic review was conducted using PubMed, Google Scholar, Scopus, Embase and Web of Science databases from inception through November 2020 to identify the studies which explored the association between history of tonsillectomy and BC in females. The Newcastle Ottawa Scale was used to assess the quality of included studies. Odds ratio (OR) was used to measure effect size. The Random/Fixed effects model was applied to synthesize the associations between tonsillectomy and BC risk based on heterogeneity. Heterogeneity was assessed using the I-squared statistic. A forest plot was generated, and publication bias was assessed. The leave-one-out sensitivity analysis was performed to check if results were driven by a single study. **Results:** Seven studies with a total of 7259 patients were included in our analysis; out of them, 2200 patients were diagnosed with BC. Patients with a history of tonsillectomy ($n = 2843$) showed higher subsequent risk of developing BC (OR = 1.252; 95% CI = 1.115 - 1.406; $P < 0.001$; $I^2 = 9\%$) as compared to patients without a history of tonsillectomy ($n = 4416$). Using the leave-one-out sensitivity analysis to iteratively remove one study at a time, we confirmed that no single study had a substantial influence on the overall effect size. **Conclusions:** Our study supports and confirms the evidence that a history of tonsillectomy is associated with an increased risk of breast cancer. These findings are also an argument in support of the hypothesis that recurrent childhood infections are linked with adulthood breast cancer. Research Sponsor: None.

Trends in incidence and mortality of squamous cell carcinoma of the skin: An observational analysis of the Global Burden of Disease database from 1990 to 2017. *First Author: Dorothy Yang, St George's University Hospitals NHS Foundation Trust, London, United Kingdom*

Background: Epidemiological data relating to non-melanoma skin cancer (NMSC), including squamous cell carcinoma (SCC), is highly under-reported and under-studied due to its lower metastatic potential. In recent years, incidence and prevalence of SCC has increased in many countries due to earlier detection, increased ultraviolet light exposure, as well as increasing life expectancy. This investigation compared trends in SCC incidence, mortality and disability-adjusted life years (DALYs) in 33 countries. **Methods:** We utilized the Global Burden of Disease (GBD) database for 33 countries, including the European Union nations as well as other selected high-income countries including the UK and USA. We extracted data including age-standardized incidence rates (ASIRs), age-standardized mortality rates (ASMRs) and DALYs for SCC of the skin from 1990 to 2017. Joinpoint regression analysis was used to describe the trends. **Results:** For both sexes, the highest ASIRs were seen in the USA and Australia: ASIRs were 362.8/100,000 and 283.7/100,000 respectively for males, and 171.2/100,000 and 152.4/100,000 respectively for females. Males had higher ASIRs than females at the end of the observation period in all countries. In contrast, the highest ASMRs for males were observed in Australia (2.77/100,000) and Latvia (2.44/100,000), while the highest ASMRs for females were observed in Romania (0.95/100,000) and Croatia (0.90/100,000). The highest DALYs for both sexes were seen in Australia and Romania: DALYs were 58.4/100,000 and 43.8/100,000 respectively for males, and 16.9/100,000 and 14.9/100,000 respectively for females. Over the observation period, there were more countries demonstrating decreasing trends in mortality than in incidence. There was also a disparity between which countries had comparatively high mortality rates and which had high incidence rates – for instance, the USA, which had by far the highest SCC incidence rates, had among the lower mortality rates. Overall reductions in DALYs were observed in 24 of 33 countries for males, and 25 countries for females. **Conclusions:** Over the past 27 years, although trends in SCC incidence have risen in most countries, there is evidence that mortality rates have been decreasing, especially towards the end of the observation period. Overall, burden of disease as assessed using DALYs has decreased in the majority of countries. Future work will explore potential explanatory factors for the observed disparity in trends in SCC incidence and mortality. Research Sponsor: None.

Demographical differentials of lung cancer survival in Bangladeshi patients. *First Author: Muhammad Rafiqul Islam, National Institute of Cancer Research and Hospital, Dhaka, Bangladesh*

Background: Lung Cancer is the leading cause of cancer-related mortality and most common cancer in worldwide with more than a million deaths annually. 20.8% cancer related death caused by lung cancer and more than half of lung cancer occurred in Asia. Differences In the epidemiology of lung cancer among the developing country may shed light on possible genetic and demographical influences on lung cancer survival. Demographic stratification of lung cancer patients of Bangladesh is remain unclear due of lack of data We tried to figure out the demographic pattern and its impact on survival in Bangladeshi lung cancer patient. **Methods:** Previously diagnosed primary lung cancer patients attending Medical Oncology department of National Institute of cancer research and Hospital, a tertiary care center of Bangladesh, between 2018 and 2019 were included. Demographic and clinical data were collected retrospectively from the medical records. **Results:** A total of 1868 consecutive patient (1580 males, 288females) diagnosed to have lung cancer; Mean age was 60 years which quite early compare to other countries. Older than 70-year age groups had worse survival outcome (hazard ratio 1.04: 95% confidence interval: 1.17–1.68). Below 50-year group had better outcome with standard adjuvant or palliative chemotherapy whereas older groups had better survival with sequential radiotherapy and chemotherapy or concurrent chemo radiation (Hazard Ratio 0.45; 95% confidence interval: 0.30–0.67). Sex was not a predicting factor for overall survival (Hazard ratios 1.04 95% confidence interval 0.89- 1.22, P = 0.621). But, Male had better treatment response than the female (Hazard ratio and 95% confidence interval: 0.51 and 0.42-0.61, P = < 0.001). Education level had significant impact on survival outcome (Hazard ratio 0.58 and 95% confidence interval: 0.47-0.71, P = < 0.001). Underweight group had worse survival than the normal BMI group (Hazard ratio1.18 and 95% confidence interval 1.05-1.31, P = 0.005). Having the Comorbid condition at the time of diagnosis had shorter survival (Hazard ratio 1.16 and 95% confidence interval 1.04-1.30 P = 0.007). Histological variation had no survival benefit among the squamous, small cell or other histological types (p = 0.214, 0.494, 0.658 respectively). But adenocarcinoma or small cell carcinoma had better treatment response outcome. Eastern Cooperative Oncology Group performance status (ECOG-PS) 4 had worse outcome (Hazard ratio 1.95, 95% confidence interval 1.37–2.79; P = < 0.001). **Conclusions:** The socio-demographic related survival in lung cancer needs to be fully elucidated because of its implication in the design of experimental protocols for targeted chemoprevention, early disease screening, molecular marker based staging, and individualized treatment. Due to its extraordinary disease burden and the international variability in demographic variables, the lung cancer requires continual monitoring. Research Sponsor: None.

Prognostic value of *pre-infection* routine laboratory parameters for COVID-19 mortality in tumor patients: Results of the ADHOK Coronavirus Tumor Registry. *First Author: Romina Roesch, Technische Universität Dresden, Dresden, Germany*

Background: Tumor patients (pts.) are considered susceptible to severe COVID-19 after SARS-CoV-2 infection. However, they represent a heterogeneous group of individuals with variable risk. Identification of vulnerable subgroups is important for prioritization of vaccination strategies and possible early therapeutic intervention after infection. **Methods**: Tumor pts. with PCR-confirmed SARS-CoV-2 infection were included in the multicentric ADHOK registry by 22 institutions. Detailed information about tumor disease and treatment, as well as routine laboratory parameters determined at least 10 days prior to SARS-CoV-2 infection, was collected retrospectively. The primary endpoint was defined as the outcome of the SARS-CoV-2 infection, graded according to the WHO: asymptomatic, mild, moderate, severe, critical, and COVID-19-related death. **Results**: Until Feb. 5, 2021, 215 pts. (67% with solid tumors, 33% with hematological neoplasms) were included in the registry. 74% of the pts. had an active malignancy. The course of SARS-CoV-2 infection was rather variable: 66% of the pts. remained asymptomatic or showed a mild-to-moderate course, while the rest developed severe or critical disease. The COVID-19-related mortality rate was 24%. *Pre-infection* routine laboratory values were available for 104 pts., obtained at a median of 21 days before SARS-CoV-2 infection. Compared to COVID-19 survivors, COVID-19 non-survivors showed significantly higher median levels of absolute neutrophil count (ANC: 3.6 vs. 6.4 /nL; p = 0.006, n = 91), neutrophil-to-lymphocyte ratio (NLR: 2.2 vs. 7.2; p = 0.005, n = 75), C-reactive protein (CRP: 9.9 vs. 42.0 mg/L; p = 0.001, n = 104), and lactate dehydrogenase (LDH: 213.0 vs. 267.0 U/L; p = 0.016, n = 78). When categorized by a median split, COVID-19 mortality was significantly higher in pts. with ANC > 4.4 /nL (4% vs. 55%, p < 0.001), NLR > 4.1 (5% vs. 58%, p < 0.001), CRP > 15.4 mg/L (18% vs. 46%, p = 0.003), LDH > 236 U/L (15% vs. 49%, p = 0.003) and lymphocytes < 1.3 /nL (41% vs. 11% p = 0.002). In multivariable analysis, ANC and CRP showed a strong and significant association with COVID-19-related death (OR 23.0 and 7.7, p = 0.007 and 0.029, respectively). To develop an easy-to-apply *pre-infection* score, we combined ANC and CRP and were able to separate three groups of pts. with significantly different COVID-19 outcomes (p < 0.001) (Table). **Conclusions**: Our results unveil subgroups of tumor pts. who may be at increased risk of severe COVID-19 and point to *pre-infection* routine laboratory parameters with potential prognostic power: ANC and CRP may help identify pts. at risk for severe COVID-19 before SARS-CoV-2 infection. Research Sponsor: Arbeitsgemeinschaft der Haematologen und Onkologen im Krankenhaus e.V, Research funds of the Klinikum Bayreuth GmbH, Germany.

Pre-infection parameters	Score = risk for severe COVID-19	COVID-19-related mortality (%) (n = 83)
Absolute neutrophil count (ANC) < 4 /nL	0 = low	0%
ANC > 4 /nL and CRP < 20mg/L	1 = increased	30%
ANC > 4 /nL and CRP > 20mg/L	2 = high	68%

Outcomes for hospitalized cancer patients with COVID-19 during the height of pandemic in New York City. *First Author: Amelia Sawyers, NYU Grossman School of Medicine, New York, NY*

Background: Several reports have suggested that cancer patients are at increased risk for contracting severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and suffering worse coronavirus disease 2019 (COVID-19) outcomes. However, little is known about the impact of cancer status on presentation and outcome. Here, we report on the association between cancer status and survival in hospitalized patients who tested positive for SARS-CoV-2 during the height of pandemic in New York City. **Methods:** Of the 6,724 patients who were hospitalized at NYU Langone Health (3/16/20 - 7/31/20) and tested positive for SARS-CoV-2, 580 had either active cancer (n = 221) or a history of cancer (n = 359). Patients were classified as having active malignancy if they either received treatment within six months of their COVID-19 diagnosis or they had measurable disease documented at the time of their hospitalization. Patients were categorized as having a history of cancer if there was no evidence of measurable disease or there were no treatments administered within six months of their COVID-19 diagnosis. We compared the baseline clinicodemographic characteristics and hospital courses of the two groups, and the relationship between cancer status and the rate of admission to the intensive care unit (ICU), use of invasive mechanical ventilation (IMV), and all-cause mortality. **Results:** There was no differences between the two groups in their baseline laboratory results associated with COVID-19 infection, incidence of venous thromboembolism, or incidence of severe COVID-19. Active cancer status was not associated with the rate of ICU admission ($P = 0.307$) or use of IMV ($P = 0.236$), but was significantly associated with worse all-cause mortality in both univariate and multivariate analysis with ORs of 1.48 (95% CI: 1.04-2.09; $P = 0.028$) and 1.71 (95% CI: 1.12-2.63; $P = 0.014$), respectively. **Conclusions:** Active cancer patients had worse survival outcomes compared to patients with a history of cancer despite similar COVID-19 disease characteristics in the two groups. Our data suggest that cancer care should continue with minimal interruptions during the pandemic to bring about response and remission as soon as possible. Additionally, these findings support the growing body of evidence that malignancy portends worse COVID-19 prognosis, and demonstrate that the risk may even apply to those without active disease. Trends in breast cancer incidence among young women aged 20 to 49 years in the United States. *First Author: Shuai Xu, Washington University School of Medicine, St. Louis, MO*

Background: Breast cancer in young women is diagnosed at more advanced stages and has a less favorable prognosis. We investigated trends in breast cancer incidence by race/ethnicity, hormone receptor status, and tumor stage in women aged 20-49 years over the past 25 years, as well as the impact of period and cohort effects on these trends. **Methods:** We used data from Surveillance, Epidemiology, and End Results (SEER) 13 registries for 1993-2002 and SEER 18 registries for 2003-2017. We calculated age-standardized incidence rates and annual percent change (APC), and stratified by race/ethnicity, hormone receptor status (estrogen receptor [ER] and progesterone receptor [PR]), and tumor stage (I-IV) for 222,424 women aged 20-49 years with a primary invasive breast cancer. We performed age-period-cohort analysis (presented as incidence rate ratios [IRR]) to investigate the effects of age, period, and cohort on incidence trends using the 1948 cohort and 1993-1997 period as the reference groups, respectively. **Results:** Between 2010-2017, invasive breast cancer incidence increased (APC = 0.67%, 95%CI: 0.32 to 1.03) among women aged 20-49 years, after being stable from 1993-2010. There were differences by race over the 25-year period (1993-2017). We observed significant increases in incidence among non-Hispanic White (NHW) (APC = 0.25%, 95%CI: 0.16 to 0.34), non-Hispanic Asia/Pacific Islander (NHAPI) (APC = 0.58%, 95%CI: 0.34 to 0.82), and Hispanic women (APC = 0.59%, 95%CI: 0.34 to 0.83), but not among non-Hispanic black (NHB) women (APC = 0.14%, 95%CI: -0.06 to 0.34). Incidence increased for ER+ tumors but decreased for ER- tumors: ER+/PR+ (APC = 2.39%, 95%CI: 2.20 to 2.58), ER+/PR- (APC = 1.46%, 95%CI: 1.05 to 1.87), ER-/PR+ (APC = -6.33%, 95%CI: -7.31 to -5.33), and ER-/PR- (APC = -0.70%, 95%CI: -1.09 to -0.32). The decrease in ER-/PR- tumors appeared largely driven by decreases among HNW women. Incidence for stages I (APC = 0.31, 95%CI: 0.07 to 0.55), II (APC = 0.99, 95%CI: 0.82 to 1.16), and IV (APC = 2.88, 95%CI: 2.37 to 3.39) tumors increased while that for stage III tumors decreased (APC = 0.81%, 95%CI: -1.04 to -0.59). Both the cohort and period effects impacted incidence, with the cohort effect almost 10 times larger than the period effect. Age-specific relative risk by birth cohort initially decreased between 1948 and 1958 but steadily increased from 1958 to 1993. Breast cancer incidence was higher among women born in the 1988 (IRR = 1.17, 95%CI: 1.07 to 1.28) and 1993 (IRR = 1.22, 95%CI: 0.99 to 1.51) cohorts than for those born in 1948 cohort. **Conclusions:** Breast cancer incidence is increasing among young women, mainly driven by increases in ER+ tumors. Prevention efforts need to focus on how we can address factors driving the increase in ER+ tumors and also learn from what has worked for decreasing ER- tumors. Socioeconomic background in relation to stage at diagnosis in women with breast cancer. *First Author: Juan Manuel Ariza, Cancer Registry (Loire-Atlantique, Vendee), Nantes, France*

Background: Breast cancer (BC) has been associated with socioeconomic deprivation and rural residence. However, it's still unclear how these factors interplay to affect the frequency and incidence of early and advanced BC. **Methods:** Taking advantage of the Loire-Atlantique/Vendée cancer registry (France), we investigated the association between early (TNM stage < 2) and advanced (TNM stage ≥ 2) BC and the socio-economic background (SB) of women diagnosed in the study region from 2008 to 2015. Socioeconomic status was studied using the residence information of every patient linked to the European Deprivation Index (EDI), an ecological index constructed to reflect individual deprivation experienced at the smallest geographical unit of France (IRIS = 2000 inhabitants). To investigate SB, we created a composite variable using the EDI and the urban/rural context information, to define 4 categories: affluent-urban, affluent-rural, deprived-urban, and deprived-rural. Two statistical approaches were implemented: i) mixed-effects logistic regression models to examine the likelihood (relative risk, RR) of being diagnosed with advanced BC, and ii) Poisson regression for modeling incidence rates of early and advanced stages. Analyses were stratified by age (< 45, 45 to 74, $>$ 75 years) with a random intercept at the IRIS level. For the strata 45 to 74, the models were adjusted for organized screening. **Results:** During the study period, 14,542 BC cases were recorded. Compared to the women diagnosed in the most affluent-urban areas, a higher proportion of cancer diagnosed at an advanced stage was observed in the women living in more deprived-rural areas (aged < 45 years, RR = 1.48 95% CI 1.17 - 1.73; aged 45 to 74 years, RR = 1.22, 95% CI 1.02-1.42; aged > 74 years, RR = 1.08, 95% CI 0.85-1.27). Furthermore, while in the population under 74 years, incidence rates of early BC in deprived-rural women were reduced by 25-85 % in comparison to affluent-urban women (IRR: 0.33 to 0.97 95% CI 0.16 -0.98), the rates of advanced BC were unaffected by deprivation-rurality (Deprived rural vs Affluent urban, IRR: 1.06 to 1.13 95% CI 0.79 -1.72). For the population over 74 years, we were unable to detect any associations between SB and BC incidence by stage at diagnosis. **Conclusions:** Advanced stage at diagnosis was more frequent among deprived–rural women aged under 74 years and coincided with the low incidence rates of early stages in this population. No disparities in the incidence rates of advanced BC were detected according to their SB in any age classes, suggesting other factors may be stronger contributors to the advanced stage at diagnosis. Future research should investigate whether screening practices may influence the disparities in the early stage at diagnosis for women under 74. Research Sponsor: SIRIC-ILIAD Nantes, France.

Incidence and trend of Epstein-Barr virus-related cancer: A surveillance, epidemiology, and end results program based study. *First Author: Jiayi Shen, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Epstein-Barr virus (EBV) infection was highly prevalent, as was found in more than 90% of the adults globally. EBV infection has been found to be related with several types of cancer and classified as group 1 carcinogen by the International Agency for Research on Cancer. The association between EBV infection and malignancy was observed in Burkitt lymphoma (BL), Hodgkin lymphoma (HL), extranodal natural killer (NK)/T-cell lymphoma (NNKTL), gastric cancer (GC) and nasopharyngeal cancer (NPC). In this study, we aimed to analyze the incidence and the trend of incidence of these virus-related cancer and to identify whether the trend was similar between them. **Methods:** This was a retrospective analysis based on the data from Surveillance, Epidemiology, and End Results (18 registries, 2000-2017), which totally included 71,415 patients. EBV-related cancers were defined as BL, HL, NNKTL, GC and NPC. Age-adjusted incidence rates were displayed as per 100,000 persons. In terms of incidence trend, we calculated the average annual percent change (AAPC). AAPC was considered significantly different from 0 when the *P*-value was smaller than 0.05. The impact of the epidemiological and clinical characteristics on the incidence trend was estimated, with cancer type, histology, age, sex and race considered. **Results:** Incidence rates of EBV-related cancers were 6.68 per 100,000 persons in 2000 and 5.80 in 2017, of which the AAPC was -0.8 (95%CI, -1.1 - -0.5, *P*-value < 0.001). (Table) Similar with EBV-related cancer as a whole, the APCCs of BL, HL and GC were statistically significantly smaller than 0, except that the APCCs of NNKTL and NPC were statistically significantly larger than 0 and not statistically significantly different from 0 respectively. The incidence of EBV-related cancer also decreased in mixed cellularity classical HL, nodular sclerosis classical HL, adenocarcinoma of GC, signet ring cell carcinoma in GC, undifferentiated carcinoma of NPC, squamous cell carcinoma of NPC, patients diagnosed at the age of 20-39 years old and 60-79 years old, male patients and race as white, black or Asian, but increased in classical HL, NOS, nodular lymphocyte predominant HL and non-keratinizing carcinoma of NPC. **Conclusions:** Incidence of EBV-related cancer decreased during 2000 and 2017, which was consistent in BL, HL and GC. Research Sponsor: None.

Rate and APCC of EBV-related cancers.

EBV-related cancers	Rate in 2000	Rate in 2017	APCC	*P*-value
EBV-related cancers	6.68 (6.46 - 6.90)	5.80 (5.62 - 5.99)	-0.80 (-1.10 - -0.50)	< 0.001
BL	0.37 (0.32 - 0.43)	0.32 (0.28 - 0.37)	-1.60 (-3.00 - -0.10)	< 0.001
HL	2.93 (2.79 - 3.07)	2.53 (2.41 - 2.65)	-0.80 (-1.30 - -0.40)	< 0.001
NNKTL	0.02 (0.01 - 0.03)	0.09 (0.07 - 0.11)	1.90 (0.20 - 3.60)	< 0.001
GC	2.77 (2.63 - 2.92)	2.35 (2.24 - 2.46)	-0.70 (-1.10 - -0.40)	< 0.001
NPC	0.59 (0.53 - 0.66)	0.52 (0.47 - 0.58)	-0.60 (-1.30 - 0.10)	0.10

Leukemia in hospitalized patients with inflammatory bowel disease: An analysis of the National Inpatient Sample (NIS) database. *First Author: Colin Wikholm, MedStar Georgetown University Hospital, Washinton, DC*

Background: Inflammatory bowel disease (IBD) and use of immunosuppressive therapy in IBD is linked with increased risk of leukemia. We studied the NIS database from 2003-2017 to analyze trends in any type of leukemia in IBD hospitalizations over time and examined the role of age, sex, and race. **Methods:** We analyzed NIS data of all adult hospitalizations for ulcerative colitis (UC) or Crohn's disease (CD) with any type of leukemia as a primary or secondary diagnosis using validated ICD 9/10 codes. Age, sex, and racial demographics were collected. Trend analysis of leukemia was performed with Cochran-Armitage and Jonckheere-Terpstra tests. **Results:** Overall Trends: From 2003-2017, a total of 11,385 of 2,235,413 (0.51%) CD hospitalizations and 8,105 of 1,324,746 (0.61%) UC hospitalizations contained diagnosis of leukemia. An increase in leukemia was seen in both CD and UC group from 0.24% to 0.79% (pTrend < 0.0001) and 0.28% to 0.81% (pTrend < 0.0001) respectively. Sex: In both UC and CD patients, leukemia diagnoses were predominantly male in 2003 but approximated a near 1:1 ratio by 2017 (Table). In CD, the proportion of female (FEM) leukemia diagnoses grew from 31.33% to 45.05% from 2003 to 2017 (pTrend = 0.1898). In UC, the proportion of female leukemia diagnoses grew from 27.49% to 45.79% from 2003 to 2017 (pTrend = 0.0030). Age: Leukemia was more common with increasing age, with no significant changes in proportion of cases between age groups over time (pTrend $> .05$). Ethnicity: White patients composed 87.80% and 84.24% of leukemia diagnoses in CD and UC, respectively. In CD, an increasing proportion of leukemia diagnoses occurred in black (BK) patients, and a decreasing proportion occurred in white patients (pTrends $<.0001$; Table 1) during the study time. No trends in race were observed in the UC group (pTrend = 0.4229). **Conclusions:** Our study showed an increased prevalence of leukemia in CD and UC hospitalizations from 2003-2017 which may be related to increasing use of immunosuppressants such as anti-TNF medications. In both CD and UC, leukemia was male-predominant, but increasingly female by 2017. Rate of leukemia diagnosis increased with age. In the CD group but not the UC group, leukemia was increasingly prevalent in black patients. Research Sponsor: None.

	Leukemia (%) Prevalence		Sex and Leukemia		Race and Leukemia

The global burden of 29 cancer groups from 2010 to 2019: A systematic analysis for the Global Burden of Disease study 2019. *First Author: Jonathan M Kocarnik, Institute for Health Metrics and Evaluation, Seattle, WA*

Background: Cancer is a major cause of morbidity and mortality worldwide, and global efforts to reduce health loss from cancer require systematic estimates that can measure progress from national to global levels. As part of the Global Burden of Diseases, Injuries, and Risk Factors Study 2019 (GBD 2019), we examined global cancer burden in order to highlight areas where cancer burden is inequitably distributed and to inform cancer control efforts around the world. **Methods:** Using estimation methods from GBD 2019, we analyzed the incidence, mortality, years lived with disability, years of life lost (YLLs), and disability-adjusted life years (DALYs) for 29 cancer groups and 204 countries and territories from 2010 to 2019. Cancer burden was compared to health burden from other categories of diseases and injuries in the GBD. Results were assessed globally and by socio-demographic index (SDI), a summary measure of income per capita, average educational attainment, and total fertility rate. Point estimates and 95% Uncertainty Intervals (UIs) are reported. **Results:** There were 23.6 million (95% UI 22.2-24.9 million) incident cancer cases globally in 2019 (17.2 [15.9-18.5] million excluding non-melanoma skin cancer), and 10.0 (9.36-10.6) million cancer deaths. There were 250 (235-264) million DALYs globally due to cancer, 97% of which came from years of life lost. The leading five cancers by DALYs in 2019 were: tracheal, bronchus, and lung cancer (45.9 [42.3-49.3] million); colon and rectum cancer (24.3 [22.6-25.7] million); stomach cancer (22.2 [20.3-24.1] million); breast cancer (20.6 [19.0-22.2] million; and liver cancer (12.5 [11.4-13.7] million). Compared to other diseases and injuries in the GBD, cancer was responsible for the second-highest number of deaths, YLLs, and DALYs globally in 2019. These rankings of cancer burden differed by SDI quintile: cancer was the leading cause of absolute DALYs in high SDI countries but was ranked 10th in low SDI countries. From 2010-2019, the number of global cancer cases increased by 26.3% (20.3-32.3%), deaths by 20.9% (14.2-27.6%), and DALYs by 16.0% (9.29-22.8%). The largest annualized rate of change in absolute cases and deaths over this period occurred in the low and low-middle SDI quintiles. **Conclusions:** Cancer cases and deaths are growing globally, with the largest relative growth over the last decade occurring in low to middle SDI countries. Improvements in cancer prevention efforts and ensuring access to timely diagnosis and care will be necessary to make equitable progress in reducing the global burden of cancer. The lung cancer obesity paradox: An analysis of 432,924 patients. *First Author: Brittany Miles, UTMB Health, League City, TX*

Background: The lung cancer obesity paradox is the unexpected inverse relationship between body mass index (BMI) and lung cancer mortality. While there is a growing body of evidence to support the existence of the obesity paradox in lung cancer, little is known about its magnitude and relationship to cancer incidence and its impact on outcomes from surgery, chemotherapy, immunotherapy, and radiation treatment. **Methods:** To evaluate the impact of obesity on lung cancer incidence, we used TriNetX, a global federated health research network providing access to electronic medical records (diagnoses, procedures, medications, laboratory values, genomic information) from approximately 69 Million patients in 49 large Healthcare Organizations. We evaluated 2 patient cohorts of 216,462 adult smokers aged 18 to 75 that were matched for age, race, gender, and ethnicity. One cohort of patients carried a diagnosis of overweight and obesity (ICD-10 code E66), while the other cohort required exclusion of those diagnoses. **Results:** We found a statistically significant decrease in lung cancer incidence for patients with obesity (1.407% vs 2.039%, $p < 0.0001$), in addition to superior overall survival (95.344% vs 92.039%, $p < 0.0001$). A subset analysis of patients who contracted lung cancer showed a statistically significant benefit in median survival in favor of patients with overweight and obesity (851 vs 602 days, p value 0.0009). **Conclusions:** These findings support the existence of the obesity paradox in lung cancer, and its positive impact on both lung cancer incidence and outcome. Research Sponsor: None.

Hereditary cancer testing in an ethnically diverse U.S. population. *First Author: Michele Basiliere, Progenity, Inc., Ann Arbor, MI*

Background: The clinical utility of hereditary cancer multigene testing is well-established. Most testing has been performed in the White European population, with a relative shortage of data in other ethnic groups. Evaluation of hereditary cancer variants within diverse ethnic populations is important to drive accurate variant interpretation. This study aims to review the outcomes of hereditary cancer testing in an ethnically diverse U.S. population. **Methods:** We conducted a retrospective analysis of 8,888 test results from a 31-gene hereditary cancer test using next-generation sequencing with copy number variant analysis. Results were separated into seven categories based on the ethnicity selected on the test requisition: African American (AA), Asian (A), Ashkenazi Jewish (AJ), Hispanic (H), White (W), Other (O), and Unknown (U). O was used for any handwritten ethnicity or if multiple ethnicities were selected and U if no ethnicity was chosen. We quantified the number of negative, positive (pathogenic or likely pathogenic (P/LP) variant) and variant of uncertain significant (VUS) results for each ethnic group. We tallied the gene and variant for each result with a positive, negative or VUS. We used a Fisher's Exact test and Bonferroni-adjusted p-values to account for multiple hypothesis testing. **Results:** Of the 8,888 orders reviewed, 45% were non-White ethnic groups. The P/LP variant rate was lower for AA (4%, p=2e-04) compared to W (9%). The VUS rate was higher for O, AA and A (48%, 56%, and 57%; p=0.0045, 3.1e-17 and 4.8e-06, respectively), compared to 38% in W. Lower negative rates were found in A and AA (37% and 40%; p=0.00024 and 9.4e-10, respectively), and trending lower in O (46%, p=0.0097), compared to 58% for W. The VUS rate for H is 41% (p value = 0.095). **Conclusions:** Our results suggest that non-Whites may be at a disadvantage when it comes to hereditary cancer multigene testing due to the higher rate of VUS results. The inverse correlation between the overall rates of VUS and negative results when comparing these populations suggests there may be limited variant information for the non-White population in medical literature and available databases. This underrepresentation may make it more difficult to accurately characterize a variant. Despite the small sample size, these findings are consistent with previous publications; however, gene specific outcomes could not be evaluated. This finding suggests that providers could give these patients uninformative results more often, which has potential to impact screening protocols for these families. More research is needed to understand the impact of variant classification across ethnicities to decrease health disparities. Research Sponsor: None.

Point of care genetic testing in a breast cancer survivorship clinic. *First Author: Lori Ranallo, University of Kansas Cancer Center, Westwood, KS*

Background: : Breast cancer survivorship care (BCSC) includes the ongoing assessment of personal and family cancer history and offering genetic education, counseling and testing to survivors who meet NCCN, ASBrS and Medicare guidelines for germline genetic testing. It is reported that approximately 8% of patients with breast cancer (BC) will have a clinically actionable germline mutation. However, lower than expected rates of testing are seen in both the acute and extended phases of BCSC. We sought to identify the number of patients seen in a long-term survivorship clinic who had previously undergone or currently qualified for germline testing, and the prevalence of germline variants in BC survivors. **Methods:** In a Nurse Practitioner (NP) led clinic, 2,184 non-selected BC survivors were screened to determine if: germline testing was previously completed or if update germline testing or initial germline testing is needed (with a 3-generation review of family history). BC survivors eligible for initial or update germline testing (411 patients) were provided with genetic education, counseling, and offered multigene panel testing. Seven (7) BC survivors declined testing. **Results:** From May 2019 – January 2021, 2,184 BC survivors were seen in the clinic. The average age of survivors = 60.2 yrs; average time since diagnosis = 10.7 yrs; and average age at diagnosis = 50.1 yrs, gPV were identified in 10.4%. Out of pocket cost on average was $50.00 for 2.0% of those tested. **Conclusions:** Within a comprehensive Breast Cancer program where genetic testing is common practice, there is an ongoing need to screen breast cancer (BC) survivors for genetic testing eligibility. A significant number of BC survivors will test positive for a pathogenic mutation (10.4%) a decade after an initial diagnosis. Genetic testing is a necessary step to stratify a BC survivors' risk of developing secondary cancers, appropriate screening and prevention strategies, cascade testing, and for some, treatment planning. This individualized approach to BCSC is often described, but difficult to put into action. Time/access and drop rates with a referral model are barriers. Incorporating a point of care genetic testing model requires additional support (genetic extender), professional development, education, and a commitment to provide patient centric care. Research Sponsor: None.

Germline Testing	Total Tested (n = 404)

Germline pathogenic variants in cancer predisposition genes among women with invasive lobular cancer of breast. *First Author: Siddhartha Yadav, Mayo Clinic, Rochester, MN*

Background: The prevalence of germline pathogenic variants (PVs) in cancer predisposition genes among women with invasive lobular breast cancer (ILC) and the risk of ILC in PV carriers is not well-defined. **Methods:** The study included 2,999 women with ILC and 32,544 unaffected controls from a population-based cohort; 3,796 women with ILC and 20,323 women with invasive ductal carcinoma (IDC) undergoing clinical multigene panel testing (clinical cohort); and 125,748 exome sequences from unrelated women without a cancer diagnosis in the gnomAD 3.0 dataset. Frequencies of germline PVs in breast cancer predisposition genes (*ATM, BARD1, BRCA1, BRCA2, BRIP1, CDH1, CHEK2, PALB2, PTEN, RAD51C, RAD51D*, and *TP53*) were compared between women with ILC and unaffected controls in both cohorts and between women with ILC and IDC in the clinical cohort. **Results:** The frequency of PVs in breast cancer predisposition genes among women with ILC was 6.5% in the clinical cohort and 5.2% in the population-based cohort. In case-control analyses, *CDH1* and *BRCA2* PVs were associated with high risks of ILC (Odds ratio (OR) $>$ 4), and *CHEK2*, *ATM* and *PALB2* PVs were associated with moderate (OR = 2-4) risks. *BRCA1* PVs and *CHEK2* p.Ile157Thr were not associated with clinically relevant risks (OR $<$ 2) of ILC. PV frequencies in these genes in ILC and IDC were similar except for PV frequencies in *BRCA1* and *CDH1*. **Conclusions:** The study establishes that PVs in *ATM*, *BRCA2*, *CDH1*, *CHEK2* and *PALB2* are associated with an increased risk of ILC, whereas *BRCA1* PVs are not. The similar overall PV frequencies for ILC and IDC suggest that cancer histology should not influence the decision to proceed with genetic testing. While, multigene panel testing may be appropriate for women with ILC, *CDH1* should be specifically discussed in the context of low prevalence and attendant gastric cancer risk. Rate of incidental germline findings detected by tumor-normal matched sequencing in cancer types lacking hereditary cancer testing guidelines. *First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Up to 10% of all cancers are associated with hereditary cancer syndromes; however, guidelines for germline testing are currently limited to patients and families with specific cancer types (ovarian, breast, prostate, pancreatic, etc.). Although germline alterations have been shown in genes associated with cancers such as bile-duct, head & neck, brain, bladder, esophageal, and lung cancers, genetic testing is not routinely offered (PMID: 28873162). In such cancers, a guidelines-based approach may fail to detect cancer risk variants found by tumor-normal (T/N) matched sequencing. Here, we report the prevalence of incidental germline findings in patients with the aforementioned 6 cancer types and highlight frequently mutated genes by cancer type. **Methods:** We retrospectively analyzed next-generation sequencing data from de-identified records of 19,630 patients tested using TempuslxT T/N matched assay. Incidental germline findings (i.e., single nucleotide variants and small insertions/deletions) detected in 50 hereditary cancer genes were determined for: bile duct (n = 466), head & neck (n = 673), esophageal (n = 395), brain (n = 1,391), bladder (n = 810), and lung (n = 5,544), where n = total patients. For comparison, we also included 4 cancer types that frequently undergo germline testing: ovarian (n = 2,042), breast (n = 3,542), prostate (n = 2,146), and pancreatic (n = 2,621). **Results:** We detected incidental pathogenic/likely pathogenic germline variants (P/LPV) in 6.5% (601/9,279) of patients diagnosed with the 6 selected cancer types lacking hereditary cancer testing guidelines. The highest prevalence of P/LPV was identified in patients with bladder (8%), brain (6.9%), and lung (6.5%) cancers. Frequently mutated genes (Table) include *ATM* (n = 62), *BRCA2* (n = 60), *BRCA1* (n = 33), *APC* (n = 27), and *CHEK2* (n = 21). Of note, the Ashkenazi Jewish variant (p.I1307K) was the most frequent mutation in APC. For cancer types where patients frequently undergo germline testing, the rates of incidental germline findings in descending order were ovarian (15%), breast (12%), prostate (9.4%), and pancreatic (8.5%) cancers. **Conclusions:** In addition to enhanced variant calling, T/N matched sequencing may identify germline variants missed by a guidelines-based approach to testing. The identification of such germline findings may have clinical implications for the patient, as well as at-risk family members, thereby resulting in the opportunity for genetic counseling and risk-stratified intervention. Research Sponsor: None.

Variant reclassification and its impact on clinical care in an Asian cancer center. *First Author: Jianbang Chiang, National Cancer Centre Singapore, Singapore, Singapore*

Background: Genetic testing has demonstrated clinical utility in the identification and subsequent surveillance of patients with cancer predisposition syndromes. However, the increased likelihood of encountering a variant of uncertain significance (VUS) in individuals of non-European descent such as Asians may be challenging to both clinicians and patients in interpretation and management. VUS can be reclassified as more data becomes available. VUS reclassification is important, as it may have implications for surveillance and treatment. This study aims to evaluate the prevalence and patterns of variant reclassification in an Asian country and its impact on patient management. **Methods:** A prospective cohort of patients seen at the Cancer Genetics Service at the National Cancer Center Singapore between February 2014 to March 2020 was evaluated. The frequency, direction and time to variant reclassification was assessed by comparing the reclassified report against the original report. **Results:** A total of 1412 VUS were reported in 49.9% (845/1695) of patients. Over six-years, 6.7% (94/1412) of variants were reclassified. Most VUS (94.1%; 80/85) were downgraded to benign/likely benign variant, with a smaller proportion of VUS (5.9%; 5/85) upgraded to pathogenic/likely pathogenic variant. Actionable VUS upgrades and pathogenic/likely pathogenic variant downgrades, that resulted in management changes, happened in 31.0% (39/126) of patients. The median and mean time taken for reclassification were 1 and 1.62 year(s) respectively. **Conclusions:** Clinicians need to put in place a system for review of variants, as variant reclassification can lead to changes in management in nearly 1/3 of patients. Management should be based on the patient's personal history, family history and variant interpretation. We propose a clinical guideline to standardize management of patients with VUS. For clinically relevant or suspicious VUS, follow-up is recommended every two years, as actionable reclassifications may happen during this period. An evaluation of gender discrepancies in genetic referrals for BRCA testing for indicated malignancies. *First Author: Wesley Smith, Prisma Health-Upstate, Greenville, SC*

Background: Tumor suppressing genes BRCA1 and BRCA2 were discovered in 1990 and 1994, respectively, with mutations linked to hereditary breast-ovarian cancer syndromes (HBOCs). The discovery of these mutations has led to screening of at-risk patient populations and their family members. Women with BRCA1 or BRCA2 mutations are generally recommended to have prophylactic bilateral mastectomies and oophorectomies to decrease their future risk of cancer. While the initial discovery mostly focused on cancers in women, research has shown that BRCA mutations increase the risk of other cancers such as prostate cancer and pancreatic cancer, that also affect men. Previous research suggests that men are three times less likely to receive genetic testing in cancer driven by a 10:1 disparity in HBOC genetic testing. This was thought to be due to the lack of information on the importance of HBOC testing along with social roles in health. We wanted to evaluate the magnitude of the potential gender gap in BRCA testing in men compared to women. **Methods:** This was an IRB-approved, single center retrospective study to evaluate the rate of referrals to genetics for BRCA testing. Eligible patients had a personal history of cancer meeting criteria for BRCA testing per NCCN recommendations. Chart review was performed for patients with ovarian cancer, female breast cancer 45 years and younger, female triple negative breast cancer 60 years and younger, metastatic prostate cancer, all male breast cancer that have made an office visit since 2017, and pancreatic cancer since 2019. Rates of referral for genetic testing was the primary outcome and the groups were compared via the Chi-Square test. **Results:** 1,320 patients were included in the study, of which 664 were men and 656 were women. 128/664 (19.3%) of men were referred to genetics for screening compared to 527/656 (80.3%) for women ($p < .001$). Additionally, 42/128 (32.8%) men who were referred for screening did not complete genetic screening compared to 72/527 (13.7%) women ($p < .001$). A total of 62/541 (11.5%) patients who completed screening had either a BRCA1 or BRCA2 mutation. **Conclusions:** In our study, men were referred for BRCA testing significantly less than women for primary cancers, despite recommendation from the NCCN. In addition, men were also more than twice as likely not to complete genetic screening even if referred. The integration of genetics and oncology will continue to grow as personalized medicine continues to drive more treatment options. Closing this gender gap is important not only for familial screening purposes but also for treatment implications as patients with germline BRCA mutations are eligible for poly ADP ribose polymerase (PARP) inhibitors (e.g. olaparib) in both metastatic prostate cancer and pancreatic cancer. Further quality improvement initiatives are needed in order to close this gap by increasing education of the importance of BRCA testing in men. Research Sponsor: None.

Germline testing and somatic tumor testing for *BRCA1/2* pathogenic variants in ovarian cancer: What is the optimal sequence of testing? *First Author: Janice S. Kwon, University of British Columbia, Vancouver, BC, Canada*

Background: In 2020 ASCO recommended that all women with epithelial ovarian cancer have germline testing (GT) for *BRCA1/2* mutations, and those without a germline pathogenic variant (PV) should have somatic tumor testing (TT), to determine eligibility for PARP inhibitor (PARPi) therapy (GT-TT strategy). An alternate strategy is to start with tumor testing first, and to conduct germline testing only in those with a PV in the tumor, or a significant family history (TT-GT strategy). The objective was to conduct a cost-effectiveness analysis comparing the 2 testing strategies. **Methods:** A Markov Monte Carlo simulation model compared the costs (USD) and benefits of the 2 testing strategies. According to local empiric data, a sufficient tissue sample for TT was available in 99% of cases, otherwise the patient would only have GT. Sensitivity of TT was 99% for detecting germline PV. Only those with *BRCA1/2* PV were eligible for PARPi. Primary outcomes included the number of women eligible for PARPi, with progression-free years of life (PFLY) gained based on SOLO1 data, and the incremental cost-effectiveness ratio (ICER). Monte Carlo simulation estimated the number of women who would have GT and TT, and the total with germline or somatic *BRCA1/2* PV eligible for PARPi. Sensitivity analyses accounted for uncertainty around various parameters. **Results:** The GT-TT strategy was more effective but more costly than TT-GT in identifying patients eligible for PARPi. Table summarizes the average lifetime costs, benefits, and Monte Carlo simulation estimates for 10,000 women diagnosed with advanced epithelial ovarian cancer annually in the USA. The incremental benefit from the GT-TT strategy would be achieved at substantial cost to the health care system, with an ICER of $119,340 per PFLY gained relative to the TT-GT strategy. The results were highly sensitive to the sensitivity of TT to detect germline PV, and the costs of GT and TT. Assuming that GT was less than 50% of the cost of TT, the sensitivity of TT had to exceed 98% for the TT-GT strategy to be cost-effective. **Conclusions:** Although the ASCO recommended strategy of *BRCA* germline testing followed by tumor testing for those without a pathogenic variant may be more effective in identifying ovarian cancer patients for PARP inhibitor therapy, it is more costly. The ASCO strategy is justified if the sensitivity of tumor testing is not sufficiently high. However, assuming high tumor testing performance rates, tumor testing first followed by germline testing if there is a PV in the tumor and/or family history is a cost-effective strategy. Research Sponsor: Michael Smith Foundation for Health Research, Pharmaceutical/Biotech Company.

		TT-GT	GT-TT

Clonal hematopoiesis association with cardiac function and mortality in patients with solid tumors. *First Author: Jessica A. Regan, Duke University Medical Center, Department of Medicine, Durham, NC*

Background: Clonal hematopoiesis (CH) is the presence of expanded somatic clones in hematopoietic cells and is associated with higher overall mortality (OM). Studies suggest atherosclerotic cardiovascular disease may drive mortality, but the detailed mechanisms remain unclear. CH mutations can be detected in solid tumor sequencing, often confounding genomic tumor analysis. We evaluated the association of CH in solid tumor next-generation sequencing (NGS) with echocardiographic findings and OM. **Methods:** Sequential adult patients treated at the Duke Cancer Institute with solid tumor NGS analysis by FoundationOne were captured retrospectively. CH mutations present at a variant allele fraction ≥2% across 57 genes previously associated with hematologic malignancies were included. Patients with echocardiograms between 2 years before NGS testing and up to 5 years afterward were analyzed. Association between CH mutations with cardiomyopathy (CM, left ventricular ejection fraction $< 45\%$) and global longitudinal strain (GLS) was determined using logistic and linear regression, respectively. In a subset of patients with detailed cancer diagnosis date and clinical follow-up, Cox proportional hazard models were used to associate CH mutations with OM, with or without *TP53*/*KRAS* (included in most CH analyses but highly prevalent in solid tumors). Analyses were adjusted for age, gender and race. **Results:** Of 3029 patients with NGS testing, 2212 (73.0%) carried at least one CH related mutation, the majority of which were in *TP53*/*KRAS*. When excluding *TP53*/*KRAS,* CH mutations were observed in 806 of 3029 (26.6%) patients. CH mutations were associated with age (est 2.1, 95% CI 1.1-3.2, $p < 0.001$). Excluding *TP53*/*KRAS* strengthened the association between CH and age (est 2.8, 95% CI 1.8-3.9, $p < 0.001$). Echocardiogram data were available in 828 patients, of whom 48 (5.8%) had CM. CH mutations were not associated with CM (OR 1.3, 95% CI 0.6-2.6, $p = 0.5$), however when excluding *TP53* and *KRAS*, CH mutations were associated with lower odds of (OR 0.4, 95% CI 0.1-0.9, $p = 0.03$). GLS was available in 423 patients and was not associated with CH mutations ($p = 0.8$ with *TP53*/*KRAS*; $p = 0.4$ without *TP53*/*KRAS* as CH). In 222 patients with clinical information, OM did not differ between the CH vs no CH cohorts (HR 0.8, 95% CI 0.6 = 1.2, $p = 0.3$ inclusive of *TP53*/*KRAS*). When excluding *TP53*/*KRAS* mutations, in this population of patients with cancer, non-*TP53*/*KRAS* CH was associated with less OM (HR 0.6, 95% CI 0.4-0.9, $p = 0.01$). **Conclusions:** In this patient population with cancer, CH mutations did not associate with higher CM. In contrast to prior studies, CH detected in solid tumor does not associate with OM in this population. CH mutations confound tumor sequencing and these findings support the value of paired tumor-blood sequencing to determine true CH. Consensus around CH variants should be undertaken in future studies. Research Sponsor: Duke University.

Genetic assessment of hereditary breast and ovarian cancer in the Harris Health System: A five-year, single-center experience. *First Author: Nicole Higashiyama, Lester and Sue Smith Breast Center, Dan L. Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX*

Background: Identifying patients with hereditary breast cancer is critical since lifetime breast cancer risk is as high as 85% for those with germline BRCA1/2 mutations and preventive interventions can reduce that risk. However, genetic assessments and counseling are often underutilized among racial/ethnic minority populations. Reducing this genetic testing gap is important since hereditary breast/ovarian cancer syndromes occur among racial/ethnic minorities at least as frequently as non-Ashkenazi Jewish, non-Hispanic White populations. More information on variants in these populations is also needed to better define their genetic susceptibility. **Methods:** We conducted a retrospective study of adult patients evaluated for genetic testing for hereditary breast/ovarian cancer by a genetic counselor between October 1, 2009 and September 30, 2014 in Harris Health System which is a large, county health system composed mostly of underserved and minority patients. Data from 2015-2019 is currently being extracted and we are reporting the first 5 years of data. Descriptive statistics were used to summarize patient data. **Results:** 659 patients underwent genetic counseling (10.5% non-Hispanic White, 24.4% Black, 56.9% Hispanic, 5.9% Asian, and 2.3% other). Five patients had Ashkenazi Jewish ancestry. The majority of patients completed testing (87.4%) with 72.7% receiving financial assistance. Among those who did not complete testing, only 12.0% declined, while 66.3% did not meet guideline-based criteria or were recommended to have an affected relative tested. Multigene panel testing was not available until April 2014, so most underwent BRCA sequencing (75.0%) and/or a BRCA large rearrangement test (61.0%). 36.1% received multigene panel testing, 4.6% single site analysis, and 4.4% p53 sequencing. Deleterious mutations occurred in 98 (14.9%) patients: BRCA1 (n = 60), BRCA2 (n = 25), PALB2 (n = 7), ATM (n = 3), and other (n = 3). The distribution of races/ethnicities among those with deleterious mutations was similar to the overall population (7.1% non-Hispanic White, 18.4% Black, 69.4% Hispanic, 3.1% Asian, and 2.0% other). 80.6% of those with deleterious mutations had breast cancer. High rates of bilateral mastectomies were performed in patients with deleterious mutations: BRCA1 60%, BRCA2 55%, PALB2 57.1%, and ATM 33%. Risk-reducing salpingectomy or salpingo-oophorectomy was performed in 56.7% BRCA1, 60% BRCA2, 28.5% PALB2, and 33.3% other mutation carriers. **Conclusions:** We demonstrate that with the support of financial assistance programs, most patients who receive genetic counseling will accept genetic testing in a socioeconomically underserved, racially/ethnically diverse population. Identification of high-risk patients in these groups is critical since pathogenic variants in this population were common and more than half underwent risk-reducing procedures. Research Sponsor: None.

Testing for mutations in *BRCA1* and *BRCA2* among ovarian cancer patients at a diverse academic medical center. *First Author: Caitlin Taylor, Emory University Hematology Medical Oncology-Fellowship Program, Atlanta, GA*

Background: Testing for mutations in *BRCA1* and *BRCA2* is recommended for all women with ovarian cancer (OC), given important implications for treatment and prognosis. Despite this recommendation, studies show that only a small percentage of OC patients (pts) undergo genetic testing (GT). In this study, we evaluated rates of genetics referral, counseling and testing among OC pts at an academic medical center. Our goal was to identify factors associated with lower rates of GT. Given the large Black population at our center, we specifically wanted to evaluate the association between race and GT given limited existing data on this issue. **Methods:** Retrospective chart review was performed evaluating rates of referral and uptake for GT, and percentages of *BRCA* mutation carriers among pts with OC diagnosed and treated at Emory's Winship Cancer Institute between 2008 and 2018. Associations between age, race, histology, family history (FH), performance status, provider characteristics and genetics referral and testing were evaluated using logistic regression models. **Results:** Of the 171 pts who met inclusion criteria, the majority were age 55 or older (62%) with high grade serous carcinoma (60.8%). Pts were predominantly Caucasian (59.4%), followed by Black (29.1%), Asian (10.3%) and Hispanic (1.2%). Overall, GT rates were low with 44.7% of pts referred for genetic counseling and 39.8% receiving testing. Among pts who did receive GT, the percentage of deleterious *BRCA1* and *BRCA2* mutations identified was 11% and 8.8% respectively. Variables correlating with higher likelihood of genetics discussion, referral and testing included serous histology (50% vs 23.9% non-serous, $p < 0.001$), Caucasian or Asian race (87.5% Asian, 58.8% Caucasian vs 42.2% Black, $p = 0.003$) and seeing a medical oncologist (67.5% vs 44.7% seeing gynecologic oncologist alone, $p = 0.004$). Notably, while fewer Black women were referred for GT (25.9% vs 74.1% Caucasian), those that did undergo GT were found to have higher rates of *BRCA1* and *BRCA2* mutations when compared to Caucasian pts (22.2% vs 8.2% *BRCA1*; 11.1% vs 6.0% *BRCA2*). Pts with a FH of OC were more likely to undergo GT (69.2% vs 37.9%, $p = 0.027$), and pts with a FH of breast cancer were more likely be referred for testing (57.1% vs 39.6%, $p = 0.042$), suggesting that FH impacted referral patterns. **Conclusions:** The rates of GT among OC pts at our institution were lower than expected despite the broad recommendation for GT in this population. It is imperative to improve access to GT for all OC pts regardless of FH, and in particular among Black pts given the higher rates of *BRCA* mutations in this population. Pts and providers must work together to overcome barriers to genetics referral and testing in order to improve GT rates and clinical outcomes. Further research is needed to design interventions that may help improve adherence to this important recommendation in the future. Research Sponsor: None.

A comprehensive literature review and meta-analysis on prevalence of BRCAm, HRRm and HRD+ across tumor types. *First Author: Changxia Shao, Merck & Co., Inc., Kenilworth, NJ*

Background: Poly (ADP-ribose) polymerase inhibitor (PARPi) may have broad application in the treatment of cancer patients with mutations in BRCA (BRCAm) or other homologous recombination repair genes (HRRm) or with homologous recombination deficiency positive (HRD+). A literature review and meta-analysis were conducted to evaluate the prevalence of BRCAm, HRRm, and HRD+ across tumor types. **Methods:** Comprehensive searches for eligible studies in Ovid MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, and Cochrane reviews were performed in May 2020 to capture studies published in English, within 10 years for manuscripts and 3 years for abstracts across geographic regions. A weighted summary estimate was calculated for BRCAm. A summary estimate with corresponding 95% CI was calculated using random-effects models for HRD+ and HRRm. **Results:** A total of 342 eligible studies with at least 100 samples were included in the review of BRCA1/2m prevalence, containing a total of over 469,000 samples across 24 tumor types. The most frequent indications examined in the included studies were breast (study number n = 144), ovarian (53), prostate (17) and pancreatic (11) cancers. The prevalence of germline BRCA1m (gBRCA1m) and gBRCA2m was 5% and 4% for breast, 12% and 5% for ovarian, 1% and 3% for prostate, and 1% and 4% for pancreatic cancer, respectively. The prevalence of somatic BRCA1m (sBRCA1m) and somatic BRCA2m (sBRCA2m) was 3% and 3% for breast, 7% and 5% for ovarian, 3% and 5% for prostate, and 1% and 3% for pancreatic cancer, respectively. Few studies evaluated endometrial, lung and colon cancers, the prevalence of gBRCA1m or gBRCA2m was generally less than 1%, and the prevalence of sBRCA1m and sBRCA2 ranged 1 to 3%. Seven publications were identified where HRD+ was defined by either BRCAm or genomic instability score (GIS) $\geq$ 42 across breast, ovarian and pancreatic cancers. The overall HRD+ prevalence was 56% (95%CI: 48, 64), with similar prevalence observed across the 3 tumor types and was 50% (34, 66) for the 3 studies only counting GIS$\geq$ 42. 194 studies across 26 tumor types were identified that examined HRRm as mutations in one or more HRR genes other than BRCA1/2m. The definitions of HRRm varied substantially across the studies, and ATM (2.8%), CHEK2 (1.6%), and PALB2 (1.6%) accounted for most of the observed mutations among HRR genes. **Conclusions:** Prevalence of BRCAm, HRRm and HRD+ varied by cancer type. This comprehensive meta-analysis enriches the knowledge in this field and demonstrates the need to standardize the measurement of HRRm and HRD.Understanding the prevalence of these biomarkers could have important clinical implications. Research Sponsor: Merck & Co.

Distribution of BRCA1/2 germline and somatic alterations across cancer type. *First Author: Jingde Chen, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China*

Background: PARP inhibitors (e.g. Olaparib or niraparib) have been approved by FDA as a targeted therapy for many tumors harboring germline or somatic BRCA1/2 (g or sBRCA1/2), including ovarian cancer, prostate cancer, breast cancer and pancreases cancer. It is imperative to study the distribution of BRCA1/2 across cancer type. In this study, we aim to assess the landscape of BRCA1/2 alterations in solid tumors and evaluate the feasibility of circulating tumor DNA (ctDNA) tested by next-generation sequence (NGS) as a tool to detect BRCA1/2 alterations. **Methods:** For tissue specimen, genomic DNA from formalin fixed paraffin-embedded (FFPE) tumor specimens or fresh tumor tissues was used for sequence analysis. Genomic DNA (gDNA) from white blood cells was extracted using the QIAamp DNA Mini Kit (Qiagen). For ctDNA, cell-free DNA libraries were prepared using the KAPA Hyper Prep Kit following the manufacturer's protocol. The captured libraries were loaded onto a NovaSeq 6000 platform (Illumina) for 100bp paired-end sequencing. The testing was performed in the College of American Pathologists (CAP) and Clinical Laboratory Improvement Amendments (CLIA) -certified 3D Medicines Library. **Results:** A total of 27, 835 patients were tested using tumor tissue during Jan. 1th 2017 to June 1th 2020, including 43% (N = 12089) of non-small cell lung cancer, 19% (N = 5357) of colorectal cancer, 8% (N = 2181) of liver cancer, 6% (N = 1621) of gastric cancer, 5% (N = 1479) of biliary tract cancer, 4% (N = 1084) of kidney cancer, 4% (N = 1045) of pancreas cancer, 3% (N = 689) of breast cancer and 2% (N = 599) of ovarian cancer. Across all tumor types, the known or likely deleterious BRCA1/2 alterations were identified in 2147 (7.7%) patients. Ovarian cancer had the highest frequency of BRCA1/2 alteration (23.4%), followed by endometrial cancer (12.7%) and breast cancer (10.6%). BRCA1/2 alteration was found in 8.8% prostate cancer and 4.2% pancreas cancer respectively. Across all tumor types, the known or likely deleterious gBRCA1/2 alterations were identified in 369 (1.3%) patients. Notably, ovarian cancer had the highest frequency of gBRCA1/2 alteration (13.9%), followed by breast cancer (7%), prostate cancer (4.4%) and endometrial cancer (4.1%). No clear hotspot mutations and mutated codons were spread throughout g or sBRCA1/2 mutations. Additionally, among 15699 patients who suffered ctDNA sequencing, any known or likely deleterious sBRCA1/2 alterations were identified in 358 (2%) patients. Similar to the results of tissue sequencing, ovarian cancer had the highest frequency of sBRCA1/2 alteration (16.67%), followed by endometrial cancer (9.68%), prostate cancer (7.18%) and breast cancer (5.58%) in the blood cohort. **Conclusions:** BRCA1/2 alterations existed across tumor types and the landscape of g or sBRCA1/2 alterations varied according to cancer type. Furthermore, ctDNA can be used as a potential tool to detect BRCA1/2 alterations. Research Sponsor: None.

Racial disparities in genetic testing of breast cancer patients. *First Author: Solange Bayard, Weill Cornell Medicine, New York, NY*

Background: TNBC is disproportionately prevalent in African American (AA) populations and in women with BRCA-1 germline mutations. BRCA mutation carriers are candidates for targeted therapy with PARP-inhibitors, and testing results may influence risk-reducing surgery choice. **Methods:** We evaluated genetic testing patterns and outcomes for TNBC patients treated in the prospectively maintained databases of academic cancer programs in two metropolitan cities in the Northeast (New York City, NYC) and Midwest (Detroit, Det), 1998-2018. Median follow up was 3.73 years. Testing patterns were also analyzed by time, comparing pts diagnosed before versus after the mid-2013 Supreme Court ruling that expanded testing availability by banning gene patenting. **Results:** Of 810 pts, 600 were from NYC and 200 from Det; 202 were AA and 488 WA. Pts undergoing genetic testing were younger (median age 50 vs 62; $p < 0.0001$). Compared to WA, AA pts were less likely to undergo genetic testing overall (23.8% vs 42.0%; $p < 0.0001$) and within site (NYC: 25.6% vs 42.8%, $p = 0.008$; Det: 22.3% vs 38.6%, $p = 0.025$). No significant differences were seen in frequency of pathogenic BRCA mutations (AA-14.6%; WA-29.3%) or VUSs (AA-6.3%; WA- 4.9%); $p = 0.20$. Genetic testing disparities were reduced among pts diagnosed after mid-2013 (AA-31.4% vs WA-44.0%; $p = 0.01$) compared to pre-mid-2013 (AA-18.3% vs WA-40.7%; $p < 0.0001$). No differences were seen in local or distant recurrence free survival between patients with BRCA, BRCA variants of uncertain significance, non-BRCA mutations, and patients without genetic mutations (local recurrence $p = 0.827$; distant recurrence $p = 0.574$). This outcome equivalence was consistent when stratified by WA vs AA identity. **Conclusions:** Genetic testing has increased for TNBC pts following the mid-2013 Supreme Court ban on gene patenting, but race-associated disparities persist. Pts undergoing genetic testing are more likely to undergo risk-reducing mastectomy, but testing results do not affect survival outcomes, regardless of race. Addressing genetic testing disparities will become increasingly important as mutation-associated targeted therapies are identified through advances in precision medicine. Research Sponsor: None.

Oncologists' (ONCs) perceptions of tumor genomic profiling (TGP) and barriers to communicating secondary hereditary risk to African American (AA) patients. *First Author: Michael J. Hall, Fox Chase Cancer Center, Philadelphia, PA*

Background: TGP identifies targets for precision cancer treatments. TGP may also identify secondary hereditary cancer risks, necessitating complex decision support during informed consent. ONCs are poorly trained in the communication of genetic information, particularly for patients with low health literacy, poor knowledge of genetics, and high medical mistrust. AA patients are especially vulnerable in this setting. **Methods:** We conducted semi-structured interviews with 10 ONCs to assess perceived barriers related to communication of secondary hereditary risks of TGP, probing barriers unique to AA patients. Informed by results, an Internet-based survey was developed/distributed to a convenience sample of 50 ONCs nationwide to assess TGP knowledge, genomics confidence, and perceptions related to communication of secondary hereditary risk. **Results:** Six themes emerged from interviews: risk/benefits of TGP, knowledge of genetics, discussing hereditary risk, value/harm of TGP, unique risks in AA, and training needs. Most ONCs felt uncomfortable discussing hereditary risks of TGP w/patients. Seven out of 10 identified socio-economic status, medical mistrust, discrimination, genetic counseling non-compliance, low health literacy and family relationships as factors important to consider with AA patients. Online survey participants were 52% White, 66% male, with median age of 42 years. Education in the interpretation/communication of TGP was largely informal (56% reported only informal training) and 46% reported perceived gaps in their education. Genomic confidence was associated w/higher use of TGP ($p = 0.05$), but was not associated w/knowledge or years in practice; however, low knowledge was associated w/more perceived barriers to TGP and w/negative attitudes toward the value of TGP and the challenge of communication of possible hereditary risks ($p = 0.05$). Early-career ONCs were more likely to endorse perceived barriers to communication of genetic risk information from TGP to AA patients. Overall 86% ONCs felt additional online training in communication of secondary hereditary risks of TGP would be useful. **Conclusions:** ONCs recognize unique needs and barriers for AAs related to communication of secondary hereditary genetic information from TGP. Many feel uncertain about how/whether to address barriers and recognize the need to improve their skillset to do so. Training is critical to ensure informed decision making in vulnerable populations. Evaluation of proband adherence and satisfaction with a prospective cascade testing protocol. *First Author: Maria Smith, NYU Grossman School of Medicine, Brooklyn, NY*

Background: We sought to evaluate the feasibility of a Cascade Testing (CT) protocol for family members of probands with actionable germline mutations associated with endometrial or ovarian cancer. Here, we characterize proband compliance with contacting family members for CT and proband satisfaction/regret. **Methods:** In this prospective study, consenting patients with pathogenic germline mutations associated ovarian or endometrial cancer completed a demographic survey and were asked to contact first- and second-degree relatives with genetic testing results. After a 1–3-month period, probands completed a survey indicating how many relatives had been contacted. At 3 months following consent, probands were asked to complete the validated Impact of Event Scale (IES) and Decision Regret Scales (DRS). Characteristics of probands who contacted relatives and those who did not were compared. **Results:** The study has accrued 57 probands since opening in March 2019. Germline mutations identified in the 57 probands include 27 *BRCA1* (47.4%); 21 *BRCA2* (36.8%); 3 *BRIP1* (5.3%); 2 *MLH1* (3.5%); 2 *MSH2* (3.5%); 3 *MSH6* (5.3%); 3 *PMS2* (5.3%); 1 *EPCAM* (1.8%); 1 *RAD50* (1.8%). Twenty-four (42.1%) probands had a history of cancer (breast 12; ovarian 8; uterine 2; other 5). Of the probands, 32 (56.1%) completed follow-up questionnaires and 29 (50.9%) had contacted relatives about participating in CT. In total, 67 relatives were contacted. Probands contacted an average of 1 relative, ranging from 1-20. Of the 29 probands who contacted relatives, 13 (44.8%) completed IES and DRS questionnaires. The median IES score was 0 out of 75 (IQR 0.0-4.5) and the median DRS score was 0 out of 100 (IQR 0.0-11.3). When comparing characteristics of probands who contacted relatives with those who did not, those with annual household incomes <$75,000 were more likely to contact relatives vs those with incomes ≥$75,000 (77.8% vs 39.5%; p=0.01). There was no association between contacting relatives and personal cancer history, race/ethnicity, education status, or age (Table). **Conclusions:** Half of probands enrolled in this study contacted relatives about CT, and those with household incomes <$75,000 were more likely to contact relatives than those with higher incomes. Overall, probands reported little/no regret or distress after contacting relatives about genetic testing results. Research Sponsor: None.

Multicancer hereditary syndrome testing: Genetic counselors' perspectives. *First Author: Christine B. Weldon, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: The accessibility of cancer hereditary syndrome testing has increased, and the cost has declined significantly in the past few years. We conducted a national, quantitative survey of genetic counselors (GCs) to assess their perspectives on what influences hereditary cancer genetic testing decisions and practices, with a focus on cost. This survey was funded by NIH, conducted by UCSF TRANSPERS, and supported by the National Society of Genetic Counselors (NSGC). **Methods:** The survey was developed through literature review, expert interviews, and a pilot. Sent to the NSGC Cancer Special Interest Group via email. Chi-square tests were used to examine variability. **Results:** The survey response rate was 56% (202/363). Multiple hereditary cancer syndrome tests are discussed often/always by 86% of genetic counselors (GCs). The existence of an institutional protocol on multiple hereditary cancer syndrome testing was reported by 35.4% of GCs. When asked about GC counseling encounters, GCs report insurance rarely/never pays for: 25.2% pre-test in-person, 39.7% for pre-test tele-genetics, 35.4% post-test in-person, and 52.9% post-test tele-genetics. GCs rated clinical factors higher than cost as influencing decision for multiple hereditary syndrome cancer testing (table); the total cost of the test was least important. These patterns were similar across the GCs institution types and years in practice. **Conclusions:** We found consistent use of multiple hereditary cancer syndrome tests, with less focus on cost, out-of-pocket, and insurance coverage and more of a focus on clinical indicators. GCs reported challenges with reimbursement for GC counseling encounters. The shift toward more genetic counseling encounters via tele-genetics necessitates evaluation of insurance reimbursement. Research Sponsor: U.S. National Institutes of Health.

How important are the following factors in your decision to discuss and possibly order multiple hereditary cancer syndrome testing?	Moderately / Very Important n = 202 %
Limited family structure, unknown family history, and/or patient adopted without biological relative history knowledge	81
Patient's request and or question about multi-gene syndrome testing	81
Personal and family history reveal only one major cancer type	56
Single syndrome test is more clinically appropriate for patient	53
Concern about increased likelihood of variants of uncertain/unknown significance	51
Concern about unexpected pathogenic/likely pathogenic variant in a gene not associated with phenotype	49
Expectation that patient may be willing to pay for test if insurance doesn't cover it	47
Standards or protocol of your clinic, organization, institution	44
Concern that patient share of payment / out of pocket is too much	43
Concern that patient's insurance may not cover multiple-syndrome testing	41
Patient with no phenotype based on personal or known family history	38
Concern that total cost of test (cost to insurance/payer plus co-pay) is high	32

Prevalence and spectrum of pathogenic variants among patients with multiple primary cancers. *First Author: Brittany L. Bychkovsky, Cancer Genetics and Prevention, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Multiple primary cancers (MPCs) are a hallmark of cancer predisposition syndromes. We aim to characterize the frequency of germline pathogenic/likely pathogenic variants (PVs) among patients with MPCs. Herein we report the frequency of PVs by sex, number of cancers and age at diagnosis among a laboratory-based cohort of patients with MPCs. **Methods:** Patients with MPCs who underwent germline genetic testing with Ambry Genetics from 3/2012 to 12/2016 were included in our cohort. Eligible individuals had multigene panel testing, which included 21 genes, at minimum**:** *ATM, BARD1, BRCA1, BRCA2, BRIP1, CDH1, CHEK2, EPCAM, MLH1, MSH2, MSH6, MUTYH, NBN, NF1, PALB2, PMS2,PTEN, RAD51C, RAD51D, STK11,* and *TP53*. Clinical factors including age at diagnosis, age at testing and cancer type were obtained from test requisition forms and clinical notes. Patients with > 1 PVs were excluded from the analysis. Using Rv.3.3.3., the frequencies of PVs by sex, number of cancers and age at diagnosis were compared using two-sided $\chi 2$ tests or Fisher's exact test when the number was < 10. **Results:** Of the 9820 patients with MPCs tested for the 21 genes above, 104 (1.1%) had multiple PVs and were excluded. Among the remaining 9716 patients in the analytic cohort, most were female (91.1%) and white (71.0%). The median age at testing was 63 years (IQR: 16) and the median ages of first and second cancer diagnosis were 49 (IQR: 18) and 58 (IQR: 17) years, respectively. Overall, 1406 (14.5%) were found to have PVs: 14.3% of females and 16.2% of males. The prevalence of PVs increased with the number of primary cancers (PCs) as follows, 2 PCs: 13.1% (95% CI:12.4-13.8%), 3 PCs: 15.9% (95% CI:14.0-18.0%), >4 PCs: 18.0% (95% CI:13.7-23.3%), (p < 0.01). Among patients with 2 PCs (n = 8145), differences in the prevalence of PVs by age at diagnosis were significant: 2 PCs diagnosed at an age < 50 (13.5%, 95% CI:12.0-15.1%), 1 PC diagnosed at an age < 50 (14.8%, 95% CI:13.4-16.5%), 2 PCs diagnosed at age >50 years (12.1%, 95% CI: 11.1-13.2%), (p = 0.01). PVs were most frequently identified in: *BRCA2* (2.2%) *BRCA1* (2.0%), *CHEK2* (1.9%) and *ATM* (1.5%). There were also significant differences in the frequencies of PVs in *BRCA1*, *BRCA2* and *MLH1* by sex (p < 0.05). **Conclusions:** These data demonstrate a high frequency of germline PVs among both males and females with MPC. The frequency of PVs was higher among patients with a higher number of PCs. Differences in the prevalence of PVs by age at cancer diagnosis while significant, were not meaningful as 12.1% of individuals with 2 PCs diagnosed at age >50 years had germline PVs. Limitations include the homogenous testing population (predominately female and white) and small numbers in some patient categories. These data may aid in counseling patients with MPCs and their families as well as encourage less restrictive genetic testing of this population. Further analysis of PV frequencies by specific cancer combinations was conducted and will follow. Research Sponsor: None.

Identification of potential germline (GL) variants by routine clinical comprehensive genomic profiling (CGP) and confirmatory GL testing in 24 tumor types. *First Author: Kristen Hanson, Advocate Aurora Health, Milwaukee, WI*

Background: Tumor CGP may identify both somatic and GL variants, though confirmatory testing is required to verify which variants originate from the GL. Studies have shown CGP can identify patients who both do and do not meet criteria for genetic counseling (GC). Ideally, improved annotation from tumor CGP could more appropriately direct GC referrals. We explore how a computational algorithm might be used to influence GC and confirmatory GL testing for variants in inherited cancer predisposition genes. **Methods:** 849 patients from the Aurora Oncology Precision Medicine Program who had routine hybrid-capture based CGP by Foundation Medicine from 8/2018-8/2020 were eligible. A previously published algorithm, SGZ (Sun et al PMID 29415044) which incorporates allele frequency, aneuploidy, and admixed copy number modeling was used to predict whether each single nucleotide variant (SNV) was GL or somatic. SGZ predictions for SNVs in 24 actionable inherited cancer predisposition genes were available to Aurora for review as part of standard screening to identify appropriate GC referrals. For patients who had GL testing, variants in genes on both assays were compared. **Results:** 76 pathogenic (P) or likely pathogenic (LP) variants predicted to be GL by SGZ were detected in 73/849 (9%) patients: *ATM* (7), *BAP1* (2), *BRCA1* (13), *BRCA2* (8), *BRIP1* (1), *CHEK2* (18), *FH* (0), *FLCN* (2), *MLH1* (1), *MSH2* (0), *MSH6* (3), *MUTYH* (12), *PALB2* (3), *PMS2* (1), *POLE* (0), *RAD51C* (1), *RAD51D* (0), *RET* (1), *SDHA/B/C/D* (0,0,0,0), *TSC2* (0), and *VHL* (3). 27/73 (37%) patients had GL testing. 25/26 (96%) variants were confirmed to be GL in origin and 1 additional variant was detected by CGP in a region not interrogated by the GL assay: *ATM* (2/2), *BRCA1* (6/6), *BRCA2* (2/2), *BRIP1* (1/1), *CHEK2* (9/9), *FLCN* (0*/1), *MSH6* (1/1), *MUTYH* (2/2), *PALB2* (1/1), *RAD51C* (1/1), and *VHL* (0/1). Variants were confirmed in bladder, breast, CRC, glioma, NSCLC, ovary, pancreas, prostate, sarcoma, and gastric cancer. The *VHL* variant was discordant in a leiomyosarcoma. **Conclusions:** We identified the potential real-world clinical impact of computationally screening solid tumor patients undergoing routine CGP for potential P/LP GL variants. Predicting GL results with SGZ for 24 inherited cancer predisposition genes was highly concordant with confirmatory GL testing independent of tumor type. CGP annotations can facilitate GC referral and GL testing for at-risk patients, particularly in tumor types which may not typically meet guidelines for GL testing. Research Sponsor: None.

Prevalence of germline testing criteria in breast cancer patients in the Brazilian public health system: A retrospective study. *First Author: Robson dos Santos dos Santos Borges, Grupo Oncoclinicas, Hospital Felicio Rocho, Hospital Alberto Cavalcanti, Belo Horizonte, Brazil*

Background: Identification of a germline mutation in a breast cancer predisposition gene has implications for the patients and their families. The National Comprehensive Cancer Network (NCCN) has published guidelines for genetic testing. In Brazil, this assessment is covered by health insurance in accordance with criteria defined by the National Supplementary Health Agency (ANS). For the majority of the population, served by the public health system (SUS), the assessment is not routinely available. **Methods**: In order to determine the prevalence rates of NCCN and ANS criteria for germline testing in breast cancer (primary outcome) we retrospectively analyzed data from patients treated at two SUS oncology centers in Belo Horizonte, Minas Gerais, Brazil, between 01/01/18 and 12/31/19. The secondary outcomes were comparisons between the groups with and without germline testing criteria (NCCN and ANS) regarding overall survival, clinical and epidemiological characteristics. The association between qualitative variables was calculated using the Chi-square and Fisher tests. The Kaplan-Meier method was used to analyse the survival data and the differences between the groups were tested using the log-rank test. The level of significance was 5%. **Results**: A total of 357 patients were included in the final analysis. The presence of germline testing criteria were found in 126 patients (35%) according to NCCN guidelines and in 82 patients (23%) according to ANS guidelines. None of them were tested for germline mutations. The most common criteria were women up to 60 years old with triple negative tumors (n = 43, 12% of all patients) and diagnosis of cancer up to 45 years old (n = 75, 21% of all patients) according to ANS and NCCN criteria, respectively. When the group of patients who met at least one criterion for germline testing were compared with the group who did not met any criteria, we found in the first group: more ductal carcinomas and less lobular tumors ($p = 0.009$), more grade 3 tumors ($p = 0.002$), more triple negative tumors ($p < 0.001$), more neoadjuvant treatments ($p = 0.008$) and less hormonal therapies ($p = 0.011$). After a median follow up of 13.5 months there were 22 deaths in the cohort, 7 in the group with testing criteria (5.7%) and 15 in the group without testing criteria (6.4%). There was no statistical significant difference between the groups in terms of overall survival ($p = 0.77$). **Conclusions**: To our knowledge this is the first study to evaluate the prevalence of NCCN and ANS criteria for germline testing in patients with breast cancer treated in the Brazilian public health system. Our results show that more than a third of those patients are candidates for germline testing. Moreover, the data highlight a serious shortcoming in the management of breast cancer and must be considered in the development of public health policies for routine germline testing in that population. Research Sponsor: None.

Impact of race on biomarker testing among HER2- advanced breast cancer (ABC) patients (pts) in the United States: Results from a real-world study. *First Author: Reshma L. Mahtani, Sylvester Cancer Center, University of Miami, Deerfield Beach, FL*

Background: African Americans (AA) have the highest breast cancer (BC) mortality rate. Access to treatment is a known contributing factor. In the past 4 years, several targeted therapies for HER2- BC have become available which require testing for specific biomarkers. This study assessed the impact of race on biomarker testing rates in HER2- ABC pts receiving treatment in the US. **Methods:** Oncologists were recruited to abstract data from medical charts for the next 8-10 pts receiving treatment with HER2- ABC during Sept 2019-Apr 2020. Pts records were stratified by race and categorized into 3 mutually exclusive cohorts [White/Caucasian (White), AA, Other]. The other race cohort was excluded from this analysis due to small sample size. Differences in pt demographics/clinical characteristics were analyzed via Fisher's exact tests. Testing rates for actionable biomarkers (i.e. *BRCA1/2*, PIK3CA, PD-L1) were compared between White and AA pts utilizing logistic regressions controlling for age, known family history of a *BRCA*-related cancer, hormone receptor (HR) status and practice setting (academic vs. community). Further analyses by age will be presented. **Results:** This analysis included 378 pts records, provided by 40 oncologists. Mean age was 64 years; 77% had HR+/HER2- ABC; 20% had advanced triple negative breast cancer (TNBC), 3% had ABC with an unknown HR status. Compared to White pts, AA pts were significantly more likely to have advanced TNBC (27% vs. 18%, $p<0.05$). Compared to White pts, AA pts had significantly lower *BRCA1/2* mutation (mut) testing rates (Table). Numerically lower rates of PIK3CAmut and PD-L1 testing were observed among AA pts (Table). *BRCA1/2*mut positivity rate (germline [g] and/or somatic [s]) was higher among AA vs. White pts (30% vs. 22%). Positivity rate for PIK3CAmut was lower for AA vs. White pts (8% vs. 11%). **Conclusions:** A higher than expected *BRCA1/2*mut positivity rate was observed than previously reported in the literature. This is likely because this analysis included s*BRCA1/2*mut and represented a high risk pt population. Across all biomarkers assessed, AA pts had lower testing rates than White pts. This suggests racial disparities in testing rates of actionable biomarkers. Consistent with guidelines, and with the increased availability of targeted therapies, focused efforts should be developed to increase biomarker testing in AA pts. Funding: Pfizer Biomarker Testing Rates by Race. Research Sponsor: Pfizer.

Compliance with germline testing in pancreatic cancer in a rural tertiary care hospital. *First Author: Catherine Travaline, Geisinger Medical Center, Danville, PA*

Background: Pancreatic cancer is the 7th most common cause of cancer death worldwide and is projected to be the second leading cause of cancer death in the next decade. Personalized care is becoming more of a reality with pharmacological regimens targeting specific genetic mutations. In March 2019, the National Comprehensive Cancer Network (NCCN) guidelines were updated to recommend germline testing (GT) in all patients with pancreatic adenocarcinoma (PDAC) considering 1 in 10 may have a germline mutation (GM). The goal of this study was to quantify compliance with these recently updated guidelines. **Methods**: The electronic medical records and survivorship data of all patients diagnosed with PDAC between January 1, 2017 and October 1, 2020 were reviewed. April 1, 2019 was used as the transition point (TP) for guideline updates. Descriptive statistics for all variables were determined. The rate of ordered referrals to genetic counseling (GC), as well as completion rate, was calculated. **Results:** A total of 304 patients were diagnosed with PDAC during the study period (223 prior to the TP). A total of 54 patients were referred for GC and 41 had GT ordered. The rate of GC referrals ordered after the TP was significantly higher than before the TP (22/81, 26.6% vs. 32/223, 14.4%; p-value 0.010). Almost 60% of patients who had genetic evaluation had private insurance. The patients who completed GT were significantly more likely to have a documented family history of cancer (61.0% vs 4.2%; p-value <.0001Patients who completed GT had more problems on their problem list (median 10 vs 7, $p = 0.001$). The median overall survival (OS) for all patients in the study was 7.8 months (95% CI: 6.3-9.8). **Conclusions:** Overall compliance with the updated NCCN guidelines significantly improved; however, it was below 25%. This study showed that there may be some lingering bias toward GT in PDAC solely for those who have a family history of cancer. Although patients with stage IV PDAC have poor outcomes, GT may still improve surveillance for family members. The approval of olaparib in patients with BRCA1/2 mutations based on the POLO trial is likely to increase provider compliance as it provides a viable maintenance strategy in these patients. Patient complexity was unlikely to affect GT rate. Assessment of provider awareness was outside the scope of this study. There is need for continued advocacy for awareness and implementation of guidelines that highlight the importance of germline evaluation on prevention, surveillance, and treatment in pancreatic adenocarcinoma. Research Sponsor: None.

Evaluation of cohort diversity in development and validation studies of hereditary cancer genetic risk assessment models. *First Author: Amanda Gammon, Huntsman Cancer Institute, Salt Lake City, UT*

Background: Multiple models estimate a person's chance of harboring a pathogenic variant increasing cancer risk. Some pathogenic variants are more common in individuals from specific ancestries, such as the *BRCA1* and *BRCA2* founder variants in Ashkenazi Jews. Yet data remains limited on the larger variant spectrum seen among people of different ancestral backgrounds and whether or not the pathogenic variant frequency differs in many populations. Due to this, it is important that genetic risk assessment models be validated in a diverse cohort including Black, Indigenous, People of Color (BIPOC). **Methods:** A literature search was conducted to identify published development and validation studies for the following genetic risk assessment models: BRCAPRO, MMRPRO, CanRisk/BOADICEA, Tyrer-Cuzick, and PREMM. Validation studies that only evaluated the cancer risk prediction capabilities of the models (and not the genetic variant risk prediction) were excluded. The following participant information was abstracted from each study: total number of participants, gender, race, and ethnicity. Authors were contacted to obtain missing information (if available). **Results:** 12 development and 12 validation studies of the genetic risk assessment models BRCAPRO, MMRPRO, CanRisk/BOADICEA, Tyrer-Cuzick, and PREMM were abstracted. Of the validation studies, five were internal validation studies conducted by the model developers, and seven were external validation studies. Four external validation studies compared multiple models. 75% (18/24) of papers did not include reporting of participant race or ethnicity information in their published reports. External validation studies (4/7, 57%) more often reported participant race/ethnicity than development (0/12, 0%) or internal validation (2/5, 40%) studies. The external validation studies for BRCAPRO reporting race/ethnicity information involved cohorts that ranged from 50-51% non-Ashkenazi Jewish white, 28% African American, 1% Asian, 2-49% Hispanic, and 19-42% Ashkenazi Jewish. The external validation studies for MMRPRO and PREMM reporting race/ethnicity information involved cohort that ranged from 0-82% white, 4-100% Asian, 7% Black, and 7% Hispanic. **Conclusions:** Increased reporting of participant ancestry and ethnicity is needed in the development and validation studies of genetic risk assessment models. BRCAPRO's validation cohorts have included a higher percentage of Hispanic and Black/African American participants, while MMRPRO and PREMM have been validated in a higher percentage of Asian participants. As debate continues about the utility of currently used racial categories in genetics research, it will be important to determine how best to report on participant diversity. These findings highlight the continued need for genetics researchers to engage BIPOC and identify ways to diversify their participant cohorts. Research Sponsor: None.

Assessing somatic and germline variants in cancer patients. *First Author: Charité Ricker, Division of Oncology, USC Keck School of Medicine, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: The increasing integration of somatic and germline testing into oncology practice allows physicians to target oncologic therapy and identify those with cancer predisposition. We explored the impact of a somatic assay (liquid biopsy, LB) on the identification of patients appropriate for germline genetic testing. **Methods:** We identified a cohort of diverse cancer patients with LB to assess for targetable somatic gene variants at LAC+USC Medical Center between 2016 and 2020 (n= 467). To enrich the cohort for variants that may reflect germline findings, we focused on the 46 patients (9.9%) who had at least one variant identified with a cell-free DNA (cfDNA) fraction of 25.00% or greater. Retrospective chart review extracted demographics and medical history with variables related to cancer history and treatment. LB variants were classified based on whether germline confirmation was indicated and the results of germline tests, when done, were reviewed. **Results:** Table summarizes the characteristics of the 46 patients identified to have at least one variant on LB in ≤ 25% of the cfDNA. The most frequently mutated genes on LB were *TP53* (n=18, 39%), *KRAS* (n=11, 24%), *APC* (n=8, 17%), *BRCA2* (n=7, 15%), *PIK3CA* (n=6, 13.0%), and *BRCA1* (n=4, 9%). Seventeen patients (40%) were referred for genetic counseling and 13 (30%) underwent germline testing of whom 10 (77%) carried pathogenic variants (PV). All germline PV were concordant with LB variants identified. Four patients with PV *BRCA2* on LB and confirmed to be germline, had lung or biliary tract diagnoses, which are not part of the typical *BRCA*-tumor spectrum. Thirty-three patients were not referred for genetic counseling, though 24 (72%) had LB-identified variants in cancer predisposition genes and 18 (54%) merited a genetics referral. Among patients with germline mutations, three (23%) had targeted therapy and two (15%) had preventive surgery to address second primary cancer risk. Among the 467 patients with LB results, there were an additional 13 patients (not included in the enriched group) known to have a cancer predisposition gene PV. Only two (15%) had findings on LB reports that suggested germline testing would be indicated. **Conclusions:** While the purpose of somatic testing is to identify targeted therapy, it can provide germline insight, especially for patients not typically referred for genetic assessment. Further education and guidance is needed to assure that this aspect of somatic testing is appreciated by oncology providers and acted upon. Research Sponsor: None.

Circulating tumor DNA (ctDNA) as a tool to help guide germline testing in patients with solid malignancies. *First Author: Nikita P. Patel, Department of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: As the use of circulating tumor DNA (ctDNA) is more widely implemented, incidental identification of pathogenic variants reflecting germline alterations in cancer predisposition genes will occur more frequently. Such mutations are expected to have a high mutant allele frequency (MAF) or occur in genes typically associated with inherited syndromes. When a similar analysis was conducted by our group, we found that MAF of about 30% or greater in *BRCA1/2* was associated with confirmed putative germline mutations in patients with breast cancer (Jacob et al & Davis et al, SABCS 2020). In this study, we extended this analysis to non-breast malignancies. **Methods:** Patients with non-breast solid malignancies and ctDNA testing between 2015-2020 were retrospectively identified from Northwestern Medicine. All ctDNA was analyzed using Guardant 360 (Guardant Health, Inc. Redwood City, Ca). Patients with ctDNA samples with mutations at high MAF (>30%) and those with *BRCA1/2* mutations at any MAF were identified. We reviewed these charts for referral to genetic counselors and/or CLIA-approved germline testing. Descriptive analysis was reported for these findings. Genetic alterations were classified as pathogenic or of unknown significance based on OncoKB (Chakravarty et al, JCO PO 2017). **Results:** We identified ctDNA samples of 548 patients with non-breast solid malignancies, of whom 56 had gene mutations occurring at high MAF (>30%). Predominant cancer subtypes were lung (48%), colorectal (21%), pancreatic (7%), ovarian (3.5%), prostate (3.5%), and gastroesophageal (3.5%). The most common gene mutations identified were *TP53* (46%), *BRCA1/2* (18%), *EGFR* (18%), *APC* (13%), and *KRAS* (9%). 87.5% were pathogenic and 12.5% were of unknown significance. 11 patients (19.6%) had germline testing of whom 6 tested positive. These germline mutations were in *BRCA2* (n = 3), *EGFR*, *APC*, and *TP53*. In addition to the 10 patients with *BRCA1/2* mutations at high MAF (>30%), we identified 70 patients with *BRCA1/2* mutations at low MAF (< 30%). 54% were pathogenic and 46% were of unknown significance. 11 patients (14%) had germline testing of whom 3 tested positive for *BRCA2*, all at high MAF. 1 patient with a *BRCA2* mutation at low MAF of 1.4% tested positive for a different germline *BRCA2* variant. **Conclusions:** In patients with advanced cancers, ctDNA analysis can reveal variants with MAF >30% that are reflective of a germline mutation. Unfortunately the rate of genetic testing in these patients was low (20%). Future studies with germline testing in patients with high MAF variants would help understand the prevalence of germline variants. This can facilitate developing a more standardized approach for genetic counselor referral to identify families that may benefit from interventions for early detection or prevention of future cancers. Research Sponsor: None.

10603 **Poster Session**

Prospective genomic testing of unselected cancer patients yields insights about cancer susceptibility and noncancer disease with therapeutic implications. *First Author: Stacy W. Gray, City of Hope, Duarte, CA*

Background: Clinicians have used strict criteria to determine eligibility for cancer susceptibility (CS) testing and have limited genetic assessment to cancer-related genes. However, half of all CS mutation carriers are missed by criteria-based testing and there may be an unrecognized opportunity to modify care for patients who have rare but actionable genetic disorders as defined by the American College of Medical Genetics (ACMG). With the aim of improving patient outcomes through precision genomics, we initiated an enterprise-wide program to offer somatic and germline sequencing to all patients. **Methods:** We offer consented patients clinical grade paired somatic & germline WES/ RNA seq and panel germline testing for cancer (156 genes) and ACMG disorders (59 genes). Results are reviewed by a Precision Oncology Tumor Board. Somatic results are returned by the treating team. Germline results are returned by phone (genetic counselor, GC) followed by a clinic visit (GC+MD) for those with pathogenic/likely pathogenic (P/LP) mutations and selected variants of uncertain significant. We evaluated the proportions of patients with somatic findings suggestive of germline conditions and those carrying P/LP mutations in CS and ACMG genes. **Results:** 1,804 patients enrolled and received somatic sequencing: 52% female; 51% non-Hispanic White/ 20% Hispanic White/ 18% Asian/ 4% Black/ 7% other; median age 64. Review of somatic data suggest that 14% have findings suggestive of germline conditions based on factors such as TMB, MSI, and young age. Of the patients offered germline testing, >95% opted to receive CS/ACMG results. To date, we have sequenced 684 patients for CS and 647 for ACMG. 18% of patients had P/LP mutations in CS genes and 4% had P/LP mutations in ACMG non-cancer genes (Table). **Conclusions:** Prospective somatic/germline sequencing of unselected cancer patients reveals tumor findings suggestive of germline disorders and identifies patients with CS and non-cancer genetic conditions. These findings highlight the promise of a comprehensive sequencing approach to help guide cancer treatment, management of unrecognized cancer risk and the need for concomitant management of rare disorders such as arrhythmogenic cardiomyopathy and susceptibility to adverse reactions with anesthesia. Subsequent primary cancers among survivors of adolescent and young adult onset cancers in the United States. *First Author: Hyuna Sung, American Cancer Society, Atlanta, GA*

Background: Adolescent and young adult (AYA) cancer survivors are at increased risk of subsequent primary cancer (SPC); however, a comprehensive examination of risk patterns across cancer types is lacking in the U.S. **Methods:** SPC incidence and mortality was calculated among >1-year cancer survivors aged 15 to 39 years at first primary cancer (FPC) diagnosis during 1992-2016 in 12 Surveillance, Epidemiology, and End Results registries. Rates were expressed as number of cases/deaths per 10,000 person-years and compared with those expected in the general population using standardized incidence (SIR) and standardized mortality ratios (SMR). **Results:** Among 202,440 survivors of AYA-onset cancers (mean age at FPC diagnosis, 31.8 years; 60.7% women), 6,675 SPC cases (34.3 per 10,000) and 3,786 SPC deaths (19.4 per 10,000) occurred during 1,955,119 person-years of follow-up (mean, 9.7 years), corresponding to an SIR of 1.58 (95%CI = 1.54-1.62) and SMR of 4.19 (95%CI = 4.06-4.33. In men, overall incidence and mortality SPC rates were statistically significantly higher for each of 21 FPC types compared with risks in the general population, except for thyroid cancer mortality. In women, risk was statistically significantly higher for 14/23 FPC types for incidence and 19/23 FPC types for mortality. SIRs were highest in survivors of pancreatic cancer (SIR = 5.68, 95% CI = 2.94-9.93; 84 per 10,000), Kaposi sarcoma (SIR = 5.15, 95%CI = 4.62-5.73; 116 per 10,000) and liver cancer (SIR = 4.97, 95%CI = 2.57-8.68; 68.4 per 10,000) in men, and acute lymphoid leukemia (SIR, 3.27, 95% CI = 2.22-4.64; 49.5 per 10,000), Hodgkin lymphoma (SIR = 2.47, 95% CI = 2.22-2.73; 51.6 per 10,000), and bone sarcoma (SIR = 2.41, 95%CI = 1.80-3.16; 47.6 per 10,000) in women. SMRs were highest in survivors of pancreatic cancer, acute lymphoid leukemia, and stomach cancer in men, and liver cancer, acute lymphoid leukemia, and soft tissue sarcoma in women. **Conclusions:** Overall and type-specific risk patterns of SPCs among AYA cancer survivors differ considerably across FPC type, highlighting the need for targeted approaches for cancer prevention and surveillance in survivorship care planning. Mutant *PPM1D* and *TP53* populate the hematopoietic compartment after peptide receptor radionuclide therapy (PRRT) exposure. *First Author: Abhay Singh, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Mutations in *TP53* and *PPM1D* are putative drivers associated with therapy related-myeloid neoplasm (T-MN) and have been identified in pre-treatment blood samples obtained at the time of primary malignancy, predating clinically evident T-MN. Genomic analysis of patients(pts) who undergo leukemogenic therapies will help understand T-MN biology and devise risk mitigation strategies. PRRT (Lu 177) for neuroendocrine tumors is associated with enhanced risk of T-MNs. The mechanism for T-MN induced by PRRT is largely elusive due to the novelty of this drug. **Methods:** We analyzed initial (n=13) and serial blood samples (n=4) prior to and following PRRT for clonal mutations in order to elucidate the role of PRRT in exerting selective pressures on HSCs. Genomic DNA was analyzed using a targeted myeloid 100-gene panel and a variant allele frequency (VAF) cutoff 1% was used to call clonal hematopoiesis (CH). **Results:** Fifty-four percent pts had CH, despite relatively young age of cohort (median age 58 years, range 41-75) and minimal chemo-radiotherapy exposure; baseline characteristics and molecular profile of cohort is published [Singh et al. *Blood* 2020; 136 (Supplement 1): 35–36]. Serial sample analysis in 4 pts (Table 1) demonstrates that PRRT exposure is associated with clonal evolution and accompanying cytopenias in 75% (3/4) pts. Pt-1 (age 67) with normal baseline hemogram developed persistent cytopenias after PRRT, accompanied by emergence and expansion of mutant-*PPM1D* (m*PPM1D;* VAF 20%). These data suggest that cytopenias result from repopulation of the HSC compartment by m*PPM1D* cells. In Pts 2 and 3 (age 74 and 75), we note expansion of m*TP53* and m*PPM1D* clones respectively, also associated with the development of cytopenias. Pt-4 was younger (age 59) and developed no cytopenias. Exposure to PRRT was associated with loss of m*TET2* and m*DDX41*, possibly due to lack of clonal fitness of m*TET2/DDX41* clones and the relatively young HSC microenvironment. **Conclusions:** We conclude that mutations in *PPM1D* and *TP53* are clinically relevant, contribute to clonal cytopenias and may increase risk of future T-MN. The temporal association of m*TP53* and m*PPM1D* expansion with PRRT exposure in our analysis suggests selection of these clones in response to PRRT-induced stress, outcompeting wild type and less therapy-resistant HSCs. Our study along with others will inform future efforts to strategize methods of surveillance and early detection for clonality assessment and chemoprevention, to reduce adverse effects of leukemogenic therapies. Research Sponsor: KL2/BTC award from University of Buffalo's CTSI (S.T.).

A phase II open label, single arm study to evaluate the efficacy of pembrolizumab for leukoplakia. *First Author: Ashleigh Porter, UCLA, Los Angeles, CA*

Background: The presence of pre-cancerous oral lesions such as leukoplakia or erythroleukoplakia are known risk factors for the development of squamous cell carcinoma of the head and neck (SCCHN), however preventative agents have not yet shown clinical benefit. The risk of malignant transformation varies but has been quoted as high as 36% in some studies. While the primary mode of treatment of these lesions is largely surgical, recurrence rates are high. Pembrolizumab is a potent and selective humanized monoclonal antibody that is designed to directly block the interaction between PD-1 and PD-L1 (as well as PD-L2) that is currently FDA-approved for treatment of SCCHN. We have hypothesized that the treatment of oral premalignant lesions with pembrolizumab would be an effective and well-tolerated strategy to prevent transformation to invasive cancer. **Methods:** This study is an open-label, phase II study that will accrue 26 patients with leukoplakia, erythroleukoplakia, or proliferative verrucous leukoplakia with documented moderate to severe dysplasia or carcinoma in situ to be treated with pembrolizumab 200mg every 3 weeks for a total of 6 months. Patients must have visible and measurable lesions that will be both photographed and measured in two dimensions at each visit from the start of treatment until 12 months post-enrollment. Biopsies will be required at diagnosis and following the final treatment, with an optional biopsy following cycle 2 and at progression of disease. Major exclusion criteria include patients with mild dysplasia or hyperplasia, prior chemotherapy, targeted small molecule therapy, or radiation therapy within 2 weeks of Day 1 of study, or patients with a known additional malignancy that is active. Patients will also be excluded if they have received anti-PD-1, anti-PD-L1 or anti-PD-L2 treatments in the past. The primary objective is clinical response rate at 6 months, and will be quantified as the percentage of patients with a complete response (CR) and partial response (PR) at 6 months. A CR is defined as complete resolution by visual inspection for 4 weeks of more and a PR is defined as 50% or greater reduction of the product of the 2 dimensions of a single lesions or the sum of all lesions. Progressive disease (PD) is defined as unequivocal increase (greater than or equal to 5mm in one dimension and greater than 20% increase) or the development of new lesions. Secondary objectives will include histologic response rate at 6 months, change in clinical impression based on photographs, clinical response rate at 9 and 12 months, and toxicity. Additional exploratory objectives will include PD-L1 expression in leukoplakia lesions as well as p16 expression, presence of tumor infiltrating lymphocytes, and immunohistochemical as well as RNA sequencing gene expression profiling which may allow for the identification of novel biomarkers. Enrollment began in June 2019 and is ongoing. Clinical trial information: NCT03603223. Research Sponsor: Merck.

TPS10607 **Poster Session**

A PAncreatic cancer screening study in individuals with New-onset or DeteriOrating diabetes MEllitus (PANDOME study). *First Author: Richard C. Frank, Nuvance Health, Norwalk, CT*

Background: Pancreatic adenocarcinoma (PC) has a persistently high mortality as it presents in the advanced stages and has largely not benefited from the genomic and immunotherapeutic revolutions in oncology. Improvements in screening to detect early stage cancers are therefore urgently needed. Screening studies such as those from the International CAPS Consortium have demonstrated improved survivals in hereditary high risk individuals. In the sporadic population, individuals with new-onset diabetes (NOD) or long-standing deteriorating diabetes (DD) are at substantially increased risk of PC in the 12 months following these diagnoses and have been proposed as target populations for screening efforts. This trial will study the benefits of PC screening in the latter populations in a community setting. **Methods:** Individuals $\geq$ 50 years of age with either NOD or DD will be eligible. Criteria for NOD (within the past 12 months) include: fasting blood glucose $\geq$ 126 mg/dL, random blood glucose $\geq$ 200 mg/dL, or HbA1c $\geq$ 6.5%, with confirmed prior normal values. For those without prior glycemic values, a HbA1c $\geq$ 7.0% is required. Transition from pre-diabetes requires an increase in HgA1c of $\geq$ 0.5%. DD is defined by an increase in HbA1c of $\geq$ 2% within the past six months that is not associated with medication noncompliance or weight gain. Study participants will undergo every 6 months: evaluation by an APRN, testing for anxiety and depression and blood donation for biobanking purposes. High resolution MRI/MRCP with gadolinium will be performed at study entry and annually for 2 years. Images will be reviewed at a multi-disciplinary tumor board consisting of body-image certified radiologists, interventional gastroenterologists, hepatobiliary surgeons and medical oncologists. MRI results will be classified according to a novel PANC-RADS system. High-risk pancreatic findings will be further interrogated by endoscopic ultrasound (EUS). Study endpoints include detection rate of high-risk lesions, referrals for EUS and surgery and detection of incidental findings leading to unnecessary procedures. Adverse psychological impacts will be assessed through HADS testing. Target accrual: 500 patients within 3 years. Clinical trial information: NCT03937453. Research Sponsor: The Naughton Family Fund.

TPS10608 **Poster Session**

Comparing the clinical impact of pancreatic cyst surveillance programs: A trial of the ECOG-ACRIN cancer research group (EA2185). *First Author: David Weinberg, Fox Chase Cancer Center, Philadelphia, PA*

Background: The optimal surveillance strategy for pancreatic cysts, which occur in up to 20% of the adult population, is ill defined. Although risk of malignant degeneration of these cysts is low, pancreatic cancer mortality remains high. Two cyst surveillance guidelines, one proposed by an international consensus group (Fukuoka) and the other by the American Gastroenterological Association (AGA), are accepted standards. Both rely on radiographic and endoscopic ultrasonographic imaging. They differ in indications for, and intervals between, imaging tests, with the Fukuoka guideline advocating more intensive imaging. Clinical guidelines that provide discordant recommendations may undercut the quality and/or value of care, and have implications for societal health care costs. The primary objective of this prospective trial is to compare the clinical effectiveness and associated resource utilization of the Fukuoka and AGA guidelines for pancreatic cyst surveillance. Secondary objectives include a comparison of resource utilization and patient reported outcomes. We are also collecting and banking radiomics data and biospecimens to identify novel methods that might improve cancer risk stratification. **Methods:** 4606 asymptomatic patients with newly identified pancreatic cysts $\geq$1cm in diameter are being randomized 1:1 to high intensity (Fukuoka) or low intensity (AGA) surveillance. The primary endpoint is a composite of any pancreatic cancer without surgery, unresectable pancreatic cancer or cancer $>$ T1a, N0 at surgery, and benign disease at surgery. This sample size will provide 90% power to identify a 30% relative difference in the primary outcome at 5 years between the two study arms. Study duration is 8 years in total, allowing for 2 years of cohort enrollment, 5 years of prospective follow-up, and six months reserved for study initiation and close out. Study participants must be $\geq$ 50 years and $\leq$ 75 years with an ECOG Performance Status 0-1 at baseline. Participants must have received a CT or MRI within 6 months of registration that identifies a new $\geq$1 cm pancreatic cyst. Patients with a prior diagnosis of a pancreatic cyst, pancreatic malignancy or a history of pancreatic resection are not eligible. Additional exclusion criteria include a history of acute or chronic pancreatitis, a family history of pancreatic adenocarcinoma in 1 or more first degree relatives, imaging findings or clinical signs that would prompt immediate surgical consideration (enhancing mural nodule, solid component in cyst, pancreatic duct $>$ 10mm, cyst causing obstructive jaundice), a comorbid illness that precludes pancreatic cyst resection, pregnancy or current participation in an established surveillance program. As of February 4, 2021, thirty three (33) participants have been enrolled from two hundred (200) potential sites. Clinical trial information: NCT04239573. Research Sponsor: U.S. National Institutes of Health.

Engaging the radiology community in the National Clinical Trials Network: The ECOG-ACRIN TMIST experience. *First Author: Etta Pisano, Beth Israel Deaconess Medical Center, Boston, MA*

Background: ECOG-ACRIN launched the Tomosynthesis Mammographic Imaging Screening Trial (TMIST) through the National Cancer Institute's National Clinical Trials Network (NCTN)— a network of academic medical centers, community hospitals, and private clinical practices that are committed to participating in NCI-funded clinical trials. The NCI NCTN was developed to support rapid trial start-up of NCI-funded cancer control/prevention, cancer treatment, and non-therapeutic clinical trials that occur within the institution through centralized institutional administration and shared clinical resource allocation (personnel, lab services). TMIST is a randomized clinical trial assessing two breast cancer screening imaging modalities, tomosynthesis and digital mammography, in the population of women presenting for screening mammography and therefore requires active involvement of radiology. **Methods:** TMIST seeks to enroll 164,946 women, ages 45 to 74 years who present for screening mammography. Because the population under evaluation are women already scheduled for screening mammography, the mammography clinic is critical to successful recruitment as well as adherence to imaging randomization assignments over a 5-year period and therefore must be actively engaged in this trial with a breast imaging radiologist championing the trial within this service. To get active engagement of breast imaging radiologists, we needed to first make them aware of TMIST. Breast imaging radiologists that were already actively involved in the NCTN received notification of the trial through the NCTN email lists. So our goal was to come up with a strategy to reach out to breast imaging radiologists that were not active members in the NCTN. This was achieved through in-person informational sessions to introduce the trial at national and international breast imaging meetings, introduction of the trial and the workings of the NCTN network to the radiology community through articles placed in American College of Radiology (ACR) newsletters, ads promoting TMIST on ACR social media platforms, and direct email by the TMIST study chair to key radiology stakeholders. As of February 15, 2021, there are 115 sites open: 106 in the U.S. and 9 internationally with an additional 54 sites planning to open. A total of 39,366 women are enrolled in the trial with two-thirds also consenting to optional blood and/or buccal cell collection. Minority populations' participation in the trial is over 20%. A significant drop in enrollment occurred in Spring 2020 coinciding with the suspension of mammography services globally due to COVID-19 beginning mid-March 2020. Enrollment and follow-up screening visits for TMIST restarted in May 2020 and gradually ramped back up to pre-COVID totals in September 2020. Our highest monthly accrual so far occurred in November 2020 with 2,148 subjects enrolled. Clinical trial information: NCT03233191. Research Sponsor: U.S. National Institutes of Health.

Novel approach to improve the diagnosis of pediatric cancer in Kenya via telehealth education. *First Author: Tyler Severance, Riley Hospital for Children, Division of Pediatric Hematology Oncology, Indianapolis, IN*

Background: Childhood cancer has an annual incidence of 150-160 cases per million children worldwide but remains vastly under-diagnosed in low to middle income countries (LMIC) such as in Sub-Saharan Africa. Moi Teaching and Referral Hospital (MTRH) is the only tertiary referral hospital in western Kenya and serves a population of 25 million people, including 10 million children. The average number of pediatric cancer diagnoses was 216 cases annually in 2017-2019, well below the anticipated 1500 cases based on cancer epidemiology data. We recently completed a comprehensive Needs Assessment suggesting that due to inadequate pediatric oncology education, many clinical diagnoses are missed and correct diagnostic tests are not obtained at county hospitals. Local medical staff expressed interest in educational programs to help augment their understanding and diagnostic evaluation of pediatric oncology. **Methods:** To address these disparities in medical knowledge, we implemented Project ECHO – a validated virtual guided practice and telementoring model – to connect multidisciplinary specialists at MTRH with staff in medically underserved communities in western Kenya for ongoing training, technical assistance, and mentorship. The ECHO program follows a Hub-and-Spoke design where the specialists at MTRH and pediatric oncologists at Riley Hospital functioned as the "hub" team and the health care workers at county hospitals were the "spokes". Sessions were freely available on Zoom twice monthly and featured both a didactic topic presented by experts and a spoke-led case-based discussion. The discussion utilized dialogue education to promote learning and engagement among the spokes with mentorship from the hub team. **Results:** The ECHO program launched successfully in January 2020 with a curriculum focused on pediatric oncology for general health care workers. A total of 22 sessions occurred with an average of 23 learners (primarily staff at community hospitals within the referral region) per session. Despite the COVID-19 pandemic, the year-end analysis in January 2021 demonstrated 286 new pediatric patients were diagnosed with cancer at MTRH representing a 33% increase over the 3-year average. **Conclusions:** The implementation of a telehealth education platform – Project ECHO – focused on diagnosing pediatric cancer in medically underserved communities in Kenya, is a useful model to increase the recognition and earlier referral of childhood cancer in LMICs. Research Sponsor: Takeda Pharmaceutical Company, Indiana Clinical and Translational Sciences Institute.

Sexual harassment of oncologists. *First Author: Ishwaria Mohan Subbiah, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Few studies have used comprehensive validated measures to investigate the incidence and impact of workplace sexual harassment experienced by physicians (and none, to our knowledge, by oncologists). **Methods:** We conducted a cross-sectional survey of ASCO's Research Survey Pool with targeted social media outreach to examine the prevalence and types of sexual harassment (SH) experienced by oncologists. Using the Sexual Experiences Questionnaire (SEQ), we measured their work experience of three SH forms (gender harassment [GH], unwanted sexual attention [USA], sexual coercion [SC]) in the past year by institutional insiders (peers/superiors) and patients/families separately. Controlling for race, career stage & specialty, multivariable (MV) regression models assess the impact of SH (independent variable) on 4 dependent variables of mental health (MHI5), perceptions of workplace safety (single item), job satisfaction (MOAQ) & 3-item measure of turnover intentions (in non-trainees). **Results:** Of 271 respondents, 250 were physicians in practice and 21 were residents/fellows; 153 (56%) were women, 168 (62%) practiced in academic settings & 227 (84%) were medical oncologists. SH by peers/superiors was reported by 189 (70%) overall, including 80% of women and 56% of men ($p<0.0001$). GH was reported by 79% of women and 55% of men ($p<0.0001$), USA by 22% of women and 9% of men ($p=0.005$), and SC by 3% of women and 2% of men ($p=0.42$). SH by patients and/or families was reported by 67% of women and 35% of men ($p<0.0001$), GH by 66% of women and 34% of men ($p<0.0001$), USA by 5% women and 6% men ($p=0.80$), and SC by 1% women and 1% men ($p=0.72$). MV analysis showed past-year SH from peers/superiors was significantly associated with decreased mental health (β -0.45, p 0.004), workplace safety (β -0.98, $p<0.001$) and increased turnover intentions (β 0.93, $P<0.0001$). SH from patients/families was similarly significantly associated with mental health (β -0.41, p 0.002), workplace safety (β -0.42, p 0.014) and turnover intentions (β 0.58, p 0.0004). SH from insiders (β -0.64, p 0.001) but not patients (p 0.55) was significantly associated with job satisfaction. Furthermore, there were no significant interactions between the respondents' gender and the SH scores in any of the models of impact. **Conclusions:** This is the first study in oncology to systematically characterize the incidence of sexual harassment experienced by oncologists. Our findings demonstrate the impact of sexual harassment on men and women oncologists on multiple domains of workplace experience. This study provides critical data to inform the need for and design of effective protective and preventive workplace policies in oncology. Research Sponsor: None.

11002 **Clinical Science Symposium**

A post-COVID survey of current and future parents among faculty, trainees, and research staff at an NCI-designated cancer center. *First Author: Annie P. Im, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Challenges for women in science and academic medicine have been well documented, which include gender disparities related to parental and domestic responsibilities that interfere with work or career opportunities. We aimed to evaluate the experiences and working environment at an NCI-designated Cancer Center for current and future parents in the post-COVID era. We hypothesized there would be differences in the experiences of parents between men and women, and between trainees, faculty, and staff. **Methods:** A 61-question online survey for current and future parents was developed by the Women's Task Force of the Hillman Cancer Center (HCC) in Pittsburgh, Pennsylvania. Questions focused on perceived attitudes towards parents, the supportive nature of the working environment for parents, experiences with breastfeeding as a working parent, and childcare responsibilities pre- and post-COVID. The survey was sent to 562 scientific faculty, physicians, trainees, and research staff at HCC. Comparisons between groups of interest were performed using a chi-square test. **Results:** There were 214 respondents (38% response rate) with even representation: 38% were faculty, 27% were trainees, and 35% were research staff; 59% were female. 6% of respondents reported being "discouraged or excluded from participating in specific activities due to having or planning children", and 24% felt "moderately supported" as a parent at work. Regarding breastfeeding, 58% reported that the decision to breastfeed was moderately impacted by returning to work, and of the women who were currently or recently breastfeeding, 42% reported that there were not enough lactation rooms in their building. Other questions in the survey aimed to evaluate what further support would be helpful for parents. 40% reported that on-site childcare would help better support them as a parent, especially because 47% documented that finding childcare was difficult and 53% documented that they looked at ≥4 daycares or nannies. Further, 49% reported that they did not know where to look for resources in finding childcare. Pre-COVID, 32% reported spending 2-3 hours a day on childcare and/or home responsibilities; post-COVID, 55% reported spending ≥4 hours a day. These effects were more pronounced in women compared to men ($p < 0.05$). Pre-COVID, 40% reported that they were unable to participate in work events due to childcare responsibilities, which increased to 54% post-COVID, and was most pronounced in faculty and trainees compared to staff ($p < 0.05$). **Conclusions:** Our survey describes some of the universal challenges of working parents in Oncology, which have been exacerbated by COVID. The impact of COVID was more pronounced in women. Further studies are needed for systematic interventions or policies that improve support for working parents, including unified resources and working groups for current and expecting parents. Research Sponsor: Cancer Center funds.

11003 **Poster Discussion Session**

Digital footprint of hematology-oncology fellowship programs: Identifying gaps after the first virtual recruitment season. *First Author: Ana I. Velazquez Manana, University of California, San Francisco, San Francisco, CA*

Background: The COVID-19 pandemic has led to unprecedented restrictions to travel and in-person activities that limit hematology/oncology (HO) fellowship programs' (FP) recruitment activities. Prospective applicants rely on websites and social media (SOME) to guide their decisions of applying or ranking a FP. We aim to evaluate HO FP's digital footprint in order to identify informational gaps. **Methods:** The AMA Fellowship and Residency Electronic Interactive Database (FREIDA) was queried for all HO programs. We searched Google, Twitter, Instagram, Facebook, and YouTube for HO FP pages. Content was evaluated using published criteria. Qualitative content analysis of SOME posts is planned. **Results:** Our analysis includes 176 FP that actively recruited during the 2020 match season. Over half (57%, n = 100) were university-based and the median number of fellow positions per year was 4 per FP (range 0-16). Most FP had websites (95%, n = 167) with varying information (Table) for prospective applicants. Twenty percent (n = 33) included a diversity statement. While 63% (n = 106) of FP provided application information, only 51% discussed visa requirements. Few FP websites included key information such as why fellows chose a particular FP (7%, n = 12), accolades of fellows (3%, n = 5), or employment location of alumni (25%, n = 44). Only 42% (n = 69) provided city , and 5% (n = 8) showed fellows socializing. Thirty-four FP (19%) have informational videos (range 1-10) in YouTube (length range: 1:37-18:15min). Most (82%; n = 28) were published since May 2020 in alignment with the FP recruitment season. Twitter was the second most common SOME platform, used by 19% (n = 32) of FP. 56% (n = 18) joined Twitter since May 2020 correlating with the current recruitment season. The number of Twitter followers (median 119, range: 0-1408) and posts (median 47, range: 0-687) varied across FP. Only 4% used Facebook and 6% Instagram. **Conclusions:** Our analysis of FP's digital footprint revealed that applicants participating in the 1st virtual HO recruitment season were provided limited online information. Programs can use online content to provide information on resources, research opportunities, and achievements of faculty and fellows that can guide applicant decision making. In the era of COVID-19, highlighting the diversity and breath of each FP, hospital, and city are vital to attract a diverse and talented pool of trainees. Research Sponsor: None.

Analysis of hematology and oncology fellowship website content and diversity representation. *First Author: Arun Muthiah, Rhode Island Hospital-The Warren Alpert Medical School of Brown University, Providence, RI*

Background: Fellowship in hematology and oncology (HO) is widely sought after but lags behind all other internal medicine subspecialties in attracting applicants underrepresented in medicine (URM). An approach to appealing to URMs involves preexisting in-person strategies but also adapting virtual tools to promote inclusion. Specifically, program websites serve as the first impressions of a program, as well as influence the perception of diversity and inclusion. We evaluated the content and diversity representation of HO program websites to facilitate a generally more informed and URM-considerate recruitment. **Methods:** The websites of 2019-2020 ACGME accredited HO programs were assessed between June 1st to July 1st, 2020. Data focused on 30 informational categories, derived from published methodology, along with three additional categories concerning diversity, based on suggestions for inclusive graduate medical education recruitment strategies, were compared using two-tailed *t* tests. We defined websites with 70% or more of the 30 informational categories as "comprehensive websites." Affiliation with a National Cancer Institute (NCI) Designated Cancer Center, NCI Designated Cancer Center + National Cancer Center Network (NCCN) member institution, and a top 50 ranked cancer hospital by U.S. News was also considered in the analysis. **Results:** A total of 156 program websites were analyzed: 37.2% NCI; 19.9% NCCN; 29.5% U.S. News ranked. Only 31 (19.9%) were "comprehensive websites," and 34 (21.8%) had information pertaining to at least one of the diversity categories. There was a significant association between inclusion of diversity content and being a "comprehensive website" ($p = 0.001$). Compared to those that were neither designated nor ranked, programs designated by NCI, NCCN, or ranked by U.S. News were more likely to have more complete information available ($p < 0.001$, $= 0.008$, and < 0.001, respectively). However, only programs ranked by U.S. News were more likely to include information about diversity on their websites ($p = 0.006$). **Conclusions:** The vast majority of HO fellowship program websites were not comprehensive, including a lack of diversity and inclusivity content. NCI designation, NCCN participation, and US News ranking were significantly associated with more complete fellowship websites. Given the context of the COVID-19 pandemic in which institution visitation is restricted, program websites may have elevated importance in recruitment. HO programs should direct resources to offering more complete and inclusive websites to better inform applicants, including URM residents. Research Sponsor: None.

COVID-19 and medical education: Rethinking student assessment—The Virtual Observational Standard Clinical Examination. *First Author: Mariana Abal, Instituto Oncologico Henry Moore, Capital Federal, Buenos Aires, Argentina*

Background: The COVID-19 pandemic introduced new challenges for medical education. In particular, student assessment posed some of the most urging questions. How do we evaluate practical skills when our universities are on lockdown and our hospitals are working on a shortage of personnel? Is it possible to evaluate these skills via online means, mitigating the effects in students' career development? This paper presents an online evaluation experience implemented at Instituto Oncológico Henry Moore-Universidad del Salvador, Buenos Aires in the postgraduate program of Clinical Oncology. The Virtual Observational Standard Clinical Examination (V-OSCE) is a technology-based adaptation of the Observational Standard Clinical Examination (OSCE) (JCO 34 (15), Abstract e18150, 2017) implemented in previous years. **Methods:** The V-OSCE took place in November 14, 2020 and consisted on a half-day evaluation during which students rotated through 8 stations (Table). The exam ran on three platforms: Blackboard Collaborate for the interactive elements of all stations; University online campus (Moodle platform) for student questionnaires, and Google Forms for the evaluators' assessment of each student. Students and evaluators participated in various training sessions, and were given a month to practice before the exam. All interactions were recorded and an anonymous survey on students' experience and opinions was conducted after the exam. **Results:** A total of 25 postgraduate Oncology students participated in the V-OSCE. 24 students (96%) completed all stations on time with minimum or no network connection issues. Student opinions: 24 students completed the exam experience anonymous survey; 23 found the exam tech-friendly and valued the practice time provided. When asked to score the exam in a scale of 1 to 10: 80% of the students ranked the exam with 9 or 10; and 20%, with 7 or 8. **Conclusions:** A) It is feasible to design new ways to assess medical students via online means. B) The experience of an OSCE can be translated to an online environment with minimum technological requirements. C) The COVID-19 pandemic effects are extensive, with serious implications in medical education. However, it has proved to be an opportunity to rethink our educational practices, design innovative formative experiences, and assess new skills that will remain significant even long after the pandemic has ended. Research Sponsor: None.

V-OSCE stations.

Station		Skills assessed	Duration
I	Interaction with a curable patient	Doctor-patient online interaction	30 min
II	Interaction with an incurable patient		30 min
III	Ethics Committee	Online collaborative work and peer interaction	60 min
IV	Tumor Board		60 min
V	Scientific paper reading comprehension	Individual knowledge and skills	15 min
VI	Differential diagnosis with patient images		15 min
VII	Genetic report interpretation		15 min
VIII	Scans interpretation		15 min

Trends in female representation in clinical practice guidelines (CPGs) among major cancer organizations. *First Author: Madhuri Chengappa, Nazareth Hospital, Philadelphia, PA*

Background: While women representation and sex disparities in National Comprehensive Cancer Network (NCCN) and European Society of Medical Oncology (ESMO) has been studied in a limited set of CPGs, the sex representation and disparity trend over time among all NCCN and ESMO CPG panelists has not been studied. Our study evaluates the current sex disparities and female representation for all NCCN and ESMO CPGs as of 2020 and compared it to the 2010 CPGs of both organizations. **Methods:** The 2010 and 2020 version of NCCN and ESMO CPGs were examined from their respective websites and archives. We catalogued the number of female versus male panelist for each CPG. We discerned the sex of the panelists based on google search and the panelists' affiliated institutional websites. **Results:** 60 NCCN (2020), 51 NCCN (2010), 78 ESMO (2020) and 55 ESMO (2010) CPGs inclusive of all cancers by site, detection prevention and risk reduction, supportive care, and guidelines for specific population were reviewed. NCCN 2020 CPGs had 55.5% female representation. 35 (58%) NCCN CPGs had predominant female representation (>50% of the members being female) whereas 24 CPG (40%) were male predominant (>50% of the members being male). Solid tumors had 24 CPGs with male predominance and hematological malignancies had 14 CPGs with female predominance. Cancers specific to women had higher proportion of female panelist. NCCN 2010 CPGs had 27.1% female representation. Both solid tumors and hematological malignancies had male predominance (82% and 75% respectively). Breast cancer screening, palliative care and older adult oncology CPGs were female predominant. ESMO 2020 had 27.8% female representation. Both solid tumors (37 CPGs) and hematological malignancies (17 CPGs) had predominant male representation (72% and 85% respectively). Breast and ovarian cancer CPGs were female predominant. ESMO 2010 had 23.2% female representation. Male representation was predominant in both solid tumors (35 CPGs) and hematological malignancies (9 CPGs). Breast, cervical and ovarian cancer CPGs were female predominant. **Conclusions:** Over the last decade, proportion of female panelists in NCCN CPGs has doubled with more than 50% representation among its 60 CPGs, indicating adequate representation of women. In ESMO, although there has been a significant improvement in female representation in hematological malignancies over time, it continues to have overall female underrepresentation (<30%). Research Sponsor: None.

	Total CPGs	Total Panelist	Total Female	Total Male	Solid tumor panelist		Hematological Malignancies panelist	
					Female	Male	Female	Male
NCCN 2010	51	1267	343 (27.1%)	924 (72.9%)	136 (18.1%)	617 (81.9%)	43 (25.4%)	126 (74.6%)
NCCN 2020	60	2522	1400 (55.5%)	1122 (44.5%)	532 (49.2%)	550 (50.8%)	336 (56.6%)	258 (43.4%)

Where are the women and underrepresented minorities in medicine? Race/ethnicity and gender representation in oncology journals' editorial boards. *First Author: Shruti Rajesh Patel, Mayo Clinic, Rochester, MN*

Background: The proportion of women & underrepresented groups in medicine (URM) in the field of hematology and oncology remains low, particularly in academic leadership positions. Editorial board appointments allow physicians to have a substantial impact on the nature of the published scholarly work and serve as a platform for academic opportunities. We aimed to assess gender and race/ethnicity representation in editorial board positions in hematology and oncology journals. **Methods:** Editorial leadership board members from 60 journals from oncology, hematology, radiation oncology, and surgical oncology were reviewed, 54 journals were included in the analysis. Gender and race/ethnicity were determined based on publicly available data for editor-in-chief (EiC) and second-in-command (SiC) (including deputy, senior, or associate editors). Descriptive statistics and chi-squared were estimated. **Results:** A total of 793 editorial board members are included in the analysis. 72.6 % were men and 27.4 % were women. 71.3% of editorial leadership were non-Hispanic white with Asian editorial board members representing the second largest majority at 23.3%. The editorial position was significantly different among men and women ($p = 0.038$) with women filling only 15.9% (10/63) of the EiC positions. Of these 10 women, the racial breakdown was 90% white and 10% Asian. In the prevalence odds ratio (pOR), women were about half as likely to be in the EiC position compared with men [pOR: 0.47, 95%CI (0.23, 0.95, $p = 0.03$)]. Women represented 28.4% (207/730) of SiC editorial positions. White editors had the highest representation at 71.0% in the SiC editorial positions, followed by Asian editors at 16.0%. Notable differences were seen in gender proportions between journal specialties ($p = 0.001$); with surgical oncology and hematology having the lowest female representation at 11.9% and 22.7%, respectively. **Conclusions:** Women and UIM are markedly underrepresented in leadership roles on Editorial Boards in hematology and oncology journals. Importantly, the representation of minority women physicians in EiC positions is at an inexorable zero which is a sign of unconscious attitudes that may exclude women and minorities from certain positions. It is imperative that we work to move towards a more diverse and inclusive editorial board to ensure critical perspectives are heard and scientific discovery is fostered. Research Sponsor: None.

Editor's Race/Ethnicity (%)	Editor-In-Chief Female n (%)	Editor-In-Chief Male n (%)	Second-In-Command Female n (%)	Second-In-Command Male n (%)

Authorship gender equity in global oncology publications. *First Author: Paula Hornstein, Northeastern University, Boston, MA*

Background: There is increasing recognition of authorship inequity in academic medicine specialty publications. Analyses in other specialties note that female authors consistently comprise a minority of the first authors and an even smaller percentage of last authors. While this trend may be improving, we hypothesize that significant authorship gender disparities still exist in global oncology journals. **Methods:** This study comprehensively analyzes the gender distribution of authors for articles published in the Journal of Clinical Oncology Global Oncology (JCO GO), a premier journal in the field, from its inauguration in 2016 to March 2020. A total of 608 articles were identified as matching one of the following six article types: original report, editorial, commentary, case report, special article, and review article. We collected data such as the author's position, gender, institutional affiliation, and country affiliation. Author gender was categorized as male, female, or indeterminate based on first name probabilities assessed by genderize.io, with a threshold probability of 0.8 based on prior studies. Authorship distribution was analyzed by region and country income level according to the World Bank classification. **Results:** Of the 608 article first authors, 47.5% were identified as male, while 41.4% were female. Male authors made up a comparatively higher proportion of the 592 last authors; 57.1% were identified as male compared to 32.1% who were female. A similar trend was seen among the 4102 middle authors; 51.4% were identified as male and 38.1% were female. The percentage of authors deemed indeterminate in the cohort was less than 11%. Female authors were more underrepresented among authors from low-income countries; they made up 21.6% of first authors and 9.1% of last authors. Authorship gender by world regions is summarized in Table below. **Conclusions:** Our analysis shows that authorship inequities persist in global oncology publications. Female authors from lower-income countries, and regions in Sub-Saharan Africa and South Asia, were markedly underrepresented. The underlying reasons for underrepresentation of female authors are multifactorial; further studies are needed to elucidate these factors and to develop and evaluate mitigating strategies. Research Sponsor: None.

Summary of author gender percentages by world regions.

	Overall	East Asia & Pacific	Europe & Central Asia	Latin America & Caribbean	Middle East & North Africa	North America	South Asia	Sub-Saharan Africa

11009 **Poster Discussion Session**

Gender and racial/ethnic disparities in academic oncology leadership. *First Author: Gavin Jones, University of Kentucky, Lexington, KY*

Background: Gender & racial/ethnic leadership disparities have been independently identified in academic hematology/oncology (HO) and radiation oncology (RO). Here, we evaluate gender and racial/ethnic intersectionality from the trainee to the leadership level. **Methods:** All ACGME accredited HO and RO training program websites were queried to identify constituent trainees, academic faculty, program directors (PD) and department chairs (DC), with a leadership position defined as PD or DC. Individual gender & race/ethnicity was determined using externally validated software tools (Gender-API, NamSor, & Onolytics), publicly available descriptors, and image review. We grouped individuals into 6 categories: White Male (WM), White Female (WF), Asian Male (AM), Asian Female (AF), Underrepresented Groups in Medicine (as defined by AAMC) Male (URMM) and Female (URMF). The chi-squared goodness-of-fit test was applied to examine if deviations exist between the observed vs. expected proportions of gender/race dyads in trainees, PD, and DC compared to academic faculty. **Results:** We identified 7,722 individuals from 2019-2020: 1,759 trainees (HO=1525; RO=234), 5,726 faculty (HO=4834; RO=892), 242 PD (HO=149; RO=93) and 237 DC (HO=144; RO=93). Leadership positions were most often comprised by WM (52.6%), and least often comprised by URMF (2.9%). Combined HO/RO analysis revealed significant differences in the observed representation of trainees & DC vs expected levels based on total faculty, respectively: WM (33.7% & 60.3% vs. 42.3%), WF (19.2% & 13.9% vs. 22.3%), AM (20.75% & 16.9% vs. 16.4%), AF (17.9% & 2.5% vs. 12.7%), URMM (4.09% & 5.5% vs. 3.5%) and URMF (4.3% & 0.8% vs. 2.8%), $p<0.01$. No differences were seen between PD vs total faculty. On subset analysis, there were significant differences observed in HO programs at the trainee, PD and DC levels compared to total faculty, whereas significant differences in RO programs were seen only at the DC level [Table]. **Conclusions:** Gender & racial/ethnic disparity is present in academic oncology. Specifically, women of all races/ethnicities are proportionally underrepresented in DC positions in HO and RO programs. These data can serve as a benchmark to raise awareness and monitor progress towards a more balanced workforce in oncology. Research Sponsor: None.

Program	Role	WM (%)	WF (%)	AM (%)	AF (%)	URMM (%)	URMF (%)	p-value

U.S. radiation oncology and medical oncology department faculty diversity trends by sex and underrepresented in medicine status over five decades. *First Author: Sophia C. Kamran, Department of Radiation Oncology, Massachusetts General Hospital, Boston, MA*

Background: Academic faculty are critical in training future generations of oncologists to care for our increasingly diverse cancer patient population. It is unclear if the growing imperative to address disparities in racial/ethnic and gender representation in the medical field has resulted in corresponding progress in the composition of academic radiation and medical oncology (RO, MO) departments. Herein we report trends in faculty diversity, overall and by academic rank, among US radiation and medical oncologists over the past 5 decades. **Methods:** Data were acquired from the Association of American Medical Colleges (AAMC) Faculty Roster between 1970-2019 for academic RO and MO departments to determine sex and race/ethnicity trends over five decades. Underrepresented in Medicine (URM) was defined as individuals identifying as Black, Hispanic, and Native American. Linear regression models were used to estimate slopes and associated p-values. **Results:** Total faculty complements grew over time in both RO and MO departments. The number of URM female faculty increased by 0.85/year in RO and 0.79/year in MO (P-trend<0.001), compared to non-URM female faculty, which increased by 11.3/year in RO and 7.9 in MO (P-trend<0.001). URM male faculty increased by 1.4/year in RO and 1.1/year in MO (P-trend<0.001), compared to non-URM male faculty, which increased by 25.5/year for RO and 12.2/year for MO (P-trend<0.001). Males represented the majority of URM and non-URM faculty for both RO and MO. The proportion of females grew more than the proportion of URM faculty over the study period for both RO and MO. There were also significant differences in diversity by faculty rank. Although MO outperformed RO in terms of the proportion of female faculty members with more advanced rank, female faculty members had a lower academic rank than their male counterparts in both specialties. At every rank, there was a low number of URM faculty represented among both MO and RO (Table). **Conclusions:** Gender and racial/ethnic diversity of academic RO and MO faculty has increased over time but has not kept pace with the diversity of the US population served, particularly with respect to URM status. The proportion of female faculty in both specialties demonstrates more promising growth, and may inform measures to achieve similar progress in recruiting and retaining URM faculty in both MO and RO. Research Sponsor: None.

2019 rank among RO and MO faculty.

	Instructor	Assistant Professor	Associate Professor	Full Professor
RO Females	42.2%	30.2%	27.5%	20.8%
MO Females	41.0%	42.7%	41.8%	28.0%
RO URM	6.1%	6.2%	3.9%	4.0%
MO URM	4.5%	6.6%	7.3%	4.7%

Minding the gap: Gynecologic oncology practices differ by gender. *First Author: Sarah Madhu Temkin, Washington, DC*

Background: Although most gynecologic oncologists (GOs) are now women, gender differences in clinical practice and compensation persist. Practice characteristics and infrastructural support that may influence gender-based differences were explored. **Methods:** Every 5 years, the Society of Gynecologic Oncology (SGO) conducts a member survey that provides details on member demographics, practice characteristics, activities, and revenue. Between 8/15-9/30/19 SGO members received a direct link to the survey. Gender was self-identified. Differences in responses were evaluated by gender. **Results:** Of 1425 surveys delivered, 690 were completed (48% response rate). 312 (45%) identified as male; 367 (53%) as female; 1 nonbinary; 1 other; 7 no response. Male GOs were more likely white (75 vs 68%, p=0.048), married (91 vs 81%, p<0.001), heterosexual (94 vs 90%, p=0.045), and hold an academic rank of professor (23 vs 12%, p<0.001). Practice setting and number of partners were similar. Chemotherapy prescribing was more common for females (82 vs 73%, p=0.004), but other clinical activities were similar (Table). Female GOs had lower clinical volumes than males for cervical, ovarian, vaginal/vulvar cancer and benign gynecologic procedures. Females reported fewer medical assistants and transcriptionists supporting their clinical activities. Overall and practice support was higher for male GOs although hospital support was similar for both genders. Female GOs reported more time spent on research (26 vs 19%, p=0.005), but the same research support. **Conclusions:** Clinical activities, specifically chemotherapy prescribing, and support differ for male and female GOs and may explain gender inequities. Clinical support should be equalized to maximize workplace productivity regardless of gender. Coordination of support between the practice and hospital and standard compensation for chemotherapy prescribing could decrease the large gender wage gap in this specialty. Research Sponsor: None.

The positive impact of mentoring on burnout: Organizational research and best practice interventions for cancer hospital employees. *First Author: Katelyn Cavanaugh, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: While burnout is not a new concept, combating it is becoming an increasingly important focus for organizations across all industries. Recently, the World Health Organization recognized burnout as an "occupational phenomenon" (WHO, 2019), and it was included in the 11th Revision of the International Classification of Diseases, where it is defined as "a syndrome conceptualized as resulting from chronic workplace stress that has not been successfully managed." The University of Texas MD Anderson Cancer Center addresses burnout at the institutional level in support of all 22,000 workforce members. One avenue of this work focuses on mentoring. Mentorship, both formal and informal, has demonstrated positive effects to include empirical investigations that demonstrate its benefit in reducing risk of burnout in multiple settings for a variety of audiences (Qian et al., 2014; Thomas & Lankau, 2009; van Emmerik, 2004; Varghese at al., 2020). Although mentoring is not as flashy as other interventions, what the last year has shown is that people need human connection now more than ever. **Methods:** In order to investigate the relationship between burnout and mentoring in our organization, we analyzed responses to our biennial voluntary employee survey, in which all employees were asked whether they are involved in a mentoring relationship and completed a single-item burnout scale. **Results:** We analyzed the survey data using a chi-square test and found that employees participating in mentoring relationships were less likely to report burnout than employees who are not participating in a mentoring relationship, $\chi 2$ (1, 14,486) = 17.431, $p < 0.005$. The same pattern held for all types of employees; faculty, classified staff, leaders, clinical employees, and non-clinical employees, indicating that the experience of mentorship may be universal regardless of role, rank, and type of work. We suspect that the benefits of mentoring are bi-directional for mentors and mentees, though this should be investigated directly. **Conclusions:** Both formal and informal types of mentoring programs exist within MD Anderson to support retention, professional fulfillment, and reduce burnout. All employees have access to a centralized online mentoring platform to find a mentor. Formal mentoring support is also provided through various programs developed for specific professional cohorts, including physicians, advanced practice providers, and registered nurses. In addition, informal mentoring support is offered in the form of employee volunteer wellness champions. Together, these formal and informal mentoring programs have positively influenced burnout across the organization. Research Sponsor: None.

Perpetrators of workplace bullying and gender discriminations experienced by women gynecologic oncologists. *First Author: Linda Hong, Loma Linda University School of Medicine, Loma Linda, CA*

Background: A high prevalence of gender discrimination and harassment has been described among gynecologic oncologists (GOs). This study examined the work environment for women GOs and delineated the perpetrators of negative behaviors. **Methods:** An internet-based, IRB exempt survey of members of a 472-member Facebook group "Women of Gynecologic Oncology (WGO)" was conducted. Using REDcap survey platform, members provided demographics, practice infrastructure, personal experience with workplace bullying, gender discrimination, microaggressions, and outcomes. Demographic, practice and work environments and perpetrators of negative behaviors were summarized using descriptive statistics. **Results:** Between 7/20 and 8/19/2020, 250 (53%) of active WGO members participated in this survey. Most respondents were younger than 50 years old (93.6%); white (82.2%) and non-Hispanic (94.3%). A majority were married (84.7%) with children (75.2%). Practice environments included academic (152, 61.0%), private practice (31, 12.4%), and hospital employed (57, 22.9%). 89.9% supervised trainees. 130 (52.0%) respondents reported bullying, 140 (56.0%) gender discrimination, and 83% having experienced gender-based microaggressions. Age, race, ethnicity, practice setting, division director or chair gender or department reporting structure were not significantly associated with these experiences. Perpetrators of bullying, gender discrimination, and microaggressions were widely distributed (Table). Of those reporting bullying, 61 (46.6%) reported a male perpetrator, 25 (19.1%) female and 45 (34.4%) an equal gender distribution; of those reporting discrimination 105 (74.5%) reported a male perpetrator, 9 (6.4%) female and 27 (19.1%) an equal gender distribution. 32.9% of survey respondents acknowledged having been written up for speaking up in a way that would have been tolerated from a male colleague. 18.3% of respondents have changed jobs because of bullying; 13.5% because of discrimination. **Conclusions:** Women GOs report high rates of workplace bullying, gender discrimination, and microaggressions regardless of practice setting that often impact their careers. Perpetrators of these behaviors are multiple and varied. Proactive and deliberate interventions to improve the work environments for women GOs are urgently needed. Research Sponsor: None.

Impact of COVID-19 on work-related fatigue and satisfaction among oncology providers in Latin America: An analysis of the HOLA COVID-19 study. *First Author: Ana I. Velazquez Manana, University of California, San Francisco Medical Center, San Francisco, CA*

Background: The well-being of oncology providers (OP) is in jeopardy with increasing workload, limited resources, and personal challenges that result from the COVID-19 pandemic. We aim to evaluate the impact of COVID-19 on work-related (WR) satisfaction and fatigue among OP in Latin America. **Methods:** We conducted an international cross-sectional online survey of OP practicing in Latin America. The survey was administered in English, Spanish, and Portuguese. Data was analyzed using descriptive statistics and Chi-square tests. **Results:** In August 2020, 704 OP from 20 Latin American countries completed the survey (77% of 913 who started the survey). Table outlines baseline characteristics. Higher frequency of WR fatigue (67% vs. 58%, p=0.010) and exhaustion (81% vs. 70%, p=0.001) were reported by OP who cared for patients with COVID-19, compared to OP who cared for patients without COVID-19. Providers that observed delays in referrals to radiation (p=0.002) and surgery (p=0.04) reported WR fatigue at higher rates than their counterparts. Higher exhaustion (p=0.016) and dissatisfaction (p=0.046) were reported by OP who lacked access to supportive services, as social work. A significantly higher proportion of women reported WR fatigue (72% vs. 56%, p=0.003) and exhaustion (86% vs. 68%, p=0.001), when compared to men. Women were more likely than men to endorse higher current levels of fatigue when compared to pre-COVID-19 (61% vs. 46%, p=0.0001). To reduce stress, women were more likely than men to cut the time spent watching the news (p=0.002). Both genders declined research collaborations and speaking opportunities. **Conclusions:** Fatigue and dissatisfaction with work-life were prevalent among OP in Latin America. Higher rates of WR fatigue were seen in women, OP caring for patients with COVID-19, and OP with patients who experienced cancer care delays. Our data imply that OP may be a prime target for psychosocial support, particularly as current challenges will continue for the foreseen future. Baseline characteristics (N=704). A pilot study to prevent burnout in junior oncology doctors during the COVID-19 pandemic in a tertiary U.K. center. *First Author: Alfred Chung Pui So, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background: Burnout is a syndrome defined by emotional exhaustion, depersonalisation and loss of personal accomplishment. It is a growing concern amongst doctors, particularly in oncology, who face the added stress of delivering life changing results to patients and managing end of life care. This has potential for negatively impacting mental health, job satisfaction and ultimately patient care. This has been compounded by the COVID-19 pandemic and the uncertainty around complex oncological treatment decisions, longer working hours, redeployment, and constant changes to working patterns to meet the evolving clinical need. In response to this, a novel wellbeing intervention was designed by the educational lead consultant and psychologists to prevent burnout during the pandemic. **Methods:** Junior doctors working at a single UK cancer centre during the COVID-19 pandemic were invited to attend weekly 30 minute wellbeing sessions facilitated by a clinical psychologist throughout their oncology placement (average 4-6 months). Sessions had an average attendance of 3-6 doctors and began with a 5 minute breathing and relaxation exercise followed by a mixture of clinical debriefing, reflective practice, and mindfulness strategies. Trainees were invited to have individual sessions if required. Surveys based on the 14 point Warwick Edinburgh Well Being Scale (WEMWBS) were conducted at the start and end of placement. Additional qualitative feedback was collated. **Results:** Throughout a 6 month period, 10 doctors participated in this study. Baseline WEMWBS scores revealed average mental wellbeing (n = 8), high mental wellbeing (n = 1) and probable depression (n = 1). Median baseline WEMWBS score was 52(41-62). Median number of sessions attended was 11(3-14). Post intervention, there was no significant deterioration in baseline WEMWBS score (mean change +2.2; p= 0.34). When doctors were asked about their optimism for the future, there was a significant increase by +0.4 points (p= 0.037). With respect to participant feedback, 100% were either 'satisfied' (n = 1) or 'very satisfied' (n = 9) with the group facilitation and 100% found the group sessions either 'helpful' (n = 7) or 'very helpful' (n = 3). Trainee feedback described the benefits of reflecting in a structured and safe environment, breathing exercises, and learning mindfulness strategies. **Conclusions:** Burnout is a serious concern amongst junior oncologists and is rising as a result of COVID-19. We present a novel intervention that promoted psychological flexibility and importantly maintained mental wellbeing throughout the pandemic. Further studies are planned to develop evidence based interventions to tackle this important issue. Research Sponsor: None.

Prevalence and risk factors of burnout among female oncology professionals from the Middle East and North Africa (MENA). *First Author: Atlal Abusanad, Faculty of Medicine, Department of Medical Oncology, King Abdulaziz University, Jeddah, Saudi Arabia*

Background: Burnout (BO) is a recognized challenge among oncology workforce. It affects both genders with a higher frequency among women. This study examined the factors contributing to the development of burnout among women in oncology from the Middle East and North Africa (MENA). **Methods:** An online cross-sectional survey was distributed to oncology professionals from different countries in the MENA region. The validated Maslach Burnout Inventory (MBI) of emotional exhaustion (EE), Depersonalization (DE), and Personal Achievement (PA) plus questions about demography/work-related factors and attitudes toward oncology were included. Data were analyzed to measure BO prevalence and related factors. **Results:** Between February 10 and March 15, 2020, 545 responses were submitted by female professionals. The responses pre-dated the COVID-19 pandemic emergence in the region. BO prevalence was 71% among female professionals. Women aged $<$ 44 years represented 85% of the cohort. Sixty-two percent were married, 52% with children and one-third practiced a hobby. Two-thirds worked in medical oncology, worked for $<$ 10 years and 35% worked in academia. The majority (73%) spent $>$ 25% on administrative work daily. Nearly half of the respondents (49%) expressed a recurring thought of quitting oncology and 70% had no burnout support or education. Inability to deliver optimal care was reported as distressing for career development in 82%. Factors significantly influencing the BO risk are listed in Table. Marital status, having children, academia and years in practice did not impact the risk of BO among female oncologists form MENA. **Conclusions:** High BO prevalence was reported among female oncology professionals from MENA. The majority of women oncology workforce were young and early- to mid-career in this cohort. Younger age, practicing in North African countries, high administrative load and the recurring thought of quitting were associated with increased risk of burnout. Whereas, practicing a hobby and enjoying oncology communication decreased the BO risk. Burnout support and education specifically for women in oncology is needed. Research Sponsor: None.

Multivariate logistic regression analysis for factors affecting the risk of developing burnout in female oncology professionals.

Factors	Ad-OR (CI 95%)	P Value
Age < 44 years	2.26 (1.22 - 4.19)	0.010
North Africa	2.43 (1.35 - 4.38)	0.003
Admin work > 50%	1.75 (1.07 - 2.86)	0.026
Always thinking about quitting	11.91 (3.37 - 42.05)	<0.001
Sometimes thinking about quitting	5.61 (3.28 - 9.62)	<0.001
Practicing hobby	0.60 (0.02 - 1.52)	0.042
Enjoying inter-personal and professional communication of oncology	0.42 (0.26 - 0.68)	<0.001

Self-reported gender bias encountered by hematology and oncology fellows. *First Author: Nino Balanchivadze, Henry Ford Hospital, Detroit, MI*

Background: Gender-related bias and discrimination have been well documented, particularly in male-dominated fields such as surgery, and have been associated with increased risk for physician burnout. In hematology/medical oncology, women make up between 41% and 49% of first-year fellows, but represent less than 40% of the academic hematology/oncology workforce. We aimed to study current hematology/oncology fellow perceptions about gender-related bias and challenges to inform interventions that promote gender equity. **Methods:** An anonymous 18-question survey was sent online to 165 adult and 75 pediatric hematology/oncology fellowship programs. Two group comparisons to analyze survey responses between genders were performed using chi-square, or Fisher's test (if cell counts $<$ 5), and Wilcoxon Rank Sum tests. **Results:** A total of 133 fellows completed the survey, where 88 self-identified as female (66%) and 45 (33.83%) self-identified as male. Most participants were White (52%), followed by Asian (29%), Hispanic (9%), Middle Eastern (5%), and Black (3%). Most respondents (n = 100; 75%) were age 31-40 years. More than half (54%) were enrolled in adult hematology/oncology fellowships, 24% were enrolled in pediatric hematology/oncology fellowship programs, and 88% practiced in University-based programs. Compared to male respondents, female fellows were more likely to report experiencing gender bias ($p < 0.001$), felt more insecure in their job ($p = 0.043$), felt second-guessed by colleagues ($p < 0.001$), and were more likely to believe that they had been unfairly denied a promotion ($p = 0.003$). In addition, female respondents were more likely to report having been mistaken as a non-physician ($p < 0.001$) and were more concerned about perceived gender bias. Female respondents reporting gender bias used techniques such as wearing a white coat ($p < 0.0001$), emphasizing a professional look ($p < 0.0001$), and ensuring "Doctor" ($p < 0.0001$) was clearly written on their badge more often than male fellows. When asked about how to combat gender-related challenges, female fellows more often recommended formal lectures and instruction about gender bias for attending physicians and non-physician staff. Suggestions about mitigating gender-related bias included encouraging same-sex mentors and open discussions about existing bias. **Conclusions:** Female hematology/oncology fellows reported facing gender-related bias and challenges in daily practice and often used specific techniques to face these challenges. Transparency and directed education about gender bias may help mitigate these challenges to create better working environments for fellows. Research Sponsor: None.

Moral distress, organizational climate, and the risk of burnout among oncology physician assistants. *First Author: Eric Daniel Tetzlaff, Fox Chase Cancer Center, Philadelphia, PA*

Background: Moral Distress (MD) is the result of barriers or constraints that prevent providers from carrying out what they believe to be ethically appropriate care and has been associated with burnout. Advances have been made in our understanding of burnout in the oncology (Onc) workforce but our understanding of MD remains limited. This study was initiated to explore associations between moral distress, burnout, and the organizational climate (OC) for Onc Physician Assistants (PAs). **Methods:** A national survey of onc PAs was conducted in 2020. MD and Burnout were assessed with the Maslach Burnout Inventory and the Measure of MD – Healthcare Professionals (MMD-HP). To assess OC, the Nurse Practitioner Primary Care OC Questionnaire (NP-PCOCQ) was revised for Onc PAs and assessed professional visibility (PV), administrative relations (AR), physician relations (PR), and professional autonomy and support (PAS). A robust Poisson regression model was used to estimate risk ratios (RR) for burnout associated with MD and OC variables. **Results:** Respondents who completed the survey included 146 Onc PAs that were mostly female (90%), White/Caucasian (84%), married/partnered (78%), and in medical Onc (73%). Mean MMD-HP score was 71.5 and burnout was reported by 39.7% of PAs. MMD-HP scores did not differ based on specialty, practice setting or practice type. PCOCQ subscale scores were lower for PAs with burnout vs. without burnout ($p=0.003$ to $p < 0.001$). Increasing levels of MD were associated with increased levels of emotional exhaustion ($p<0.001$), depersonalization ($p<0.001$) and a higher overall rate of burnout. For Low, Medium and High MMD, burnout rates were 10%, 44% and 66% respectively ($p<0.001$). Risk of burnout was associated with increasing levels of MD, which remained when adjusted for the PCOCQ subscales. An interaction model with the PCOCQ subscales and the association between burnout and MD was not significant. **Conclusions:** Higher levels of MD and unfavorable organizational climate are associated with Onc PA burnout. The relationship between MD and burnout does not appear to be moderated by organizational climate. Additional research is needed to identify potential moderators of the MD/Burnout relationship. Risk Ratio estimate for Burnout. Research Sponsor: Association of Physician Assistants in Oncology, Other Government Agency.

Covariate adjustment for Organizational Climate Subscales*	Medium vs Low Moral Distress		High vs Low Moral Distress		
	RR estimate	95% CI	RR estimate	95% CI	p-value**
Moral Distress (MD) only	4.34	1.78-10.63	6.60	2.81-15.52	<0.001
MD + Professional Visibility	4.18	1.76-9.92	5.98	2.57-13.93	<0.001
MD + Administrative Relations	3.73	1.52-9.17	5.38	2.24-12.95	<0.001
MD + Physician Relations	4.42	1.87-10.45	6.28	2.72-14.54	<0.001

Impact of COVID-19 pandemic on well-being and work-related burnout among healthcare workers at an academic center. *First Author: Richa Dawar, Jackson Memor Hosp, Miami, FL*

11019**Background:** COVID-19 pandemic has not only caused an unprecedented distress in the community, but also significant physical and psychological exhaustion amongst healthcare workers (HCWs), that could lead to serious effects on our healthcare system. This study was conducted to assess burnout among oncologists and other healthcare professionals at a large academic center. **Methods:** An electronic 10-minute questionnaire was sent to actively employed physicians, APRNs and PAs at the University of Miami. Survey items evaluated various personal and professional characteristics including COVID related stress. Burnout was examined with Maslach Burnout Inventory (MBI), which evaluated severity across two domains: emotional exhaustion and depersonalization. The logistic regression model was used to estimate association between study variables and high burnout levels. Odds ratio (ORs) and corresponding 95% confidence interval (CI) were obtained. Continuous variables were tested using two-sample t-test by high burnout status. **Results:** The survey was sent to 739 HCWs, out of which 182 (24.6%) completed the entire survey; 63.7% were physicians, 8.6% fellows, and 27.4% APRN or PA. The pandemic led to rescheduling of professional activities (22.2%), increased workload (59.5%), job insecurity (28.6%), and decreased leadership opportunities (32.2%). 62.3% of respondents reported decreased exercise; 44.8% reported new sleep disorder; 56.1% reported increased home responsibilities; childcare arrangements were affected in 60.6%; 61.4% struggled to maintain work-life balance. 70 of 182 respondents were broadly from the fields of Oncology and Palliative Care. 9 out of these 70 respondents reported high depersonalization, 27 reported high emotional exhaustion, and 33 reported overall high burnout symptoms on either emotional exhaustion or depersonalization scales. Amongst physicians holding positions from PGY4 through licensed attendings with less than 5 years' experience, 62.5% (95%CI=35.4-84.8) showed high burnout rate (10 of 16), which was not statistically different from older physicians (11 of 27=40.7% (95%CI=22.4-61.2)). No difference in burnout was seen for other study variables including gender, marital status, and race/ethnicity. **Conclusions:** COVID-19 pandemic has incited not only an unmatched level of practice changes, but also extraordinary psycho-social uncertainty, leading to a considerable impact on HCWs' well-being. Long working hours, lack of sleep, fear of losing job, transition to tele-medicine, risk of getting infection and putting their family at risk, lack of childcare, pressure of home schooling-all seem to have caused an increased physical and psychological pressure among HCWs and warrants an examination of potential coping mechanisms. This study sets the stage for more elaborate research to illustrate and guide the development of wellness programs imperative to the well-being of HCWs. Research Sponsor: None.

Gender disparities in National Institute of Health funding for hematologic malignancies, hematopoietic stem cell transplantation, and cellular therapeutics. *First Author: Raheel Sufian Siddiqui, Division of Hematologic Malignancies and Cellular Therapeutics, University of Kansas Medical Center, Kansas City, KS*

Background: Gender inequality in research funding has been studied extensively; however, the literature lacks evidence in Hematology. We investigated trends in National Institutes of Health (NIH) funding for hematologic malignancies (HM), hematopoietic stem cell transplantation (HSCT), and cellular therapeutics (CT). **Methods:** The data on Hematology funding was retrieved from NIH Research Portfolio Online Reporting Tools (RePORT) Categorical Spending for fiscal years 2018 and 2019. A total of 6351 entries were reported. Only grants (n=1834) that were related to HM, HSCT, and CT were included. After excluding non-relevant, 975 principal investigators (PIs) were included in the analysis. Additional data regarding PIs was ascertained from the Scopus database, LinkedIn, Doximity, and departmental websites, including the number of publications, number of years of active research, H-index, highest degree, gender, and institution. Data were analyzed using SPSS version 21. Bivariate analyses, using chi-square and t-test, and linear regression analyses were performed. **Results:** In 2018 and 2019, 1834 grants totaling $799.4 million were awarded by the NIH for malignant hematology research (men 1301, 71% vs women 533, 29%). Of 975 PIs, 680 (70%) were men and 295 (30%) were women. Table highlights gender disparities in NIH funding and associated factors. Most of the grant recipients were Ph.D. or M.D./Ph.D. About 70% of total funding was awarded to male PIs. There were no gender differences in the mean number of grants and mean grant amount. Women had significantly lower years of active research and academic productivity. **Conclusions:** Although the gender gap in academic hematology has decreased in recent years, the latest trend suggests significant gender inequality in NIH funding for malignant hematology, transplantation, and cellular therapy. Research Sponsor: None.

Demographic characteristics of all NIH Grant Recipients in Malignant Hematology (HM, HSCT, CT), 2018-2019.

PIs	Total (n=975)	Men (n=680)	Women (n=295)	P value
Total grants awarded, n (%)	1834 (100)	1301 (71)	533 (29)	
Total amount, sum (range)	$799,386,695 (3,184-31,000,002)	$554,274,945 (3,184-10,427,034)	$245,111,750 (4,344-31,000,002)	
Number of grants per PI, mean (SD)	1.9 (1.4)	1.9 (1.5)	1.8 (1.1)	0.265
Total grant amount, mean (SD)	$819,884 (1,420,226)	$815,110 (1,073,553)	$830,887 (2,005,088)	0.873
Publications, mean (SD)	139.7 (175.9)	159.5 (195.7)	94.0 (105.4)	<0.001
Years of active research, mean (SD)	24.5 (12.1)	26.0 (12.4)	21.1 (10.8)	<0.001
H-index, mean (SD)	40.0 (32.7)	44.0 (34.6)	30.9 (25.4)	<0.001
Degree, n (%)				
MD	296 (30)	213 (31)	83 (28)	0.005
MD/PhD	221 (23)	167 (25)	54 (18)	
PhD	440 (45)	284 (42)	156 (53)

Corresponding about death: Analyzing letters from patients with cancer to medical students. *First Author: Tianyi Zhang, University of California, San Francisco, San Francisco, CA*

Background: Clinicians frequently discuss death and dying with patients who have cancer. However, the doctor-patient hierarchy and the unfamiliar clinical environment may prevent these patients from discussing death and dying authentically. Patients may feel more comfortable expressing themselves when given the time and space to write at home. Firefly, an award-winning program at UCSF, facilitates written correspondence between patients with cancer and medical students over the course of one year. Firefly's archive contains thousands of patient letters and constitutes a unique resource for analyzing authentic patient expression outside of the clinical context. The aim of the current study is to improve curricula pertaining to severe illness and end-of-life by providing educators with an analysis of authentic patient perspectives about death and dying expressed in these letters. **Methods:** We (two medical students, an expressive artist, and an oncologist) read all Firefly letters written by patients between 2014 and 2019 and identified 12 patients whose letters meaningfully discussed death or dying. We performed a thematic analysis of these letters using the Buckman three-stage model of dying as a reference. **Results:** Four themes emerged: turmoil; grief; making peace; and past, present and future. The first three themes aligned with the Buckman stages. The fourth theme—past, present and future—spanned the three stages and also elaborated the Buckman model by describing multiple paths that patients may take after passing through these stages. **Conclusions:** The authentic ways in which patients with cancer discussed death and dying in their letters provided deep insight into their coping process. The Buckman model appears useful for framing death and dying from the patient perspective but may not fully reflect modern oncologic care in which many patients live for years beyond a severe or terminal diagnosis. Educators can use the identified themes to shape medical school curricula pertaining to severe illness and end-of-life care. Research Sponsor: None.

11022 **Poster Session**

The clinician educator career in oncology. *First Author: Meredith Elana Giuliani, Department of Radiation Oncology, University of Toronto; Radiation Medicine Program, Princess Margaret Cancer Center, Toronto, ON, Canada*

Background: There has been progress in both the definition of the work of a clinician educator (CE) and the skillset required. The CE career pathway has not been studied in oncology. Our aim is to study the current state of oncologists' identification as a CE and their perceptions of the barriers and enablers for a CE career. **Methods:** A 27-item cross-sectional survey was completed by ASCO program directors (PDs) and associate/assistant PDs (APDs). The survey asked about their current career and perceptions about CE careers including barriers/enablers. Prior to distribution, the survey was reviewed by experts in oncology education and approved by the ASCO Education Council. Frequency statistics are presented. **Results:** Eighty-eight of 297 PDs/APDs responded (30%). 70 (80%) perceived CE as a viable career track, 48 (55%) had a CE track available to faculty at their institution and 72 (82%) considered themselves as a CE. Most PDs/APDs (59; 67%) reported no formal medical education training for their trainees and the majority (67; 76%) did not have a CE track for their fellows. While medical education responsibilities are perceived to be common amongst graduates (39% reporting >50% of graduates), 59 (67%) of PDs/APDs reported <10% of their trainees pursue medical education as a research focus. Compared to clinical, laboratory or discovery research, 71 (81%) of PDs/APDs felt their fellows were less or significantly less prepared for a career in education research. Table highlights the perceived barriers/enablers to a CE career. **Conclusions:** Many PDs/APDs perceive themselves as clinician educators. However, little to no formal education training currently exists to identify and nurture trainees into careers in education. Identification of training milestones in education and establishing guidelines for academic promotion for CEs in oncology are needed. Research Sponsor: None.

Top Perceived Barriers/Enablers to a Clinician Educator Career in Oncology.

Barriers

1. **Unclear career path and/ or lack of opportunity for future academic promotions**
2. **Lack of jobs or career options focused on education**
3. **Competing expectations to pursue academic career in clinical, translational, or lab-based research**
4. **Perceived difficulty in obtaining funding for medical education research**
5. **Lower perceived importance relative to clinical or basic science research**
6. **Perceived decreased prestige of an education focused career**
7. **Insufficient mentorship by senior faculty**

Enablers

1. **Develop a toolkit for training program directors**
2. **Provide guidance on a clinician educator academic career pathway**
3. **Provide more educational sessions at ASCO on medical education topics**
4. **Develop a network of clinician educators to promote collaboration and community of practice**
5. **Sponsor mentored postdoctoral fellowships in medical education**
6. **Provide mentorship opportunities (virtually or in-person) to existing clinician educators**
7. **Provide special sessions for fellows on careers in medical education**

Faculty development: What do we know about barriers, enablers, and satisfaction levels among African oncology faculty? *First Author: Miriam Claire Mutebi, Department of Surgery, Aga Khan University Hospital, Nairobi, Kenya*

Background: Faculty development (FD) programs and initiatives have been shown to improve teaching, learning, and overall satisfaction levels of academic faculty. However, these benefits are not fully realized in resource constrained settings like those found in some Sub-Saharan African academic institutions, that often face many FD challenges. Improving FD activities in the region may enhance the capacity of oncology faculty to address these challenges. We sought to examine African oncology faculty's satisfaction and the perceived enablers and barriers with current FD opportunities. **Methods:** We randomly surveyed oncology faculty ($n = 21$) through the African Organization for Research and Training in Cancer (AORTIC) listserv and conducted semi-structured interviews with nine ($n = 9$) faculty involved in African oncology training programs to ascertain their perspectives on faculty development activities including curriculum development, teaching, and learning. All survey respondents and interview participants are current members of the AORTIC. Descriptive and inferential statistical techniques, and thematic analysis were used to analyze the survey and interview data respectively. **Results:** Interim survey results revealed that 64% of academic oncology faculty believe that there are barriers to their FD at their current academic institutions. Barriers cited for FD from the interviews include the competitive nature of FD courses and programs, limited online learning opportunities, poor internet access, time constraints, language barriers, and high costs associated with FD activities. A significant minority of the survey respondents (43%) were dissatisfied with their overall FD. Access to curriculum development opportunities ($\chi^2 = 10.97$, $p = 0.001$) and longer duration of practice ($\chi^2 = 7.9$, $p = 0.019$) were significantly associated with an increased overall satisfaction with FD of oncology faculty. Themes emerging from the interviews also revealed that participants believe that addressing issues relating to access to local institutional support and opportunities including funding, reduced fees for individuals from low- and middle-income countries, getting time off work from local institution, and availability of online FD education will enable them to increase their participation in FD activities. **Conclusions:** A considerable number of African oncologists face many FD challenges and are therefore dissatisfied with the current state of their FD. Incorporating the recommendations offered by participants into faculty development planning activities may improve faculty satisfaction levels, remove barriers, and improve outcomes for learners. Also, the finding that access to curriculum development opportunities leads to increased levels of satisfaction with FD could guide FD for faculty in African oncology training programs. Research Sponsor: Royal College of Physicians and Surgeons of Canada(RCPSC).

Design, implementation, and assessment of an online-based oncology education program for medical students: An ASCO Oncology Student Interest Group initiative. *First Author: Duaa Kanan, Bahçeşehir University School of Medicine, Istanbul, Turkey*

Background: Undergraduate medical education in oncology is often fragmented and non-standardized among medical schools (BMC Med Educ 17:100, 2017). Oncology education initiatives are thus critically needed to increase cancer awareness and improve medical students' understanding of the principles and multidisciplinary approach of oncology. We designed and implemented an online education program with the aim of providing medical students with an early exposure to the field of oncology. Our program was adapted from the *Australian Ideal Oncology Curriculum for Medical Schools* and included six sessions covering the basics of cancer biology, prevention and screening, diagnosis and patient management, principles of treatment modalities, principles of surgical oncology, as well as counselling and communications skills. **Methods:** Medical students at our institution were invited to participate. We also invited medical students from other faculties via the support of student groups namely the nation's medical student union and our ASCO Oncology Student Interest Group (OSIG). Invitations were sent by email and/or via social media along with a brochure outlining the conference's program and instructions to use the Zoom platform. Students were asked to voluntarily fill online pre- and post-conference anonymous surveys. Students self-assessed their competency, personal attributes, future career aspirations, and provided an evaluation of the program. A five-point Likert scale was used for most questions, in which 1 indicated strong disagreement and 5 indicated strong agreement with the statement. **Results:** Nearly 300 students from over 50 medical schools in Turkey attended the live program. Only students (n = 228) who completed both the pre- and post-conference surveys were included in our study. ASCO OSIG members made up 24.1% (n = 55) of the students. Among the participants, 73.7% (n = 168) were preclinical students (years 1-3) and 26.3% (n = 60) were clinical students (years 4-6). Students' overall self-reported rating of their knowledge significantly improved in each of the six sessions, with the greatest pre-post difference observed for diagnosis and patient management (2.51 ± 1 vs 3.87 ± 0.81) followed by principles of treatment modalities (2.54 ± 0.96 vs 3.79 ± 0.88), $P < 0.001$. Most students believed the program was beneficial in improving their current understanding of oncology with a mean of 4.43 ± 0.76. Most students (92.5%) were "likely" or "very likely" to recommend the program to their colleagues. **Conclusions:** Students' evaluation of the online oncology program demonstrated significant benefit and knowledge improvement. Our successfully piloted teaching model of oncology for medical students can be adapted and implemented at medical schools globally. Further development and continuation of our educational initiative is undergoing. Research Sponsor: None.

Improving feedback for hematologists and oncologists in training. *First Author: Ilana Schlam, Medstar Washington Cancer Institute, Washington, DC*

Background: Feedback is an integral part of the learning process, allowing learners to remain on course in reaching competence in clinical, research, and interpersonal skills. However, the impact of teaching feedback during hematology-oncology training has not been studied. We aimed to identify barriers in delivering and receiving high-quality feedback in our fellowship program and to create a curriculum aimed at teaching fellows and faculty how to engage in more effective feedback conversations. **Methods:** This pilot study aimed at determining and addressing perceived barriers to high-quality feedback in the hematology-oncology fellowship program. A pre-intervention questionnaire, consisting of Likert scale and open-ended questions, was administered to identify barriers to giving feedback and to assess satisfaction with the quality of feedback received in our fellowship program. The results of the baseline questionnaire were utilized to build a virtual interactive three-session workshop provided by the ASCO Quality Training Program in which the importance of feedback and methods of providing effective feedback were taught. Topics included feedback set-up, low-inference observation, and a structured approach to reinforcing and modifying feedback. One month after the intervention the participants completed a follow up questionnaire. This project was developed through the ASH Medical Educators Institute. **Results:** Each questionnaire was completed by 11 participants. The two main barriers to high-quality feedback identified were the discomfort with both giving and receiving feedback, and the lack of protected time. At baseline only 54% of the participants reported they were comfortable giving feedback, increasing to 81% post- intervention. Pre-intervention, 81% of participants reported they did not have protected time for feedback, decreasing to 64% after the intervention and institution of weekly protected time for feedback. Half of the participants reported that the feedback was not actionable in the initial questionnaire, decreasing to 10% post-intervention. Overall, fellows reported that their feedback was mostly focused on notes, followed by presentations and interpersonal skills. Faculty reported that most of the feedback they received was about time management and patient care. **Conclusions:** This pilot study helped address a major barrier to improvement and growth within our training program and confirmed that feedback skills must be taught and practiced. A 6-hour virtual workshop showed tangible results in the satisfaction with and quality of feedback given to both fellows and faculty. Our findings are salient as we completed the intervention during the COVID pandemic. Limitations of the study include its single-institutional design and sample size. A major challenge anticipated is sustainability, which will be addressed by maintaining periodic lectures and assigning protected time for feedback. Research Sponsor: None.

11026 **Poster Session**

Impact of advanced clinical and translational research educational programs on oncology specialties and career development. *First Author: Aron Simkins, Division of Hematology & Oncology, George Washington University School of Medicine & Health Sciences, Washington, DC*

Background: The Clinical and Translational Science Award (CTSA) Program currently supports more than 50 leading medical research institutions in the U.S. with the aims of training, promoting and developing future translational science researchers, with particular emphasis on advanced Clinical and Translational Research (CTR) education. No prior studies have evaluated career development in oncologists who have completed CTR training. The objective of this study is to examine the impact of advanced CTR training on career development, return-on-investment and research productivity in Oncology specialties. **Methods:** With IRB approval, we conducted a survey study of U.S.-based Hematology/Oncology (H/O), Radiation Oncology (RO), and Surgical Oncology (SO) members of the American Society of Clinical Oncology who completed CTR training. Data was anonymized and collected through Research Electronic Data Capture (REDCap). Outcomes were compared using Chi-square test for frequency data. **Results:** We received 225 survey responses (62.1% H/O, 23.3% RO, 13.2% SO, 1.4% others). About 28.4% (n = 64) of the respondents had a PhD or Master's degree in CTR (Group A) compared to 71.6% (n = 161) with graduate certificates or non-degree granting courses in CTR (Group B). Specialty ratio was equally distributed between both groups. Overall, 79.7% vs 57.5%; $P < 0.001$ of respondents worked in academia, of which 55.2% had tenure track positions. Over 49 different CTSA Programs throughout the U.S. were represented. In terms of impact with new research projects, the ability to secure funding and opportunities for multidisciplinary collaboration, satisfaction with CTR training was higher among Group A compared with Group B ($P < 0.001$; $P < 0.01$; $P < 0.01$ respectively). In terms of research output, higher satisfaction was seen in Group A (67.2% vs 47.4%; $P < 0.01$), however total publications per year were not statistically significant ($P = 0.135$). Usefulness of a CTR degree on career advancement, a difference of 50.0% vs 19.1%; $P < 0.001$ was noted. Similarly, usefulness regarding new job opportunities and return-on-investment also favored Group A ($P < 0.001$). Overall satisfaction with training was significantly higher in Group A (73.4% vs 48.7%; $P = 0.004$). **Conclusions:** This study is the first to report satisfaction ratings for CTR training among oncology specialties. Although no significant difference was observed in terms of publication output, those with higher levels of advanced degrees were more satisfied with their CTR training, and viewed it as more impactful to career advancement and research productivity. The evidence presented is useful for informing career development for oncology residents and fellows offered CTR degrees during their training. Research Sponsor: None.

The cognitive load of inpatient consults: A convergent parallel mixed methods study using the consult cognitive load instrument. *First Author: Sam Brondfield, University of California, San Francisco, CA*

Background: Consultation is crucial for inpatient care and a primary responsibility of fellows. Understanding the cognitive load associated with the complex skill of consultation would enhance fellow learning. The authors aimed to determine themes describing the fellow experience during consults, align these themes with Consult Cognitive Load (CCL) scores, and identify strategies to manage cognitive load. **Methods:** The authors studied 16 fellows using mixed methods. Fellows who accepted an invitation completed a consult followed by the CCL, a measure of cognitive load during consults, and an interview. Three authors conducted a thematic analysis. Member checks and triangulation with fellows supported theme trustworthiness. Subsequently, three authors rated the extent and cognitive demand of each theme expressed in each transcript. The authors measured interrater reliability and used Spearman correlation to describe the association of these ratings with CCL scores. The authors examined themes to identify strategies that educators might use. **Results:** Analysis revealed four themes: "nature and scope," which conceptually aligned with intrinsic cognitive load (IL); "leveraging resources," which had elements of both IL and extraneous cognitive load (EL); "extraneous factors," which aligned with EL; and "drivers," which aligned with germane cognitive load (GL). Interrater reliability for extent and demand ratings ranged from 0.57 to 0.79. The correlation between "nature and scope" and IL was 0.37, "extraneous factors" and EL 0.71, and "drivers" and GL 0.32. "Leveraging resources" did not correlate with IL (0.06) or EL (-0.09). Potential strategies based on themes included offering level-appropriate assistance to match IL, focusing the fellow's attention to reduce EL, and providing succinct teaching to promote GL. **Conclusions:** This study provided deep insight into the fellow consult experience and suggested trustworthy strategies that educators can use to design and guide consult learning. The theme "leveraging resources" merits further exploration. Research Sponsor: UCSF Education Innovations Grant.

11028 **Poster Session**

Oncology trainees' perceptions and knowledge of therapeutic cannabis use. *First Author: Poorva Bindal, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Evidence shows that cancer patients are interested in learning about medicinal cannabis and frequently ask their oncologists for recommendations. To determine whether oncology training is adequately preparing physicians to address this topic, we conducted a national survey of oncology trainees to determine attitudes, practices, and knowledge about medical cannabis in cancer care. **Methods:** An interdisciplinary team developed an electronic questionnaire assessing trainees' current practices regarding cannabis recommendations in cancer care and their knowledge of its effectiveness and risks compared with conventional care for cancer-related symptoms. We contacted 155 oncology training programs throughout the U.S. and asked that they distribute the survey to their trainees. Primary outcomes were: whether trainees reported discussing or recommending cannabis with/to patients and whether they felt sufficiently informed to make such recommendations. We presented data as proportions and used chi-square tests to compare proportions between groups. **Results:** Forty training programs from 25 states participated; of the 462 trainees in these programs, 187 completed surveys, yielding a response rate of 40%. Of the participants, 52% were female, 53% White, 33% Asian, and 5% Hispanic. One third (34%) graduated medical school before 2015, and 22% attended medical school outside the US. While 24% of trainees reported having received training regarding medical cannabis, only 12% felt sufficiently informed to make cannabis recommendations. Despite this, 91% reported having discussed cannabis with patients, and 58% reported recommending cannabis clinically to more than five patients in the prior year. Many viewed it as useful adjunctive therapy that was at least as effective as conventional treatments for: anorexia/cachexia (72%), nausea/vomiting (45%), and pain (41%). Over half (55%) believed that cannabis was beneficial to patients at the end of life; 31%, patients in active treatment; 11%, cancer survivors; 20%, the elderly with cancer and 16%, young adults with cancer. Peer-reviewed material (30%), lectures or webinars by another physician (29%), and patients and their families (22%) were the most commonly cited sources of information regarding medical cannabis. Oncologists who reported at least one area of focus as supportive/palliative care were more likely to feel sufficiently informed to make recommendations than oncologists without this focus (17% vs. 4%, $P = 0.01$); no other demographic or practice characteristics were associated with feeling sufficiently informed (all $P > 0.10$). **Conclusions:** Although most oncology trainees discuss cannabis use with their patients, the majority do not feel sufficiently informed about its use in cancer care. This represents an unmet need in contemporary oncology training, trainee satisfaction, and patient care. Research Sponsor: None.

Cancer specialists in the VA as early adopters of clinical genetic services. *First Author: Maren Theresa Scheuner, San Francisco VA Health Care System, San Francisco, CA*

Background: Genetic testing has become essential to delivery of cancer treatment, risk assessment, surveillance, and prevention. We sought to understand the use of genetic tests by clinicians in the Department of Veterans Affairs (VA). **Methods:** We administered a web-based survey to clinicians at 20 VA facilities with precision oncology programs. We excluded respondents if they were: not at one of the 20 VA facilities; not seeing patients in VA; not a physician, nurse practitioner (NP), physician assistant (PA), or pharmacist; a medical geneticist or specialty was not reported; or if the survey was incomplete. Using multiple logistic regression, we assessed the association between genetic test ordering, genetics referral, and clinician characteristics. **Results:** There were 909 (909/11,442, 8%) eligible respondents with 61% women and 64% under age 55. There were 571 physicians (63%), 200 NPs (22%), 93 pharmacists (10%), and 45 PAs 5(%). There were 361 (40%) primary care providers (PCPs), 90 (10%) cancer specialists, and 458 (50%) non-cancer specialists. Only 21% of clinicians reported feeling prepared to use genetic tests in their practice. In the past year, only 8% had ordered at least one multi-gene cancer test (germline, tumor or both), 12% a pharmacogenetic test, and 0.2%, an exome. Compared to physicians, NPs were 60% less likely (OR = 0.42, 0.23-0.77, p = 0.005), pharmacists, 80% less likely (OR = 0.22, 0.08-0.62, p = 0.005), and PAs, 90% less likely (OR = 0.08, 0.01-0.58, p = 0.01) to have ordered a genetic test. Compared to PCPs, cancer specialists were almost 5 times more likely to order a genetic test (OR = 4.74, 2.57-8.73, $p < 0.0001$); there was no difference in genetic test ordering between PCPs and non-cancer specialists. Among clinicians (n = 72) who had ordered cancer genetic tests, only about two-thirds were confident in knowing the indications for testing; discussing the potential benefits, harms and limitations of testing; understanding the test report; and knowing implications of results on disease management and prevention. Clinicians (n = 106) who had ordered pharmacogenetic tests had lower frequencies of confidence in these tasks. About half (52%) of the cancer specialists had referred patients to genetics in the past year; they were 1.8 times more likely than PCPs to refer (OR = 1.82, 1.10-3.03, p = 0.02), and non-cancer specialists were about 50% less likely than PCPs to refer (OR = 0.46, 0.33-0.64, $p < 0.0001$). **Conclusions:** In the VA, cancer specialists are integrating genetic testing and genetics referral into their practice more than PCPs and other specialists. However, genetic testing is underutilized, and many clinicians remain unprepared to use genetic tests in their practice. These results will inform workforce planning, clinician education, and development of clinical decision support to facilitate genetic risk assessment, informed consent, and ordering of genetic tests. NCI Awardee Skills Development Consortium (NASDC): Applicant profiles. *First Author: Claire F. Verschraegen, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: In 2020, the NCI funded a new educational consortium, NASDC (NCI Awardee Skills Development Consortium**,** RFA-CA-19-010 and -011), through four institutionally granted UE5 awards to deliver a specific course each and a U24 award as a Coordinating Center. The goal is to teach current early-career faculty NCI grantees skills in areas critical for successful independent academic cancer research careers. Courses focus on leadership and socioemotional skills, health disparities, immuno-oncology, and cell and gene therapy. Teaching will initially be virtual, given the COVID pandemic. **Methods:** A steering committee and four working groups were established to build the consortium infrastructure, including the NASDC (osu.edu) website. Clientele are early-career faculty PD/PI of a current NCI-funded grant (K01, K07, K08, K22, K23, K25, R00, R21, DP1, DP2, DP5, R01, R23, R29, R37, R56, RF1, RL1, U01), of whom 454 were directly contacted. Blast emails and social media were also used. We are reporting the characteristics of 154 applicants, who completed the RedCap application online. **Results:** 85% of the applicants are within the first 5 years of a faculty appointment, 87% at the assistant professor rank, and 65% on tenure track. 40% hold an M.D. degree and 72% a Ph.D. 81% are US citizens, 52% females, and 45/33/16/2/4%-11% are White/Asian/Black/Native Americans/Other–Hispanics/Latino. 76% work at NCI-designated comprehensive cancer centers. Mean protected research time is 80%. Non-mutually exclusive fields of research interest are therapeutics (46%), basic science (37%), disparities (34%) prevention (32%), public health (28%), and pediatrics (10%). 66% have received a K-award grant, 13% each an R21 or R00, and 3% an R01. Additionally, 35% had a second NCI grant as PI, 10% a third grant, and 60% had non-NCI grants. Reasons for applying included (1) not quite ready to lead a research team (42%), (2) need for stronger career mentoring (37%), and (3) not being fully confident in research skills (21%). **Conclusions:** Applicants to the new NCI educational consortium (NASDC) have a successful start to their academic career with a third having obtained more than one NCI award. Most applicants work at NCI-designated comprehensive cancer centers. As cancer research continues to evolve and has the potential to address critical health care needs of the nation, NASDC will strive to equip scientists to be leaders, teach advances in technology, and impart confidence in research skills. Efficacy of a fully remote primary lecture series at an academic hematology and oncology fellowship program. *First Author: Sassine Ghanem, State University of New York Downstate Medical Center, Brooklyn, NY*

Background: 615 fellows began training in American combined hematology/oncology fellowship programs in July 2020. These new fellows face a steep learning curve. The coronavirus pandemic has significantly affected how we learn, with programs having to convert most collective learning to a completely virtual format. Research on the efficacy of introductory lecture series in academic hematology/oncology programs is limited especially regarding virtual formats. We introduced a virtual introductory lecture series with the goal of increasing the clinical confidence and knowledge base of first-year fellows. **Methods:** A once weekly remotely-delivered two-hour primer series was designed with lectures given by both third-year fellows and faculty from July-August 2020. Fellows were asked to complete pre & post-test evaluations of each lecture. Evaluations included a combination of knowledge-based questions & self-reported confidence assessment. **Results:** 14 fellows were assigned pre- and post-tests in the study. 1 fellow was excluded due to lack of participation. A total of 123 paired pre and post-tests were compared. Data analysis was performed with SPSS v 24.0 using the paired samples t-test. Pre and post-tests were graded on a scale of 0-100. The pre to post mean difference compares the mean test result of the post tests to that of the corresponding pretests. Questions were divided into 2 groups. The 1st group tested the fellow's medical knowledge regarding the pathology while the 2nd group tested the comfort in the management, diagnosis and treatment. In the statistical analysis, these questions were defined as "Knowledge" and "Comfort" accordingly, the sum as "Complete". A statistically significant improvement in post-test knowledge for fellows of all years was noted with a pre to post test mean difference of 12.52, $P < .0001$. The difference was more pronounced among 1st year fellows with a pre to post test mean difference of 16.84, $P < .0001$. A similar improvement was seen for the comfort in management questions. The post-test comfort pre to post test mean difference was 10.48, $P < .0001$ for fellows of all years and 6.70, $P < .0001$ for first year fellows. **Conclusions:** A remotely-delivered introductory lecture series for fellows in a hematology/oncology training program increases both clinical knowledge and clinical confidence in fellows of all years of training. Research Sponsor: None.

Factors associated with open access publishing costs in oncology journals. *First Author: Alex Koong, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The open access (OA) publishing model represents an exciting opportunity to facilitate dissemination of scientific information to global audiences. In contrast to many traditional models, which require readers to pay subscription fees or rely upon institutional subscriptions for article access, the OA model grants free access to all consumers. However, OA publication is often associated with significant article processing charges (APCs) for authors, which may thus serve as a barrier to publication. In this investigation, we aimed to identify journal-level factors associated with OA publication costs in oncology journals. **Methods:** We identified oncology journals using the SCImago Journal & Country Rank database. All journals under the "Oncology" category that offer an OA publishing option with APC data openly available were included. For all journals, we searched journal websites and tabulated journal characteristics, including APC amount (USD), OA model (hybrid vs full), journal 2-year impact factor (IF), H-index, number of citable documents, primary treatment modality (surgery, radiation, medical, non-specific), treatment site (e.g. breast, etc), and continent of origin. Pearson correlation was used to evaluate univariate linear relationships between variables; for variables with significant correlation, we generated a multiple regression model to identify journal characteristics independently associated with OA APC amount. **Results:** Of 367 oncology journals screened, 266 met final inclusion criteria. The median APC was 2810 USD (range 0 – 5200). On univariate linear correlation regression testing, journals with the full OA model ($p < 0.001$), higher journal IF ($p < 0.001$), higher H-index ($p < 0.001$), greater number of published articles ($p < 0.001$), and those from North America or Europe ($p < 0.001$) tended to have higher OA publishing costs. When these co-variates were analyzed in a multiple regression model, only full OA status ($p < 0.001$), higher IF ($p < 0.001$), and North American or European origin ($p < 0.001$) persisted as independently associated with greater OA APC. **Conclusions:** Large APCs may serve as a barrier to OA publication and therefore create or exacerbate disparities among scientific investigators seeking to share their research. In this investigation, we find that OA publication costs are greater in oncology journals that utilize the hybrid OA model, have higher IF, and are based in North America or Europe. These findings may inform targeted action to help the oncology community fully appreciate the benefits of open science. Research Sponsor: None.

How to teach Breast ERAS protocols: Surgical residents' perspectives and perioperative practices for mastectomy patients. *First Author: Kristen Jogerst, Mayo Clinic, Phoenix, AZ*

Background: Breast enhanced recovery after surgery (ERAS) protocols emphasize multimodal analgesia to decrease pain and expedite home recovery, but variability remains for same-day discharge and pain management. The purpose of this qualitative study is to examine how residents learn and apply breast surgery ERAS protocols, how they conceptualize pain management for breast surgery patients, and what influences their decision to discharge a patient home on the day of surgery. **Methods:** A semi-structured interview guide was adapted from existing instruments in the pain management qualitative literature. Surgical residents who rotated on the breast surgery service within the previous 12 months were interviewed by a single researcher. Interviews were recorded, transcribed, de-identified, and independently inductively coded by two researchers. A codebook was developed and refined using the constant comparative method until interrater reliability (Cohen's kappa) reached greater than 0.9. Codes were grouped into coding categories and explored for thematic analysis. **Results:** Twelve interviews were completed with plastic and general surgery residents. Participants spanned postgraduate years 1-4. Preferred discharge narcotic regimens for mastectomy patients ranged from 5-30 tablets of 5mg oxycodone and participants rarely reported the same quantity. Ultimately, 365 primary codes were collapsed into 26 parent codes, with a Cohen's kappa of 0.93. Six emerging themes were identified. Three themes describe how participants learned through a mixture of templated care, formal education, and informal experiential learning. Two themes delineate how residents would teach breast surgery ERAS protocols: by emphasizing buy-in and by connecting the impetus behind ERAS with the implementation in daily workflow. One theme illustrates the patient-centered culture and how that impacts postoperative management and same-day discharges. **Conclusions:** Residents learn breast surgery ERAS and postoperative pain management from imitating their seniors, observing patient encounters, completing templated orders, and translating concepts from other ERAS services, more so than from a formal lecture. When implementing new same-day discharge protocols for mastectomy patients, it is important to consider how informal learning and local culture influence postoperative pain management and discharge rates. Factors associated with successful publication of abstracts in women malignancies: Are we closing the gender gap? *First Author: Ankita Kapoor, Rochester General Hospital, Rochester, NY*

Background: We aimed to determine abstract characteristics associated with successful peer-reviewed publication after presentation at ASCO annual meeting in the women's malignancy category (breast & gynecologic cancer). Awareness of this could help meeting organizers & attendees understand factors associated with impactful abstracts. **Methods:** All oral & poster abstracts (OA: n = 53 & PA: n = 527) in Breast (Loco/Regional/Adjuvant & Metastatic) & Gynecologic cancers category (2017 & 2018 meeting) were included. Subsequent publication was confirmed by searching PubMed by title, names of first & last authors for abstracts published by January 2021. Time to online publication, US or foreign journal publication & impact factor (IF) were recorded. We also recorded number of authors, single/ multi-institution studies & gender of first/ last author, which was confirmed by viewing biography details on their institutional websites. Descriptive analysis was performed & association between above factors & publication matrix was analyzed using multiple logistic regression model, Chi-square and t-test. **Results:** 45/53 OA (85%) & 269/527 PA (51%) were published in peer-reviewed journals. Median number of authors for published PA was 12 vs 11 for unpublished ($p = 0.24$). Females (F) presented 34% (18/53) OA & 49.3% (260/527) PA. 55% (143/260) PA presented by female authors & 47.1% (126/267) presented by male (M) authors ($p = 0.073$) were published. No difference in publication between single vs multi-institution studies ($p = 0.76$) for PA was noted. Average time to journal publication for OA & PA was 15.45 (SD +/- 3.37) & 17.73 (SD +/- 1.27) months (mo) respectively. Mean IF for OA was 27.95 (SD+/- 6.18) while for PA was 10.96 (SD+/- 1.75). For published OA, 33% (15/45) had female first & 29% (13/45) had female last authors. For published PA, 50.2% (135/269) had female first while only 37.5% (101/269) had female last authors. There was no association between gender of last author to IF ($p = 0.39$), single vs multi-institution study ($p = 0.48$) or time to publication ($p = 0.44$) for PA. **Conclusions:** More than 75% of OA & 50% of PA were successfully published regardless of gender, number of authors or institutions involved. We observe a slight disparity in senior authorship for females and although this was not statistically significant, we are encouraged that the gap is closing in first authorship. Research Sponsor: None.

The Johns Hopkins Molecular Tumor Board Precision Oncology elective for Medical Oncology fellows. *First Author: Kristen Marrone, Johns Hopkins University School of Medicine, Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: The accelerated impact of next generation sequencing (NGS) in clinical decision making requires the integration of cancer genomics and precision oncology focused training into medical oncology education. The Johns Hopkins Molecular Tumor Board (JH MTB) is a multi-disciplinary effort focused on integration of NGS findings with critical evidence interpretation to generate personalized recommendations tailored to the genetic footprint of individual patients. **Methods:** The JH MTB and the Medical Oncology Fellowship Program have developed a 3-month precision oncology elective for fellows in their research years. Commencing fall of 2020, the goals of this elective are to enhance the understanding of NGS platforms and findings, advance the interpretation and characterization of molecular assay outputs by use of mutation annotators and knowledgebases and ultimately master the art of matching NGS findings with available therapies. Fellow integration into the MTB focuses on mentored case-based learning in mutation characterization and ranking by levels of evidence for actionability, with culmination in form of verbal presentations and written summary reports of final MTB recommendations. A mixed methods questionnaire was administered to evaluate progress since elective initiation. **Results:** Three learners who have participated as of February 2021 were included. Of the two who had completed the MTB elective, each have presented at least 10 cases, with at least 1 scholarly publication planned. All indicated strong agreement that MTB elective had increased their comfort with interpreting clinical NGS reports as well as the use of knowledgebases and variant annotators. Exposure to experts in the field of molecular precision oncology, identification of resources necessary to interpret clinical NGS reports, development of ability to critically assess various NGS platforms, and gained familiarity with computational analyses relevant to clinical decision making were noted as strengths of the MTB elective. Areas of improvement included ongoing initiatives that involve streamlining variant annotation and transcription of information for written reports. **Conclusions:** A longitudinal elective in the JHU MTB has been found to be preliminarily effective in promoting knowledge mastery and creating academic opportunities related to the clinical application of precision medicine. Future directions will include leveraging of the MTB infrastructure for research projects, learner integration into computational laboratory meetings, and expansion of the MTB curriculum to include different levels of learners from multiple medical education programs. Continued elective participation will be key to understanding how best to facilitate adaptive expertise in assigning clinical relevance to genomic findings, ultimately improving precision medicine delivery in patient care and trial development. Incorporating HER2/HER3 targeted therapies across solid tumors: Assessing the impact of digital education on clinician practice patterns. *First Author: Tariqa Ackbarali, PlatformQ Health Education, Needham, MA*

Background: Improved understanding of the interactions between HER2 and HER3, the heterogeneity of HER-expressing disease, and mechanisms of resistance to anti-HER2 therapy has led to increasing number of treatment options to address clinical needs. Tumor types of interest, impacted by HER2/HER3 expression and pathophysiology were breast cancer, non-small cell lung cancer (NSCLC), gastric cancer, and colorectal cancer (CRC). Increasing competency in these areas is deemed critical to clinician's ability to individualize treatment plans and improve patient outcomes. **Methods:** A 2-hour CME activity was broadcast live-online in September 2020 and remains on-demand through September 2021 at OMedLive.com. The educational initiative was divided into one hour addressing HER2 and HER3, testing guidelines, resistance mechanisms and emerging data elucidating recent and ongoing clinical trials across NSCLC, gastric cancer, and CRC. The second hour focused on individualizing metastatic HER2+ breast cancer, HER2-low breast cancer as an emerging subtype, and management of side effects. Knowledge and competence questions were administered pre-, immediate post-, and 2 mos. post-activity. Behavioral impact questions were also asked at follow-up. Data from these questions were analyzed to determine engagement and clinical impact. **Results:** To date, 448 clinicians participated in the activity. Across the seven CME test questions, improvements in knowledge and competence were observed in the clinical applications of HER2-directed agents and HER3 antibody drug conjugates (ADCs), first-line standard of care for HER2+ breast cancer, and adverse event management for HER2 ADCs. At 2-mos. follow-up, 67% reported improved behavioral impact on both clinical practice and patient experience and outcomes. Clinicians provided specific write-in examples of these changes, noting improved patient-reported outcomes, improved treatment adherence, improved competence developing treatment plans, and increased understanding of HER2/HER3 pathophysiology. Updated and expanded results will be shared. **Conclusions:** The activity was successful in improving clinician understanding of the relationship between HER2/HER3, pathophysiology across tumor types, and applications of emerging targeted therapies. Open-ended responses to behavioral impact questions illustrated clear improvements in clinician-reported patient experience and outcomes, clinical practice management, and knowledge of emerging HER2/HER3 therapies and their uses across multiple solid tumors. Supporting the mental well-being of healthcare professionals during a pandemic. *First Author: Ana Maria Lopez, Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia, PA*

Background: Burnout amongst healthcare professionals has been well-documented as a phenomenon that compromises the quality and viability of patient-centered care, particularly in oncology. Due to the extraordinary demands of the pandemic, burnout has emerged as a public health crisis that warrants immediate attention to preserve the wellbeing of healthcare staff. At the onset of the pandemic, The Sidney Kimmel Cancer Center (SKCC) at Jefferson, an urban NCI-designated cancer center, translated its support offerings to virtual events. Initially, healthcare providers (HP) sought support by attending patient programs. In response, SKCC initiated virtual programming to support the well-being and needs of the HP team. **Methods:** Within weeks of the state shutdown due to the pandemic, programs were initiated to address HP self-reported distress: Coping Effectively and Mindfulness Moments Each 30-minute session was facilitated by a licensed psychologist and social worker. Coping Effectively offers strategies from evidence based treatment including Dialectical Behavior Therapy, Acceptance and Commitment Therapy, and Cognitive Behavioral Therapy, to cope with distress and burnout. Mindful Moments draws from Mindfulness Based Stress Reduction practices including observing breath and guided meditations. These programs have been offered consistently throughout the pandemic. Schwartz Rounds, geared towards supporting the human side of healthcare, provided "hot" topic moderated discussions, four of which focused on the pandemic These discussions allow for HP to come together to discuss difficult topics and emotions impacting a variety of professionals. All programming was evaluated with a single question to measure the impact of the session on reducing distress. Each program began and ended with a poll asking, "How distressed do you currently feel?" Attendees respond on a Likert scale from 0 to 10, in which10 indicated the highest level of distress. **Results:** Since March 31st, 340 staff have attended Mindful Moments and 236 staff have attended Coping Effectively. From March 2020-February 2021, 382 attendees measured their distress before and after attending a staff program. Schwartz Rounds hosted 471 HP from a variety of disciplines. Participants were asked to complete an evaluation following rounds. 31% of program participants' completed an evaluation form and 89% rated the program exceptional/very good. **Conclusions:** Despite the challenges of COVID-19, the pivot to virtually create programs to support staff during the pandemic was swift and thoughtful. The increased attendance and the feedback from evaluations are promising indicators of decreasing burnout amongst HP. How Distressed do you Currently Feel? (Average Score scale 1-10) Research Sponsor: None.

Impact of the COVID-19 pandemic on the wellbeing of international fellows training in hematology/oncology at the Princess Margaret Cancer Centre (PMCC). *First Author: Carlos Stecca, Princess Margaret Cancer Center, Toronto, Canada*

Background: The COVID-19 pandemic has led to significant disruptions across all levels of medical training. International fellows in subspecialty training programs are essential members of the frontline physician workforce, who may be facing additional and unique challenges being far away from their home country. We aimed to understand the impact of the pandemic on the wellbeing of current international fellows in the Hematology/Oncology training program. **Methods:** We conducted an online survey of 52 international fellows at the PMCC from July 6-August 10, 2020. There were 60 questions divided into 4 sections: demographics, wellbeing assessment using the validated Short Warwick Edinburgh Mental Wellbeing Scale (SWEMWBS), fellowship specific questions (personal and professional) and coping strategies using the validated brief COPE scale. **Results:** Response rate was 46% (n = 24). Relevant demographics include: married (65%), male (54%), age between 31-35 years (48%), have children (48%), and home country from Asia (48%). Mean SWEMWBS score was 21, indicating lower overall wellbeing than the general population (23.6). Compared to pre-COVID-19, many reported a decline in their wellbeing (63%), sense of guilt for not being with their family (45%) or helping their country (41%), stress in personal relationships (26%), fatigue (50%), sleep disorders (38%) and loss of interest in daily activities (38%). Personal events were altered by almost 80% and 20% plans to extend their fellowship. According to the Brief-COPE scale, most fellows used more adaptive coping mechanisms (mean score 39.2) as opposed to maladaptive ones (mean score 21.8). **Conclusions:** The ongoing COVID-19 pandemic has negatively affected the overall wellbeing of international fellows. Understanding the specific challenges and coping mechanisms of international fellows may help Institutions develop better targeted strategies to promote their overall wellbeing, professional development and high-quality patient care during these unprecedented times. Research Sponsor: None.

Impact of *#ASCO* Twitter impressions on the oncology community. *First Author: Gilberto Morgan, Department of Medical and Radiation Oncology, Skåne University Hospital, Lund, Sweden*

Background: The oncology community is embracing social media (SM) platforms like Twitter to gain exposure to research, to network, and to engage in real-time discussions. The emergence of SM activity around the ASCO annual meetings has dramatically increased over the past 5 years, with factors such as the COVID-19 pandemic further accelerating use of digital platforms. This growth in SM engagement within the oncology community has previously been presented by totaling the quantity of tweets within a given time frame. Here, we explore the impact of specific trends through impression data. **Methods:** To evaluate activity trends among certain oncology stakeholders, we utilized an SM analytics platform, Symplur, to conduct a content analysis around ASCO conferences (2016-2020) using hashtags (#ASCOyy) as the search criterion. We focused our analysis on trends in impressions, defined by the theoretical maximum number of Twitter users a given tweet could have directly reached in a follower's timeline. We gathered impressions data to quantitatively assess overall ASCO engagement and evaluate topics of interest, and to discover common ASCO themes and reach within specific stakeholder groups. **Results:** Our results show the largest increase in impressions was during #ASCO20, despite a plateauing effect seen in the actual number of tweets (Table). The cumulative number of impressions for #ASCO16 was 468.2 million compared with approximately 1.12 billion for #ASCO20. Differentiating this result from the number of tweets related to ASCO, there was stabilization in the absolute number from #ASCO17 onward. When compiling impressions by doctors and by patient advocates, a similar trend emerged, with the most impressions captured during #ASCO20 (Table). **Conclusions:** As SM use continues to expand in the oncology community, stakeholders have turned to their digital voice to express views and opinions. The impact of impressions versus absolute number of tweets will continue to grow with a stakeholder's follower count, thus building on the digital presence in oncology. Research Sponsor: Eisai Inc.

		#ASCO16	#ASCO17	#ASCO18	#ASCO19	#ASCO20
Cumulative impressions (millions)	**Total**	468.2	504.8	595.1	583.4	1125.8
	Doctors	66.6	134.9	121.6	139.4	187.1
	Patient advocates	15.6	20.5	10.7	18.9	26.2
Number of tweets (thousands)		89.0	116.7	104.8	112.9	98.1

OCEAN (wOmen's Career choicEs About oNcology) Study: Motivations to pursue or not pursue academic oncology. *First Author: Grace Blitzer, University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI*

Background: Although women outnumber men in US medical school enrollment, women constitute < 50% of faculty in academic oncology. This study aimed to determine factors affecting women oncologists' decisions to pursue academic versus non-academic oncology in Hematology/Oncology (HO), Pediatric Oncology (PO), Radiation Oncology (RO), and Surgical Oncology (SO), and to characterize the challenges women oncologists face. **Methods:** A survey was designed to collect cross-sectional data on factors affecting career choices among US women oncologists. The survey was distributed via email and social media. Data were collected anonymously and analyzed using t-tests for continuous variables and Chi-squared tests for categorical variables. **Results:** Six hundred sixty-seven women oncologists responded: 245 (45.3%) specialized in HO, 173 (25.9%) RO, 88 (13.2%) PO, 56 (8.4%) SO, and 48 (7.2%) other. Four-hundred twenty-two (63.2%) women identified as an academic oncologist (AO); 245 (36.8%) women identified as a non-academic oncologist (non-AO). Approximately 1/4 of women oncologists reported their partner (156, 23.5%) or family (176, 26.4%) extremely or moderately impacted their decision whether to pursue academic practice. There was no difference in the timing of childbearing between AO and non-AO. AO perceived the biggest sacrifice of pursuing academics to be time with loved ones (181, 42.9%). Non-AO perceived the biggest sacrifice for AO to be pressure for academic promotion (102, 41.6%), which was the third most common response (44, 18.0%) among AO. Thirty-three (7.9%) AO and 5 (2.0%) non-AO reported feeling that they rarely or never have a sense of belonging in their work environment ($p < 0.01$). AO and non-AO had significantly different perceptions on how their gender impacted their ability to obtain a chosen job ($p < 0.01$), with 100 (23.8%) AO and 52 (21.2%) non-AO reporting a negative or somewhat negative impact, and 116 (27.6%) AO and 101 (41.2%) non-AO reporting a positive or somewhat positive impact. More than half of women surveyed (230 AO, 54.6%; 123 non-AO, 50.6%; $p = 0.61$) felt that they were somewhat or much less likely to be promoted compared to male colleagues. The majority of women reported they would choose the same career path again (71% of AO, 69% of non-AO); however, 92 (21.9%) of AO responded that they were likely or very likely to pursue a career outside academics in the next 5 years. **Conclusions:** While partners/family have a substantial impact on 1 in 4 women oncologists, this does not differ between AO and non-AO. Significantly more non-AO find their gender to have positively impacted their ability to obtain their chosen job. In contrast, a meaningful number of AO report a poor sense of belonging and perceived discrimination in obtaining jobs and being promoted; 1 in 5 are considering leaving academia. Academic oncology remains at high risk for continued gender inequality if the culture is not addressed. Research Sponsor: University of Wisconsin School Medicine and Public Health.

11041 **Poster Session**

Specialty representation on national comprehensive cancer network guideline committees. *First Author: Bismarck Odei, Ohio State University Wexner Medical Center, Columbus, OH*

Background: Among the National Comprehensive Cancer Network (NCCN) guidelines, the existence of Category 1 evidence for cancer management decisions remains low, resulting in the reliance on multispecialty perspective to determine optimal treatment approach. Multiple studies suggest that the specialty composition of oncological teams is important in the trajectory of decision-making. Consequently, we sought to determine if there was adequate representation of radiation oncologists (ROs) on NCCN committees (NCMs). **Methods:** NCMs with Category 1 or 2A recommendations for radiotherapy use were identified. Committee members were documented including specialty, academic rank, and committee role. H-index and gender was assessed for each member. A minimum arbitrary threshold of < 10% was used to define underrepresentation of ROs. Univariate and multivariate (MVA) logistic regression identified factors predictive of underrepresentation. **Results:** Of 57 assessed guidelines, 38 (66.7%) NCMs recommended radiation as Category 1 or 2A from which a total of 1284 committee members were identified. Median committee size was 33 (range 29-38). Overall, 42.2% were Medical Oncologists (MOs), 23.9% were Surgical Oncologists (SOs), and 11.5% were ROs [22.4% were a mix of Radiologists, Pathologists, other specialty physicians, and non-physician members like Patient Advocates]. ROs constituted 4.4% of NCM Chairs (MOs: 68.9%, SOs: 13.3%, Other: 13.3%); 29% of Vice Chairs (MOs: 35.5%, SOs: 35.5%); and 5.9% of the discussion writing committee (MOs: 70.6%, SOs: 23.5%). The representation of ROs was highest for Head/ Neck Cancer NCM (38.8%) and Prostate Cancer NCM (25.8%). 42% of the NCMs recommending radiation had < 10% representation of ROs; 17% of guidelines recommending radiation had 1 or less RO including 4 NCMs which did not have a single RO committee member. On univariate analysis, factors predictive of RO underrepresentation were low SO representation ($p = 0.038$) and low median H-index of the NCM ($p = 0.013$); low proportion of full professors trended towards significance ($p = 0.060$). On MVA, median H-index had a negative association with RO underrepresentation ($p = 0.038$) —no association was found to rank, gender or specialty. **Conclusions:** Our study shows alarmingly low representation of ROs among NCCN committees which include radiation as a Category 1 or 2A recommendation. This can both limit the discussion during guideline development and negatively impact the diversity of perspectives in management recommendations. Efforts to ensure more proportional representation of ROs on NCCN guideline committees are warranted including exploring potential barriers to committee leadership. Research Sponsor: None.

Hematology/medical oncology fellow responses to the initial development of an antiracism curriculum. *First Author: Erica C. Nakajima, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: While the American Council on Graduate Medical Education (ACGME) set up a Planning Committee for Diversity in GME in 2018, no formalized milestones or training mandates have been announced. The nation-wide protests for racial justice following the senseless killings of Breonna Taylor, Ahmaud Arbery and George Floyd further brought to the forefront the need for immediate action to address widespread inequities across graduate medical education, our healthcare system and society as a whole. Therefore, the Johns Hopkins Hematology/Medical Oncology Fellowship Program focused on creating an anti-racism curriculum to foster dialogue on systemic racism and discrimination, grounded in the institutional and geographic context of our training program. **Methods:** Using the Kern six step curriculum development method, we created a comprehensive anti-racism initiative, which included virtual townhalls with Black alumni of the fellowship, book clubs, readings, and lectures. We sought to deepen the fellowship's awareness of the impact of racism and inequity upon trainees, underrepresented minority oncologists and hematologists, and patients in order to develop initiatives to confront them productively. Trainees received a survey 6 months after the start of the curriculum to assess the impact of the initiatives upon trainees, and inform iterative changes to the curriculum. **Results:** 25 of 34 fellows across all post-graduate years (PGY) completed the survey. Fellows agreed that the curriculum was helpful (68%) and encouraging (60%). Collectively, fellows reported that the curriculum increased their awareness of instances of racism in medicine, caused them to think about next steps that the fellowship could take to address racism, and enabled them to identify available resources for support and further education. Respondents selected community engagement and recruitment of diverse fellowship classes as the most pressing priorities for the program. **Conclusions:** Social justice and anti-racism education belong in the formalized training of our hematology/medical oncology fellows. To this end, our ongoing curricular expansion is focusing on anti-racism training, diverse recruitment and youth mentorship. Collectively, a comprehensive yet program-specific approach facilitates opportunities for learning, engagement and development of the skills necessary to engage in this life-long work for ourselves, our communities and our patients. Research Sponsor: None.

Representation trends in radiation oncology training programs in the United States. *First Author: Emilie Garcia, The University of Toledo College Of Medicine and Life Sciences, Toledo, OH*

Background: The ASCO and American Society of Radiation Oncologists (ASTRO) have recently committed to initiatives on increasing URM representation in the radiation oncology workforce. This study aims to assess representation trends in radiation oncology training programs across five academic years in order to understand representation trends and better guide initiatives moving forward. **Methods:** Data on racial and ethnic representation from the ACGME Data Resource Books over a span of five academic years (2015-2020) was included. URM was defined as those who identified as Hispanic, Black, or Native American/Alaskan in concordance with AAMC definition. Chi square testing was used to compare the proportion of residency positions occupied by URM residents by self-identified race and ethnicity in radiation oncology to that of hematology and medical oncology, complex general surgical oncology, and all other specialties. **Results:** A total of 3,315 radiation oncology positions were identified over the study period, 2015 and 2020. 1,938 (58.5%) of radiation oncology residency positions were filled by residents who identified as White, 967 (29.2%) as Asian/ Pacific Islander, 126 (3.8%) as Hispanic, 120 (3.6%) as Black, 7 (0.2%) as Native American/ Alaskan, and 157 (4.7%) as Other. URM representation was 7.6% in total and was relatively stagnant, remaining between 7.3% and 8.0% across study years. Results of chi square comparative analysis demonstrated lower rates of representation in radiation oncology in comparison to hematology and medical oncology as well as all other specialties (Table). **Conclusions:** There is lack of racial and ethnic diversity in radiation-oncology residency training positions in the United States. Over the five-year study period, only 7.6% of trainees identified as URM. URMs have significantly lower rates of representation in radiation-oncology compared to hematology and medical oncology, and other specialties. Efforts to mitigate disparities require a multifaceted approach. Research Sponsor: None.

Specialty	% URM (95% CI)	Comparator	% URM comparator (95% CI)	Total N (both groups)	*P* value
Radiation Oncology	7.6 (6.7-8.5)	Hematology and Medical Oncology	9.0 (8.3-9.6)	10,502	0.024*
Radiation Oncology	7.6 (6.7-8.5)	Surgical Oncology	7.8 (5.4-10.2)	3,788	0.884
Radiation Oncology	7.6 (6.7-8.5)	All Other Specialties	13.1 (13.0-13.2)	518,430	0.000**

Results of chi square comparative analysis for representation in radiation oncology in comparison to hematology and medical oncology, surgical oncology, and all other specialties in total over study period. *denotes significance at $P < 0.05$ **denotes significance at $P < 0.01$.

Factors associated with endowed chair allocation in medical oncology divisions and departments in the United States. *First Author: Lena Jia, Washington University School of Medicine, St. Louis, MO*

Background: Despite an increasing number of female physicians in the workforce, a gender disparity remains in many leadership roles in medicine. Endowed chairs can provide a multitude of research and career opportunities; thus, they are coveted positions in academic medicine. We examined factors associated with holding endowed chairs in oncology across the US, with a focus on whether a gender difference existed, as has been demonstrated in top internal medicine departments more generally. **Methods:** In 2019, we identified 95 academic oncology divisions/departments in the US, using the Oncology Division Chiefs & Department Chairs listing in the American Society of Clinical Oncology (ASCO) myConnection forum to define the institutions included. We requested a list of full professors and endowed chairs in those divisions/departments, relying on public data on websites when an institution did not respond. Using public data (e.g., institutional websites, NIH reporter, Scopus, state licensing boards), we collected information on gender, degree, total NIH funding as PIs, H-indices, publication and citation numbers, and graduation year for these individuals. We then created a multivariable logistic regression model to examine if, after controlling for other variables, gender was independently associated with an increased likelihood of holding an endowed chair. **Results:** One thousand thirty-three oncology full professors were identified, 290 (25.6%) of whom held endowed chairs. Overall, and in an adjusted model, greater research productivity (as measured through publications, citations, and h-index) and greater levels of NIH funding were significantly associated with having an endowed chair. Gender was not significantly associated with endowed chair status (21.9% [95% CI:17.2-27.3] of females and 26.8% [23.8-29.9] for males held endowed chairs; $p = 0.11$) on bivariable analysis, nor was it significant in the adjusted multivariable model ($p = 0.50$). Power to detect the observed difference given the total number of professors and their gender distribution was found to be ~53%, suggesting a 47% chance of failing to reject the null hypothesis of equal gender distributions in endowed chairs when the observed difference is as large as estimated. **Conclusions:** Among oncology full professors, gender was not significantly associated with endowed chair status, although the number of professors in this field is too small to definitively rule out a modest gender difference. This finding contrasts with prior work that revealed a more substantial difference by gender that remained significant after controlling for other factors in a study, including all divisions in the Departments of Internal Medicine at top medical institutions. Further work is necessary to understand what specialty-specific and institutional cultural factors may help mitigate challenges in the pursuit of equity, diversity, and inclusion. TK216 for relapsed/refractory Ewing sarcoma: Interim phase 1/2 results. *First Author: Joseph Aloysius Ludwig, Sarcoma Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ewing Sarcoma (ES) is a rare cancer of the young with very few treatment options in the relapsed/refractory (R/R) setting. Fusions of the EWS gene and one of five different ETS transcription factors are dominant drivers of ES. TK216 was designed to bind ETS proteins directly, disrupt protein-protein interactions, and inhibit transcription factor function. TK216 plus vincristine (VCR) exerted synergistic activity in non-clinical models. Here, we report updated interim results of the Phase 1/2 trial of TK216 ± vincristine in R/R ES. **Methods:** TK216 was administered by continuous IV infusion to adult and pediatric patients (pts) with R/R ES using a 3+3 design. Dosing duration of 7 days was later extended to 10 and 14 days. Dose limiting toxicity was evaluated during Cycle 1. VCR could be added after Cycle 2. The MTD for the 14-day infusion was 200 mg/m^2/d, which was selected as the recommended Phase 2 dose (RP2D) for the Expansion cohort, with VCR started in Cycle 1. **Results:** Thirty-two R/R pts in 9 dose and schedule escalation cohorts, and 31 pts in the Phase 2 Expansion cohort were enrolled. Thirty-five pts were treated at the RP2D. Mean age was 30.6 years and 61% were males. Median prior treatment regimens for recurrent/metastatic ES were 3 (range 0-13). Median time from initial diagnosis of ES to study start was 3.5 years (range 0.3-18.1). Prior procedures included surgery (84%) and radiation (81%). At study entry, all pts had metastases with sites being bone only (13%), pleuropulmonary only (39%), and other metastatic (47%). As of the 20JAN2021 safety cutoff, the most common AEs observed in 62 treated pts, regardless of causality, included anemia (n = 34), neutropenia (n = 30) and fatigue (n = 25). Myelosuppression observed was transient, reversible, and responsive to growth factors. No deaths were attributed to TK216. As of the 06FEB2021 efficacy cut-off, 28/35 pts treated at the RP2D were evaluable for efficacy: Complete response (CR) 7.1%, stable disease (SD) 39.3%, progressive disease (PD) 53.6%, for an overall clinical benefit (CR+PR+SD) rate of 46.4%. SD median duration was 113 days (range 62-213). Three tumor responses were notable. One pt had regression of the target lesion after 2 cycles of TK216 alone, then after 6 cycles of TK216 + VCR therapy a residual non-target lesion was removed, for a surgical CR, without PD at 24 months on study. A second pt had a CR after 6 cycles of combination therapy, without PD at 18 months on study. After 4 cycles of TK216 + VCR therapy, a third pt had a PR of the target lesion, is receiving local therapy for PD of a non-target lesion and remains on study. Pts treated with the RP2D had a longer PFS than those in the dose escalation cohorts. **Conclusions:** TK216 plus VCR was well tolerated and showed encouraging early evidence of anti-tumor activity in this heavily pre-treated/ high tumor burden ES pt population. Clinical trial information: NCT02657005. Research Sponsor: Oncternal Therapeutics, Inc, Other Foundation.

Efficacy of dose intensification in induction therapy for localized Ewing sarcoma: Italian Sarcoma Group (ISG) and Associazione Italiana Ematologia ed Oncologia Pediatrica (AIEOP) ISG/AIEOP EW-1 study. *First Author: Roberto Luksch, Pediatric Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: The role of dose intensification of chemotherapy in Ewing sarcoma (ES) is under evaluation in prospective trials. This is a controlled, randomized phase III study evaluating the impact on event-free survival (EFS) of two arms at different intensity of induction therapy in localized ES at onset. **Methods:** Newly diagnosed localized ES patients aged 2-40 were eligible. They were randomized to receive 4-courses induction therapy - 1 every 21 days - either with a standard arm (arm A) as per ISG/SSGIII protocol (Ferrari S, et at, Ann Oncol. 2011;22(5):1221) or with an intense arm B, consisting of vincristine 1,5mg/sqm+ doxorubicin 80mg/sqm+ifosfamide 9g/sqm for each course. After induction, patients underwent surgery and/or radiotherapy,followed by an adaptive treatment. Good responders received standard courses chemotherapy: arm A pts received 9 courses, while arm B pts received 5 courses. Poor responders in both arms received 4 courses followed by high-dose busulfan/melphalan+autologous stem cell rescue. The primary outcome measure was EFS for the 2 arms in the intention-to-treat population. Kaplan-Meier curves compared with log-rank test and Cox model were performed to assess differences between study arms. A secondary outcome was toxicity differences, assessed by means of the Fisher's exact test. Initial sample size was 230 pts, type I error rate 5%, power 80%. **Results:** Between 2009 and 2019, 234 patients were randomized (arm A-115; arm B-119). M:F ratio was 1.8; median age 14 years (range 2-40); tumour site extremity in 55%, axial/pelvis in 45%; tumour volume $<$ 200ml in 31% and $\geq$200ml in 69%. A good response was obtained in 56% in arm A and 60% in arm B. Median follow-up was 68 months. EFS was not significantly different between arms; HR: 0.85; 95% CI: 0,51-1,41, 5-year EFS (95% CI) was 73% (64-82%) in arm A and 75% (67-83%) in arm B ($p = 0.526$). Good responders in arm A and in arm B and poor responders in arm B had comparable results: 5-year EFS (95% CI) was 80% (71-91%), 77% (67-88%), and 72% (59-86%), respectively, while poor responders in arm A showed a worse, not statistically significant (p = 0.164) performance (63%; 50-78%). Subgroup analyses showed similar outcome for age, tumour site and volume in both arms. Hematological, gastrointestinal, and cardiovascular grade $\geq$3 toxicities were more pronounced in arm B ($p < 0.05$). **Conclusions:** Intense induction therapy with arm B did not improve 5-year EFS when compared with the standard arm A. The higher toxicity observed in arm B than in arm A was counterbalanced, in good responders, by a similar outcome with a shorter treatment plan. For poor responders, with almost 30 patients per arm event-free and with $<$ 48-month FUP, better 5-year EFS in arm B than in arm A was observed but needs further observation. Clinical trial information: NCT02063022. Research Sponsor: None.

Association of treatment delays with an unfavorable outcome in patients with localized Ewing sarcoma: A retrospective analysis of data from the GPOH Euro-E.W.I.N.G.99 trial. *First Author: Uta Dirksen, Pediatrics III, West German Cancer Center, University Hospital Essen, German Cancer Consortium (DKTK), Essen, Germany*

Background: Outcome in EwS has improved by the implementation of dose or time intense systemic treatment. Aim of the study was evaluate whether treatment delays have impact on outcome of patients with localized Ewing sarcoma (EWS). **Methods:** Data from 692 patients with a tumor of the extremities, the pelvis, the chest wall and the trunk registered in the international database of the German Society for Pediatric Oncology and Hematology (GPOH) and treated in the Euro-E.W.I.N.G. 99 trial (NCT00020566) were analyzed. All patients underwent surgical treatment after induction chemotherapy. The optimal interval cut-off values for survival analyses were calculated with receiver operating characteristics curves. Hazard ratios (HR) were estimated with respective 95% confidence intervals (CI) in multivariate Cox regression models. **Results:** As per protocol, patients were to receive six cycles of VIDE induction chemotherapy in 21-day intervals. The duration between induction cycles as per protocol was fulfilled in only 5% of patients. In 72% of patients, the average interval duration between induction chemotherapy cycles was 25 days. Median interval between day 1 of the first induction chemotherapy cycle and definitive tumor surgery was 141 (IQR, 133 – 153) days in patients receiving six VIDE cycles prior to surgery. The optimal cut-off value for survival analyses in these patients amounted to 150 days. Patients with a duration of induction chemotherapy $>$ 150 days were at higher risk to develop an event (HR, 1.546; 95% CI, 1.103 – 2.166) and had a higher risk of death (HR, 1.574; 95% CI, 1.095 – 2.262), compared to patients with a duration of induction chemotherapy $<$ 150 days. Patients with delays during the induction chemotherapy also experienced a significant delay between VIDE 6 and surgery (36 vs. 27 days, $p < 0.001$) and were treated significantly more often at smaller low-volume centers (63% vs. 48%, p = 0.005). Patients with a prolonged interval $>$ 21 days between surgery and day one of postoperative chemotherapy were at a higher risk to develop an event (HR, 1.406; 95% CI, 1.011 – 1.955), and also had a significantly higher rate of postoperative complications (26% vs. 11%, $p < 0.001$), compared to patients with a shorter interval. **Conclusions:** Delays between induction chemotherapy and surgery and between surgery and consolidation chemotherapy are independently associated with a poor outcome in patients with localized EWS. Our results also underscore the need to treat EWS patients in larger and experienced sarcoma centers. The implementation of new and standardized methods in the operative strategy and optimized supportive care during systemic therapy are required to reduce perioperative morbidity and treatment delays. Research Sponsor: German Cancer Aid.

P10015/SARC033: A phase 2 trial of trametinib in patients with advanced epithelioid hemangioendothelioma (EHE). *First Author: Scott Schuetze, University of Michigan, Ann Arbor, MI*

Background: EHE is a rare vascular cancer arising in liver, lung, soft tissue and bone. The natural history of metastatic disease varies considerably from indolent growth over years to rapid growth with fatal outcome in months. Treatment of patients (pts) with metastatic EHE with antiangiogenic therapy induces tumor response in a minority of pts, and median PFS is 6-12 months. TAZ-CAMTA1 translocation results in activation of MAPK pathway and is an oncogenic driver in EHE. We sought to evaluate the effect of MEK inhibition using trametinib in pts with unresectable EHE. **Methods:** A phase 2 trial of trametinib 2 mg daily was conducted in pts with EHE though the Experimental Therapeutics Clinical Trials Network supported by NCI in collaboration with SARC. Additional support was provided by the EHE Rare Cancer Charity and the EHE Foundation. Pts had to have evidence of objective tumor progression or EHE-related pain requiring narcotics for relief prior to enrollment. Presence of TAZ-CAMTA1 translocation was analyzed by fusion-FISH after enrollment. Primary trial endpoint was objective response rate (ORR) per RECIST1.1 with at least 1 objective response required in the 1st 13 pts to expand enrollment to 27. The trial was amended after stage 1 to continue enrollment to 27 pts with TAZ-CAMTA1 detected by FISH with goal of $>$4 objective responses in this group. Secondary objectives were PFS and OS rates, safety and change in pt-reported global health and pain scores per PROMIS questionnaires. **Results:** 43 pts were enrolled between 6/2017 – 9/2020 across 10 sites and 41 started therapy. TAZ-CAMTA1 fusion was detected in 26, not detected in 7, test failed in 5 and was not performed due to insufficient tumor in 5. Median pt age was 54 (range 22-81 yrs) and 11 were $>$65 yrs; 25 were female; ECOG was 0 in 23, 1 in 16 and 2 in 3 pts. Most pts experienced reduction in tumor size. ORR per RECIST was 7% (3/41); in pts with TAZ-CAMTA1 detected, the ORR was 0% (0/26). Mean pain intensity and interference scores had a statistically significant improvement and global quality of life scores did not statistically change after 4 weeks of therapy. 17 pts remained on treatment $>$ 6 months and 7 $>$ 12 months. 25 pts stopped trametinib due to EHE progression, 6 died during treatment, 6 withdrew from treatment, 3 stopped drug due to adverse event and 1 is on treatment. The most common AEs related to trametinib were rash, fatigue, nausea/vomiting, diarrhea, alopecia and edema; Grade $>$3 AEs included anemia, dyspnea, hypoxia, hypotension, syncope and dermatitis. **Conclusions:** To our knowledge, this is the largest prospective clinical study focused on pts with EHE. Although the trial did not meet the ORR goal, stable disease $>$ 6 months was seen in 40% of pts, and EHE-related pain improved on treatment. Trametinib was associated with expected cutaneous and GI adverse effects. Additional pt-reported outcomes and biomarkers of inflammation are undergoing analysis. Clinical trial information: NCT03148275. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

SPEARHEAD-1: A phase 2 trial of afamitresgene autoleucel (Formerly ADP-A2M4) in patients with advanced synovial sarcoma or myxoid/round cell liposarcoma. *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: This phase 2, open-label trial (SPEARHEAD-1; NCT04044768) is designed to evaluate the efficacy, safety, and tolerability of afamitresgene autoleucel in 45 patients (pts) with advanced/metastatic synovial sarcoma or Myxoid/Round Cell Liposarcoma (MRCLS). **Methods:** Eligible pts are HLA-A*02 positive with MAGE-A4-expressing tumors. Pts undergo leukapheresis for collection of autologous T-cells for processing and manufacture into afamitresgene autoleucel cells. Pts were treated with afamitresgene autoleucel doses between $1–10 \times 10^9$ transduced T-cells after receiving lymphodepleting chemotherapy. The primary endpoint is overall response rate per RECIST v1.1 by independent review. An independent Data Safety Monitoring Board reviews ongoing safety and benefit: risk during the interventional phase. **Results:** As of Feb 4, 2021, 32 pts received afamitresgene autoleucel. Of these pts, 59% were male, 87.5% had synovial sarcoma, the median age was 43 yrs (range: 24–73), and they had a median of 3 prior systemic lines of therapy. The MAGE-A4 antigen expression level (histoscore) ranged from 112–300, and the transduced cell dose ranged from 2.7–9.9 x 10^9. At the data cutoff, 25 pts were evaluable for preliminary efficacy (23 with synovial sarcoma and 2 with MRCLS) and 7 pts (5 with synovial sarcoma and 2 with MRCLS) had insufficient follow-up (<8 weeks follow-up and/or awaiting first scan). Of the 25 evaluable pts, the investigator-assessed responses were: complete response (2 pts), partial response (8 pts), stable disease (11 pts), and progressive disease (4 pts). All responses were confirmed. Nine of the 10 responders had ongoing response at the data cutoff and 3 responders had MAGE-A4 antigen histoscores <200. The most common AEs of any grade (>30% pts) were neutropenia, lymphopenia, nausea, cytokine release syndrome, leukopenia, fatigue, pyrexia, and anemia. Cytokine release syndrome of any grade occurred in 19/32 pts; 95% of those events were ≤Grade 2. No immune effector cell-associated neurotoxicity syndrome (ICANS) has been reported to date. Cytopenia (≥G3) at 4 wks post-infusion was observed in 6 pts (anemia 3 pts, neutropenia 2 pts, and thrombocytopenia 1 pt). **Conclusion**: These preliminary data demonstrate afamitresgene autoleucel is efficacious and well tolerated in heavily pre-treated pts. Objective responses are reported across a wide range of MAGE-A4 antigen levels and deep responses have been observed. Initial durability data is encouraging. Preliminary response data in SPEARHEAD-1 is comparable to the findings of the prior Phase 1 trial [1]. To date, the safety profile of afamitresgene autoleucel has been favorable, with mainly low-grade cytokine release syndrome and tolerable/reversible hematologic toxicities. [1]. Van Tine BA, et al. CTOS; November 18-21, 2020; Virtual. Clinical trial information: NCT04044768. Research Sponsor: Adaptimmune Limited.

11505 **Oral Abstract Session**

A phase III study (APROMISS) of AL3818 (Catequentinib, Anlotinib) hydrochloride monotherapy in subjects with metastatic or advanced synovial sarcoma. *First Author: Brian Andrew Van Tine, Siteman Cancer Center, Washington University in St. Louis, St. Louis, MO*

Background: AL3818 (Catequentinib, Anlotinib) is a novel, orally administered, small molecule tyrosine kinase inhibitor. The primary objective of this Phase 3 study is to evaluate the efficacy of AL3818 monotherapy in patients (pts) with synovial sarcoma (SS) comparing with dacarbazine in randomization setting. **Methods:** Patients with a diagnosis of synovial sarcoma requiring second line or further line treatment were eligible for enrollment. The regimen was a 21-day cycle with oral AL3818 administered on 14 days on and 7 days off. This phase 3 trial is randomized in 2:1 ratio of AL3818 comparing to dacarbazine with option of crossover after PD of dacarbazine treatment. Progression free survival (PFS) with Log Rank test is the primary endpoint and this trial for SS is currently completed enrolled in US and Italy. **Results:** Total 79 pts initiated treatment and are evaluable, 52 received AL3818 as treatment arm (T), and 27 received dacarbazine (D) as control arm (C). Arms T/C median ages were 40.5/42.0 years (range: 18-70+) and 20/16 (38.5%/59.3%) were male. Overall, PFS was 2.89 months (95% CI: 2.73 – 6.87) for AL3818 and 1.64 (95% CI: 1.45 – 2.70) for D. The PFS of study met the primary endpoint with a p-value of 0.0015 and a HR of 0.449 (95% CI: 0.270– 0.744). At the month 4, 6, and 12, the percentages of progression free patients for AL3818 were 48.1%, 42.3% and 26.9%; and for D were 14.85%, 11.1% and 3.7%. For grade 3 treatment-related adverse events, 12(23.1%) of pts experienced for AL3818 and 7(25.9%) of pts experienced for D. The most common AL3818 related grade 3 AEs were diarrhea (5.8%) and hypertension (3.8%). **Conclusions:** This phase III trial demonstrates improved disease control and superior progression free survival for AL3818 vs dacarbazine in advanced SS. In addition, the study further confirms the acceptable benefit-risk profile of AL3818 from the prior randomized Phase 2b soft tissue sarcoma study (NCT02449343). AL3818 is a meaningful treatment option for pts with advanced SS. Clinical trial information: NCT 03016819 Clinical trial information: NCT03016819. Research Sponsor: Advenchen Laboratories.

11506 **Oral Abstract Session**

NCI protocol 10250: A phase II study of temozolomide and olaparib for the treatment of advanced uterine leiomyosarcoma. *First Author: Matthew Ingham, Columbia University Irving Medical Center, New York, NY*

Background: Uterine leiomyosarcoma (uLMS) is an aggressive sarcoma subtype with frequent metastatic relapse. After failure of front-line chemotherapy, remaining options provide limited benefit (trabectedin: ORR 11%, mPFS 4.0 mos; pazopanib: ORR 11%, median PFS 2.9 mos; dacarbazine: ORR 9%, mPFS 1.5 mos). Recent molecular studies suggest uLMS harbors characteristic defects in the homologous recombination (HR) DNA repair pathway, including somatic biallelic *BRCA2* deletion in 10%, implicating potential sensitivity to PARP-inhibitor based treatment approaches. In preclinical uLMS models in which temozolomide (T, an oral equivalent to dacarbazine) or the PARP inhibitor olaparib (O) showed limited single agent activity, the combination of T + O was highly effective in inhibiting uLMS tumor growth and promoting apoptosis. **Methods:** NCI protocol #10250 is a single-arm, open-label, multi-center phase II study evaluating T + O in advanced uLMS. Pts had progression on ≥ 1 prior line and ECOG PS ≤ 2. Pts received T 75 mg/m^2 PO daily + O 200 mg PO BID days 1-7 in 21-day cycles. Primary endpoint was ORR. A one-stage binomial design was used. If ≥ 5/22 responded, the treatment was considered promising (95% power; $\alpha = 0.06$). All pts underwent paired tumor biopsies. Correlative assays to evaluate for HR deficiency (whole exome sequencing/RNAseq, RAD51 foci formation) and for intrinsic PARP inhibitor resistance (SLFN11 expression) will be correlated with response. **Results:** 22 patients were evaluable (median age 55, median prior treatment lines 3). Median follow-up was 10.8 mos. Primary endpoint, ORR within 6 mos of initiating treatment, was 23% (5/22). Overall ORR was 27% (6/22). Median PFS was 6.9 mos (95% CI: 5.4 mos – not estimable (NE)). Median duration of response (DOR) was 12.0 mos (95% CI: 9.5 mos – NE). Hematologic toxicity was common (grade 3/4 neutropenia, 77%; thrombocytopenia 32%) but manageable with dose modification. Correlative assays are ongoing with plans to present at the meeting. An immunohistochemical assay for RAD51 foci has been adapted for uLMS samples and clearly distinguishes *BRCA2*- deleted and wild-type tumors. **Conclusions:** NCI 10250 met the prespecified primary efficacy endpoint of ORR in a population of patients with heavily pre-treated uLMS. Responses are durable (median DOR 12 mos). Correlative assays are being completed to evaluate whether uLMS tumors with HR deficiency or with preserved SLFN11 expression are most sensitive to T + O and may underlie durable responses. A randomized study of the combination is planned. Clinical trial information: NCT03880019. Research Sponsor: U.S. National Institutes of Health, Conquer Cancer Foundation of the American Society of Clinical Oncology.

11507 **Oral Abstract Session**

PD1 inhibition in soft-tissue sarcomas with tertiary lymphoid structures: A multicenter phase II trial. *First Author: Antoine Italiano, Early Phase Trials Unit, Institut Bergonié, Bordeaux, France*

Background: PD1 inhibition has shown limited activity in all comers clinical trials including patients with advanced soft-tissue sarcomas (STS). In the PEMBROSARC study, objective response rate, progression-free (PFS) and overall survival (OS) were respectively 2.1%, 1.4 and 7.1 months respectively (Toulmonde et al. Jama Oncol 2017). We have recently shown that the presence of tertiary lymphoid structures (TLS) may represent a biomarker to select patients who are more likely to benefit from immunotherapy (PetitPrez et al., Nature 2020). We report here the first clinical trial investigating the efficacy of PD1 inhibition in TLS-positive STS. **Methods:** PEMBROSARC is an open-label multicenter phase II study of pembrolizumab in combination with low-dose cyclophosphamide in pts with STS selected based on the presence of TLS. TLS status has been assessed centrally has previously described (PetitPrez et al., Nature 2020). Eligible patients received pembrolizumab 200mg IV q21 days and cyclophosphamide 50 mg BID 1week on, 1 week off. All patients had confirmed progressive disease at inclusion based on central review of two imaging performed at less than 6 months interval. The primary efficacy endpoint was 6-month non-progression (as per RECIST evaluation criteria v1.1). Based on the following hypotheses: 15% 6-month non-progression rate (H0), 40% acceptable 6-month non-progression rate (H1), 5% type I error rate, 90% power, a total of 29 assessable patients were necessary and 8 patients or more had to be progression-free at 6 months to reach the first endpoint. **Results:** 240 patients were screened for TLS status between September 2018 and January 2020 in 7 centers of the French Sarcoma Group. Among them, 48 were found to be TLS+ as per central review and 35 were included in the study. The three most frequent histological subtypes were: well-differentiated/dedifferentiated liposarcoma (n = 13); UPS (n = 6), and leiomyosarcoma (n = 4). 30 patients were eligible for efficacy. Of those, as per central imaging review, 13 patients (43.3%) had tumor shrinkage resulting in partial response in 8 patients (26.7%) and stable disease in 5 cases (16.7%). 10 patients had progressive disease. Twelve patients were progression-free at 6 months (40.0% 95%CI = [22.7 – 59.4]).Median PFS and OS were 4.1 months (95%CI, 1.4-9.6) and 14.5 months (95%CI, 8.5- 18.3 months), respectively. **Conclusions:** With an objective response and a 6-month non-progression rates of 26.7% and 40% respectively versus 2.1% and 4.2% in all comers, the PEMBROSARC study confirms that selection based on TLS status is an efficient approach to tailor immunotherapy in STS patients. Clinical trial information: NCT02406781. Research Sponsor: MSD.

11508 **Oral Abstract Session**

Phase II trial of pegylated arginine deiminase in combination with gemcitabine and docetaxel for the treatment of soft tissue sarcoma. *First Author: Brian Andrew Van Tine, Siteman Cancer Center, Washington University in St. Louis, St. Louis, MO*

Background: Soft tissue sarcoma (STS) is dependent on extracellular arginine as it often lacks expression of argininosuccinate synthase 1 (ASS1), the urea cycle enzyme needed to produce intracellular arginine. PEGylated arginine deiminase (ADI-PEG 20) is an extracellular arginine-degrading enzyme that causes ASS1 deficient tumors to enter the starvation state. Preclinical data demonstrated that addition of docetaxel (D) with ADI-PEG20 upregulates expression of the transporter for gemcitabine (G), overcoming transporter level resistance, and causing increased cell death. In vivo modeling demonstrated that the combination of ADI-PEG20 with G+D was superior to G+D alone. Therefore, we performed a phase 2 trial testing the addition of ADI-PEG20 to G+D. **Methods:** We performed an investigator-initiated, phase 2, multicenter, multi-arm clinical trial of ADI-PEG20 with G (90minute infusion)+D in STS, Ewing's, osteosarcoma and small cell lung cancer. We are reporting Arm A, the STS arm. Eligible patients had STS that would be standardly treated with G+D that had progressed on at least one prior line of therapy with measurable disease by RECIST1.1 and had adequate organ function Based on a historic median PFS of 6.2 months for G+D, we targeted to enroll N = 75 patients in cohort A to detect a 2.8 month improvement with 80% power at a 5% alpha level. Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), clinical benefit rate (CBR), safety, tolerability, cancer related mortality, and correlation with ASS1 expression by IHC. We evaluated PFS by Kaplan-Meier method and estimated overall response rate (ORR). **Results:** 75 patients were treated and deemed evaluable. The trial underwent two dose reductions by the data safety monitoring board due to prolonged neutropenia and thrombocytopenia preventing the use of day 8 G+D, consistent with preclinical mechanism of action data showing that ADI-PEG 20+D enhanced G uptake. Originally, the G dose was 900mg/m2 reduced first to 750mg/m2 then to 600mg/m2. D was dose reduced at the time of the second dose reduction from 75mg/m2 to 60mg/m2. ADI-PEG20 was given at a fixed intramuscular dose (36 mg/m2) weekly. The need for two dose reductions affected the PFS. The PFS/OS (months) were for the 600mg/m2 group (n = 31) was 6.0/N.D., leiomyosarcoma (LMS) (N = 33) 7.2/22.5, liposarcoma 5.1/17.4, and other (N = 36) 2.8/15.0. Responses were 8% complete (6/75) (3 LMS, 1 synovial and 2 angiosarcoma), 17% partial (13/75), and 43% stable disease (32/75), for an ORR of 25% (19/75) and CBR of 68% (51/75). There was a trend for ASS1 negative tumors to benefit more than ASS1 positive tumors. **Conclusions:** The combination of ADI-PEG20 with G+D can be safely and effectively given at a dose of 600mg/m2 G and 60mg/m2 D. Future randomized trials of ADI-PEG20 with G+D are planned. Clinical trial information: NCT03449901. Research Sponsor: U.S. National Institutes of Health, Polaris.

Molecular predictors of response to selinexor in advanced unresectable de-differentiated liposarcoma (DDLS). *First Author: Christopher James Walker, Karyopharm Therapeutics Inc, Newton, MA*

Background: Patients (pts) with recurrent inoperative DDLS have a poor prognosis and limited treatment options. Selinexor is an oral, selective inhibitor of nuclear export (SINE) compound approved for previously treated pts with myeloma and diffuse large B-cell lymphoma. SEAL was a Phase 2-3 randomized, double-blind, study of selinexor versus placebo in pts with progressive DDLS and 2-5 prior systemic therapies. SEAL showed significantly prolonged progression-free survival (PFS, HR = 0.70, p = 0.0228) with well managed toxicity. A biomarker predictive of clinical activity could be used to optimize selection of pts with DDLS for selinexor. **Methods:** Pts were randomized 2:1 for Phase 3: 188 received twice weekly selinexor (60mg) and 97 received placebo. Three exploratory biomarker analyses (RNA sequencing of biopsies) from selinexor-treated pts were performed: discovery set of sensitive (n = 8) or resistant (n = 9) tumors; a validation set of pts with favorable (n = 19) or poor (n = 14) tumor control based on PFS, and paired lesions from a pt who harbored both a responsive and resistant lesion. Tumor biopsies from 24 pts on placebo with short (< 5 months, n = 18) and long (> 6 months, n = 6) PFS were RNA sequenced. Gene expressions were compared using a negative binomial distribution with DeSeq2. Pathway analyses were performed using Gene Set Enrichment Analysis (GSEA) with MSigDB Cancer Gene Neighborhoods. **Results:** RNA sequencing analysis comparing 17 sensitive and resistant tumors identified 114 differentially expressed genes (adjusted p-values < 0.05). Expression of *CALB1*, which encodes the calcium-binding protein calbindin, was significantly lower in sensitive tumors (adjusted P [P_{adj}] = $7.5x10^{-20}$), and expression of *GRM1*, which encodes a metabotropic glutamate receptor that activates phospholipase C, was higher in selinexor sensitive tumors (P_{adj}= 0.003). These findings were confirmed in an independent validation set (P_{adj} = 0.01 – 0.02). In the pt with paired sensitive and resistant lesions, *CALB1* expression was 52-fold lower in the sensitive tumor. In a comparison of placebo-treated pts, neither *CALB1* or *GRM1* was differentially expressed between pts with short or long PFS, indicating they are markers of response to selinexor treatment, rather than general markers of disease aggressiveness. Gene set enrichment analyses revealed that selinexor sensitive tumors in the discovery and validation sets showed upregulation of cancer genes related to SNRK and the netrin 1 receptor tumor suppressor DCC. The resistant tumors showed upregulated EIF3S2 translation initiator-related genes. **Conclusions:** Selinexor sensitive DDLS tumors showed low expression of *CALB1* and high *GRM1*. If validated, pts with DDLS whose tumors match this expression profile are especially likely to benefit from selinexor. Clinical trial information: NCT02606461. Research Sponsor: None.

11510 **Clinical Science Symposium**

Prognosis value of S45F mutation of CTNNB1 in desmoid-type fibromatosis (DF): Prospective analysis of 500 consecutive patients (pts) from ALTITUDES trial. *First Author: Nicolas Penel, Department of Medical Oncology, Centre Oscar Lambret and Lille University Hospital, Lille, France*

Background: DF rare locally aggressive fibroblastic non-metastasizing tumor, with an unpredictable course. Its management remains challenging, there is a current shift in standard of care from large surgical resection (SR) to active surveillance (AS). Most of DF display somatic mutation of CTNNB1, with three major hotpots: S45F, T41A and S45P. The poor prognosis of S45F is a matter of debate (Timbergen et al. Ann Surg 2019). **Methods:** ALTITUDES (NCT02867033) is a nationwide prospective registry of DF, diagnosed from January 2016 to December 2020 and confirmed by central pathological review. CTNNB1 mutations were identified by NGS. Primary endpoint was event-free survival (including disease progression or relapse). We have selected pts managed by AS, SR or systemic treatments as front-line. Pt undergoing R2 resection and then managed by follow-up were part of AS group. Prognostic factors were assessed using univariate and multivariate Cox Model. **Results:** From the 630-pts enrolled in ALTITUDES, 500 (79.3%) were eligible for the present analysis. Exclusion criteria were diagnosis before 2016 in 13 pts, multiple DF in 33 pts, 39 pts without CTNNB1 mutation analysis, and 45 pts receiving other treatments. The study population included 349 females (69.8%), the median age was 40 years (range 1-89). Abdominal wall was the predominant primary site: 161 pts (32.2%). In 430 (86.0%) cases, there was a CTNNB1 mutation, including, S45F in 56 cases (11.2%). In 70 cases (14.0%), we did not identify CTNNB1 mutation. The front-line managements were AS in 361 pts (72.2%), SR with R0/R1 margins in 57 cases (11.4%) and systemic treatments in 82 pts (16.5%). The median follow-up was 23 months (Range, 0.4-55). Overall, progression or relapse occurred in 128 pts (25.6%). We observed a significant EFS-difference between treatment groups, both in univariate and multivariate analysis with, compared to AS, a better outcome in patients with SR and worse outcome in patients who had received a systemic treatment (p = 0.01 in multivariate analysis). The risk of event was significantly associated with the tumor size, with a HR = 1.46 in tumors larger than 50 mm compared to smaller tumors (95%CI, 1.01-2.10, p = 0.04). We did not observe any significant association between the CTNNB1 mutational status and the outcome: compared to patients with another mutation, the hazard ratio associated with a S45F mutation was HR = 0.84 (95%CI, 0.48-1.46, p = 0.53) in multivariate analysis. Age, gender, location (abdominal wall versus other) were not associated with EFS. **Conclusions:** In this large prospective study, S45F was not an independent poor prognostic factor in DF. Size and front-line treatment drive both the outcome. The understanding and prediction of natural course of DF require further studies. Research Sponsor: Ligue contre le Cancer.

11511 **Clinical Science Symposium**

Inflammatory indexes neutrophils/lymphocytes, platelets/lymphocytes and red-cell distribution width (RDW) as prognostic biomarkers in advanced solitary fibrous tumors (SFT) treated with pazopanib: Correlative study of GEIS-32 trial. *First Author: Javier Martin Broto, Virgen del Rocio University Hospital, Institute of Biomedicine Research (IBIS)/CSIC/ Universidad de Sevilla, Seville, Spain*

Background: Pazopanib (P) was assessed prospectively in a phase 2 study in SFT resulting in a longer progression free survival (PFS) and overall survival (OS) compared to historical controls treated with chemotherapy. No statistical correlation was found between angiogenic factors and P in its pivotal phase III sarcoma trial. In the last two years, a soaring interest on the prognostic and predictive value of inflammatory indexes such as neutrophil/lymphocyte (NLR) and platelet/lymphocyte (PLR) is emerging in sarcomas. A retrospective analysis of inflammatory indexes of patients who entered the GEIS-32 (NCT02066285) trial was performed. In that trial advanced SFT patients were treated with P from front-line. **Methods:** All eligible patients who entered in the typical- and malignant-SFT cohort of the GEIS-32 trial were included in this analysis. To determine NLR and PLR, baseline values of platelets ($10e^9$/L), neutrophils ($10e^9$/L) and lymphocytes ($10e^9$/L) were obtained from complete blood count tests. Additionally, RDW (standardized as 1 = upper value of normal range) values at baseline were also determined. The impact of NLR, PLR and RDW on OS, PFS and Choi response were analyzed by univariate and multivariate analysis. MAXSTAT was used to determine optimal cut-off points for overall survival. Metastasis free interval (MFI), mitotic count and ECOG were also analyzed, among others. **Results:** Sixty-seven out of 70 enrolled SFT patients, median age 63-y and 57% female, were considered for this analysis. The median follow-up from treatment initiation was 20.0 months. High standardized RDW value at baseline (cut-off 1.03) was significantly associated with worse OS [10.7 months (95% CI 3.8-17.5) vs 49.8 months (95% CI 9.4-90.2), p $<$ 0.001] and worse PFS [8.8 months (95% CI 0.9-7.0) vs 9.8 months (7.4-12.3), p = 0.001]. High PLR (cut-off 242) significantly correlated with worse OS [10.7 months (95% CI 5.2-16.2) vs 49.8 months (95% CI 14.6-85.0), p $<$ 0.001] and worse PFS [4.5 months (95% CI 2.0-7.0) vs 10.1 months (95% CI 6.3-13.9), p = 0.005], and high NLR (cut-off 3.78) was significantly associated with worse OS [11.7 months (95% CI 3.5-19.8) vs NA, p $<$ 0.001] and worse PFS [4.5 months (95% CI 1.9-7.0) vs 10.8 months (95% CI 8.7-12.9), p = 0.010]. Independent variables in multivariate analysis were NLR, RDW, MFI and mitosis for PFS; while RDW and ECOG for OS (see table). Further, NLR and mitosis were independent factors for Choi progressive disease (as best response). **Conclusions:** High NLR and RDW values were independent biomarkers of worse outcome in advanced SFT patients treated with pazopanib. Research Sponsor: None.

	Factor	HR	95% CI	P
PFS	MFI	2.1	1.0-4.1	0.042
	NLR	2.8	1.3-5.9	0.008
	RDW	2.8	1.3-6.3	0.012
	MITOSIS	5.0	2.3-10.4	< 0.001
OS	RDW	7.4	2.4-23.0	0.001
	ECOG	8.8	1.9-40.5	0.005

11512 **Clinical Science Symposium**

Large scale multiomic analysis suggests mechanisms of resistance to immunotherapy in leiomyosarcoma. *First Author: Galina Lagos, Columbia University Medical Center, New York, NY*

Background: Leiomyosarcomas (LMS) have been reported to have immunohistochemical (IHC) and gene expression signatures suggestive of an immune-responsive tumor microenvironment. Despite this, immune checkpoint inhibitors have demonstrated minimal activity in LMS. We examined molecular profiles of LMS specimens from multiple institutions to explore mechanisms of immunotherapy (IO) resistance. **Methods:** LMS specimens (n = 1115), including 701 uterine (uLMS) and 414 soft tissue site (stLMS) samples, underwent next-generation sequencing (NGS) of DNA (592-gene panel or whole exome) and RNA (whole transcriptome, n = 537) at Caris Life Sciences (Phoenix, AZ). A threshold of 10 mut/Mb was used to identify high tumor mutational burden (TMB-H). IHC was performed for PD-L1 (SP142; 2+|5% positive). Deficient mismatch repair (dMMR)/high microsatellite instability (MSI-H) was tested by IHC and NGS, respectively. RNA expression was analyzed using Gene Set Enrichment Analysis and Microenvironment Cell Populations-counter, with results compared to melanoma (n = 1255) as a representative immunogenic tumor type. P-values were adjusted for multiple hypothesis testing. **Results:** TMB-H was observed in 3.8% (n = 41) of LMS specimens, with a median of 5 mut/Mb (IQR 3.3-6.7). dMMR/MSI-H was rarely detected (1.5%, n = 17), whereas 8.2% (n = 88) were positive for PD-L1 expression. uLMS and stLMS did not differ in TMB-H (3.4 vs 4.5%, p = 0.277), PD-L1 expression (8.6 vs 7.4%, p = 0.322), or dMMR/MSI-H (2.0 vs 0.7% p = 0.207). stLMS demonstrated upregulation of immune-related gene sets, including interferon γ (p = 0.035) and α (p = 0.033) response, inflammatory response (p = 0.038), interleukin-6/STAT3 signaling (p = 0.030), and TNFα signaling (p = 0.026) compared to uLMS. Immune cell infiltration was increased in stLMS over uLMS, most notably for CD8 T-cell and B-cell abundance ($>$ 2-fold increase, $p < 0.0001$). Compared to melanoma, all LMS had lower abundance of CD8 T cells, cytotoxic lymphocytes, and B-cells ($>$ 2-fold decrease, $p < 0.0001$). Fibroblasts were more prevalent in LMS relative to melanoma (3.2-fold increase, $p < 0.0001$). Interestingly, while higher CD8 T-cell infiltration was positively associated with dMMR/MSI-H among LMS specimens (p = 0.032), TMB-H and PD-L1 expression were associated with lower CD8 T-cell infiltration ($p < 0.01$). **Conclusions:** Only a small proportion of LMS are TMB-H or MSI-H, suggesting that the neoantigen burden in LMS may be insufficient to promote a robust anti-tumor response, even in the presence of PD-L1 positive tumor cells. Traditional predictive biomarkers of response to IO are unlikely to be useful in LMS. Furthermore, both uLMS and stLMS have an immune microenvironment characterized by a high fibroblast and low T cell abundance relative to melanoma. Future IO trials in LMS should focus on combination therapies that may reverse the observed T-cell exclusion/desmoplastic phenotype. Research Sponsor: None.

11513 **Poster Discussion Session**

A phase II trial of sitravatinib, a multireceptor tyrosine kinase inhibitor, in patients with advanced well-differentiated/dedifferentiated liposarcoma. *First Author: Jay Oza, Columbia University Irving Medical Center, New York, NY*

Background: Well-differentiated/dedifferentiated liposarcoma (WD/DD LPS), a sarcoma of adipocytic origin, lacks effective treatment options for advanced disease. Pazopanib, a receptor tyrosine kinase (RTK) inhibitor active upon angiogenic RTKs, is approved for non-adipocytic sarcomas but failed to show activity in LPS. In a phase 2 study, pazopanib provided a progression-free rate at 12 weeks of 26% in LPS. Our preclinical work implicated IGF1R, MET, and PDGFRα/ß in liposarcomagenesis. Sitravatinib (S) is a novel, orally available, potent, small molecule RTK inhibitor active upon these and related targets. In preclinical WD/DD LPS models, S demonstrated significant activity *in vitro* and *in vivo* and appeared superior in efficacy to pazopanib, imatinib and crizotinib. **Methods:** We performed a phase II, single-arm, multi-center, Simon 2-stage study to evaluate S in adult pts with unresectable/metastatic WD/DD LPS who had received ≥ 1 prior line of systemic therapy and had evidence of disease progression $\leq$ 12 wks prior to enrollment. Pts received S 120 mg PO daily in continuous 21-day cycles. Primary endpoint was the progression-free rate at 12 wks (PFR_{12}). Secondary endpoints were objective response rate (ORR), progression free survival (PFS) and safety/tolerability. Based upon historical controls, $PFR_{12} \leq 20\%$ was considered inactive whereas $PFR_{12} \geq 40\%$ was considered promising. If $\geq$ 3/13 met PFR_{12} in stage 1, the study proceeded to full accrual. If $\geq$ 9/29 met PFR_{12} overall, S was considered promising. Design provided 85% power with α= 0.10. A subset of pts underwent paired biopsies. **Results:** 29 pts initiated treatment and are evaluable. Median age was 62 yrs (range: 28-88). 16 (55%) were male. 28/29 had DD LPS. 3 pts remain on treatment and 26 pts have discontinued (22 for disease progression, 2 for adverse events). In the first stage, 5/13 pts met the PFR_{12} endpoint; therefore, the study proceeded to full accrual. Overall, 12/29 pts (41%) were progression-free at 12 weeks and the study met the primary endpoint. ORR by RECIST was 3.4%. Median PFS was 11.7 weeks (95% CI: 5.9 - 35.9 wks). 12/29 (41%) of pts experienced grade 3 treatment-related adverse events. Common S-related grade 3 AEs were hypertension (24%), fatigue (7%) and hyponatremia (7%). There were 2 grade 4 events (hypertension, reversible posterior leukoencephalopathy syndrome). Hypertension was easily managed with medication. A subset of pts underwent paired tumor biopsies that will be analyzed using next generation sequencing and reverse phase protein array. **Conclusions:** S met the predefined efficacy endpoint with 12/29 pts (41%) progression-free at 12 weeks, indicating clinically meaningful activity potentially superior to pazopanib. The drug was well tolerated. Further study of S in WD/DD LPS is warranted. Clinical trial information: NCT02978859. Research Sponsor: Mirati Therapeutics.

11514 **Poster Discussion Session**

Phase 1 trial of seclidemstat (SP-2577) in patients with relapsed/refractory Ewing sarcoma. *First Author: Damon R. Reed, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Ewing sarcoma (ES), a rare bone and soft tissue sarcoma mainly of adolescents and young adults, is characterized by a chromosomal translocation resulting in a fusion oncoprotein. Lysine specific demethylase 1 (LSD1) has been shown to associate with the fusion oncoprotein and promote oncogenic transcriptional activity making LSD1 an attractive target for ES treatment. Seclidemstat is a novel, selective, reversible oral LSD1 inhibitor capable of inhibiting both LSD1's catalytic and scaffolding functions. This is the first report of an LSD1 inhibitor in a Phase 1 trial focused exclusively on ES. **Methods:** SALA-002-EW16 is a Phase 1 trial of single agent seclidemstat in patients (pts) with relapsed or refractory (R/R) ES. This report describes the completed monotherapy dose escalation. Pts $>$ 12 years received oral SP-2577 twice daily in 28-day cycles under fasting conditions at the assigned dose level. The primary objective was safety and tolerability. Secondary objectives include to determine maximum-tolerated dose (MTD), recommended Phase 2 dose (RP2D), preliminary efficacy, pharmacokinetics, and pharmacodynamics. **Results:** As of December 30, 2020, 27 pts with R/R ES were enrolled. Pts received escalating doses of SP-2577 at 75 (n = 1), 150 (n = 2), 300 (n = 4), 600 (n = 6), 900 (n = 8), or 1200 mg PO BID (n = 6). The median age was 25 years (range 15–68), 63% were male, and pts had received a median of 3 (range 2–12) prior systemic therapies. There were no treatment-related deaths. The most common ($>$ 5%) grade 3 treatment-related adverse events (TRAEs) were vomiting (15%), abdominal pain (11%), and hypokalemia (11%). One pt (4%) with grade 3 pancreatitis reported a grade 4 AE of elevated lipase. All remaining grade 3 TRAEs, including hematological TRAEs, were reported in only one pt each. Four pts discontinued study for an AE (weight loss, pancreatitis, vomiting, abdominal pain). Three pts had a dose reduction. The first cycle dose-limiting toxicities were gastrointestinal-related AEs observed in 2 pts at 1200 mg BID. Thus, the MTD/RP2D was established as 900 mg BID. Peak plasma concentrations occurred at a median of 4 hours (h) post-dose and median terminal half-life was 6 h; exposure was dose proportional through 900 mg BID. One pt at 600 mg BID achieved a reduction in target lesions starting at end of C2 with further target lesion tumor shrinkage through end of C4 and C6 (maximum 76% tumor shrinkage) with coincident new non-target lesion appearance at end of C2. Of pts evaluable for response at the end of C2 (12 pts), two additional pts (16.7%) at 600 mg BID and 900 mg BID had overall stable disease. **Conclusions:** Seclidemstat has a manageable safety profile with proof-of-concept preliminary activity in heavily pretreated pts with relapsed/refractory ES. These data support the planned Phase 2 expansion of seclidemstat as single agent and in combination with chemotherapy in ES and other sarcomas that share similar translocations. Clinical trial information: NCT03600649. Research Sponsor: Salarius Pharmaceuticals Inc, Other Foundation, Other Government Agency.

11515 **Poster Discussion Session**

Outcomes in the dedifferentiated liposarcoma cohort of SAR-096, a phase II trial of ribociclib in combination with everolimus in advanced dedifferentiated liposarcoma (DDL), and leiomyosarcoma (LMS). *First Author: Margaret von Mehren, Fox Chase Cancer Center, Philadelphia, PA*

Background: Dedifferentiated liposarcoma (DDL) is characterized by ring chromosomes of chromosone12, which includes amplification of MDM2 and CDK4. Exposure to CDK4 inhibitors in Rb+ leiomyosarcoma (LMS) cell lines leads to decreased cell proliferation, and increased senescence, and G0/G1-phase arrest. When combined, ribociclib a CDK4 inhibitor and everolimus, an mTOR inhibitor show synergistic growth inhibition in multiple tumor models. We hypothesized that this combination could lead to increased disease control in patients with DDL. **Methods:** This study enrolled patients (pts) into one of two cohorts: DDL or Rb+ LMS. LMS pts were required to have 1 prior line of therapy; DDL pts required no prior therapy. There were no limits to prior therapies in either group. Measurable disease by RECIST 1.1 was also required. Ribociclib was given at 300 mg daily for 21/28 days and everolimus was given continuously at 2.5 mg daily in 28 day cycles. The primary endpoint was progression free rate at 16 weeks. A Simon two-stage design was utilized and if at least 8 out of 24 pts were progression free at 16 weeks, the treatment was declared promising for the cohort. Here in we present data on the DDL cohort. **Results:** To date, 21 DDS pts, median age of 63 (range 40-79), of which 43% (n = 9) female were treated. Median prior lines of therapy was 1 (range 0-6). Of 19 pts with complete data, 8 (42%) met the primary endpoint of non-progression at 16 weeks. Confirmed partial response was seen in 2 pts (10%). Median PFS was 16 weeks, and stable disease occurring as best response in 11 (55%) pts. Grade 3-4 toxicities were uncommon except for lymphopenia (24%) and neutropenia (33%); no episode of neutropenic fever were observed. There was one death on study secondary to myocardial infarction, considered possibly related to therapy. Results of optional tissue biopsies pre and on therapy obtained to assess pharmacodynamic changes in PTEN, pAKT, CDK4, Rb and pS6 will be presented. **Conclusions:** The combination of ribociclib and everolimus demonstrates activity in DDL with prolonged stable disease ($>$16 weeks) meeting the primary protocol endpoint. Notably partial responses were also observed. The combination was well tolerated with acceptable side effects. Updated outcomes will be presented. Clinical trial information: NCT03114527. Research Sponsor: Novartis, Fox Chase Cancer Center.

11516 **Poster Discussion Session**

Eribulin and gemcitabine in previously treated patients with advanced liposarcoma or leiomyosarcoma: A multicenter, single-arm, phase 2-trial. *First Author: Chang Gon Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Eribulin and gemcitabine have shown encouraging efficacy in soft-tissue sarcoma (STS) as a monotherapy. Here, we evaluated the activity and safety of combined use of eribulin and gemcitabine in two most common histologic types of STS, liposarcoma and leiomyosarcoma. **Methods:** In this non-randomized, multi-center phase 2 study, patients were included if they had progressive disease after one or two prior chemotherapy including doxorubicin. Patient were given eribulin 1.4 mg/m^2 and gemcitabine 1,000 mg/m^2 on day1 and day 8 every 3 weeks. The primary endpoint was progression-free survival rate at 12 weeks ($PFSR_{12wks}$) with null and alternative hypothesis of $PFSR_{12wks} \leq 20.0\%$ and $\geq 40.0\%$, respectively. **Results:** Of 37 patients included, 22 had leiomyosarcoma, and 15 had liposarcoma. At 12-weeks after treatment, 16 and (72.7%) 11 (73.3%) patients in leiomyosarcoma and liposarcoma were progression-free. Overall $PFSR_{12wks}$ was 73.0%, satisfying the primary endpoint. Objective response rate, disease control rate, median progression-free survival, and median overall survival were 16.2%, 78.4%, 23.9 weeks, and 88.9 weeks, without any statistical differences according to histologic subtypes. No new safety signals and treatment-related death were observed. **Conclusions:** Eribulin and gemcitabine showed promising activity and manageable safety profile in patients with STS of liposarcoma and leiomyosarcoma histology. Updated outcomes for ongoing patients will be presented. Clinical trial information: NCT03810976. Research Sponsor: None.

11517 **Poster Discussion Session**

Phase (Ph) 1b/2 evaluation of olaratumab in combination with gemcitabine and docetaxel in advanced soft tissue sarcoma (STS). *First Author: Steven Attia, Mayo Clinic, Jacksonville, FL*

Background: Doxorubicin (doxo) remains standard first-line therapy for advanced STS. Doxo in combination with olaratumab (O) demonstrated superior clinical activity compared to doxo alone in a Ph 2 trial (NCT01185964), although this was not confirmed in the subsequent Ph 3 trial (NCT02451943). Gemcitabine (G) plus docetaxel (D) is a second line therapy for advanced STS. Here, we report a concurrent Ph 2 study that explored a second-line addition of O to G and D for advanced STS (ANNOUNCE 2 NCT02659020). **Methods:** Adult patients (pts) with unresectable locally advanced or metastatic STS, $\leq$ 2 prior lines of systemic therapy, and ECOG PS 0-1 were eligible. Pts were enrolled from 2 cohorts: O-naïve and O-pretreated. In both cohorts, pts were randomized 1:1 to either O, G plus D or placebo (PBO), G plus D. Pts received 21-day cycles of O (20 mg/ kg cycle 1 and 15 mg/kg other cycles, day (d) 1 and d8), G (900 mg/m^2, d1 and d8) and D (75 mg/m^2, d8). Pts continued treatment until progression, toxicity, or withdrawal. Randomization was stratified by histology (leiomyosarcoma [LMS] vs non-LMS), prior systemic therapy, ECOG PS, and prior pelvic radiation. The primary objective was overall survival (OS) in the O-naïve population using an alpha level of 0.20. Secondary endpoints included OS (O-pretreated) and other efficacy parameters, as well as safety and pharmacokinetics (PK). **Results:** 167 pts were enrolled in the O-naïve cohort and 89 pts in the O-pretreated cohort. Baseline patient characteristics were well balanced. OS for O-naïve pts was 16.8 vs 18.0 months (m) (hazard ratio [HR] = 0.95, 95% CI: 0.64-1.40; p = 0.78) for the investigational vs control arm, respectively. Other efficacy outcomes are presented in the table. Safety was manageable across treatment arms. PK parameter estimates for O were consistent with previous studies. **Conclusions:** There was no statistically significant difference in OS between the two arms in the O-naïve population. However, while not statistically significant, the combination of O, G and D demonstrated favorable OS in the O-pretreated cohort, and PFS and objective response rate (ORR) in both cohorts. For O-naïve pts, a clinically meaningful progression-free survival (PFS) improvement was observed. Further investigations in specific histological subtypes are ongoing. Clinical trial information: NCT02659020. Research Sponsor: Eli Lilly.

Updated results of European Organization for Research and Treatment of Cancer (EORTC) phase 2 trial 1202 cabazitaxel in patients with metastatic or inoperable locally advanced dedifferentiated liposarcoma. *First Author: Roberta Sanfilippo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Treatment options for patients with unresectable and/or metastatic dedifferentiated liposarcoma (DDLPS) are limited. The most effective agents include doxorubicin, ifosfamide, trabectedin and eribulin, but, in general, objective response rates (ORR) and progression free survival (PFS) are modest. Cabazitaxel exerts its effect through inhibition of microtubular disassembly and has been shown to be relatively safe, effective and well-tolerated. EORTC 1202 assessed whether cabazitaxel demonstrated sufficient antitumor activity in patients with metastatic or inoperable locally advanced DD LPS to justify further investigation in a phase III setting. **Methods:** This was an international multi-center, open label single arm phase II trial. The clinical cut-off date for the primary analysis was performed on August 31, 2020. Data base lock was performed on February 2, 2021. Eligible patients with metastatic or inoperable locally advanced DD LPS, after a centralized pathological review, were treated with cabazitaxel 25mg/m^2 IV infusion over 1 hour every 21 days. Primary endpoint was PFS rate at 12 weeks assessed by local investigator per RECIST 1.1. Based on a Simon two-stage design, at least 4 out of 17 (Stage 1) and 11 out of 37 (Stage 2) eligible and evaluable patients who are progression-free at 12 weeks were needed. Currently, a centralized radiological assessment is ongoing. **Results:** Forty patients were registered by 10 institutions in 4 countries between March 2015 and March 2019, with 2 patients being ineligible. One patient was still on treatment at the clinical cut-off date. The number of cycles ranged from 1 to 30, with a median of 5; 26 patients (65%) received at least 4 cycles of cabazitaxel. PFS at 12 weeks was 55% (conditional 1-sided 95% CI 40.8-100), achieving the primary study endpoint. The median FU was 21.6 months, median PFS was 6 months and median OS 21 months. RR was 8% with one CR and two PR. Twenty-three(60.5%) pts had a SD. Disease control (PR+SD) was achieved in 26 patients (68%). The most common cabazitaxel -related grade >3 adverse events in all 40 registered patients were Neutrophil count decreased (50%), febrile neutropenia (25%), fatigue (12.5%), and anemia (10%). There were no cabazitaxel-related deaths. **Conclusions:** EORTC 1202 met its primary endpoint, with 21/38 pts (55%) being progression-free at 12 weeks. Results of this trial confirm activity of cabazitaxel in patients with metastatic or inoperable locally advanced DD LPS and looks interesting if compared to the other available options and experimental drugs recently reported in this patient population. Clinical trial information: NCT01913652. Research Sponsor: Sanofi Aventis.

11519 **Poster Discussion Session**

Phase II study of atezolizumab in advanced alveolar soft part sarcoma (ASPS). *First Author: Abdul Rafeh Naqash, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: ASPS constitutes < 1% of soft tissue sarcomas and frequently presents in adolescents and young adults. There are no approved therapies for ASPS. We are currently evaluating the clinical activity of atezolizumab (atezo), an anti-PD-L1 antibody, in patients (pts) with advanced ASPS. **Methods:** This is a multicenter, open-label, single-arm phase II study where atezo is administered at a fixed dose of 1200 mg in adults or 15 mg/kg (1200 mg max) in pediatric pts age $\geq$2 once Q21 days. The primary objective is to determine the objective response rate (ORR) of atezo using RECIST 1.1. Secondary objectives include duration of response and correlating response with the immune effects of atezo in blood and paired tumor biopsies (pre- and post-treatment). Tumor specimens were analyzed with multiplex immunofluorescence immuno-oncology panels to quantify CD8+, PD-1+, and PD-L1+ cells/mm^2 in the tumor microenvironment. CD8+ density was calculated as the total number of CD8+ cells divided by the entire area (mm^2) of the tumor and invasive margins of the biopsy. **Results:** As of February 4, 2021, 44 pts have been enrolled. The median age in the study was 31 years (range, 12–70) with equal male: female distribution. 54.5% of pts were Caucasian. Baseline ECOG $\leq$1 was present in 97.7%. The median time on study was 11.5 months (range, 0.8–40.3 months). At data cutoff, response evaluation was available for 43 pts with an ORR of 37.2% (16/43). One pt experienced a complete response and 15 pts experienced a partial response (PR), of which 14 were confirmed. The median time to confirmed response was 3.5 months (range, 2.1–14.9 months). The median duration of confirmed response was 16.5 months (range, 4.9–38.1 months). Stable disease (SD) was present in 58.1% (25/43). One or more grade 3 adverse events potentially related to atezo were identified in 16.3% (7/43) pts. These include diarrhea, hypothyroidism, transaminitis, anemia, vertigo, extremity pain, myalgia, pneumonitis, rash, and stroke (n = 1 each). No grade 4 or 5 events have been reported. Among 8 cases with evaluable biopsy pairs, both baseline and C3D1 specimens in all cases demonstrated CD8+ T cell infiltration and PD-L1 expression. PD-1 expression was detected at baseline in 5 cases and at C3D1 in 7 cases. In 6 cases (3 SDs and 3 PRs), treatment did not change CD8+ cell density. In the other 2 cases (both PRs), CD8+ density increased > 3x above baseline by C3D1. Analysis of T cell activation using pharmacodynamic response biomarkers, along with whole exome and RNA-seq to evaluate the genomic and transcriptomic landscape of ASPS, are ongoing. **Conclusions:** Atezo is well tolerated and demonstrates promising single agent activity with durable responses in advanced ASPS. Preliminary tumor biomarker analysis confirms the presence of multiple PD-1/PD-L1 immune checkpoint (IC) components, indicating that advanced ASPS is an ideal candidate for therapeutic IC inhibition. Funded by NCI Contract No HHSN261200800001E. Clinical trial information: NCT03141684. Research Sponsor: U.S. National Institutes of Health.

High clinical activity of pembrolizumab in chordoma, alveolar soft part sarcoma (ASPS) and other rare sarcoma histotypes: The French AcSé pembrolizumab study from Unicancer. *First Author: Jean-Yves Blay, Centre Léon Bérard, Lyon, France*

Background: AcSé Pembrolizumab is a Phase 2, non-randomized parallel arms, open-label, multicentric study from Unicancer investigating the efficacy and safety of pembrolizumab monotherapy in different cohorts of patients with rare cancers (NCT03012620). Here we report the results of pembrolizumab in the rare sarcoma cohort. **Methods:** Selected histotypes were all rare sarcomas patients (pts) (incidence $< 0.2/100,000$/year). Main inclusion criteria were age > 18, ECOG PS$\leq$1 and advanced or metastatic disease resistant to standard treatment. Patients received pembrolizumab 200 mg IV as a 30-minute infusion on Day 1 of every 21-day cycle for a maximum of 2 years. The primary endpoint was the confirmed objective response rate according to RECIST v1.1 at 12 weeks. Secondary endpoints included clinical benefit rate, duration of response, progression-free survival (PFS), overall survival (OS), and safety. Five groups of pts were distinguished, namely chordoma, alveolar soft-part sarcoma (ASPS), desmoplastic small round cell tumor (DSRCT), smarca4 deficient malignant rhabdoid tumor (SMRT), and other histotypes. **Results:** 98 patients including 34 with chordoma, 14 ASPS, 11 SMRT, 8 DSCRT and 31 with other histotypes, were included from July 2017 to December 2020. The median number of cycles was 5 (range, 1 to 35) with 78 (79.6%) patients who discontinued the trial after a median of 4 cycles. There were 6 (7.3%) partial response (PR) at 12 weeks. The best response was CR in 1 patient (1%), PR in 14 patients (14.3%), and stable disease (SD) in 33 (33.7%). Median duration of response was 8.2 months [IQR, 4.1 to 9.0]. The occurrence of best response depended on the histotype, with 3 (8.8%) responses in chordoma, 7 (50%) in ASPS, 3 (27%) in SMRT, 1 (12.5%) in DSCRT and 1 (3.2%) in other histotypes ($p = 0.0011$). At the data cut off, median PFS was 2.75 months, and median OS was 19.7 months on the overall population. Outcomes differed according to the histotype group, with the 12 months PFS rates at 31.2% (chordoma), 35.7% (ASPS), 18.2% (SMRT), 0% (DSCRT) and 3.3% (other), respectively ($p < 0.0001$), and median PFS at 6.6 (chordoma), 7.5 (ASPS), 1.1 (SMRT), 2.1 (DSCRT) and 2.1 months (other), while 1-year OS rates were 76.6% (chordoma), 85.7% (ASPS), 36.4% (SMRT), 17.5% (DSCRT) and 42.9% (other) with median OS only reached for SMRT (2.4 months), DSRCT (10 months), and the other histotype group (7.1 months) ($p = 0.004$). The side effect profile of pembrolizumab was similar to other tumor type. **Conclusions:** Pembrolizumab is safe and well tolerate in this pop od STS pts, AcSé study reports high levels response rate and prolonged activity in selected subtypes of rare sarcomas. Clinical trial information: NCT03012620. Research Sponsor: La Ligue Nationale contre le Cancer, Other Foundation, Pharmaceutical/Biotech Company.

11521 **Poster Discussion Session**

Safety and efficacy of letetresgene autoleucel (lete-cel; GSK3377794) in advanced myxoid/round cell liposarcoma (MRCLS) following high lymphodepletion (Cohort 2): Interim analysis. *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cancer testis antigen NY-ESO-1 is expressed in multiple tumor types, including 80–90% of MRCLS [1,2]. Overall response rates (ORRs) to MRCLS treatment are low (1L, <20%; 2L, <10%) [2]. Lete-cel, an autologous T-cell therapy, targets NY-ESO-1/LAGE-1a+ tumors using a genetically modified, high-affinity T-cell receptor. High-dose lymphodepletion (LD) was linked with better responses in synovial sarcoma [3]; the current study tested this hypothesis in MRCLS. **Methods:** This open label, pilot study evaluates lete-cel efficacy and safety in advanced MRCLS following low-dose (Cohort 1 [C1]; 30 mg/m^2 fludarabine [flu] x 3d + 600 mg/m^2 cyclophosphamide [cy] x 3d) or high-dose (Cohort 2 [C2]; 30 mg/m^2 flu x 4d + 900 mg/m^2 cy x 3d; initiated based on C1 data) LD. Key eligibility: age $\geq$18 y; HLA-A*02:01; A*02:05, or A*02:06; advanced high-grade NY-ESO-1+ MRCLS ($\geq$30% of cells 2+/3+ by IHC); prior anthracycline; measurable disease; specified washouts; and active/chronic/intercurrent illness restrictions. Stages include screening, leukapheresis, lete-cel manufacture, LD, lete-cel infusion (1– 8 $\times$ 10^9 transduced T cells), follow-up. Response is assessed at wk 4, 8, 12, and 24, then every 3 mo to disease progression/death/withdrawal. The primary efficacy endpoint is investigator-assessed ORR by RECIST v1.1. In C1 (n=10 patients [pts]), lete-cel was well tolerated and linked with 2 confirmed partial responses (PR; ORR, 20%) and stable disease (SD) in 8 pts. Planned interim analysis for C2, shown here, was done once all 10 treated pts had $\geq$3 post-baseline disease assessments or progressed/died/withdrew. Efficacy data will be correlated with transduced cell kinetics and pharmacodynamics marker profiles. **Results:** Durable (1.0–7.8 mo) PR (4/10 pts [ORR, 40%]; 2 ongoing) and prolonged (2.7–10.6 mo) SD (5/10 pts; 3 ongoing) with tumor regression were observed. Treatment-emergent cytopenias occurred in all pts. All experienced T-cell related cytokine release syndrome (5 serious adverse events; 30% Grade 3), with onset $\leq$5d of infusion and median duration 7.5d. Graft-vs-host disease, immune effector cell–associated neurotoxicity syndrome, pancytopenia, or aplastic anemia were not reported. **Conclusions:** A single lete-cel infusion after high LD showed antitumor activity in advanced MRCLS and a manageable safety profile consistent with other lete-cel studies. The trial is active but no longer recruiting (NCT02992743). MRCLS is included in a separate, ongoing lete-cel study (NCT03967223). References: 1. 11522 **Poster Discussion Session**

A phase II, open-label, randomized trial of durvalumab (D) with olaparib (O) or cediranib (C) in patients (pts) with leiomyosarcoma (LMS). *First Author: Olubukola Ayodele, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The use of immune checkpoint blockade (ICB) in non-inflamed (cold) tumors is associated with limited clinical efficacy. Combination of ICB with certain molecularly targeted agents (MTA) is hypothesized to increase tumor immunogenicity by recruiting tumor infiltrating lymphocytes in cold tumors, such as LMS. Here, we present the results of LMS cohort treated on the DAPPER study (NCT03851614). **Methods:** LMS pts with ECOG 0-1 were randomized to either D+O (arm A), or D+C (arm B). In a 28-day cycle, D 1500mg i.v. q4w with either O 300mg bid po qd or C 20mg po qd 5d/week were administered. Overall response rates (ORR) were determined using RECISTv1.1. Evaluation of tumor kinetics (TK) was performed by calculating tumor growth rate (TGR) of target lesions on CT images at baseline and on-treatment, adjusted to account for the time difference between scans. TGR is expressed as % tumor growth/week (Ferte C et al. CCR, 2014). Additionally, paired FFPE samples (from baseline and on-treatment biopsies) were assessed using multispectral fluorescent immunohistochemistry (IHC) panel: CD3, CD8, CD20, CD68, FOXP3 and cytokeratin. Tumor areas were identified by a pathologist and immune cells were quantified using InForm image analysis software. **Results:** 25 metastatic LMS pts were randomized to arm A (n = 11) or B (n = 14) over 21 months. Median age was 53 years, 96% were females and 60% of pts had $\geq$3 lines of therapy. In 23 evaluable pts, no responses were seen, 7 pts had stable disease (SD) while 16 has progressive disease (PD). TK analysis was evaluable for 18 pts (arm A = 8, B = 10). 5/8 pts (62.5%) in arm A and 6/10 pts (60%) in arm B showed decreased TK (defined as $TGR^{baseline} > TGR^{on\text{-}treatment}$). In 4/5 (80%) pts who had deceleration of TK in arm A, SD was maintained for $\geq$6 months. The reduction in TGR on treatment, compared to baseline was significant in arm A but not in arm B (measured as median % tumor growth/week of 0.5 vs 5.1, 95% CI 0.2-4.3, $p = 0.035$ in arm A; and 1.3 vs 2.9, 95% CI 0.2-2.7, $p = 0.088$ in arm B). The median PFS of arm A and B were 9 (95% CI 3-12.8) and 4 (95% CI 2.2-4.6) months respectively. There were no statistically significant differences in tumor-infiltrating immune cells when comparing baseline and on-treatment biopsies from arm A or B. In arm A, one pt with SD > 6 months had a 2.5-fold increase in CD8 (CD3+CD8+) T cells and a 7.6-fold increase in macrophages (CD68+). **Conclusions:** D+O or D+C resulted in stable disease in 30% of pts, mostly on arm A (D+O). TK analysis may identify pts with prolonged SD on treatment. Although a cold-to-hot immunophenotype change was not generally seen, changes in tumor infiltrating immune cell subsets were observed in one patient with prolonged stable disease. These findings support further molecular and immunophenotype characterization in LMS patients treated with D+O or D+C. Clinical trial information: NCT03851614. Research Sponsor: Princess Margaret Cancer Centre.

11523 **Poster Discussion Session**

Demographics, outcomes, and risk factors for patients (Pts) with sarcoma and COVID-19: A multi-institutional cohort analysis. *First Author: Michael J Wagner, University of Washington, Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA*

Background: Sarcoma pts often receive aggressive, highly immunosuppressive therapy and may be at high risk for severe COVID-19. Demographics, outcomes and risk factors for pts with sarcoma and COVID-19 are unknown. We aimed to describe the course of COVID-19 in sarcoma pts and to identify factors associated with adverse outcomes. **Methods:** The COVID-19 and Cancer Consortium (NCT04354701) is an international registry of pts with cancer and COVID-19. Adult pts ($\geq$18 years old) with a diagnosis of sarcoma and laboratory confirmed SARS-CoV-2 were included from 50 participating institutions. Data including demographics, sarcoma diagnosis and treatment, and course of COVID-19 infection were analyzed. Primary outcome was the composite rate of hospitalization or death at 30 days from COVID-19 diagnosis. Secondary outcomes were 30 day all-cause mortality, rate of hospitalization, O2 need, and ICU admission. Descriptive statistics and univariate Fisher tests are reported. **Results:** From March 17, 2020 to February 6, 2021, N=204 pts were included. Median follow up was 42 days. Median age was 58 years (IQR 43-67). 97 (48%) were male. 30 (15%) had ECOG performance status $\geq$2. 104 (51%) received cancer treatment, including surgery or radiation, within 3 months of COVID-19 diagnosis. 153 (75%) had active cancer, of whom 34 (22%) had lung metastases. 100 (49%) pts met the composite primary endpoint; 96 (47%) were hospitalized and 18 (9%) died within 30 days from COVID-19 diagnosis. 64 (31%) required oxygen, and 16 (8%) required ICU admission. Primary endpoint rates were similar for pts who received cytotoxic chemotherapy (38/58, 66%) or targeted therapy (16/28, 57%). Pts with higher rates of the primary endpoint included patients $\geq$60 years old (59% vs 40%, OR 2.04, 95% CI 1.12-3.74, p=0.016), pts with ECOG PS $\geq$2 vs 0-1 (90% vs 41%, OR 12.2, 95% CI 3.44-66.8, p<0.001), pts receiving any systemic therapy within 3 months of COVID-19 diagnosis (62% vs 39%, OR 2.65, 95% CI 1.43-4.97, p=0.001), and pts with lung metastases (68% vs 42%, OR 2.77, 95% CI 1.19-6.79, p=0.013). Primary endpoint rates were similar across sarcoma subtypes (Table). **Conclusions:** This is the largest cohort study of pts with sarcoma and COVID-19 to date. Sarcoma pts have high rates of complications from COVID-19. Older patients, those with poor performance status, those recently receiving systemic cancer therapy, and those with lung metastases appear to have worse outcomes. Research Sponsor: U.S. National Institutes of Health.

11524 **Poster Discussion Session**

Randomized, double-blind, placebo (PL)-controlled, phase III trial of pimitespib (TAS-116), an oral inhibitor of heat shock protein 90 (HSP90), in patients (pts) with advanced gastrointestinal stromal tumor (GIST) refractory to imatinib (IM), sunitinib (SU) and regorafenib (REG). *First Author: Yoshitaka Honma, National Cancer Center Hospital, Tokyo, Japan*

Background: Pimitespib (PIM) is a novel class of orally active selective HSP90 inhibitors. KIT and PDGFRA are clients of HSP90 for their functional stability; therefore, HSP90 is a rational therapeutic target on GIST in pts with acquired resistance, such as secondary mutation in *KIT*, to approved tyrosine kinase inhibitors. A phase II trial showed clinical activity of PIM in pts with advanced GIST refractory to standard treatments whose medical need remains unmet. This phase III trial evaluated the efficacy and safety of PIM for this unmet clinical need. **Methods:** Eligible pts had histologically confirmed advanced GIST refractory to IM, SU, and REG, ≥1 measurable lesion, and ECOG performance status 0 or 1. Pts were randomized 2:1 to receive either PIM 160 mg once daily on a 5-days-on/ 2-days-off schedule or PL. Pts eligible for unblinding at the time of progressive disease were allowed to crossover to open-label PIM. The primary endpoint was progression-free survival (PFS) by blinded central radiological review based on modified RECIST 1.1. Secondary endpoints included overall survival (OS), PFS in the pts crossed over to PIM (secondary PFS), and safety. Crossover-adjusted OS was derived using the rank preserving structural failure time (RPSFT) model. Exploratory endpoints included pharmacogenomics (PGx). **Results:** From Oct 2018 to Apr 2020, 86 pts were randomized to receive either PIM (n = 58) or PL (n = 28). Baseline characteristics were well balanced between the two arms. Median PFS was 2.8 months (mo) (95% CI: 1.6–2.9) for PIM vs. 1.4 mo (95% CI: 0.9–1.8) for PL. The hazard ratio (HR) for PFS was 0.51 (95% CI: 0.30–0.87) ($p = 0.006$, stratified log-rank test). Median OS was 13.8 mo (95% CI: 9.2–not reached) for PIM vs. 9.6 mo (95% CI: 5.5–not reached) for PL (HR for OS 0.63; $p = 0.081$), with 60.7 % of PL pts crossed over to PIM; secondary PFS was 2.7 mo (95% CI: 0.7–4.1). The RPSFT-adjusted median OS of PL was 7.6 mo (adjusted HR for OS 0.42; $p = 0.007$). Furthermore, the results of PGx analysis suggested that PIM was also effective in pts with secondary *KIT* mutation detected from blood samples. The most common (> 5%) grade 3 or higher adverse events (AEs) in PIM/PL were diarrhea (13.8%/0%), anemia (6.9%/10.7%), decreased appetite (6.9%/0%), and tumor hemorrhage (5.2%/0%). AEs leading to PIM/PL study discontinuation were observed in 4/2 pts (6.9%/7.1%), respectively. **Conclusions:** This randomized trial demonstrated that PIM significantly improved PFS with OS prolongation in pts with advanced GIST refractory to IM, SU, and REG, as a HSP90 inhibitor for the first time. PIM was tolerated and AEs were manageable. With a mechanism of action different from that of standard therapies, PIM has the potential to be a new standard treatment in GIST. Clinical trial information: JapicCTI-184094. Research Sponsor: Taiho Pharmaceutical.

11525 **Poster Session**

Giant cell tumor of bone: Effect of longer dosing intervals of denosumab on tumor control and bone related complications. *First Author: Cindy Jiang, University of Michigan, Ann Arbor, MI*

Background: Giant cell tumor of bone (GCTB) is a benign but locally aggressive bone neoplasm characterized by osteoclast activation causing destructive osteolysis. Denosumab, a human monoclonal antibody against RANK ligand, has emerged as an effective treatment option when surgery is not recommended, but can cause significant bone toxicity. Current standard dosing is every 4 weeks after 3 weekly loading doses. As patients (pts) with GCTB are often young adults, frequent denosumab administration long-term may be burdensome and associated with increased risk of complications. We assessed whether alternative, longer dosing intervals are associated with differences in efficacy or bone toxicity. **Methods:** Retrospective chart review was conducted on GCTB pts over 18 years old at University of Michigan who received at least 1 year of standard denosumab treatment. Pts were identified using a free-text medical record search engine with keywords “giant cell tumor” and “denosumab” until August 2020. We compared bone-related adverse effects and tumor control in pts who continued denosumab every 4 weeks versus longer treatment intervals. Decision to increase interval between doses was based on provider and pt discussion and preference as part of routine medical care. **Results:** 37 GCTB pts were identified; 51% female and 49% male. Average age was 41 years (range 22-73). Most common primary location was lower extremity (38%), followed by pelvis (35%), upper extremity (14%), spine (8%), and head/neck (5%). Metastasis were present at start of treatment in 14% of pts, involving lung (n = 4) and spine (n = 1). Pts received median of 71 (range 15-139) total doses of denosumab. Dosing interval was increased in 38% (n = 14). With the first interval change, 43% changed to every 6 weeks, 29% every 8 weeks, and 29% every 12 weeks dosing. Most common final dosing interval was 12 weeks (n = 8). 6 pts (16%) had bone complications after mean of 56 doses. This included osteonecrosis of the jaw (n = 4), atypical fracture (n = 1), and non-healing dental wounds (n = 2). All pts with bone complications were treated on the monthly dosing schedule, but there was no statistically significant difference compared to longer intervals (p = 0.22). Pts with GCT progression (n = 10) were either no longer receiving therapy or had missed denosumab doses. There was no statistically significant difference in PFS with standard vs. interval increased dosing (p = 0.97). However, 5-year PFS was superior with interval increased vs standard dosing (p = 0.036). **Conclusions:** Increasing the interval of denosumab dosing for GCTB provided similar tumor control as compared to standard dosing and is potentially associated with less bone toxicity and more convenience for afflicted pts. Further larger scale studies are needed to better define the optimal interval of denosumab administration in GCTB and the effect on efficacy, toxicity, and associated health care expense. Research Sponsor: None.

Efficacy and safety of JMT103 in patients with giant cell tumor of bone: A multicenter, single-arm, open-label, phase Ib/II study. *First Author: Xiaohui Niu, Department of Orthopedic Oncology Surgery, Beijing Ji Shui Tan Hospital, Peking University, Beijing, China*

Background: JMT103 is a novel, fully humanized IgG4 monoclonal antibody targeting RANKL, inhibiting osteoclastogenesis and osteoclast-mediated bone resorption. A multicenter, single-arm, open-label, phase Ib/II study was conducted to evaluate the efficacy and safety of JMT103 in patients (pts) with Giant cell tumor of bone (GCTB). **Methods:** Eligible pts (ECOG: 0-2) were adults with pathologically confirmed unresectable GCTB or their planned surgery is associated with severe morbidity. Pts with active dental or jaw condition requiring oral surgery, other anti-tumor therapies, anti-RANKL antibody or concurrent use of bisphosphonates were excluded. 2 mg/kg JMT103 was administrated subcutaneously every 4 weeks with a loading dose on days 8 and day 15 of the first 4 week of therapy. The primary endpoint was tumor response, defined as elimination of at least 90% giant cells or objective response of the target lesion assessed by radiologic imaging as per Modified Inverse Choi density/size (ICDS) or the Modified European Organization for Research and Treatment of Cancer (EORTC) criteria within 12 weeks. Secondary endpoints included safety profile, change of pain score using Brief Pain Inventory-Short Form, and suppression of bone-resorption biomarkers. **Results:** 38 pts (14 males) were enrolled between June 3 and December 24, 2020. The median age was 31 years (range 18-57). Lesions sites included lower extremities (39.5%), upper extremities (31.6%), spine (21.1%) and pelvis (13.2%). Among 32 pts with at least 1 efficacy evaluation within 12 weeks, 26 (81.3%, 95% CI: 63.6-92.8) had a tumor response by at least one response criteria. All 7 pts who underwent histological assessments had a tumor response. 25 of 32 pts assessed by radiology had a tumor response. As per ICDS criteria, 23 of 32 (71.9%) had a response; as per EORTC criteria, 15 of 17 (88.2%) had a response. 21 of 26 (80.8%) pts who complained of pain at baseline experienced reduced pain during the treatment. The median reductions in bone-resorption biomarkers were 71.8% (IQR 67.7-82.4) for uNTx/Cr ($p < 0.001$) and 81.4% (IQR 68.3-84.7) for sCTx ($p < 0.001$) at day 8. Of all 38 pts who were included in safety analyses, treatment-related adverse events (TRAEs) occurred in 14 pts. The most common TRAEs were hypophosphatemia (18.4%), hypocalcemia (7.9%) and blood bilirubin increased (7.9%). 1 patient (2.6%) was reported a grade 3 AE but it was not related to the treatment; other AEs were grade 1–2. **Conclusions:** JMT103 demonstrated encouraging anti-tumor efficacy and manageable safety profile in pts with unresectable GCTB or at high risk of severe morbidity after surgery. Clinical trial information: NCT04255576. Research Sponsor: Shanghai JMT-Bio Technology Co., Ltd.

ABCB1/P-glycoprotein (Pgp) expression as stratification factor for treatment of patients with non-metastaticextremity high-grade osteosarcoma: A merged analysis of an Italian (ISG) and a Spanish (GEIS) sarcoma groups' multicentric prospective trials. *First Author: Emanuela Palmerini, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy*

Background: Overexpression of ABCB1/P-glycoprotein (Pgp) predicts poor outcome in retrospective osteosarcoma series.Two prospective trials with Pgp expression and post-induction histologic response as stratification factors were activated in Italy (ISG/OS-2) and Spain (GEIS-33). **Methods:** Patients ≤ 40 years with extremity non-metastatic high-grade osteosarcoma were eligible. Analysisi of Pgp expression from diagnostic biopsy was centralized. Preoperatively, all patients received methotrexate, adriamycin, cisplatinum (MAP). Surgery was performed at week 8. All patients received a dose of adriamycin following surgery. In case of Pgp overexpression (Pgp+), mifamurtide (2 mg/m2 twice/week for 3 months then weekly for 6 months) was added after surgery, with 4 consecutive cycles of ifosfamide 3 gr/m2/day, day 1-5 (HDIFO) in case of poor histologic response (necrosis < 90%) to MAP. Patients without overexpression of Pgp (Pgp-) received MAP postoperatively, regardless the pathological response. From March 2013, an amendment increased high dose methotrexate cumulative dose from 60 g/m2 (5 cycles) to 120 mg/m2 (10 cycles). The post-amendment regimen was adopted in the observational prospective study by GEIS. Here we present the merged analysis of ISG/OS-2 patients treated post-amendment and GEIS-33. **Results:** From March 2013 to April 2018, 274 patients were included. Median age was 14 years (range 4-38), male/female: 163/111; 90 were Pgp-, 164 were Pgp+, 20 not evaluable. With a median follow-up of 48 months (1.3-78.5 months), the 3-year EFS and OS were 71.9% (95%CI 66-76.9) and 88% (95%CI: 83.2-91.5) respectively, with no inferior survival for Pgp positive patients and improved survival for good responders (Table). **Conclusions:** In this prospective uncontrolled study with a risk-adapted strategy for non-metastatic osteosarcoma, survival is superior to that of all ISG/GEIS previous series. The 3-year EFS of 71.9% compares favorably with other reports. Pgp+ patients performed well in this study, in which mifamurtide and HDIFO were added after a poor response to MAP.Clinical trial information: NCT01459484; NCT04383288. Research Sponsor: This work was supported by the Associazione Onlus ‘il Pensatore: Matteo Amitrano’, the Associazione Mario Campanacci and the Carisbo Foundation Call for Translational and Clinical Medical Research.

Activity of erlotinib in patients (pts) with advanced chordoma: A retrospective study. *First Author: Olivier Mir, Institut Gustave Roussy, Villejuif, France*

Background: Chordoma is a rare tumor with no approved therapy. Preclinical studies have shown expression of EGFR and activated EGFR family kinases (EGFR, HER2 and HER4). Erlotinib and other anti-EGFR agents (gefitinib and cetuximab) have shown clinical activity in advanced chordoma in single case reports or small series. We aimed to evaluate the activity of erlotinib in a larger, homogeneous series of pts with advanced chordoma. **Methods:** We retrospectively reviewed the electronic medical records of consecutive adult pts with advanced chordoma progressive over 6 months (+/- 2 weeks, according to RECIST 1.1), treated with erlotinib (150 mg daily) at Gustave Roussy (Villejuif, France) following multidisciplinary tumor board discussion, from January 2010 to January 2021. All cases were confirmed by an expert pathologist. Response was evaluated according to RECIST 1.1, and survival was estimated using the Kaplan-Meier method. **Results:** Thirty-one pts [median age : 60 years (range : 32-88), median PS : 2 (range : 1-3), 30 males)] were identified. Twenty-seven (87%) had locally advanced disease; the median number of metastatic sites was 1 (range : 1-2) in the remaining 4 pts. Primary tumor site was sacral (25), lumbar (3) or cervical (3). All pts but 6 had undergone prior surgery, and 29 (94%) had undergone radiotherapy of the primary tumor. Eight pts had received previous systemic treatments (imatinib in 4, sorafenib and regorafenib in 2 each). Best tumor response by RECIST 1.1 was PR (4 pts, 13%), SD (14 pts, 45%) or PD (13 pts, 42%). Median PFS was 6.2 months (95%CI : 4.5-9.8), and median OS was 15.9 months (95%CI : 10.6-20.2). Fourteen pts (45%) remained progression-free after 1 year, and three (10%) after two years under erlotinib. Grade 3 diarrhea occurred in 4 pts (13%) and grade 3 skin rash in 13 pts (42%). Twelve pts (39%) required dose reduction to 100 mg daily due to multiple grade 2 toxicities. Ongoing studies are exploring whether candidate biomarkers such as EGFR and HER2 expression or amplification, and their mutational status could help predicting the benefit of erlotinib in pts with advanced chordoma. **Conclusions:** Erlotinib has clinically meaningful but unpredictable activity in advanced chordoma. Molecular profiling would probably be of high interest in this setting. This series may serve as a benchmark for future clinical trials in chordoma. Research Sponsor: None.

GEIS 39: Phase II trial of nabpaclitaxel for the treatment of patient with multiply relapsed/refractory desmoplastic small round cell tumor (DSRCT) and Ewing sarcoma (EwS). *First Author: Jaume Mora, Pediatric Surgery Department, Hospital Sant Joan de Déu, Universitat de Barcelona, Barcelona, Spain*

Background: Nab-paclitaxel (albumin-bound paclitaxel) has shown preclinical activity against pediatric solid tumors. Preclinical data in EwS PDX models suggested high activity of nab-paclitaxel in tumors expressing high-levels of SPARC. Tumoral SPARC facilitates the accumulation of albumin in the tumor and increases the effectiveness of albumin-bound paclitaxel. Nab-paclitaxel utilizes albumin to deliver paclitaxel via caveolin-mediated endocytosis which is expressed in the EwS cells surface. We hypothesized that SPARC can be a predictive biomarker for nab-paclitaxel in EwS and DSRCT that could potentially be relevant for a better design of clinical trials and personalized treatments using nab-paclitaxel. **Methods:** Main endpoint of GEIS-39 was the overall response rate (ORR) assessed by RECIST 1.1 criteria with centralized pathology and imaging review. Secondary objectives included safety according to the CTCAE 4.0 criteria. Patients aged $\geq$ 6 months and $\leq$ 40 years, with relapsed/refractory DSRCT were eligible after having received at least one previous poly-chemotherapy line; EwS must have received at least two standard chemotherapy lines. Prior taxane therapy was accepted. Central pathology review selected for tumors with $>$ Grade 3 (intense and diffuse) expression of SPARC by immunohistochemistry to be eligible. Nab-paclitaxel was administered as follows: age $\geq$ 21 and $\leq$ 40 years: 125 mg/m2 days 1, 8 and 15 in cycles of 28 days; age $\geq$ 6 months and $\leq$ 20 years: 240 mg/m2 days 1, 8 and 15 in cycles of 28 days. A 30% ORR was anticipated with a sample size of 25 patients needed to test the hypothesis. Stopping rule was set at 1 response within the first 16 treated pts. If 5 or more successes were observed in 25 pts, the results of the trial will warrant further investigation. **Results:** Twenty-nine patients were enrolled from June 2017 until October 2019, 11 DSRCT and 18 EwS. Median age was 32 years (range 14-69), and 5 females and 24 males were included, having received a median of 3 previous systemic treatment lines. Patients received a median of 3 cycles of nab-paclitaxel (range 1-17). In the EwS cohort an ORR of 33.3% (all partial responses, median duration 2 months) and 16.7% of stabilizations were achieved. No objective responses were observed among DSRCT pts, but 27.3% of pts achieved a stabilization. Overall, median progression free survival was 2.8 months and median overall survival 12.1 months, with no significant differences between DSRCT and EwS cohorts. Most common grade 3 toxicities were neutropenia (20.7%) and diarrhea (10.3%). **Conclusions:** Single agent nab-paclitaxel in biomarker selected EwS patients, but not in DSRCT, provided clinically meaningful activity that deserves further development. Nab-paclitaxel had a manageable adverse event profile. Clinical trial information: 2016-002464-14. Research Sponsor: Celgene.

Outcome of patients with recurrent/refractory osteosarcoma enrolled in three recent phase II trials: A report from the Children's Oncology Group. *First Author: Seema Rao, Baylor College of Medicine, Houston, TX*

Background: Based on seven prior Phase 2 Children's Oncology Group (COG) trials, the 4-month event-free survival(EFS) and associated confidence interval for relapsed osteosarcoma with measurable disease according to RECIST was determined to be 12% (95% CI 6 - 19%). Three prospective clinical trials were conducted using this historical benchmark to detect activity defined by an EFS improvement of double the upper confidence interval. This report summarizes the outcome of these studies, describes whether the historical data remains an accurate baseline, and considers implications for future phase II trial study design in relapsed osteosarcoma measurable according to RECIST. **Methods:** We conducted an analysis of outcome for patients with recurrent/refractory osteosarcoma enrolled in three recent prospective COG phase II trials; AOST1321 (unresected cohort), AOST1322 and AOST1521 that used EFS at 4 months as the primary endpoint. Patients were eligible if they had osteosarcoma that had recurred or become refractory after standard therapy and had measurable disease according to RECIST. We assessed whether risk of an EFS event is modified by age, sex, race/ethnicity, number of prior chemotherapy regimens, or time to first relapse. **Results:** In each of the three phase II trials (unresected group of AOST1321, AOST1322, AOST1521), the drugs tested (denosumab, eribulin and glembatumumab) were concluded to be not effective due to a failure of the patient populations to meet the prespecified active 4-month progression free survival endpoint. The 4-month EFS for the 57 evaluable patients enrolled on these trials was 7% (95% CI 2 – 16%), similar to the 4-month EFS for 96 patients in the previous seven phase II trials of 12% (95% CI 6 - 19%). The combined EFS at 4 months for all 10 studies is 10% (95% CI 6 – 15%).There was no significant difference in EFS across trials based on age, sex, ethnicity, number of prior treatment regimens, consistent with prior analysis. Data from AOST1321 and AOST1521 were analyzed to determine the impact of time to first recurrence on EFS. Two different quantifications were applied: 1 year or less versus 2 or more years; and 2 years or less versus 3 years or more. Neither categorization was statistically significant. **Conclusions:** The EFS at 4 months in the three new phase II trials is similar to the previous seven phase II single arm trials. The combined analysis of 153 patients from 10 trials tightens the confidence interval, moving the upper 95% CI to 15%. Modification to future study designs could be considered based on this updated analysis. EFS at 4 months remains a robust primary endpoint. Single-arm trials using this endpoint based on the historical benchmark have accrued rapidly and allowed assessment of multiple novel agents in osteosarcoma. The negative trial results and continued poor outcome highlight the need for new approaches for relapsed osteosarcoma. Clinical trial information: NCT02097238, NCT02470091, NCT02487979. Research Sponsor: Children's Oncology Group statistics and Data Center Grant/ Chair's Grant.

Comparison of treatment effect and long-term outcomes for pediatric and adult Ewing sarcoma patients in British Columbia, Canada. *First Author: Omar Hajjaj, BCCA Vancouver, Vancouver, BC, Canada*

Background: Treatment of Ewing Sarcoma (EWS) is challenging. While it is known to be sensitive to chemotherapy and radiation, the number of lines of therapy available are limited. This disease affects pediatric patients (PP) more often than adults (AP), and reported outcomes are worse for AP onset EWS in the literature. It is unclear if this is due to difference in the biology of disease in AP compared to PP, or if this is due to differences in treatment approach. Furthermore, optimal treatments and real world impact of treatment is unclear in both the PP and AP populations. This study identifies the features of therapy received by AP and PP with EWS in a large, mutli-institutional cohort, and provides real world evidence for the expected outcomes in both AP and PP with EWS. **Methods:** A cohort study analysis of the Sarcoma Outcomes Unit database at BC Cancer was conducted to identify patients diagnosed with EWS in British Columbia from January 1, 2000 to December 31, 2018. Data on the frequency, amount, and regimen of chemotherapy were collected. Baseline Charlson comorbidity index, age at diagnosis, progression free survival and overall survival were collected. **Results:** 108 patients with EWS were identified, 66 AP and 42 PP Median age at diagnosis for adults was 37 (19-86) and median age for diagnosis of pediatric patients was 14 (1-18). Real world median PFS and OS for AP were 23 mos and 79 mos, and for the PP were 32 mos and NE. Five year overall survival was 54% in AP and 77% in PP. Overall, there was no difference in the number of lines of therapy received between PP and AP, but the type of therapy was more dose-dense in the PP than in the AP, (85% vs 28% for dose dense chemo). 5 year overall survival was longer for PP who received dose dense regimens compared to non-dose dense regimens (HR 0.87), but was not different in the AP receiving dose dense regimens (HR 0.95), even when controlling for comorbidities. The most common chemotherapy regimen for AP was Vincristine, Adriamycin, cyclophosphamide alternating with Ifosfamide and Etoposide q3weeks, whereas in the pediatric population the most common chemotherapy regimen was the same but alternating q2weeks. **Conclusions:** The treatment plans for PP with EWS were more often dose dense compared to the AP. Outcomes for PP were vastly better than for APs, despite overall similarities in the number of lines of therapy and types of agents used. Given the lack of difference between dose dense and non-dose dense regimens for APs, this is not the likely cause of difference in survival between PPs and APs. Extrapolating pediatric protocols to the adult setting may not be appropriate given the differences in outcomes. Further work to identify effective therapies and predictive biomarkers in this disease are needed, and my further identify reasons for discrepant outcomes in pediatric and adult populations. Research Sponsor: None.

Genomic alterations and associated pathway abnormalities in Ewing sarcoma. *First Author: Adam Rock, Harbor-UCLA Medical Center, Torrance, CA*

Background: Ewing Sarcoma (ES) is an aggressive, translocation-associated, bone cancer associated with a poor prognosis in the recurrent or metastatic setting. ES is identified by the canonical balanced reciprocal chromosomal translocation involving EWSR1 and ETS transcription factors. Secondary somatic alterations in ES are rarely described and genomic alterations (GA) affecting various molecular pathways may work synergistically with ETS-FL1 translocations to promote oncogenesis. Alterations in fibroblast growth factor receptor 4 (FGFR4), a receptor tyrosine kinase protein that functions in cellular processes, have been observed to affect carcinogenesis. Moreover, the FGFR4-Gly388Arg (G388R) single nucleotide polymorphism (SNP) is found to increase the risk of cancer with mouse embryonic fibroblasts derived from knock-in strain of homologous Fgfr4 G385R mice exhibiting a transformed phenotype. We sought to further evaluate the frequency of FGFR4 G388R SNP in relation to other identifiable pathway alterations observed with Comprehensive Genomic Profiling (CGP). **Methods:** Next generation sequencing (NGS) analysis was obtained in the context of clinical care with clinical status, outcomes, and source acquisition (primary tumor, metastasis, or recurrence) unknown to Foundation Medicine. CGP, FoundationOne Heme, evaluated GAs including base substitutions, indels, amplifications, copy number alterations, gene fusions and rearrangements. 189 samples were assayed by hybrid-capture based CGP, including 406 DNA-sequenced genes in addition to 265 RNA-sequenced genes commonly reported to be rearranged in cancer, as previously described. Tumor mutational burden was assessed from a minimum 1.4 Mb sequenced DNA. Microsatellite instability (MSI) status was determined by a novel algorithm analyzing 114 specific loci. **Results:** The median age of evaluated patients was 20 (range 0-70) with the number of alterations averaging 7 per patient. Pathways noted to be altered in the presence of FGFR388R SNP occurred frequently with the following pathways most observed: MAPK (33%), WNT (32%), NOTCH1 (20%), HRR (19%), Histone/chromatin remodeling (18%). FGFR388R SNP was observed in more than half (51%) of evaluated samples. Most affected pathways irrespective of FGFR388R SNP status included: MAPK (n = 89), HRR (n = 75), and PIK3 (n = 64). All evaluated samples were TMB low ($<$ 10 mut/mb) and Microsatellite Stable. **Conclusions:** Secondary GAs affecting major pathways were observed in high frequency, often co-occurring with the FGFR4 G388R SNP. Secondary alteration of known oncogenic pathways may contribute to sarcoma formation in ES potentially informing further therapeutic strategies in the future. Research Sponsor: None.

Accumulation of genome-wide somatic loss of heterozygosity (LOH) as a prominent feature of advanced malignant soft tissue tumors and association with the BRCAness status, suppression of immune responses, and lower survival rates. *First Author: Katsuhito Takahashi, Kameda Medical Center, Center for Multidisciplinary Treatment of Sarcoma, Department of Sarcoma Medicine, Kamogawa, Japan*

Background: Malignant soft tissue tumor is a rare cancer with few therapeutic options. Recent genomic analysis revealed widespread CNA and the cumulative burden of cancer-related pathogenic germline mutations/variants, their clinical and therapeutic significance were unknown. **Methods:** We recruited 155 patients with advanced malignant soft tissue tumors (135 female and 20 male, mean age 51 at analysis, 100 LMS, 19 LPS, 4 ESS, 3 UPS, 3 AS, 3 MPT, 3 GIST and others) with confirmed metastasis/recurrence and information on familial cancer burden. Whole exome sequencing was performed in both blood and tumor samples as described in 2018ASCO. The copy number of BRCA2 gene was determined by the MLPA method. Tumor immune microenvironment was assessed by immunohistochemistry. The MSI status was analysed by PCR. **Results:** We analyzed the LOH status in 595 COSMIC genes and found that genome-wide accumulation of somatic LOH of polygenic germline mutations/variants. Patients with more than 33% LOH genes (n=102) in the total of somatic and LOH mutations showed significantly lower OS rates compared with those (n=53) with less LOH genes (5-year survival rates; 49 vs 75%, p=0.010), which constitute 78% of LMS (n=78/100) and 26% of LPS (n=5/19). Total of 41 patients (26%, n=41/155) including 33 LMS (33%, n=33/100) showed LOH in the BRCA2 locus with hemizygous VUS. Those patients with BRCA2 LOH (n=41) showed significantly lower OS rates compared with those without BRCA2 LOH (n=114) (5-year survival rates; 43 vs. 64%, p=0.019). Neither TMB nor the MSI status was associated with LOH. In contrast, accumulation of somatic LOH (mean LOH values of 71.7 vs. 15.7%) was clearly and negatively associated with CD8+T-cell immune infiltrates (T-cells; 44±23 vs 555±180/mm^2, n=7, p=0.016), CD20+B-cell accumulation in tertiary lymphoid structures (TLS) (TLS; 0.57±0.43 vs. 20.1±6.1/tumor, n=7, p=0.008) and low levels of neutrophil-to-lymphocyte ratio (NLR) (NLR; 3.63±0.45 vs. 1.71±0.17, n=7, p=0.002), hallmarks of the immunological response to tumors. **Conclusions:** This study suggests that in advanced malignant soft tissue tumors, accumulation of genome-wide LOH of germline mutations/variants is associated with the BRCAness status and suppression of the immune responses to tumors, and thus influences therapeutic response and survival of the patients. A phase Ib/II study of selinexor in combination with imatinib in patients with advanced gastrointestinal stromal tumor (GIST): SeliGIST/GEIS-41 trial. *First Author: Cesar Serrano, Vall d'Hebron Institute of Oncology, Vall d' Hebron University Hospital, Barcelona, Spain*

Background: KIT or PDGFRA oncogenic activation drives GIST progression throughout the disease course. Accordingly, currently approved agents in metastatic GIST focus on the therapeutic suppression of these receptors. However, the clinical benefit after imatinib (IM) progression is still modest, suggesting the co-operation of KIT/PDGFRA-independent mechanisms in GIST cell survival. Selinexor is an oral, selective inhibitor of XPO1-mediated nuclear export, and preclinical studies evidenced antitumoral activity in GIST as single agent and in combination with IM in both IM-sensitive and IM-resistant models. **Methods:** The phase Ib portion studied IM 400 mg daily plus weekly selinexor in patients (pts) with IM-resistant, advanced GIST. Prior intolerance to IM was not allowed. A standard 3+3 dosing schema was utilized to determine the recommended phase II dose (RP2D) of this combination. Investigator-assessed response was evaluated every 8 weeks using RECIST 1.1. **Results:** At data cutoff of Sep 25, 2020, 12 pts were enrolled and received treatment with IM 400 mg and selinexor once weekly at dose levels (DL) 1 (60 mg), DL2 (80 mg) and DL3 (100 mg). Median age 57 (range 46-77), 42% female, median prior therapies 4 (range 2-7). Although only 1/6 pts developed a dose limiting toxicity (DLT) at DL3, the RP2D was defined at DL2 (IM 400 mg daily and selinexor 80 mg once weekly) based on activity data in the DL2 and the need for dose reductions in 5/6 pts at DL3 after the DLT window. All pts were evaluable for toxicity and response. One DLT occurred at DL3 (G3 nausea). Non-DLT G3/4 toxicities were anemia (1/12 pts), neutropenia (1/12 pts), vomiting (1/12 pts) and fatigue (2/12 pts). Common G1/2 toxicities were nausea (11/12 pts), vomiting (10/12 pts), neutropenia (5/12 pts) and anemia, fatigue, diarrhea, and periorbital edema (4/12 pts each). No unexpected toxicities were observed. Overall response rate in the 12 pts evaluable for response was 67% (95% CI 0.349-0.901), with 2 pts achieving PR (17%) and 6 pts SD (50%) as the best response. Clinical benefit rate (CBR = CR, PR, SD) $\geq$ 16 weeks was 42% (95% CI 0.157-0.723). Median progression free survival was 3.5 months (95% CI 1.7-7.3). Four pts remain on trial at data cutoff. **Conclusions:** IM and selinexor combination is well-tolerated and has clinical activity in heavily pretreated GIST pts. The trial is currently exploring selinexor as single agent in the IM-resistant GIST population. Clinical trial information: NCT04138381. Research Sponsor: Karyopharm Therapeutics, Spanish Group for Sarcoma Research (GEIS).

Chromosomal complexity as a biomarker to de-escalate adjuvant imatinib treatment in high-risk gastrointestinal stromal tumor. *First Author: Kjetil Boye, Oslo University Hospital, Oslo, Norway*

Background: Gastrointestinal stromal tumors (GISTs) are characterized molecularly by oncogenic *KIT* or platelet-derived growth factor alpha (*PDGFRA*) mutations. Malignant progression of primary GISTs occurs through stepwise accumulation of additional chromosomal aberrations, such as losses of chromosome arms 14q, 22q, 1p, 15q and Xp. After surgical resection of primary GIST, three years of adjuvant imatinib treatment is recommended for patients with an estimated high risk of recurrence. Still, nearly half of high-risk patients are cured by surgery alone, indicating that selection of patients could be improved. We hypothesized that high-risk GISTs with few chromosomal aberrations had a favorable outcome, and might not benefit from adjuvant therapy. The aim of the study was to investigate if chromosomal complexity could be used as a biomarker in de-escalation of adjuvant imatinib treatment. **Methods:** GIST patients undergoing surgical resection of their primary tumor between 1998 and 2020 were identified in the sarcoma database at Oslo University Hospital. All samples with available karyotype analysis made on fresh tumor tissue were included. Karyotypes were categorized as simple if they had $\leq$5 chromosomal changes, and complex if there were $>$ 5 chromosomal aberrations. **Results:** Chromosomal aberrations were detected in 226 tumors, of which 181 (80.1 %) were gastric. The most frequent resulting imbalances were loss of 14q (75.9 %), 22q (43.5 %), 1p (36.6 %), and 15q (29.6 %). One-hundred and thirty-six tumors (60.2 %) had simple karyotypes whereas 90 (39.8 %) were complex. Cytogenetically complex tumors were larger ($P<$ 0.001), had a higher mitotic count ($P=$ 0.009), and were more often non-gastric ($P<$ 0.001). There was a strong association between chromosomal complexity and risk classification according to the modified NIH criteria ($P<$ 0.001). Thirty-eight of 58 (65.5 %) high-risk tumors were karyotypically complex compared to 37 of 144 (25.7 %) tumors that were not high-risk. In the high-risk group, 17 patients experienced disease recurrence, of whom one had a simple and 16 had a complex tumor karyotype. Estimated 5-year recurrence-free survival (RFS) for patients with simple tumor karyotypes was 94 % compared to 51 % for patients with cytogenetically complex tumors ($P=$ 0.004). Adjuvant and/or neoadjuvant imatinib treatment was administered to 40 high-risk patients with a median treatment duration of 33 months (range 2-60 months). A complex karyotype was associated with poor RFS both in patients with ($P=$ 0.016) and without ($P=$ 0.046) adjuvant imatinib. **Conclusions:** Chromosomal complexity was strongly associated with poor RFS in localized, high-risk GIST. Recurrences were infrequent for tumors with simple karyotypes, indicating that de-escalation of adjuvant imatinib treatment should be further explored in patients with cytogenetically simple GISTs. Intra-patient dose escalation (IPDE) of ripretinib after disease progression in patients with advanced gastrointestinal stromal tumor (GIST): Analyses from the phase 3 INVICTUS study. *First Author: John Raymond Zalcberg, Monash University, Melbourne, VIC, Australia*

Background: Ripretinib is a switch-control tyrosine kinase inhibitor that broadly inhibits KIT and PDGFRA kinase signaling. In the INVICTUS study (NCT03353753), patients with advanced GIST (≥4th-line) receiving ripretinib had a median progression-free survival (mPFS) of 6.3 months vs 1.0 month for patients receiving placebo (HR = 0.15, p <0.0001). In an earlier phase 1 dose escalation study, the maximum tolerated dose was not reached with doses up to 200 mg twice daily (BID). Here, we report efficacy, safety, and pharmacokinetic data for IPDE patients initially randomized to ripretinib from the phase 3 INVICTUS study based on data as of 10 Aug 2020. **Methods:** A total of 129 patients were randomized 2:1 to ripretinib 150 mg once daily (QD; n = 85) or placebo (n = 44). Patients receiving ripretinib 150 mg QD who had progressive disease (PD) as assessed by blinded independent central review (BICR) using mRECIST were given the option for IPDE to 150 mg BID. Tumor response assessments were performed every 28 days for 4 cycles and every 56 days thereafter (including after IPDE). The primary endpoint was PFS. For this exploratory analysis, PFS1 for IPDE patients was defined as the time from randomization to PD; PFS2 for IPDE patients was the time from the first dose of ripretinib 150 mg BID to PD or death. PFS1 and PFS2 were based on BICR. **Results:** Of 85 patients treated with ripretinib 150 mg QD, 43 patients with BICR PD dose escalated to 150 mg BID. Baseline characteristics of IPDE patients at time of study entry were similar to those observed in the original ripretinib QD arm and similar to the 22 patients with BICR PD who either remained on 150 mg QD or discontinued treatment. IPDE patients had a mPFS1 of 4.6 months (95% CI, 2.7–6.4) and a mPFS2 of 3.7 months (95% CI, 3.1–5.3); mPFS2/mPFS1=80%. The IPDE dosing period was well tolerated without the emergence of new safety concerns. The most common new or worsening (unchanged or improving grades not included) treatment-emergent adverse event (TEAE) for IPDE patients during the BID period was abdominal pain (30.2% all grades and 7% Grade 3–4 vs 41.9% and 4.7% in QD period, respectively). The most common Grade 3–4 TEAE in the BID period was anemia (14% vs 2.3% in QD period). IPDE from QD to BID resulted in an approximately 2-fold increase in the steady state trough concentration. **Conclusions:** Similar to the phase 1 study wherein IPDE to 150 mg BID following PD provided clinical benefit with a mPFS1 of 5.5 months and mPFS2 of 4.6 months (mPFS2/mPFS1=84%) for patients with ≥4th-line GIST, these analyses from INVICTUS indicate that IPDE to ripretinib 150 mg BID can also provide additional meaningful clinical benefit and a similar tolerability profile to the 150 mg QD regimen for patients with ≥4th-line GIST that progressed following treatment with ripretinib 150 mg QD. Clinical trial information: NCT03353753. Research Sponsor: Deciphera Pharmaceuticals, LLC.

Next generation sequencing of sarcomas: Response to crizotinib in two cases with MET amplification. *First Author: Adrienne I. Victor, University of Rochester, Rochester, NY*

Background: Sarcoma subtypes are often defined by recurrent molecular alterations. The purpose of this study is to review the utility of next generation sequencing (NGS) in sarcoma patients and report clinical outcomes to matched therapies. **Methods:** The records of all patients seen at the University of Rochester Medical Center (URMC) with sarcoma and NGS profiling between 8/2013 and 3/2020 were reviewed. Responses to agents targeting reported alterations were analyzed. In patients with fluorescent-in-situ hybridization (FISH) testing, fusion events by NGS were compared with FISH results. All highlighted pathogenic alterations on the NGS profile report as well as variants of uncertain significance (VUS) were recorded. **Results:** Seventy-five patients met inclusion criteria. Of these, 25 received a treatment based on identified alterations; 1 had a complete response (CR), 4 had partial responses (PR), and 4 experienced disease stabilization (SD). We identified two patients with MET amplified sarcoma that responded to treatment with crizotinib. One other patient with a diagnosis of leiomyosarcoma was found to have an unusually high total mutational burden (TMB) and experienced complete pathologic response to dual checkpoint blockade. In 4 cases, testing resulted in a change in subtype diagnosis. Several rare and novel fusions were identified; a sarcoma with TPM4-NTRK3 fusion responded to larotrectinib, while a sarcoma with PML-JAK1 fusion did not respond to ruxolitinib, and a sarcoma with IL7R-BCL2 fusion progressed on venetoclax. Table summarizes matched therapies in responders. **Conclusions:** NGS profiling led to a targeted therapy with a clinical benefit rate of 12% in this cohort. NGS profiling led to a change in diagnosis in 5% of this cohort. Multi-institutional collaborations to track outcomes of matched therapy would help determine the utility of therapies in rare cancers and unusual alterations. Research Sponsor: None.

Histology	Alterations	Matched therapies and Response
Leiomyosarcoma	High TMB (49 Mut/Mb)	Ipilimumab + Nivolumab – CR, ongoing 1.5+ yrs
Undifferentiated pleomorphic sarcoma	MET: amplification - 8 copies	Crizotinib – PR/CR, ongoing 6+ yrs
Malignant peripheral nerve sheath tumor	NTRK3: TPM4-NTRK3 fusion	Larotrectinib – PR, 3+ yrs
Malignant peripheral nerve sheath tumor	TSC2: A736V NF2: E108*	Temsirolimus + cyclophosphamide + vinorelbine – PR, 13 mo. Everolimus - PD
Inflammatory myofibroblastic tumor	ALK: DCTN1-ALK fusion	Crizotinib - PR, 3 mo. Alectinib - PD
Sarcoma, NOS	SMARCB1: A240fs*28	Palbociclib – SD, 6 mo. Tazemetostat – SD, 2 yrs
Chordoma	PIK3CA: M1043I, amplification	Everolimus – SD, 6 mo.
Undifferentiated sarcoma NOS	MET: amplification – 6 copies	Crizotinib – SD, 3 mo.
Undifferentiated pleomorphic sarcoma	NF1: rearrangement exon 9	Trametinib – SD, 2 mo.

Deciphering the molecular landscape and the tumor microenvironment of perivascular epitheloid cell neoplasma (PEComa). *First Author: Andreas Seeber, Department of Internal Medicine V (Hematology and Oncology), Medical University of Innsbruck, Comprehensive Cancer Center Innsbruck, Innsbruck, Austria*

Background: PEComa is a rare mesenchymal neoplasm composed of perivascular epithelioid cells. Due to its rarity, diagnosis is challenging and no standardized treatment guidelines have been established. A subgroup of PEComas are characterized by a loss of function mutation in *TSC1/2* that activates the PIK3-Akt-mTOR pathway. In the majority of patients, however, the molecular landscape and the composition of the tumor microenvironment (TME) remain largely unclear. Thus, we conducted this study to elucidate the genetic landscape of PEComas. A comparative analysis was performed with melanoma as a representative immunogenic tumor type. **Methods:** Thirty-five PEComa specimens were centrally analysed at the Caris Life Sciences laboratory. NextGen DNA sequencing (NextSeq, 592 gene panel or NovaSeq, whole-exome-sequencing), whole-transcriptome RNA sequencing (NovaSeq) and immunohistochemistry (Caris Life Sciences, Phoenix, AZ) were performed. Gene expression profiling (GEP) was performed by unsupervised hierarchical clustering. RNA deconvolution analysis was performed using the Microenvironment Cell Populations (MCP)-counter method to quantify immune cell populations (Becht 2016, Genome Biology). **Results:** The most common mutations detected in this cohort were *TP53* (47%), *ATRX* (32%), *TSC1/2* (11%/29%) and *MSH3* (17%). Interestingly, *TP53* mutations occurred less frequently (25 vs 60%, p = 0.055) in *TSC1/2*-mutated (*TSC1/2-mt*) compared to *TSC1/2*-wildtype (*TSC1/2*-wt) tumors, whereas *MSH3* (25%, n = 1/4) and *ERCC2* (14%, n = 2/14) mutations were exclusively observed in *TSC1/2*-mt cases. *TSC1/2* mutations and other mTOR signalling pathway alterations, including two TFE gene fusion transcripts, were mutually exclusive. Of note, we found that 33.3% (n = 2) of *TSC2*-mt tumors were associated with high PIK3-Akt-mTOR pathway expression, while 100% (n = 3) of *TSC1*-mt tumors demonstrated lower expression. Deficient mismatch repair/microsatellite instability-high and high tumor mutational burden were rare (2.9%, n = 1 each) and observed concurrently in absence of PD-L1 expression. Overall, PD-L1 expression was observed in 21.9% (n = 7) of patients. An exploratory comparison with melanoma revealed that PEComa TMEs were characterized by a significant increase of NK cells and fibroblasts, as well as a relevant decrease of $CD8^+$ T cells and B cells. **Conclusions:** Within this study we discovered a heterogeneous molecular landscape with a high prevalence of *TSC1/2* mutations that were in part associated with transcriptional up-regulation of the PIK3-Akt-mTOR pathway. Furthermore, the relatively immune-cold TME compared to melanoma suggests increased lymphocyte infiltration may be required to increase the efficacy of immune checkpoint inhibitors for PEComa. Research Sponsor: None.

Whole-genome sequencing to improve sarcoma diagnosis and patient care. *First Author: Luuk J. Schipper, Netherlands Cancer Institute, Department of Molecular Oncology, Amsterdam, Netherlands*

Background: With more than 70 different histological subtypes, accurate classification sarcomas is challenging. Although pathognomonic genetic events aid accurate classification, large-scale molecular profiling is generally not incorporated in regular diagnostic workflows for sarcoma patients. We hypothesized that whole genome sequencing (WGS) optimizes clinical care of sarcoma patients by detection of pathognomonic and actionable variants, and of underlying hereditary conditions. **Methods:** WGS of tumor and germline DNA was incorporated in the diagnostic work-up of 83 patients with a (presumed) sarcoma as part of the WIDE (Whole genome sequencing Implementation in standard Diagnostics for Every cancer patient) study in a tertiary referral center. WGS results were reported back to the pathologist and treating clinician. Clinical follow-up data were collected prospectively to assess impact of WGS on clinical decision making. **Results:** WGS analysis had impact on multiple levels. First, in 14% of cases (12/83 patients), the genomic profile led to a revision of the diagnosis (table). All patients had undergone multiple diagnostic procedures (mean number: 4) and pathologist assessments (mean: 6) before WGS analysis was performed. Secondly, actionable biomarkers with therapeutic potential were detected for 36/83 patients and finally, 8 pathogenic germline variants were present. Taken together, WGS had implications for clinical decision making in 52% of patients with (presumed) sarcomas. **Conclusions:** WGS is an important extension of the diagnostic arsenal of pathologists and has contributed to change of care in 52% of patients with sarcomas. Given the diagnostic complexity and high unmet need for new treatment opportunities in sarcomas we advocate the use of WGS for sarcoma patients early in the disease course. Clinical trial information: NL68609.031.18. Research Sponsor: ZonMw, the Netherlands Organisation for Health Research and Care innovation.

Diagnostic revisions after WGS analysis.

Study number	(Preliminary) diagnosis without WGS	Diagnosis after WGS	Revision based on
342	Sarcomatoid mesothelioma vs. sarcoma	Malignant Peripheral Nerve Sheath Tumor (MPNST)	Genomic profile (including lack of NF2 and BAP1 driver events)
483	Adenocarcinoma of unknown primary	Synovial sarcoma	SS18–SSX1 fusion
663	Osteosarcoma/UPS	Spindle cell/sclerosing rhabdomyosarcoma (SCSRMS)	FUS–TFCP2 fusion
711	Ewing sarcoma of soft tissue	Soft Tissue Myoepithelial Carcinoma	EWSR1–POU5F1 fusion
810, 986	Embryonal rhabdomyosarcoma, alveolar rhabdomyosarcoma	SCSRMS	MYOD p.L122R
821, 1016, 1025	Melanoma vs. sarcoma, interdigitating dendritic cell sarcoma, MPNST	Melanoma	High ML/UV-signature, TERT promoter
822	Dedifferentiated liposarcoma	RTx-associated second primary	Lack of MDM2/CDK4 co-amplification

The sarcoma microbiome as a diagnostic and therapeutic target. *First Author: Gabriel Tinoco, The Ohio State University, Columbus, OH*

Background: Sarcoma is a heterogeneous group of malignant tumors that consist of distinct histological and molecular subtypes, each with unique features. Despite immunotherapy's promise in many cancers, immunotherapeutic approaches for sarcoma have had variable response rates. Evaluating the tumor microbiome is a promising new approach that aims to improve our understanding of the immunogenicity of sarcoma subtypes, leading to improved treatment options and better clinical outcomes. **Methods:** We utilized The Cancer Genome Atlas (TCGA) and Genome Tissue Expression (GTEx) database to obtain RNA sequencing (RNAseq) data to identify microbes in sarcoma samples (all subtypes available). Due to the large number of sarcoma subtypes, we focused on three groups: dedifferentiated liposarcoma (DDLPS), leiomyosarcoma (LMS) and "other," representing all other sarcoma subtypes. We utilized ExoTIC, "Exogenous sequences in Tumors and Immune cells," a tool recently developed by Dr. Daniel Spakowicz and Dr. Xaiokui Mo. ExoTIC takes raw RNAseq reads and carefully aligns to both human and non-human reference genomes to identify low-abundance microbes. Models of association were analyzed based on each of the three groups as well as all the samples: "All" group. We performed Cox proportional hazards regression to identify the microbes associated with overall survival (OS). **Results:** We evaluated 97 LMS, 56 DDLPS and 100 "other" RNAseq samples (Table). ExoTIC identified 1304 microbes, of which 431 were statistically associated with OS in the "All" group. Of these, 50 microbes were statistically associated only with DDLPS, 54 only with LMS (e.g., Candida dubliniensis, Mycobacterium avium, Streptococcus sp. Z15), and 46 with "other." The presence of no organism was associated with improved survival. Median hazard ratios were largest in DDLPS (2.3), followed by "other" (2.1) and LMS (1.9). Only 18 microbes were found in the DDLPS, LMS and "All" groups, including Bacillus sp., Streptococcus lutetiensis, Clostridium tetani, and Pseudomonas sp. LTJR-52. Each was negatively correlated with survival with a median hazard ratio of 2.5. **Conclusions:** We found a specific relationship between microbial presence and histological sarcoma subtype (DDLPS, LMS), which also statistically correlated with OS. Assessing individual characteristics of a sarcoma histological subtype with its particular microenvironment (e.g., microbes) can lead to personalized treatment insights and improvements in outcomes. Our future research will consist of validating and correlation of the microbial profile of sarcoma subtypes with clinical outcomes retrospectively and prospectively. Research Sponsor: None.

Phase 1 trial of autologous dendritic cell vaccination with imiquimod immunomodulation in children and adults with refractory sarcoma. *First Author: Aditi Dhir, University of Miami Miller School of Medicine/ Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Sarcomas are rare, heterogeneous, and aggressive neoplasms that often affect otherwise healthy individuals. Patients with advanced or metastatic sarcomas have dismal outcomes. Immunotherapy presents promising new modalities to help treat sarcomas. One such therapy, autologous dendritic cell (DC) vaccines, using antigen-loaded DCs, intensify the adaptive immune response by enhancing T-cell activity and inducing tumor cell death through apoptosis and cytolysis. We present the results of a phase 1 study of DC vaccine for refractory sarcomas. **Methods:** A phase 1 dose-escalation study of autologous DC vaccination was conducted in children and adults with recurrent/refractory sarcomas who underwent surgical resection of a primary or metastatic tumor between 2014-2019. A 5+3 dose-escalation schema was chosen to determine safety and recommended phase 2 dose. Patient monocytes were collected by pheresis and incubated with GM-CSF plus IL-4 to generate immature DCs which were then loaded with autologous tumor lysates from the patient's surgical resection. Three dose levels, 3, 6, and 12 million DCs per treatment were tested. The DC product was administered intradermally in imiquimod-treated skin to complete in situ maturation. Treatment consisted of four weekly injections of the DC product, followed by four monthly "boosters" of tumor lysate. The primary and secondary endpoints included safety/feasibility and preliminary clinical efficacy, respectively. **Results:** Nineteen patients were enrolled with a median age 50 years (13-75 years) and 47% female. Seven patients were treated on dose level 1 and six each on dose level 2 and 3. Thirteen patients received all planned injections while the remaining six patients progressed during treatment. There was no treatment related dose limiting toxicity. Grade 1-2 fever, headache, arthralgia, injection site reaction attributable to treatment were noted in four patients. There were no adverse events $>$ grade 2. Disease progression before or after completion of study treatment was noted in 15 patients with a median PFS of 9.5 months (95%CI 5.6-28.7). The two-year PFS and OS was 36.8% and 68.1%, respectively. There were seven deaths due to disease, one patient was discharged to hospice and two patients have been lost to follow up. Five patients are currently receiving alternative therapy. Four patients remain in follow up without evidence of disease progression including three patients (pleomorphic myxofibrosarcoma, pleomorphic myosarcoma, and leiomyosarcoma) who are disease free over two years from initiating study therapy and one pediatric patient (Ewing sarcoma) disease free for over one year. **Conclusions:** Autologous DC vaccine with imiquimod immunomodulation for patients with relapsed/refractory sarcomas is feasible and well-tolerated. Refinement to augment initial and sustained antitumor activity is needed. Clinical trial information: NCT01803152. Research Sponsor: None.

Results of NC-6300 (nanoparticle epirubicin) in an expansion cohort of patients with angiosarcoma. *First Author: Richard F. Riedel, Duke University Medical Center, Durham, NC*

Background: NC-6300 is a polymeric micelle exhibiting increased tumor accumulation compared to small-molecule epirubicin through enhanced pharmacokinetics and controlled release within the tumor through a pH-sensitive linker conjugated to epirubicin. In a phase 1b trial, which accrued twenty-nine patients with various types of sarcoma as well as solid tumors, observed dose-limiting toxicities included thrombocytopenia, stomatitis, lung infection, and febrile neutropenia. The maximum tolerated dose and the recommended phase 2 dose were determined to be 185 mg/m^2 and 150 mg/m^2, respectively. The objective response rate (ORR) in soft tissue sarcoma subset (n = 17) was 18% with both angiosarcoma patients achieving partial response. To further evaluate the anti-tumor activity of NC-6300 in angiosarcoma, we conducted an expansion cohort of 10 additional angiosarcoma patients. **Methods:** Eligible patients, at least age 18 years old, with histologically confirmed angiosarcoma, including cutaneous and non-cutaneous variants, not amenable to curative treatment with surgery or radiotherapy were included. No more than two lines of prior systemic therapy were allowed. NC-6300 was administered at the dose of 150 mg/m^2 intravenously on Day 1 of a 21-day cycle. Treatment was continued until disease progression or unacceptable toxicity. Disease assessment was performed every 6 weeks using RECIST v1.1. The primary endpoint was median progression-free survival (mPFS). **Results:** Ten patients (cutaneous: 2 pts; non-cutaneous: 8 pts) were enrolled and deemed evaluable. Median line of prior systemic treatment in the advanced disease setting was 1.0 and seven patients (70%) received prior anthracycline therapy. Objective response rate (ORR) was 30% (cutaneous: 1 pt, non-cutaneous: 2 pts) and mPFS was 5.4 months (95% CI: 1.2-NA). Across all angiosarcoma patients included in the phase 1 portion and expansion cohort (phase 1b portion: 2 pts, expansion cohort: 10 pts), ORR and mPFS was 42% and 7.3 months (95%CI: 3.3-NA), respectively. All patients enrolled in the expansion cohort experienced grade 3/4 AEs and no treatment related death was observed. Most frequent grade 3/4 AEs were neutropenia without fever (80%), thrombocytopenia (40%), anemia (20%) and leukopenia (20%). AEs led to NC-6300 dose reduction and medication withdrawal were seen in 70% and 10% of patients, respectively. **Conclusions:** Promising anti-tumor activity was observed in this cohort of patients with cutaneous and non-cutaneous angiosarcoma. The safety profile of this expansion cohort was consistent with previous clinical study results of NC-6300. Our study results warrant further development of NC-6300 for angoisarcoma. Clinical trial information: NCT03168061. Research Sponsor: NanoCarrier Co., Ltd.

Long-term evaluation of the novel radioenhancer NBTXR3 plus radiotherapy in patients with locally advanced soft tissue sarcoma treated in the phase II/III Act.In.Sarc trial. *First Author: Sylvie Bonvalot, Institut Gustave Roussy, Villejuif, France*

Background: NBTXR3, a novel radioenhancer activated by radiotherapy (RT) demonstrated superior efficacy, as preoperative treatment, in patients with locally advanced soft tissue sarcoma (LA STS), compared to RT alone. Primary endpoint of pCR rate was 16% vs 8% (p=0.044) and R0 margin rate was 77% vs 64% (p=0.042) (Bonvalot et al. *Lancet Oncol.* 2019). No modification of the early safety profile of RT was observed, leading to market authorization. Here we report on the long-term safety, limb function and quality of life. **Methods:** This phase II/III randomized (1:1), international trial included adult patients with LA STS of the extremity or trunk wall, requiring preoperative RT (NCT02379845). Patients were treated with either a single intratumoral injection of NBTXR3 (volume equivalent to 10% of tumor volume, at 53.3g/L) plus EBRT (arm A), or EBRT alone (arm B) (50 Gy in 25 fractions), followed by surgery. The primary and main secondary efficacy endpoints were previously reported. Safety of NBTXR3+RT, as preoperative treatment, was evaluated as secondary endpoint. We present the safety analyses done in the "all treated population", with data recorded during at least a two-year follow-up. Important parameters related to HR-QoL, including functional outcome were studied using the EQ-5D, RNLI, TESS and MSTS questionnaires. **Results:** Patients had at least two-year follow-up and the lost to follow-up rate was very low (1.9%). RT-related SAEs were observed in 11.2% (10/89) vs 13.3% (12/90) in A vs B. Post-treatment AEs, any grade, were observed in 51.7% (46/89) vs 57.8% (52/90) and serious post-treatment AEs in 13.5% (12/89) vs 24.4% (22/90) of patients in A vs B. Second primary cancer was observed in 1 patient in arm A and 6 patients in arm B. Long-term safety continues to demonstrate that NBTXR3 plus RT has no impact on post-surgical wound complications (24.7% vs 36.7%, A vs B). Furthermore, the evaluation of radiation late toxicities in limbs such as fibrosis (4.5% vs 7.7%), arthrosis (2.2% vs 0.0%) and edema (6.7% vs 2.2%) that may alter limb function showed no difference between arms. Accordingly, HR-QoL evaluation yielded no difference in functional outcome. In addition, the intratumoral injection of NBTXR3 did not induce cancer cell seeding at the former tumor site. Finally, sequelae or chronic tissue disturbances at the former tumor localization were similar in both treatment arms, confirming that the increase of energy dose deposit and the physical presence of NBTXR3 did not impact post-treatment limb functions. **Conclusions:** The long-term safety results demonstrate that the addition of NBTXR3 to EBRT neither added toxicity nor modified the bystander effect of RT. The results presented here associated with the efficacy data reported previously reinforce the favorable benefit-risk ratio of the use of NBTXR3 in patients with LA STS. Clinical trial information: NCT02379845. Research Sponsor: Nanobiotix, SA and PharmaEngine Inc.

11545 **Poster Session**

Efficacy and safety of nivolumab and trabectedin in pretreated patients with advanced soft tissue sarcomas (STS): Preliminary results of a phase II trial of the German Interdisciplinary Sarcoma Group (GISG-15, NitraSarc) for the non-L sarcoma cohort. *First Author: Daniel Pink, Klinik und Poliklinik für Innere Medizin C, Hämatologie und Onkologie, Transplantationszentrum, Palliativmedizin, Universität Greifswald and Klinik für Hämatologie, Onkologie und Palliativmedizin-Sarkomzentrum, HELIOS Klinikum Bad Saarow, Bad Saarow, Germany*

Background: Single-agent PD-1 inhibitors have modest activity in the treatment of most STS. Potential strategies to increase efficacy include combination therapies targeting the tumor microenvironment. Considering that apart from direct growth inhibition and death of malignant cells, trabectedin (Tr) also induces macrophage depletion and/or different immunologic effects, suggesting a possible synergistic effect of combined Tr plus anti-PD-1 treatment. We therefore aimed to evaluate the efficacy and safety of combined Tr and nivolumab (Ni) as a second-line treatment in STS. **Methods:** The prospective, explorative, two group, non-randomized phase II NiTraSarc trial enrolled pretreated patients (pt) with advanced STS (Group A: lipo- or leiomyosarcomas, Group B: non-L-sarcomas). Pt were initially treated with 3 cycles of Tr 1.5 mg/m^2, followed by the combination of Tr 1.5 mg/m^2 + Ni 240 mg ("late combination cohort" (LCC)) for up to 16 cycles. After positive results of a preplanned interim analysis, pt received the combination therapy starting with cycle 2 ("early combination cohort" (ECC)). 92 pt were recruited to the trial (55 in Group A, 37 in Group B). Primary efficacy endpoint is progression-free survival rate after 6 months (PFSR6) according to RECIST v.1.1. This is a first analysis of the primary efficacy endpoint in Group B based on a modified intention-to-treat (mITT) population of evaluable 36 pt: 23 and 13 pt from the LCC and ECC, respectively. **Results:** The most common Group B subtypes comprised undifferentiated pleomorphic/not otherwise specified sarcoma (UPS/NOS, 13pt) and fibromyxoid sarcoma (FMS, 6pt). After a median follow-up of 5 months (m) PFSR6 was 13.9% for all pt, 8.7% in LCC and 23.1% in ECC. Median duration of disease stabilization (DoDS) was 4m in all pt, the LCC and the ECC. Two pt had a partial response (PR), 10 had disease stabilization (SD), while 13 pt progressed, and 11 had missing data. By subtype: PR- UPS/NOS=2 (DoDS 12.7m/12.5m). SD: UPS/NOS=3, epithelioid=2, synovial=2, FMS=1, fibrosarcoma=1, other=1. All 36 pt experienced at least one adverse event (AE) reaching a total of 579 AEs, 141 (24.4%) of which were considered to be grade ≥3 treatment-related AEs. The main grade ≥3 AEs were: leukopenia (47.2% of pt), neutropenia (41.7% of pt), thrombocytopenia (33.3% of pt), increased ALT (30.6% of pt), and anemia (27.8% of pt). **Conclusions:** Tr+Ni was well tolerated and showed activity in at least some patients with non-L-sarcomas (mostly UPS/NOS) especially in the ECC. Analyses of the collected data, including PD-L1 expression profile, with the goal to establish whether Tr+Ni should be further pursued in these patients, are ongoing. ClinicalTrials.gov Identifier: NCT03590210; EudraCT: 2017-001083-38. Clinical trial information: NCT03590210. Recurrence and disease-specific survival after 10-year disease-free interval in patients with primary retroperitoneal liposarcoma: Implications for long-term surveillance. *First Author: Mark Archer Eckardt, Department of Surgery, Yale School of Medicine, New Haven, CT*

Background: Surveillance imaging of patients with retroperitoneal liposarcoma (RP-LPS) following surgical resection is based on a projected risk of locoregional and distant recurrence. The duration of surveillance is not well defined as the long-term natural history of RP-LPS after treatment is poorly understood. We evaluate a cohort of RP-LPS patients—without evidence of disease 10 years following initial resection—to assess the long-term risk of recurrence and disease-specific survival (DSS). **Methods:** The prospectively maintained UCLA Sarcoma Database was used to identify RP-LPS patients who demonstrated 10-year progression-free survival (10yr-PFS) after initial diagnosis and treatment. Patients in the 10yr-PFS cohort were subsequently evaluated for recurrence and DSS. Time intervals start at date of initial surgical resection. Cox proportional hazards models were used to determine factors associated with recurrence and DSS. **Results:** From 1972-2010, 76 patients with RP-LPS had at least 10 years of follow-up. Of these, 37 (49%) demonstrated 10yr-PFS. Median follow-up was 15 years (range 10-35 years). Among the 10yr-PFS patients, 43% (16/37) developed a recurrence >10 years *after* the initial surgery, and 19% (7/37) died of disease. Neither long-term recurrence nor DSS were significantly associated with age, sex, tumor size, LPS subtype, surgical margin, or peri-operative treatment with radiation or chemotherapy (Table). **Conclusions:** Patients with primary RP-LPS treated with surgical resection +/- multimodality therapy have a long-term risk of recurrence and disease-specific death that is unacknowledged by current surveillance imaging guidelines. Among the patients with a 10yr-PFS, 43% developed a recurrence and 19% died of disease. These findings suggest a need for lifelong surveillance imaging in patients with RP-LPS. Research Sponsor: None.

Efficacy and safety of anlotinib plus TQB2450 in patients with advanced soft tissue sarcoma: A multicenter, single armed, phase 1b trial. *First Author: Jiayong Liu, Beijing Cancer Hospital, Beijing, China*

Background: Anlotinib, a multitargeted tyrosine kinase inhibitor, had been prove to be effective for the treatment of advanced or metastatic soft tissue sarcoma(STS) faild anthracycline chemotherapy. With the lack of prospective data of combination of PDL-1 inhibitor and antiangiogenic agent, we designed a phase 1b study to investigated the efficacy and safety of anlotinib plus TQB2450 in patients with STS. **Methods:** Eligible patients (age 18-70, ECOG 0-1, with histopathologically confirmed advanced STS, at least one measurable lesion according to RECIST 1.1, and previously received front-line anthracycline chemotherapy) were included and received anlotinib (12mg qd, D1-14, 21d/cycle) plus TQB2450 (1200 mg, IV, D1, 21d/cycle) until disease progression or intolerable toxicities.The primary endpoint was objective response rate (ORR) , secondary endpoints included safety, overall survival (OS), progression-free survival (PFS), disease control rate (DCR). **Results:** From January 2019 to January 2021, 30 pts were enrolled1, 12 alveolar soft part sarcoma and 18 others (7 synovial sarcoma, 4 leiomyosarcoma, 5 undifferentiated pleomorphic sarcoma, 1 fibrosarcoma and 1 epithelioid sarcoma). ORR by RECIST was 36.7% , DCR was 83.3%, 11/30 pts had PR, 14/30 (46.7%) had SD, 5/30 (16.7%) PD. Median PFS was 9.6 m in all pts and 4.9m. in non-ASPS, respectively. Median OS in non-ASPS was 10.27m, while mOS in all pts and both mPFS and mOS in ASPS had not been reached. Notably, to ASPS pts, ORR was 75%, and DCR was 100%. The most common 1-2 grade treatment-related adverse reaction (TRAE) was hypothyroidism (19/30,63.3%), hypercholesterolemia (16/30, 53.3%) and hypertriglyceridemia (16/30, 53.3%), the most common ≥3 grade TRAEs were hypertriglyceridemia (3/30, 10%). 6 SAE (20%) occurred, including 2 pneumothorax, 1 Immune associated hapatic injury, 1 hypotension, 1 Immune myocarditis and 1 diabetic ketoacidosis. **Conclusions:** The combination of anlotinib and TQB2450 showed promising activity in second-line treatment of advanced STS, especially in ASPS, with well tolerance and acceptable toxicity. Research Sponsor: China International Medical Foundation (No. Z-2014-06-15331).

The impact of multimodality therapies in marginally inoperable soft tissue sarcomas (STS): The Toronto Sarcoma Program (TSP) experience. *First Author: Olga Vornicova, Department of Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The mainstay therapy of operable STS remains surgery, which may include (neo)adjuvant therapies. Within the TSP, marginally inoperable STS are often treated with sequential chemo (CTX) and radiation (RT) therapy, followed by surgery (SX). Herein we present our experience of multi-modality therapies for marginally inoperable STS patients (pts). **Methods:** This was a dual-center, single program, retrospective review. Pts were included if deemed to have marginally inoperable primary or recurrent STS, as determined at the TSP tumor board. Pts included must have had CTX with the intent of having RT and SX after. Pts demographics, treatment details and clinical outcomes data were collected. Relapse free survival (RFS) and overall survival (OS) were estimated using the Kaplan-Meier method. Multivariate analysis of the influence of disease characteristics and treatment on outcomes was assessed using Cox regression. **Results:** From June 2005 to May 2019, 75 pts were identified. Median age was 52 years (range 16-72). Pts were predominantly male (55%). Histological subtypes included dedifferentiated liposarcoma (29%), leiomyosarcoma (27%), synovial sarcoma (19%) and others (25%). Primary tumor was located in the retroperitoneum (48%), extremity (23%), pelvis (12%), thorax (9%), and other sites (8%). All pts had doxorubicin and ifosfamide CTX (median 4 cycles; range 1-6), while RT dose delivered was 50.4Gy/28 fractions in 58 (77%) of cases. Twenty three pts (31%) achieved partial response, 40 pts (53%) had stable disease and 12 pts (16%) had progression of disease (PD) on CTX, of which half (8%) did not undergo further treatment. Nine pts (12%) underwent CTX followed by SX due to significant response, 9 pts (12%) underwent CTX and RT without SX due to persistent tumor unresectability or PD. The final 50 pts (67%) completed multi-modality treatment (CTX, RT & SX). Overall, 59 pts (79%) had SX; negative margins were achieved in 53 (71%). 19 pts (25%) had postoperative complications, causing death in 2 pts (2.7%). With a median follow-up of 72 months, median RFS and OS were 26.9 months (95% CI: 0-86.0), and 65 months (95% CI: 13.5-116.4). Extremity location was associated with superior RFS (median not reached [NR], HR 0.28 95% CI 0.09-0.83, p = 0.022), and OS (median NR, HR 0.29 95% CI 0.09-0.90, p = 0.032). Receipt of RT was associated with superior RFS (median NR, HR 0.23 95% CI 0.10-0.52, p < 0.001); and OS (median NR, HR 0.21 95% CI 0.09-0.50, p < 0.001). Pts who had PD after CTX were associated with poor outcomes - RFS (median 4.7 months, HR 2.03 95% CI 0.61-6.76, p = 0.24); and OS (median 21.9 months, HR 2.48 95% CI 0.73-8.47, P = 0.144). **Conclusions:** Multi-modality approach resulted in successful resection for most pts with marginally inoperable STS. Extremity location and RT administration were associated with better RFS and OS, while progression on CTX confers worse survival outcomes. Research Sponsor: None.

A phase 1b study of avelumab plus DCC-3014, a potent and selective inhibitor of colony stimulating factor 1 receptor (CSF1R), in patients with advanced high-grade sarcoma. *First Author: Evan Rosenbaum, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Select sarcomas are infiltrated with immunosuppressive myeloid cells. DCC-3014 is an inhibitor of the CSF1R kinase that decreases tumor infiltrating myeloid cells in preclinical models. We hypothesized that DCC-3014 combined with the anti-PDL1 inhibitor avelumab would be safe and tolerable, decrease immunosuppressive myeloid cells, and increase cytotoxic T cells. **Methods:** This investigator initiated, open label, single center, phase I study of DCC-3014 plus avelumab in patients (pts) with unresectable or metastatic sarcoma utilized a standard 3+3 dose escalation design. DCC-3014 was administered on days 1-3 (loading dose of 20, 30, or 50 mg) followed by oral daily maintenance (10, 14, or 20 mg) in 28-day cycles; 800 mg of IV avelumab was administered q2weeks. The primary endpoint was to determine the recommended phase 2 dose (RP2D). Secondary endpoints defined the adverse event (AE) profile and assessed clinical efficacy. Peripheral blood $CD14^{+}Lin^{-}HLA\text{-}DR^{lo}$ myeloid-derived suppressor cells (MDSCs) were measured by flow cytometry. **Results:** 13 pts were treated; median age was 61 (range 32 – 71), 8 were female, and median prior lines of therapy was 5 (range 2 – 10). Histologic subtypes included leiomyosarcoma (LMS, n = 7), undifferentiated pleomorphic sarcoma (2), dedifferentiated liposarcoma (LPS, 2), synovial sarcoma (1), and pleomorphic LPS (1). The Table lists treatment-related AEs (TRAEs) of any grade (G) occurring in ≥ 10% of pts and all G ≥ 3 TRAEs, sorted by frequency. All pts had at least 1 TRAE. Seven pts (54%) had a G ≥ 3 TRAE. Most TRAEs were either G ≤ 2 or expected on-target effects of CSF1R inhibition. 1 of 6 pts on the highest dose level had a dose limiting toxicity (G4 elevated AST with abdominal pain) that resolved with treatment cessation. The highest dose level was declared the RP2D. Best objective response by RECIST 1.1 was stable disease in 3 pts; 2 had LMS and were treated at the highest dose level. At baseline, the mean proportion of monocytes in peripheral blood samples with an MDSC phenotype was 12.2% (range 7.1 – 19.9). 5 of 7 pts with serial blood samples had decreased circulating MDSCs (mean decrease of 26.9% from baseline to last time point). **Conclusions:** DCC-3014 combined with avelumab was safe and tolerable. Study therapy decreased circulating MDSCs in select patients; T cell analyses will be reported. Study expansion at the RP2D is ongoing. Clinical trial information: NCT04242238. Preliminary results of phase 2 trial of preoperative image guided intensity modulated proton radiation therapy (IMPT) with simultaneously integrated boost (SIB) to the high-risk margin for retroperitoneal sarcomas (RPS). *First Author: Thomas F. DeLaney, Massachusetts General Hospital, Boston, MA*

Background: RPS often have local recurrence (LR) after surgery. Preoperative radiation (RT) to 50.4 Gy can reduce LR risk but is not uniformly effective, especially after (+) margin resections. Therefore, we conducted a multi-institutional, prospective Phase II study to assess efficacy and tolerability of preop IMPT with selective dose escalation to 63 GyRBE to the posterior RPS margin (clinical target volume [CTV] 2) at high risk for (+) margins to further reduce the risk of LR. This dose was tolerable in a prior phase I study (DeLaney T et al, 2017, PMID:28740917). **Methods:** Primary RPS patients (pts) >18 years received preop IMPT, 50.4 GyRBE in 28 fractions (fx) of 1.8 GyRBE to CTV1 (tumor plus adjacent tissue at risk of subclinical disease) with SIB to CTV2 to 63.0 GyRBE in 28 fx of 2.25 GyRBE. Pts with high-grade tumors could get chemotherapy(CTX) prior to IMPT. To avoid treatment delay, 11 fx of IMRT x-rays could be substituted for IMPT. Pts had restaging and surgery 4-8 weeks after IMPT. Primary study endpoint was local tumor control. Secondary endpoints included clinical and pathologic response, surgical margin status, and disease-free and overall survival. **Results:** We accrued 60 pts from January 2016 to February 2021. Histology: 35 liposarcoma(LPS) (19 dediff and 16 well diff), 22 leiomyosarcoma(LMS), and 3 undifferentiated pleomorphic sarcoma. IMPT was delivered per protocol in all pts. 51 pts have had surgery, 5 are awaiting surgery, and 4 had no surgery due to metastases(DM) on preop imaging. 22 pts had (+) margins. 2 pts had > 75% necrosis. With 23-month median (range 1-52 months) follow-up after start of RT, there were two LRs. A dediff LPS pt had a well diff LPS LR 26 months postop, resected, and is disease-free. A renal vein/IVC LMS pt treated with CTX and IMPT had LR and DM 4 months postop and died from disease. Surgical Clavien-Dindo morbidity scores: 0(21) , 1(9), 2(8), 3a (4), 3b(4), 4a(2), 4(b)1, 5(2); the periop deaths were from sepsis(pneumonia) and duodenal ulcer. The grade 3-4 periop morbidity included abscess(3), treated by catheter(2) or operative(1) drainage, prolonged hospital stays (2 pts with IVC LMS), small bowel obstruction (1), and late sigmoid colon anastomotic failure (1). Readmissions for lymphopenia(1), pneumoperitoneum (1), and volume overload (1). One late neuropathy was seen in a Type II diabetic pt with transient postop weakness after femoral nerve dissection who later had significant lower extremity weakness 3.75 years postop. Study was amended to reduce IMPT dose in diabetic pts. **Conclusions:** Preoperative IMPT with selective dose escalation to 63 GyRBE to the high risk posterior RPS margin is feasible. Early local control results with this approach appear promising. Some peri-operative morbidity was noted but appears to be in the expected range for RPS resections. Clinical trial information: NCT01659203. Research Sponsor: U.S. National Institutes of Health.

Durvalumab and pazopanib in patients with advanced soft tissue sarcoma: A single-center, single-arm, phase 2 trial. *First Author: Hyo Song Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Based on the central role played by the vascular endothelial growth factor receptor (VEGFR) in immunosuppression, we assessed the activity and safety of VEGFR inhibitor pazopanib plus anti-PD-L1 blockade durvalumab in soft tissue sarcoma (STS). **Methods:** We did a single-arm, single-center, phase 2 study that enrolled patients with metastatic or locally advanced STS aged 19 years or older, ECOG PS 0-1, with at least one measurable lesion, and received at least one previous line of systemic therapy. Patient were given pazopanib 800 mg orally daily and durvalumab 1500 mg intravenously for 60 min every 3 weeks. The primary endpoint was investigator-assessed objective response. **Results:** Between September 2019 and October 2020, 47 participants were enrolled, of whom 46 (97.9%) were evaluable for the efficacy analyses. With a median follow up of 12.3 months, complete and partial response (PR) was achieved in 1 (2.2%) and 12 (26.1%) patients, resulting in 28.3 % of objective response rate. Median time to achieve PR was 1.4 months and median duration of response was 11.0 months. The most common treatment-related adverse events of any grade include fatigue (20 [42.6%]), anorexia (17 [36.2%]), diarrhea (17 [36.2%]), and AST elevation (16, [34.0%]). Thirty-one patients (67.3%) had progressive disease, and the median progression free survival was 8.6 months (95% CI 3.6-13.6). **Conclusions:** Durvalumab and pazopanib showed encouraging activity in patients with advanced STS. Molecular predictors with whole exome and RNA sequencing will be presented. Clinical trial information: NCT03798106. Research Sponsor: None.

Immune-desert tumor microenvironment in SMARCA4-deficient thoracic sarcomas with limited efficacy of immune checkpoint inhibitors. *First Author: Justine Gantzer, Medical Oncology Department, ICANS, Strasbourg, France*

Background: SMARCA4-deficient thoracic sarcomas (SDS) are rare and aggressive sarcomas characterized by inactivating *SMARCA4* mutations, with no approved treatment to date. Previous data linking SWI/SNF deficiency with tumor immune microenvironment (TME) are contradictory. While an immunogenic microenvironment and efficacy of immune checkpoint inhibitors (ICI) were described in SMARCA4-deficient small cell carcinoma of the ovary, the TME phenotype of SDS is unknown; in addition, response of patients to ICI is lacking. **Methods:** All consecutive patients diagnosed with SDS between 2016 and 2019 in Strasbourg University Hospital were included and clinical outcomes collected. Immunostainings for immune cell markers, immune checkpoints and tertiary lymphoid structures (TLS) were assessed on available samples. Validation was performed using an independent transcriptomes dataset of SDS (n = 12), not otherwise specified (NOS) non-small cell lung cancer (NSCLC) with/without *SMARCA4* mutations (n = 14) and undifferentiated thoracic sarcoma (n = 5). Finally, chemokines (CXL9 and CXCL10) and PD-L1 expressions were assessed in NSCLC and thoracic fibroblast cell lines, treated with/without interferon gamma (IFNG). **Results:** Nine patients were identified and had all metastatic disease at presentation, with a median overall survival of 1.8 months (0.3-NR). Among them, 4 received ICI as part of their treatment. Out of 11 evaluated tumors samples, all but one case showed no TLS, consistent with an immune desert TME phenotype charted by low densities of CD3+ T-cells, CD8+ T-cells, CD20+ B-cells from one side and high density of CD68+ macrophage-cells from the other side. Conversely, the unique tumor with TLS aggregate showed an immune-rich TME phenotype associated with high mutational tumor burden. While the patient with TLS harboring tumor showed an exceptional long-lasting response, the 3 remaining patients without TLS had progressive disease at best response to ICI. Using an independent cohort, unsupervised clustering using immune cell scores identified two clusters tightly associated with cell ontogeny of cancer subtypes and immunity; while cluster 1 (C1) was enriched for NOS NSCLC independently from *SMARCA4* status (n = 9/10; 90%) (p = 0.001), C2 was enriched for SDS (n = 11/12; 91.7%) (p = 0.005) and undifferentiated thoracic sarcomas (n = 5/5; 100%) (p = 0.0005). Finally, SMARCA4 loss of function experiments revealed upregulation of chemokines (CXL9 and CXCL10) and PD-L1 expression in the NSCLC cell line with no effect on thoracic fibroblast cell line. **Conclusions:** SDS harbor an immune desert TME phenotype with limited efficacy to ICI, similar to other sarcomas. Our data suggest that TME of SMARCA4-driven tumors might vary according to the cell of origin. Further studies are needed to understand the interplay between SWI/SNF mutations, cell ontogeny and immunity. Research Sponsor: None.

ESMO Magnitude of Clinical Benefit Scale (MCBS): An evaluation of systemic treatment trials for soft tissue sarcomas (STS). *First Author: Abdulazeez Salawu, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada*

Background: Patients with STS have poor prognosis in the metastatic setting. Although some treatment options are associated with improved outcomes, such as progression-free (PFS) or overall survival (OS), the overall magnitude of clinical benefit can be unclear. The ESMO MCBS is a validated and reproducible tool developed to quantify the clinical benefit of treatments evaluated in trials (www.esmo.org/guidelines/esmo-mcbs). Herein, we report the application of ESMO MCBS to systemic treatment trials involving metastatic STS patients. **Methods:** A systematic search of Medline, Embase and Cochrane databases for adult phase II and III trials in advanced STS (01/1998 to 12/2020) was carried out. Gastrointestinal stromal tumor trials were excluded. Outcomes, including but not limited to OS, PFS, objective response rate (ORR), toxicity and quality of life (QoL) data were extracted and analyzed. Studies with outcomes that met the criteria for ESMO MCBS v1.1 were evaluated to generate a score of 1 to 5 (score of $\geq$ 4: substantial benefit). MCBS scoring of each study was performed by at least 2 co-authors for consensus. **Results:** Among 3454 abstracts screened, a total of 140 Phase II and 28 phase IIII trials were identified. A total of 41 studies fulfilled the criteria for ESMO MCBS scoring. These include 5 phase III studies, as well as 9 randomized and 27 single-arm phase II trials. Fifteen studies involved specific histology, while remaining 26 studies were of all STS subtypes. Chemotherapy, alone or in combination was evaluated in 29 trials, while molecular-targeted agents (MTA) and immune checkpoint inhibitors (IO) were evaluated in 11 and 3 studies, respectively (Table). The median MCBS score was 2 (range 1-4), regardless of drug class or combination. Only 3 studies, all randomized in design, had a MCBS score of 4. All three trials were in the 2nd line setting or beyond, where there is no standard control treatment. None of the trials, irrespective of drug class had a score of 5 and no study showed evidence of significant improvement in QoL. The observed MCBS scores were low, partly because the trials evaluated mainly comprise single-arm studies without QoL assessments, restricting to a maximum MCBS score of 3. **Conclusions:** Most systemic therapy trials in advanced STS did not confer substantial clinical benefit when evaluated using MCBS. Although randomized phase 3 trials remain the gold standard of treatment evaluation, clinical benefit evaluation of STS trials using tools such as MCBS may be useful. Incorporation of QoL evaluation, even in single-arm studies should be prioritized in metastatic STS trials. Research Sponsor: None.

First-in-human administration of CEB-01, a novel drug delivery implant matrix, in patients with recurrent or locally advanced retroperitoneal soft tissue sarcoma (RPS) after surgery: Preliminary safety and pharmacokinetics report. *First Author: José Antonio Gonzalez, Hospital de la Santa Creu i Sant Pau, Surgery Department, Barcelona, Spain*

Background: RPS local recurrence after radical surgery (SX) is frequent and a major cause of death. Locally delivered CHT by a biocompatible and biodegradable implant matrix (CEB-01) loaded with SN-38 and placed in the surgical bed during SX may increase local control and survival in RPS patients with reduced systemic toxicity. **Methods:** This is a multicentre, open label, first-in-human phase 1 trial comprising a dose-escalation phase (3 cohorts with total SN-38 doses of 9, 18 and 36 mg respectively), followed by an expansion cohort at the recommended phase 2 dose (RP2D). Recurrent or locally advanced RPS patients candidates for local surgery, with no option of systemic treatment, ECOG < 2, life expectancy > 6 months, and normal organ function are eligible. Primary objective is to determine RP2D, defined as the dose level at which less than 33% of patients present dose limiting toxicity (DLT) in a minimum of 6 at-risk patients during the first two weeks after SX. DLT is defined as any Grade $\geq$3 toxicity. Secondary objectives include safety, time to recurrence, biomarkers, pharmacokinetics (PK) and quality of life (QoL). Here we report preliminary safety, efficacy, and PK data for the initial patients enrolled. **Results:** First cohort of 9 mg SN-38 was completed in february 2021, with the inclusion of three patients with dedifferentiated liposarcoma, (grade 2-3) Patients were male, age 65 to 74, with ECOG of 0-1. Optimal SX were performed for recurrent/metastatic disease (2 patients) or locally advanced disease (1 patient) with complete (R0) and optimal (R1) outcomes. There were no surgical complications attributed to the SN-38 treatment . One patient suffered from grade 2 (Dindo Clavien classification) intestinal subocclusion due to SX complication resolved with medical treatment at day 5. Frequency and severity of adverse events (AE) was low. All the patients presented transitory abdominal discomfort and seroma. AEs consisted of one catheter infection and one hypomagnesemia, both grade 3. Only one treatment related AE (TRAE) consisting of alopecia grade 1 was reported. There were no DLTs observed during the first administrations of CEB-01 (9 mg SN38). SN38 and its glucuronidated SN-38 systemic levels were low, reaching a peak (Cmax) of 0.60 and 3.3 ng/mL at 2 and 6 hours respectively, and were detectable 27 days after CEB-01 implantation in the surgical bed, at 0.1 and 0.6 ng/mL respectively. **Conclusions:** CEB-01 biocompatible and resorbable implant matrix loaded with SN38 has proven to be safe upon first human administrations in RPS patients, with scarce low grade AEs and TRAE. Preliminary PK indicates low, prolonged, systemic SN-38 exposure as expected. Currently the second cohort of this trial is open for recruitment. Clinical trial information: NCT04619056. Research Sponsor: CEBIOTEX.

Multiomic analysis to reveal distinct molecular profiles of uterine and nonuterine leiomyosarcoma. *First Author: Tabitha Copeland, Rutgers-Robert Wood Johnson Medical School/CINJ, New Brunswick, NJ*

Background: Leiomyosarcoma (LMS) is a rare group of mesenchymal malignancies found in the uterus, retroperitoneum, skin, or other soft-tissue sites. Treatment for LMS is extrapolated from trials including both uterine (uLMS) and non-uLMS subtypes, although whether they respond similarly and have similar outcomes from treatment is not clear. We examined the molecular composition of LMS by site of origin to better inform future drug development and trial design. **Methods:** We reviewed 1115 specimens with LMS histology tested by Caris Life Sciences for targeted exome (NextSeq, 592 gene panel), whole exome, and whole transcriptome sequencing (NovaSeq). Specimens were stratified into uLMS, rpLMS (retroperitoneal), and otherLMS (non-uterine/retroperitoneal) subgroups based on tumor origin sites. Genomic data was analyzed for mutations, copy number aberrations, and fusions. RNA expression profiling included evaluation of individual genes and gene set enrichment analysis (GSEA). P-value adjustment performed by the Benjamini-Hochberg procedure. **Results:** The study cohort was comprised of 62.9% uLMS (n = 701), 14.9% rpLMS (n = 166) and 22.2% otherLMS (n = 248) specimens. Overall, LMS specimens most frequently harbored *TP53* (64%, n = 612), *ATRX* (30%, n = 219), *RB1* (22%, n = 156), and *MED12* (16%, n = 94) mutations, with these genes accounting for 74.4% (n = 1044) of all observed pathogenic/likely pathogenic mutations. *RB1* mutations were significantly less common in uLMS (15%) compared to rpLMS (30%, $p < 0.05$) and otherLMS (33%, $p < 0.01$), whereas *MED12* mutations were almost exclusive to uLMS (22% vs 1% rpLMS, 3% otherLMS, $p < 0.05$). *MAP2K4* copy number amplification were more common in rpLMS (22%, $p < 0.001$) and otherLMS (14%, $p < 0.182$) compared to uLMS (7%), with frequent co-amplification of nearby genes (*FLCN*, *GID4*, *SPECC1*, *GAS7*, *PER1*, and *AURKB*) located at chr17p11-13. Actionable gene fusions involving *ALK* (2.1%, n = 11), *FGFR1* (0.2%, n = 1), and *NTRK1/2* (0.2%, n = 1 each) were rare overall, with similar prevalence across subtypes. Genomic alteration rates were not significantly different between rpLMS and otherLMS subtypes. RNA expression profiling identified significant upregulation of PI3K/AKT/mTOR, DDR, WNT/Beta-Catenin pathway genes in non-uLMS. GSEA indicated several immune-related gene sets were enriched in rpLMS and otherLMS compared to uLMS. **Conclusions:** Comprehensive molecular profiling suggests that LMS originating from the uterus represents a molecularly distinct disease compared to other primary sites of origin. We identified key genomic patterns which have potential for targeted therapy. These data provide insight for the framework of future clinical trials designed to separate uLMS from non-uLMS histologies, although further subdivision does not appear to be warranted. Research Sponsor: Caris Life Sciences.

The efficacy and safety of anlotinib in refractory/recurrent/advanced pediatric solid tumors: A retrospective study. *First Author: Suying Lu, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Refractory and recurrent advanced pediatric solid tumors are short of effective treatment and with a dismal outcome, thus an urgent need for novel and effective treatment. The aim of the study is to evaluate the efficacy and safety of anlotinib, a novel and oral multi-target receptor tyrosine kinase inhibitor, in refractory or recurrent advanced pediatric solid tumors. **Methods:** The retrospective, single-institutional, observed study was conducted in Sun Yat-sen University cancer center in China. Refractory, recurrent, or advanced pediatric solid tumors patients treated with anlotinib between 2018 to 2020 were evaluated. **Results:** Forty-one patients and thirty patients were enrolled in the study to evaluated efficacy and safety, respectively. The objective response ratio (ORR) was 12.2% (95%CI 1.7-22.7): complete response (n = 0) and partial response (n = 5) (Table). The disease control rate (DCR) was 65.9% (95%CI 50.7-81). The median progression-free survival (PFS) was 2.87 months (95%CI 0.86-4.88). According to anlotinib treatment schedule, all patients were divided into three groups: anlotinib monotherapy (A, n = 16), anlotinib combined with immune checkpoint inhibitor treatment (A + ICI, n = 6), anlotinib combined with salvage chemotherapy (A + SC, n = 19). The ORR, DCR and median PFS for three groups were 6.3% (95%CI 7.1-19.6), 56.3% (95%CI 28.9-83.6), 2.43months, 16.7% (95%CI 26.2-59.5), 66.7% (95%CI 12.5-120.9), 1.13months, 15.8% (95%CI 2.3-33.8), 73.7% (95%CI 51.9-95.5), 2.87months, respectively. There was no significantly difference between three groups in aforementioned response index. The incidence rates of any grade and grade 3-4 adverse events were 80% and 20%, respectively. Bleeding (20%), hand-foot syndrome (13.3%), and diarrhea (13.3%) were the most common adverse events. Grade 3-4 adverse events include hypertension, hand-foot syndrome, diarrhea, anemia, and thrombocytopenia. There was no adverse events-related death. **Conclusions:** For heavily pretreated pediatric solid tumors, anlotinib may be an effective treatment with tolerable adverse events. Further prospective randomized controlled clinical study is warranted. Research Sponsor: None.

Treatment responses to anlotinib in refractory/recurrent advanced pediatric solid tumors.

Early results of intratumoral INT230-6 alone or in combination with ipilimumab in subjects with advanced sarcomas. *First Author: Matthew Ingham, Columbia University Irving Medical Center, New York, NY*

Background: Patients have limited treatment options following initial chemotherapy failure. INT230-6, a novel formulation of cisplatin (CIS) and vinblastine (VIN) with an amphiphilic cell penetration enhancer, is designed for intratumoral (IT) administration. Study IT-01 (BMS # CA184-592, NCT 03058289) evaluates INT230-6 alone or in combination with ipilimumab (IPI), an antibody to CTLA-4. INT230-6 dosing is set by a % of the volume of the tumor to be injected. The product has been shown to disperse throughout an injected tumor and diffuse into cancer cells. Cell death leads to recruitment of dendritic and T cells, the effect of which may be augmented by CTLA-4 inhibition as evidenced by increased efficacy of the combination in preclinical models. Historically, checkpoint inhibitors have limited activity in sarcoma. Considering the large volume of drug injected and retained in the tumor, coupled with immune infiltration on biopsies, RECIST response methodology may not capture the benefits of INT230-6 treatment. **Methods:** IT-01 is an open-label phase 1/2 study that is enrolling adult subjects with locally advanced, unresectable or metastatic sarcoma. INT230-6 was administered IT Q2W for 5 doses alone or with IPI 3mg/kg IV Q3W for 4 doses. The study objectives are to assess the safety and efficacy of IT INT230-6 alone and in combination with IPI. **Results:** 16 heterogenous sarcoma subjects (13 monotherapy, 3 IPI combination) having a median of 3 prior therapies (0, 8) were enrolled to date. The INT230-6 dose was up to 145 mL (72.5 mg of CIS, 14.5 mg VIN) in a single session (an amount of each agent in excess of standard IV doses). The most common ($>$ 20%) related TEAEs in sarcoma subjects (n = 16) were localized pain (63%), fatigue (38%), decreased appetite (31%), nausea (31%), and vomiting (25%) most of which were low grade; with only grade 3 TEAE above 5% being anemia (13%). There were no related grade 4 or 5 TEAEs. In 11 evaluable monotherapy subjects, the disease control rate (DCR = CR+PD+SD) was 82%. Basket studies of sarcomas, including chordoma, with Royal Marsden Hospital index (RMHI) scores of 2 or higher report median overall survival (mOS) of 4 months. In this study 75% of monotherapy subjects had a RMHI score of 2 and preliminary estimates of mOS was 21.3 (4.67, NA) months. Pilot immunohistochemistry analysis of 5 paired (pre- and 28 days post-dose) biopsy samples showed substantial tumor necrosis, reduction of viable cancer, a decreased cancer proliferation as measured by Ki67, and increased TILs. **Conclusions:** Preliminary data shows that INT230-6 administered intratumorally alone or in combination with ipilimumab is well-tolerated in this small, heterogenous sarcoma population. The preclinical cancer cell death and immune infiltration mechanism of action appears to translate to sarcoma subjects. There are early signs of efficacy, DCR and potentially OS, that need to be confirmed in randomized studies. Clinical trial information: 03058289. Research Sponsor: Intensity Therapeutics, Inc.

Regorafenib (R) in advanced solitary fibrous tumor (SFT): Results from an exploratory phase II clinical study. *First Author: Silvia Stacchiotti, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: R showed antitumor activity in a PDX model of dedifferentiated SFT (D-SFT), inducing a superior tumour growth inhibition than with other antiangiogenic agents (A), such as pazopanib (P) and axitinib (A). The efficacy of P and A in patients (pts) with advanced typical- (T-)/ malignant- (M-)SFT has been already confirmed in phase 2 clinical trials, but not in D-SFT. An exploratory phase 2 study was designed to investigate the activity of R in advanced SFT. **Methods:** An investigator-initiated exploratory phase 2 trial was started in December 2015 at the Istituto Nazionale Tumori, Milan, Italy, to evaluate the activity of R, 160 mg OD, 3 weeks on/1 week off, until progression or limiting toxicity. in $>$ 18 years old pts with advanced SFT. The target sample size was 16 evaluable pts; at least 3 responses were requested to reject the null hypothesis of 5% in favour of an alternative hypothesis of 30% (with type-I and type-II error rates fixed at the 10% level). Eligible pts had to have evidence of progression. Prior treatment with A was allowed. Centralized pathologic review was performed, distinguishing T-SFT, M-SFT and D-SFT subtypes. The primary end-point was the overall response rate (ORR) by Choi. Secondary end-points were ORR by RECIST, progression-free survival (PFS), overall survival (OS). **Results:** Enrolment was completed in February 2021. Eighteen pts were enrolled (D-SFT = 4; M-SFT = 13; T-SFT = 1). Four pts were naïve, 14 were pre-treated [12 with antiangiogenics (4 with $>$ 1 prior antiangiogenic line); 11 with cytotoxic agents]. Three pts are ongoing, 13 completed their treatment (11 = progression, 1 = toxicity, 1 = other). Fourteen pts are evaluable for response by Choi and RECIST (1 = screening failure; 1 = early discontinuation for toxicity before radiologic assessment; 2 = too early). A definitive dose reduction was required in 5 of 14 evaluable (35.7%) pts. The ORR by Choi was 42.9% (exact binomial 95% Confidence Interval [CI]: 17.7%-71.1%), with 6/14 (42.9%) partial responses (PR), 5/14 (35.7%) stable disease (SD) and 3/14 (21.4%) progressions (PD). Best responses by RECIST were: 1/14 (7.1%) PR, 10/14 (71.4%) SD, 3/14 (21.4%) PD. 5/6 pts responsive by Choi were pre-treated with another antiangiogenic. No responses were seen in the 3 D-SFT pts. At a m-FU of 23 months, m-PFS by Choi was 3.68 (IQR: 2.73-8.54) months, with 23.4% pts progression free at 1 year. m-PFS by Choi in responsive pts was 5.62 (IQR: 2.89 – 8.54) mos. Median OS was 15.7 (IQR: 7.35-not reached) months. **Conclusions:** R did not show a higher activity in D-SFT compared to P and A. The response rate was in the range observed with other A, but m-PFS was shorter. This may be due to discrepancies in pt populations and a high-rate of dose reductions with R. However, responses to R were seen also in pts previously treated with other A and almost one fourth of pts benefited from R for more than a year. Clinical trial information: 2015-002629-21. Research Sponsor: None.

A pilot study of the feasibility and utility of a fitness tracker to correlate activity level with patient reported outcomes (PROs) in sarcoma patients undergoing systemic therapy. *First Author: Elizabeth J. Davis, Vanderbilt University, Nashville, TN*

Background: The feasibility and utility of wearable devices is unknown in sarcoma patients (pts). Objective assessment of activity level, body composition, and PROs facilitate understanding of the tolerability and toxicity of cancer treatment. **Methods:** From 6/11-10/12/2020, we enrolled sarcoma pts receiving systemic therapy to a prospective study evaluating activity levels and sleep via a Fitbit Charge 3, body composition with the Inbody 570, and PROs using NIH PROMIS short forms (fatigue, pain, physical function, and sleep disturbance), the Generalized Anxiety Disorder Scale, and the Patient Health Questionnaire Depression Scale. Time on study was 12-16 weeks depending upon treatment. The Fitbit was worn continuously. Body composition and PROs were assessed every 3-4 weeks. Feasibility was defined as successful device wearing and data syncing. Data was collected through a cloud-based application, Fitabase. **Results:** 22 pts were approached and enrolled. Two pts did not complete the first study assessment due to disease progression and were excluded from analysis. 50% of pts were female. 90% of pts were white. Median age was 47 yrs (range 20-81). The most common histologies were Ewing sarcoma and leiomyosarcoma. 89.5% (17/19) of pts wore the Fibit for $>$3 weeks; median time was 68 days (5-112). 95% (19/20) of pts were able to sync data. Median step count was 2614 steps (376-19806). High step counts, defined as greater than the median, were associated with improved sleep (p=0.14) and physical function (p=0.22), and decreased pain (p=0.15), but these associations were not statistically significant. Low step counts, defined as lower than the median, were associated with skeletal muscle mass loss (p=0.22), but this was not statistically significant. **Conclusions:** Incorporating a fitness tracker is feasible in sarcoma pts receiving systemic therapy. It provides longitudinal, objective evaluation of activity levels and sleep patterns. Correlation of activity level with sleep, body composition, and PROs was limited due to small numbers; however, a larger prospective pilot study is ongoing. Research Sponsor: U.S. National Institutes of Health.

A patient reported outcomes of treatments for desmoid tumors: An international natural history study. *First Author: Danielle Braggio, The Desmoid Tumor Research Foundation, Suffern, NY*

Background: The Desmoid Tumor Research Foundation (DTRF) launched the natural history study (NHS) in 2017. At this time, there are no standard-of-care options for this rare sarcoma. The treatments, clinical descriptors, and the patient reported outcomes to pharmacologic agents are described here within. **Methods:** The web-based natural history study launched September 2017 in collaboration with the National Organization of Rare Disorders. It contains 15 surveys covering diagnostics, disease, treatment, care management, and quality of life. Treatment types included in the DTRF NHS were pharmacology, surgery, radiation, high-intensity focused ultrasound (HiFU), and active surveillance (watch and wait). **Results:** While surgery was once the primary intervention for desmoid tumor patients, the NHS participants reported that 47.6% had received active surveillance or no systemic treatment at diagnosis. This is most common for desmoid tumors located in abdominal wall (54/103; 52.4%). There were 87 reported cases of complete surgical resection, 38 incomplete resections, and 23 bowel resections. 9 amputations were reported; 8 participants reported recurrent disease following the removal of the limb. The non-surgical interventions, such as radiation and HiFU, were mostly described for participants with chest wall tumors (15 pts) and joints/extremities (10 pts). Many options for systemic therapies were described including sorafenib (44/284; 15.5%), sulindac (36/284; 12.7%), and anti-hormonal agents tamoxifen and toremifene (34/285; 10.9%) were described. Targeted agents, such as gamma secretase inhibitor, pazopanib, and sorafenib, were greater in the United States than the non-US country participants (21% vs 9%). Multiple lines of treatments were reported by 81 participants, surgery is greatest as the first intervention for all tumor locations (49/81, 60%), with the exception of those with head/neck tumors who received chemotherapy (6/11, 55%). Analysis has started to evaluate the efficacy of systemic treatments from these NHS data. The table describes the participant reported outcomes of anti-hormonal agents, chemotherapeutics, non-steroidal anti-inflammatories, and targeted agents. Both chemotherapies and targeted agents were reported to have 38.1% response rates from the participants with 34.3% and 23.8% of participants reported progressive disease on therapy, respectively. **Conclusions:** Desmoid tumor NHS study participants reported the use of many treatment modalities demonstrating a range of frequency of use by tumor location and efficacy. Data collection through the DTRF NHS is ongoing. Research Sponsor: The Desmoid Tumor Research Foundation, Other Government Agency, U.S. National Institutes of Health, National Organization of Rare Disorders (NORD).

	Tumor Shrinking/ Changing structure	Continued growth	Unknown Response
Anti-hormonal agents	8 (8.2%)	19 (18%)	26 (19.3%)
Chemotherapies	37 (38.1%)	36 (34.3%)	48 (35.6%)
Non-steroidal anti-inflammatories	15 (14.5%)	25 (23.8%)	49 (36.3%)
Targeted agents	37 (38.1%)	25 (23.8%)	12 (8.9%)

Treatment patterns, and survival of patients with metastatic undifferentiated pleomorphic sarcoma: A National Cancer Database (NCDB) study. *First Author: Hussain I Rangoonwala, Creighton University School of Medicine, Omaha, NE*

Background: Undifferentiated Pleomorphic Sarcoma (UPS) is regarded as one of the most common types of soft tissue sarcoma. Although prior studies have highlighted its metastatic potential, there have been no database studies that delineate the clinical/social characteristics and outcomes in UPS patients with metastatic disease. Utilizing the National Cancer Database (NCDB), we want to observe the complex interplay between treatment approaches and non-biologic modifiers. **Methods:** 737 patients diagnosed with metastatic UPS above the age of 17 years between 2004 and 2015 were identified utilizing the NCDB. Patients were identified with ICD-O-3 morphologic code 8830/3. Demographic factors (Race/ethnicity, biological sex, Median household income/education at zip code level, facility type, insurance) were studied in relation to the type of treatment they received: No treatment; chemotherapy only; chemotherapy and radiation therapy; chemotherapy and surgery; chemotherapy, surgery, and radiation; radiation therapy and/or surgery; and other treatments. Survival tables were utilized to generate 1-year and 3-year survival rates, and Kaplan-Meier method with associated log-rank list was used to examine the differences in unadjusted survival. **Results:** Approximately 17% of our cohort were left untreated, whereas 83% received treatment. Patients who were untreated were likely to be older, on Medicare, and had a Charlson-Deyo (CD) score of 2 or above. Patients who were more likely to receive treatment were younger educated males with private insurance, residing in areas of higher income, and receiving care at an academic program. Patients who only received chemotherapy were more likely to belong to areas with lower income and had a CD score of 0. Patients who received a combination of chemotherapy, surgery, and radiation therapy were more likely to belong to areas of high income, private insurance owners, and received care at an academic facility. Patients who received chemotherapy with surgery and without radiation therapy were more likely to be younger males from areas of highest income, and received care at an academic facility. Patients who had better unadjusted survival were younger educated patients on private insurance or Medicaid, with distant lymph nodes metastases at diagnosis, who received a combination of chemotherapy, radiation therapy and surgery at an academic program. Patients who had poorer unadjusted survival were untreated older patients on Medicare, and with bone metastases. **Conclusions:** This is one of the most comprehensive studies involving patients with metastatic UPS that analyzes demographic variables in relation to the treatment approach. Some of the major determinants that influence outcomes in these patients included age, insurance status, treatment at academic facility, CD score, and type of metastases at diagnoses. Research Sponsor: None.

A phase 2 study using ipilimumab, nivolumab, and trabectedin for previously untreated metastatic soft tissue sarcoma. *First Author: Erlinda Maria Gordon, Sarcoma Oncology Center, Santa Monica, CA*

Background: Sarcoma cells are most immunogenic earlier in the disease course and before treatment when the immune system can recognize and destroy them. Hypothesis: Immune checkpoint inhibitors would be most effective when given to previously untreated patients with metastatic soft tissue sarcoma. **Methods:** Eligible patients for this Phase 2 study are previously untreated patients $\geq$ 18 years of age with unresectable or metastatic soft tissue sarcoma, with measurable disease by RECIST v1.1. Immune checkpoint inhibitors Ipilimumab (I) and Nivolumab (N) were given with Trabectedin (T), a marine derived alkaloid with defined doses of I (1 mg/kg i.v. q 12 weeks), N (3 mg/kg i.v. q 2 weeks), and T (1.2 mg/m2 i.v. q 3 weeks). Primary endpoints: (1) Objective response rate by RECIST v1.1 via CT scan or MRI, (2) Progression-free survival (PFS): from first day of treatment to disease progression or death due to any cause; otherwise, it is censored at the time of last follow-up, and (3) Overall survival: from first day of treatment to death due to any cause; otherwise, it is censored at the time of last follow-up. **Results:** There were eighty-two evaluable subjects, having completed the first cycle of I, N, and T and have had a CT or MRI scan at the 6-week follow-up period. Best Overall Response by RECIST v1.1 = 7 CR (2 surgical CR), 9 PR, 54 SD, and 12 PD. Disease control rate was 85.4%. The median PFS was >6.4 (range: 0-32) months; 6-month PFS rate: 57.3%. The median OS was >12.0 (0-38) months; 6-month OS rate: 78.8%. Safety analysis: The most common Grade 3 TRAEs include increased ALT (26), anemia (11), increased AST (9), and fatigue (8). Common Grade 4 TRAEs include thrombocytopenia (2), increased AST (2), increased ALT (2), and increased CPK (2). There was one Grade 5 TRAE of rhabdomyolysis (1). **Conclusions:** Taken together, these results suggest that first-line combinatorial therapy with I, N, and T are (1) synergistic, and (2) may be equal or superior to, and safer than, standard first line therapy for advanced/metastatic soft tissue sarcoma. Clinical trial information: NCT03138161. Research Sponsor: Bristol-Myers-Squibb.

11563 **Poster Session**

Results of the phase 1b soft-tissue sarcoma (STS) portion of the global randomized, double-blind, placebo-controlled study of tazemetostat (TAZ) plus doxorubicin (DOX) as frontline therapy for advanced epithelioid sarcoma (ES). *First Author: Sant P. Chawla, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: ES is a rare, aggressive subtype of STS for which cytotoxic chemotherapy has limited effectiveness. TAZ, an FDA-approved EZH2 inhibitor, has shown single-agent clinical activity and a favorable safety profile in patients with metastatic or locally advanced ES. In preclinical studies, TAZ has shown synergistic antitumor activity with DOX, which is often used as frontline treatment for STS. Here, we present results of the phase 1b study (NCT04204941), designed to assess the recommended phase 3 dose (RP3D), safety, and efficacy of TAZ + DOX in patients with advanced STS. **Methods:** The open-label, phase 1b portion of this study enrolled adult patients with previously untreated advanced STS. A standard 3 + 3 design was used to assess TAZ 400 mg, 600 mg, and 800 mg orally twice daily in combination with DOX (75 mg/m^2 intravenously on day 1 of each cycle, for up to 6 cycles) as frontline therapy. Dose-limiting toxicities (DLTs) were predefined in the protocol. The RP3D of TAZ was determined by Scientific Review Committee review of the safety and pharmacokinetic data from the phase 1b trial, with a target DLT rate of $<$ 33%. **Results:** As of February 1, 2021, 16 patients are enrolled, including 2 with ES; 10 are still receiving TAZ + DOX and 6 have discontinued (5 due to disease progression, 1 due to patient withdrawal). The median age was 49.5 years (range, 2982) and all had unresectable STS. Median (range) time on treatment was 13 (0.151.1+) weeks across all dose levels evaluated. Two DLTs, both of febrile neutropenia, were observed, one in the TAZ 600 mg + DOX cohort (n = 1/6, 17%), and one in the TAZ 800 mg + DOX cohort (n = 1/3, 33%). When used in combination with DOX, the RP3D of TAZ was 800 mg. Grade 3 or 4 treatment-related treatment-emergent adverse events (TR-TEAEs) occurred in 13/16 (81.3%) patients. The most common ($\geq$ 20%) TR-TEAEs were neutropenia (n = 11, 69%), anemia (n = 10, 63%), fatigue (n = 10, 63%), stomatitis (n = 9, 56%), nausea (n = 8, 50%), febrile neutropenia (n = 7, 44%), constipation (n = 6, 38%), vomiting (n = 6, 38%), and decreased appetite (n = 5, 31%). TR-TEAEs were defined as attributable to either study agent. **Conclusions:** The combination of TAZ + DOX was generally well tolerated in this dose finding study in patients with advanced STS. The RP3D to be tested in the phase 3 randomized, double blind, placebo controlled study is TAZ 800 mg twice daily + DOX. The safety profile of this combination is consistent with the respective safety information for TAZ and for DOX. The TR-TEAEs include known toxicities of DOX or TAZ. Further comparison with DOX + placebo in the phase 3 trial will aid in assessing efficacy and safety of the combination of TAZ + DOX. The global phase 3 confirmatory trial will enroll patients with ES who have unresectable disease and have had no prior systemic therapy. Clinical trial information: NCT04204941. Research Sponsor: Epizyme, Inc.

Retrospective world-wide registry on the efficacy of immune checkpoint inhibitors in alveolar soft part sarcoma: Updated results from sixty patients. *First Author: Nadia Hindi, Institute of Biomedicine Research (IBIS)-Universitary Hospital Virgen del Rocio/CSIC/Universidad de Sevilla, Seville, Spain*

Background: Alveolar soft-part sarcoma (ASPS) is a highly metastasizing ultra-rare sarcoma subtype, frequently affecting young adults. Conventional cytotoxic drugs are not effective in ASPS, but antiangiogenics demonstrated significant improvement in tumor burden reduction and PFS in the only ever conducted comparative trial. Immune checkpoint (PD-1/PD-L1) inhibitors (ICI) are emerging promising drugs in the therapy of ASPS, from small reported retrospective and prospective series. A world-wide registry has been set up with the aim of exploring the efficacy of ICI in ASPS. **Methods:** Data from adult patients (pts) diagnosed with ASPS and treated with PD- 1/PD-L1 inhibitors for advanced disease in expert sarcoma centers from Europe, Australia and US was retrospectively collected. IRB approval was obtained. Demographics, data related to treatments and outcome were considered. Radiologic assessment was based on RECIST 1.1. Progression-free (PFS) and overall survival (OS) were calculated with Kaplan-Meier method. An updated analysis of this series is presented here. **Results:** Sixty ASPS pts (27 female/33 male) with a median age at diagnosis of 25y (range 3-61) were registered. Primary tumor arose in limbs in 47 pts (78%) and 41 pts (68%) were metastatic at diagnosis. 52/60 pts (87%) had received previous systemic therapy (including chemotherapy in 19 pts and antiangiogenics in 47pts), with a median of one previous line (0-6). All pts received ICI for metastatic disease. Immunotherapy regimens consisted of monotherapy in 31 pts (52%) and combination in 29 pts (48%) (23 with an antiangiogenic agent). 29/60 pts (48%) received ICI within a clinical trial. Among the 52 evaluable pts, there was 1 complete response (CR) and 20 partial responses (PR) (ORR 40.4%). After a median follow-up of 21 months -mos- (range 4-59), 37/60 pts have progressed to ICI, with a median PFS of 13.4 mos (95% CI 10.1-16.7). Eleven pts received a subsequent line of ICI with a median PFS of 26 mos (95%CI 0-57). 16 pts have died, being the median OS from ICI initiation 38 mos (95% CI 33-43). The 12-mos and 24-mos OS rates were 94% and 70% respectively. **Conclusions:** This registry constitutes the largest available series of ASPS treated with immune check-point inhibitors. Our results suggest that treatment with ICI provide long-lasting disease control and prolonged OS in pts with advanced ASPS, an ultra-rare entity with limited active therapeutic options. The results on subsequent ICI lines suggest a lack of cross-resistance among different ICI therapies. Research Sponsor: None.

Palbociclib (P) in patients (pts) with soft tissue sarcoma (STS) with *CDK4* amplification: Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Scott Schuetze, University of Michigan, Ann Arbor, MI*

Background: TAPUR is a phase II basket study evaluating anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in a cohort of STS pts with *CDK4* amplification treated with P are reported. **Methods:** Eligible pts had advanced STS, no standard treatment options, measurable disease, ECOG PS 0-2, and adequate organ function. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts received P at 125 mg orally once daily for 21 days, followed by 7 days off until disease progression. Pts matched to P had *CDK4* amplification and no *RB* mutations. Simon 2-stage design tested the null disease control (DC) - defined as partial (PR), complete response (CR) or stable disease at 16+ weeks (SD 16+) - rate of 15% vs. 35% (power = 0.85; α = 0.10). If $\geq$2 of 10 pts in stage 1 have DC, 18 more pts are enrolled. If $\geq$7 of 28 pts have DC, the null DC rate is rejected. Secondary endpoints are progression-free survival (PFS), overall survival (OS) and safety. **Results:** 29 pts (66% male) with STS with *CDK4* amplification were enrolled from July 2016 to Nov 2019. 1 pt was not evaluable and excluded from efficacy analyses. Demographics and outcomes are summarized in Table. One pt with partial response (PR) and 12 pts with SD16+ were observed for DC and objective response (OR) rates of 48% (95% CI: 31%, 62%) and 3.7% (95% CI: 0.1%, 19%), respectively, and the null DC rate of 15% was rejected ($p<0.001$). 9/13 pts with DC continued on treatment for >32 weeks. 14 pts had at least one grade 3-4 AE at least possibly related to P with the most common being low WBC/platelets. Other grade 3 AEs included increased alanine aminotransferase, anemia, and fatigue. **Conclusions:** Monotherapy P demonstrated antitumor activity in heavily pre-treated pts with STS with *CDK4* amplification. Additional study is warranted to confirm the efficacy of P in pts with STS with *CDK4* amplification. Clinical trial information: NCT02693535. Research Sponsor: Pfizer.

Critical impact of radiotherapy protocol compliance and quality in the treatment of retroperitoneal sarcomas: Results from the 62092-22092 STRASS trial. *First Author: Rick L.M. Haas, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The EORTC 22092-62092 STRASS trial failed to detect a superiority of neoadjuvant radiotherapy in patients with retroperitoneal sarcoma as compared to surgery alone. As radiotherapy (RT) was the experimental treatment, a comprehensive quality assurance program (RTQA) has been included in the study protocol in order to detect and correct potential RT deviations. We report here the overall trial RTQA results and its potential impact on patient's outcomes in this international phase III trial. **Methods:** Plans from all patients randomized to the experimental preoperative RT arm were submitted to a multidisciplinary RTQA team, consisting of medical physicists and radiation-oncologists. Target volume parameters and tumor dose coverage were prospectively reviewed by the RTQA team but not all plans were made compliant. In order to evaluate the impact on oncological outcomes, a composite endpoint, overall RT compliance status, was created; patients were classified into two major groups: RT compliant (RC) group and non-compliant (NRC) group, defining whether RT was as concisely per protocol or not. This composite endpoint combined the information related to PTV coverage, target delineation, total dose received and overall treatment time. Both abdominal recurrence-free survival (ARFS) and OS were compared between RC and NRC patients using Cox's proportional hazard model adjusted for age, sex, WHO performance status, tumor grade, histological subtype and tumor size at baseline (millimeters). **Results:** After final review, 75.2% (94 out of 125) of patients had compliant RT plans (65.6% were already compliant at first submission to RTQA team and 9.6% were made compliant after review). Most patients in the NRC (77.4%) had deviations linked to incorrect target volume delineations. 3-year ARFS was 67.2% (95% Confidence interval (CI): 58.0 – 77.8%) and 48.4% (34.3 – 68.2%) for RC and NRC group, respectively (adjusted HR: 2.64, 95% CI: 1.38 – 5.07, p = 0.003). Corresponding OS at 3 years was 89.9% (95% CI: 83.6 – 96.3%) and 75.4% (95% CI: 61.9 – 91.8%) in the RC and NRC group with a trend in favor of RC (adjusted HR: 2.76, 95% CI: 0.91 – 8.43, p = 0.074). **Conclusions:** To our knowledge, this is the first RTQA evaluation of a phase III sarcoma trial. The data suggests a significant benefit in terms of ARFS and a trend for OS in favor of the RT compliant group. RTQA in prospective clinical trials, investigating new RT techniques, dose levels and indications, continues to be an important and integral part of trial designing. Funding Source: EORTC, EORTC Cancer Research Fund, EUROSARC FP7 278472 and Kom op tegen Kanker (Stand up to Cancer), the Flemish Cancer Society. A phase 2 study of talimogene laherparepvec, nivolumab, and trabectedin (TNT) in advanced sarcoma. *First Author: Neal Shiv Chawla, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Combination trabectidin (T) and nivolumab (N) has been shown to be a safe and effective therapy in soft tissue sarcoma (STS). Intratumoral injection of talimogene laherparepvec (TVEC) has a local oncolytic effect, and increases immune response via enhanced recruitment of antigen presenting cells, and thereby cytotoxic immune response. This study aims to determine if the addition of TVEC to combination trabectedin and nivolumab is effective and safe in advanced sarcoma. **Methods:** Eligible patients include patients $\geq$ 18 years of age with locally advanced unresectable or metastatic STS, measurable disease by RECIST v1.1, and at least one accessible tumor for TVEC intratumoral injection. N (3 mg/kg i.v. q 2 weeks), T (1.2 mg/m^2 i.v. q 3 weeks) and TVEC (1x10e^8 PFU/ml q 2 weeks depending on tumor size) were administered. A test dose of TVEC (1x10e^6 PFU/ml) was initially given, followed three weeks later by full dose TVEC. Primary endpoint: Progression-free survival (PFS); Secondary endpoints: (1) Best overall response during treatment period, (2) PFS rate at 6 and 9 months, (3) Overall survival (OS) rate at 6, 9, and 12 months, (4) Incidence of conversion from unresectable to resectable tumor, and (5) Incidence of treatment-related adverse events. Interim. **Results:** There were 36 evaluable subjects under the Modified Intention-to-Treat (MITT) population, having completed the first cycle of TNT and a CT or MRI scan at the 6-week follow-up period. The most common histological subtypes include leiomyosarcoma (9), liposarcoma (5), spindle cell sarcoma (3), pleomorphic sarcoma (2), Ewing's sarcoma (2), and other (5). Median number of prior lines of therapy was 4 (range 1-8). Best Overall Response by RECIST v1.1 = 3 PR, 27 SD, 5 PD. One patient, with previously unresectable disease was taken for resection and was found to have 100% necrosis on surgical pathology. Disease control rate (CR+PR+SD) was 86.1%. The median PFS was 5.5 (range: 1-18) months; 6-month PFS rate: 62.1%. Median PFS on therapy immediately preceding this trial was 2.0 months (range = 1-14 months). There were 47 evaluable subjects for OS analysis under the Intention-to-Treat (ITT) population having received at least one dose of T and N. The median OS was 9.0 (range 0-20) months; 6-month OS rate: 73%. Safety analysis: There were 47 evaluable subjects under the ITT population. 28% of these patients experienced ^{3}1 SAE. The most common grade 3/4 TRAEs include anemia (12), increased ALT (8), fatigue (4), thrombocytopenia (4), neutropenia (4). There were no grade 3/4 TVEC injection site reactions. 22% of patients in the MITT cohort remain on study. **Conclusions:** These results suggest that combination therapy with TNT appears to be as effective as standard therapy, with no new safety signals seen. Furthermore, median PFS exceeded that of the immediately preceding lines of therapy in this heavily pre-treated cohort. As data matures, further data will be reported. Clinical trial information: NCT03886311. Research Sponsor: Partial funding by Amgen.

Evaluation of homologous recombination deficiency (HRD) score and immuno-tumor microenvironment (iTME) as biomarkers of soft tissue sarcoma (STS) survival and response to immune checkpoint inhibitor therapy. *First Author: Chenlu Zhang, Department of Oncology, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Soft tissue sarcoma (STS) are highly heterogenous in both histology and underlying genetic alterations, resulting in heterogenous outcomes of standard therapy. With recent stride of immunotherapies in oncology it is crucial to find the optimal match of the new therapies to disease subtypes. HRDScore and iTME parameters are two top candidate biomarkers to predict clinical outcomes in complex diseases such as STS. **Methods:** We prospectively profiled 102 Chinese STS patients who had received more than 1 line of prior treatment, mainly chemo-drugs. We then classified the patients according to their HRDScore (calculated from WES data using the Richardson method, ref. Telli M.L. et al. Clin. Cancer Res. 2016) and iTME parameters (calculated from RNAseq data using CIBERSORT method). Lastly, we tested the correlation of HRDScore or iTME with patient survival and clinic outcomes of anti-PD-1/L1 based combination therapy. **Results:** The histological subtypes of the patients included 32 LMS, 44 LPS, and 26 others (such as UPS, clear cell, myxofibrosarcoma, uterus LMS etc.). The top mutation genes (frequency > 5%) included TP53 29%, KMT2C 16%, NOTCH2 9%, ATRX 8%, NF1 8%, RB1 8% and PTEN 6%. The patients could be classified to HRD-high or HRD-low (HRDScore > or < = 42). Alternatively, unsupervised clustering of iTME revealed three patient subgroups (named iTME-I, -II, and -III). While all the three groups are characterized by a generally suppressed immune environment, iTME-I have high proportion of M0 macrophages and median M2 macrophages; iTME-II have high proportion of M2 macrophages but low M0 cells; and iTME-type III are low in both M0 and M2 cells. No significant M1 cells present in all the three iTME groups. Patient survivals were correlated with the iTME types but not HRDScore in Kaplan-Meyer analysis. The trend of survival time was iTME-III > iTME-II > iTME-I, with an HR = 0.156 for iTME-III over iTME-I (p = 0.008, log-rank test). Treatment response of anti-PD-1/L1 based combination therapies also showed a positive correlation to iTME-III, but not HRDScore although the small sample size prevented a definitive conclusion. Clinical evaluation of the 22 patients who received anti-PD-1/L1 therapy showed 1 PD (20%) and 4 SD/PR (80%) in iTME-III, 4 PD (40%) and 6 SD/PR (60%) in iTME-II, and 1 PD (33%) and 2 SD (67%) in iTME-I. **Conclusions:** iTME is a better biomarker than HRDScore in STS for survival and treatment outcomes. Differential Infiltration of M0 and M2 macrophages can distinguish patients with different survival and response to anti-PD-1/L1 combination therapy. The iTME subtypes may be used for treatment screen of combination immunotherapy but larger and randomized clinical studies are required to validate the discovery. Research Sponsor: None.

Prospective cohort study of Kaposi sarcoma treated under real-world conditions in Malawi. *First Author: Edwards Kasonkanji, Research, Lilongwe, Malawi, Malawi*

Background: Kaposi sarcoma (KS) is the leading cancer in Malawi (34% of cancers). Outside of clinical trials, prospective KS studies from sub-Saharan Africa (SSA) are few and limited by loss to follow up. We conducted a prospective KS cohort study of standard of care bleomycin/vincristine (BV) at Lighthouse HIV clinic, in Lilongwe, Malawi. **Methods:** We enrolled pathologically confirmed, newly diagnosed, HIV+ KS patients from Feb 2017 to Jun 2019. We collected clinical and treatment characteristics, toxicity, and outcomes of KS with follow-up censored Jun 2020. Patients were treated with bleomycin (25 mg/m^2) and vincristine (0.4 mg/m^2) every 14 days for a planned maximum of 16 cycles. STATA v13.0 was used to calculate descriptive statistics and Kaplan Meier survival analysis. Toxicity was graded using NCI CTCAE v5.0. **Results:** We enrolled 138 participants, median age 36 (IQR 32-44) and 110 (80%) male. By ACTG staging, 107 (78%) were T1 (tumour severity), 46 (33%) were S1 (illness severity) and 46 (33%) had Karnofsky performance status ≤70. Presenting symptoms included edema in 69 (53%), visceral disease in 9 (7%), and oral involvement in 43 (33%). Prior to KS diagnosis, 70 (51%) participants were aware of being HIV+ for median 17 months (IQR 6-60) and had been on ART for median 16 months (IQR 6-60). Median CD4 count was 197 (IQR 99-339), median HIV-viral load was 2.6 log copies/mL (IQR 1.6 – 4.8) and 57% were HIV-suppressed (< 1000 HIV copies/ml). The median number of cycles was 16 (IQR 7-16). 62 (45%) participants missed at least one dose due to stock out. Amongst patients with missed doses, the median number was 3 (IQR 2-4) for bleomycin and 2 (IQR 1-3) for vincristine. 14 (10%) participants experienced at least one reduced dose due to toxicity. 5 (4%) participants suffered grade ≥3 anaemia, 13 (9%) grade ≥3 neutropenia, and one participant had grade 4 bleomycin-induced dermatitis. There was no reported grade ≥3 bleomycin lung toxicity or vincristine-induced neuropathy. Of 115 evaluable participants, responses at the end of therapy were: complete response in 52 (45%), partial response in 27 (23%) stable disease in 5 (4%), and progressive disease in 31 (28%). Median duration of follow-up was 20 months. At censoring, 69 (50%) were alive, 36 (26%) dead, and 33 (24%) lost to follow-up. Overall survival is shown Table as crude and worst-case scenario; worst-case assumes all participants lost to follow up died. **Conclusions:** Here, we present one of the most complete characterizations of KS presentation and treatment from SSA. As in other studies from the region, the majority of patients presented with advanced disease, chemotherapy stock-outs and loss to follow up were common, and mortality was high. Studies are planned to understand the virologic characteristics, improve therapies, and better implement existing therapies. Research Sponsor: U.S. National Institutes of Health.

Crude Survival, % (95% CI)	
1 year	76 (67-83)
2 year	70 (60-78)

11570 **Poster Session**

Active surveillance in primary desmoid tumor (DT): A prospective observational study. *First Author: Chiara Colombo, Department of Surgery, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In recent years evidence of long term stabilization and spontaneous regression of primary sporadic DT resulted in a paradigm shift towards more conservative approaches. We present herein the results of an observational study aimed at prospectively assess the behavior of primary sporadic DT initially managed by active surveillance and its relation to *CTNNB1* mutational status. **Methods:** This is an Italian prospective, multicenter, observational study (NCT 02547831) to evaluate primary sporadic DT behavior in patients (pts) >16 years with primary naive or incompletely resected and measurable disease, at any site, with *CTNNB1* mutational status available. Pts were assessed by contrast enhanced MRI or CT scan at baseline, at 3, 6, 9, 12 months, then every 6 months until the third year. Tumor changes were assessed by RECIST. In case of dimensional or symptomatic progression active treatment could be proposed on an individualized basis*CTNNB1* mutational status was obtained in all patients by Sanger and deep sequencing was performed in wild-type cases. Primary end-point was progression-free survival (PFS) at 3 yrs. Treatment-free survival (TFS) was also analyzed. PFS and TFS were calculated using survival analysis methods, including Kaplan-Meier plots, log-rank test for survival curves comparison, and Cox proportional-hazard multivariable regression (age, size, anatomic site and *CTNNB1* mutational status). **Results:** From April 2013 to February 2018 108 pts were included (82% female, 18% male); median age was 39 (interquartile range, IQR 34-48) and median size 50 mm (IQR, 40-80 mm). Tumor location was: 4/108 (4%) = head&neck, 25/108 (23%) = trunk, 59/108 (55%) = abdominal wall, 3/108 (3%) = intra-abdominal, 17/108 (16%) = extremities. *CTNNB1* mutations were as follow: T41A 54/108 (50%), S45F 13/108 (12%), WT 20/108 (19%), other mutations 21/108 (19%). At a m-FU of 32.3 months, the 3-year PFS was 54.5% (95% CI, 44.9%-66.1%). 42/108 (39%) pts showed a RECIST progression, with equal distribution among the different anatomic sites. None of the variables analyzed were associated to PFS. Spontaneous regression was initially observed in 27/108 (25%) patients, while it followed dimensional progression in another 33/108 (30%). 35/108 (32%) pts received active treatment, 18/42 (43%) after RECIST progression and 17/66 (26%) after symptomatic progressions. TFS at 36 months was 65.9% (95% CI, 57.3%-75.9%). S45F mutation, larger tumor size and extremity location were associated to a shorter TFS. No dimensional or symptomatic progression were observed after 36 months of FU. **Conclusions:** Active surveillance was marked by spontaneous regressions in 60/108 (55%) pts. An active treatment was needed in 32%. If no events occur after 3 yrs of FU, more relaxed FU schedules can be considered given the low risk of subsequent progression. Attention should be paid to patients with DT located to the extremity and/or carrying a S45F mutation. Clinical trial information: NCT 02547831. Research Sponsor: Ricerca Finalizzata- Ministero della Salute.

11571 **Poster Session**

Growth rate and site of pulmonary metastasis to predict lung relapse and overall survival in patients affected by bone and soft tissue sarcomas (B-STS). *First Author: Lorenzo D'ambrosio, Ospedale Cardinal Massaia, Asti, Italy*

Background: Despite surgically resectable pulmonary metastases may lead to cure patients with B-STS (Chudgar NP 2017), a substantial proportion of patients will eventually relapse. Presently, patient selection is based on unique organ involvement, number of metastases, interval between previous surgery and pulmonary progression or relapse. We assessed the impact of anatomical site of metastasis into the lung (as if the pleural site might ease further tumor spreading) and nodule growth rate as additional predictive/prognostic factors of lung progression-free survival (L-PFS) and overall survival (OS). **Methods:** In our prospectively collected database, we retrospectively evaluated patients operated for B-STS pulmonary progression at 3 different centers from 2005 to 2019. Beyond patients' clinical features at both baseline and disease progression in the lungs, we focused on whether the relapse occurred into the parenchyma or nearby the pleura (Welter S 2012); secondly, we estimated lung metastasis growth rate, defined as tumor doubling time (TDT) (Nakamura T 2011). Statistical analyses were carried out with IBM SPSS (v. 20.0). Survival outcomes were estimated by Kaplan-Meier method. Hazard ratios (HR) were estimated by Cox regression. Multivariate analysis was performed for both L-PFS and OS according to Cox proportional hazard model. All tests were 2-sided with their corresponding 95% confidence intervals (CI95%). **Results:** We identified 138 patients who underwent lung metastasectomy [(F=66 (48%); median age at surgery 50 (14-78)]. Median PFS and L-PFS were 8.7 months (CI95% 6.6-10.9) and 8.6 months (CI95% 6.2-11.0), respectively. Median OS was 40.6 months (CI 95% 32.8-48.5). Univariate analysis showed a statistically significant impact of the following variables for both L-PFS and OS: ECOG 0, nodule number <3, being disease-free after first-line treatment, no pleural involvement, and TDT >40 days. Disease-free interval ≤ 24 months and absence of metastases at diagnosis showed significant correlation with L-PFS and OS, respectively. At multivariate analyses the following variables retained statistical significance for L-PFS: TDT >40 days (HR 0.53, CI95% 0.31-0.93, p=0.028); nodule number <3 (HR 0.54, 95%CI 0.29-0.99, p=0.048), no pleural involvement (HR 0.39, CI95% 0.22-0.70, p=0.001); and for OS: TDT >40 days (HR 0.36, CI95% 0.18-0.72, p=0.004), nodule number <3 (HR 0.35, 95%CI 0.18-0.71, p=0.004), no pleural involvement (HR 0.49, CI95% 0.24-0.98, p=0.045), and ECOG 0 (HR 0.29, 95%CI 0.14-0.59, p=0.001). **Conclusions:** Acknowledging its retrospective nature and the need for an external validation, our series highlights the key-role of the anatomical site of relapse within the lung and the impact of tumor growth rate. If confirmed, these two clinical parameters should be factored in the decision making on performing pulmonary metastasectomy. Research Sponsor: None.

Immune contexture in high-risk soft tissue sarcomas (STS): A planned analysis of the ISG-STS-1001 randomized trial. *First Author: Sandro Pasquali, Department of Surgery, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: The characteristics of immune contexture and its prognostic and predictive value in STS is left to be understood. This planned analysis of the ISG-STS-1001 trial, which compared neoadjuvant anthracycline + ifosfamide (AI) vs a histology-tailored (HT) chemotherapy (ChT), was aimed at characterizing the immune contexture after neoadjuvant ChT and investigating any association with the risk of recurrence. **Methods:** Patients registered in the ISG-STS-1001 study (ID: NCT01710176) were included if they had tumor tissue available for Tissue MicroArray (TMA), which was performed in the area of the surgical specimen with the highest lymphocyte infiltrate. The following markers were analyzed with IHC and measured quantitatively: CD3, CD8, PD1, GranzymeB, Foxp3, CD20, CD163, and PDL1. The T-Distributed Stochastic Neighboring Entities (t-SNE) analysis was used to account for the co-expression of IHC markers in each tumor. The prognostic value of each marker for disease-free survival (DFS) was assessed. **Results:** This analysis was conducted in 256 of 435 study patients. AI and HT neoadjuvant ChT did not result in any different distribution of immune contexture. Conversely, differences were observed between 'complex' karyotype STS (ck-STS: LMS, MPNST, UPS, MFS, pleomorphic liposarcoma, and pleomorphic rhabdomyosarcoma) and 'simple' karyotype STS (sk-STS: MLPS and SS). Ck-STS were enriched in both CD3+ and CD8+ cells compared to sk-STS. These cells displayed an heterogeneous distribution and were dispersed inside the tumor nest, keeping direct contact with sarcoma cells. Ck-STS also displayed an enrichment in Granzyme B+, and CD163+ cells. PDL1+ cells were occasionally identified and were more frequent in ck-STS, suggesting an immune-related expression. Most STS were negative for CD20+ cells, however, when present these cells were highly represented and organized in tertiary lymphoid-like structure. The t-SNE generated plot clustered tumors, the 'cold' mainly including sk-STS and the 'hot' mainly composed by ck-STS. In the 'hot' group, a cluster of tumors displayed an immune infiltrate enriched with a high number of CD3, CD8, GranzymeB, PD-1, and PDL-1+ cells. When the prognostic value of the immune markers was investigated, the presence of CD20+ cells was the only independent prognostic factor for DFS (HR=0.68, 95%CI 0.52-0.91) in a histology-stratified estimate adjusting for tumor size in cm (HR=1.07, 95%CI 1.03-1.12) and patient age (HR=1.0, 95%CI 0.97-1.02). **Conclusions:** Immune contexture differed across sarcoma histologies after neoadjuvant ChT, rather than across the two study arms, with ck-STS being marked by a rich immune contexture. While a CD20+ infiltrate was found to be an independent prognostic factor for a better outcome, further analyses are in progress on the prognosis of patients with the richest immune contexture. Clinical trial information: NCT01710176. Research Sponsor: EUROSARC FP7 278472, LYRICAN (INCA-DGOS-INSERM 12563), DEPGYN (RHU4).

VAC temporization pending final margins after suprafascial myxofibrosarcoma excision to reduce the rate of local recurrence. *First Author: Mitchell Stephen Fourman, Massachusetts General Hospital, Boston, MA*

Background: The microinvasive nature of suprafascial myxofibrosarcoma complicates the accuracy of intraoperative margin assessment, and tumor bed resections after soft tissue reconstruction are unreliable. For the past 3 years we have temporized the excised tumor bed with a wound VAC, delaying soft tissue coverage until final negative margins were achieved. Here, we compare the oncologic/surgical outcomes of suprafascial myxofibrosarcomas managed with VAC temporization (VT) with single-stage excision/reconstruction (SS). **Methods:** We retrospectively studied suprafascial myxofibrosarcomas managed from 1/1/2000 to 1/1/2019 who received neoadjuvant or adjuvant radiation and had at least 2-years of oncologic follow-up at a tertiary referral cancer center. Our primary outcome was local recurrence. Comparisons were performed using Fisher's Exact Test or Students t-test. A p-value < 0.05 was considered significant. **Results:** Fifty-three patients (18 VAC temporized, 35 single stage) were included. While VT patients were older (74.9 ± 10.2 vs. 63.9 ± 13.6, p = 0.003), treatment groups did not significantly differ with respect to comorbidity, tumor volume, stage and grade. VT patients had significantly fewer local recurrences (5.6% vs. 28.6% after SS, p = 0.048) and R1 resections that required an unplanned readmission for tumor bed re-excision (0% vs. 37.1% after SS, p = 0.002). VT required more total surgeries (2.8 ± 0.9 vs. 1.8 ± 0.9 for SS, p = 0.0002). Post-operative infectious and wound complications were equivalent (Table). **Conclusions:** Our VAC temporization strategy had a significantly lower LR than SS treatment. While high quality multi-institutional validation is required, VT may represent a paradigm shift in the management of myxofibrosarcoma. Research Sponsor: None.

Patient reported outcomes in patients with desmoid type fibromatosis. *First Author: Vikas Garg, All India Institute of Medical Science (AIIMS), New Delhi, India*

Background: Desmoid type fibromatosis (DTF) is a rare benign neoplasm with infiltrative growth and high local recurrences. Due to long disease course, unpredictable growth pattern, and low mortality, using only survival outcomes may be inappropriate. In this study we assessed the impact of DTF on health related quality of life (HRQoL). **Methods:** This was a cross-sectional study done in patients with DTF. The study participants were asked to fill the EORTC QLQ-C30, GAD-7 and *PHQ-9 questionnaires* to assess HRQoL, anxiety and depression. Outcomes were also compared with healthy controls. **Results:** 204 subjects (102 DTF patients and 102 healthy controls) were recruited. Study parameters have been summarized in Table. Appendicular skeleton (limbs + girdle) was most commonly involved in 59 % patients and abdominal wall or mesentery was involved in 22.5 %. Patients have received median of 2 lines of therapy. 54 % patients were currently on sorafenib and 41 % were under active surveillance. Mean global health status in DTF patient 65.58 ± 22.64, was significantly lower than healthy controls. Similarly, DTF patients scored low on all functional scales except cognitive functioning. Symptom scale showed significantly higher symptom burden of fatigue, pain, insomnia and financial difficulties. Anxiety & depression was observed in 39.22 % and 50 % of DTF patients respectively. DTF patients had higher rates of mild, moderate and severe anxiety and depression compared to healthy controls. No difference was observed based on site of disease. **Conclusions:** DTF patients have significant symptom burden, poor functioning, and heightened anxiety and depression. Patient reported outcomes should be routinely used to assess treatment efficacy in DTF patients. Research Sponsor: None.

Difference in HRQoL between healthy controls & DTF patients.

TPS11575 **Poster Session**

Phase II trial of olaparib in combination with ceralasertib in patients with recurrent osteosarcoma. *First Author: Suzanne J. Forrest, Dana-Farber/ Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Osteosarcoma is the most common primary bone tumor, occurring in children, adolescents, and young adults. In contrast to advances in treatment for most childhood cancers, there have been no significant improvements in osteosarcoma outcomes in the past 40 years. Forty percent of osteosarcoma patients will, at some point, have advanced disease which has a very poor outcome with a 5-year overall survival of approximately 20%. Genomic alterations and signatures associated with sensitivity to treatment with DNA damage response (DDR) inhibitors are observed frequently in osteosarcoma. Many osteosarcomas have a unique mutational signature (signature 3) similar to that seen in BRCA1 deficient cancer and response to PARP inhibitors has been seen in osteosarcoma cell lines. Additionally, ATRX, a protein involved in the alternative lengthening of telomeres (ALT), is often inactivated in osteosarcoma. Defects in the ALT pathway may sensitize tumor cells to ATR inhibitors and osteosarcoma cell lines have been shown to be sensitive to ATR inhibition. In vitro susceptibility of osteosarcoma cell lines to ATR and PARP inhibitors, the presence of mutations in genes involved in DDR and the presence of signature 3 in a subset of osteosarcomas serves as the basis for the development of this trial. **Methods:** This is an ongoing open label, multicenter, phase II clinical trial to evaluate the clinical activity of PARP inhibitor, olaparib, in combination with ATR inhibitor, ceralasertib, in 2 cohorts of patients aged 12-40 with recurrent osteosarcoma (NCT04417062). Patients with unresectable disease are enrolled into Cohort 1. Patients with resectable disease limited to the lung are enrolled into Cohort 2. Patients in both cohorts receive olaparib 300mg orally twice a day on days 1-28 and ceralasertib 160 mg orally once a day on days 1-7 of a 28-day cycle (adult maximum tolerated dose for the combination). For patients in Cohort 2, study treatment also includes surgical resection of lung metastases at protocol-specified timepoints. Patients can remain on treatment for up to 2 years if they have not progressed. For Cohort 1, the primary objective is to determine whether the combination treatment improves the 4-month event-free rate as compared to a historical benchmark from Children's Oncology Group (COG) trials using a Simon's two-stage design. In the first stage, ≥3 of 19 patients must be event-free at 4 months to proceed to stage 2. Enrollment into Cohort 2 continues as long as Cohort 1 enrollment is ongoing. For Cohort 2, the primary endpoint is the submission of paired pre- and post-treatment tumor samples for correlative studies. Secondary endpoints include objective response rate, event-free survival, and overall survival. Integrated correlative studies will assess tumor tissue for biomarkers of treatment response and measure circulating tumor DNA longitudinally. Enrollment began November 24, 2020 and is ongoing. Clinical trial information: NCT04417062. Research Sponsor: The Osteosarcoma Institute.

TPS11576 **Poster Session**

REGOSTA: A randomized, placebo-controlled, double-blinded, multicenter study evaluating the efficacy and safety of regorafenib (REGO) as maintenance therapy after first-line treatment in patients (pts) with osteosarcoma (OS) and non-osteosarcomas (non-OS) of bone (non-Ewing, non-chondrosarcomas and non-chordomas). *First Author: Florence Duffaud, La Timone University Hospital, Marseille, France*

Background: Pts with OS and non-OS of bone are treated with a multimodal sequence therapy of neoadjuvant chemotherapy (CT), surgery and adjuvant CT, followed by a close surveillance until recurrence. At recurrence, the prognosis remains poor with objective response rates of 3-29%, and a median Progression-Free Survival (PFS) of less than 4 months in OS. There is a clinical need to reduce the risk of recurrence after the initial treatment sequence. The REGOBONE study reported a significant clinical benefit of regorafenib compared to placebo in patients with relapsed OS (median PFS: 16.4 versus 4.1 weeks). **Methods:** This multicenter trial is ongoing to study the efficacy and safety of maintenance REGO in pts > = 16 years, with complete remission after initial treatment sequence of their bone sarcoma. 168 pts will be randomly allocated in a 1:1 ratio to receive either oral REGO or its matching placebo (control arm) at a daily dose of 120mg, continuously and for a maximum of 12 months. Randomization will be stratified according to the following risk factors: metastases (mets) at diagnosis and/or poor response to neoadjuvant CT versus no mets at diagnosis and good response to neoadjuvant CT. The primary objective is to compare the efficacy (Relapse-Free Survival) between the 2 arms. The expected 3-year RFS rates are 55% in the control arm and 74.6% in the REGO arm (HR = 0.5). 66 events will provide 80% power to show significant improvement in RFS, using a 2-sided log-rank test at a 5% level. Secondary endpoints include Time to Treatment Failure, Overall Survival, Quality of Life, safety profile, and compliance to treatment. Radiological endpoints will be evaluated using the RECIST 1.1. Translational objectives will be to identify predictive biomarkers for efficacy of REGO as maintenance therapy using liquid biopsies. As of Feb 1st, 2021, 3 patients have been randomized. 15 sites of the French Sarcoma Group will participate. Clinical trial information: NCT04055220. Research Sponsor: Bayer Healthcare.

TPS11577 **Poster Session**

Phase 1 expansion trial of the LSD1 inhibitor seclidemstat (SP-2577) with and without topotecan and cyclophosphamide (TC) in patients (pts) with relapsed or refractory Ewing sarcoma (ES) and select sarcomas. *First Author: Damon R. Reed, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Several sarcomas possess chromosomal translocations in *FET* family members (*FUS, EWSR1,* and *TAF15)* responsible for cancer development. Sarcomas caused by *FET* family gene rearrangements include ES, desmoplastic round cell small tumors (DSRCT), myxoid liposarcoma (ML), and several others. Lysine specific demethylase 1 (LSD1) is a critical protein for sarcoma development and progression through its colocalization and/or association with several *FET* family oncogenic transcription factors. This suggests that pharmacologic inhibition of LSD1 may be a therapeutic strategy. Seclidemstat (SP-2577, Salarius Pharmaceuticals) is an oral, first-in-class, small molecule with reversible, noncompetitive inhibition of LSD1 (IC_{50}: 25–50 nM). *In vitro* and *in vivo* data demonstrate seclidemstat, or analogs, modulate EWS/ETS transcriptional activity, down-regulating oncogene expression and up-regulating tumor-suppressor gene expression, leading to significant tumor growth inhibition in ES mouse xenograft studies. Seclidemstat has shown in *in vitro* ES cell lines near additivity efficacy when added to TC. In *in vitro* studies of other *FET*-translocated sarcomas, including ML (FUS/DDIT3 fusion) and clear cell sarcoma (EWS/ATF1 fusion), seclidemstat showed anti-proliferative activity. In an ongoing Phase 1 trial investigating single agent seclidemstat in advanced solid tumors (NCT03895684), three pts with metastatic *FET*-translocated sarcomas had a median progression-free survival of 5.7 months (range: 4.3–7.2) with a best response of stable disease despite having a median of 5 (range: 1–7) prior therapies. **Methods:** This dose expansion Phase 1 study (NCT03600649) assesses seclidemstat at 900 mg PO BID, the recommended Phase 2 dose, in two expansion cohorts: a single agent expansion in select sarcoma pts (n = 30) and a safety lead-in dose escalation and expansion (n = 24) of seclidemstat combined with TC in pts with ES. Pts must be ≥12 years old, have ECOG performance status of 0 or 1, with a life expectancy > 4 months. In the select sarcoma cohort, pts must have ML (n = 15) or other sarcomas with FET family translocations (n = 15) including DSRCT. One to 3 prior lines of therapy are allowed. In the ES combination cohort, up to 2 lines of prior therapy are allowed. Primary objective is safety/tolerability and secondary objective is efficacy. The trial is currently recruiting across 8 locations in the United States. Clinical trial information: NCT03600649. Research Sponsor: Salarius Pharmaceuticals Inc, Other Foundation, Other Government Agency.

TPS11578 **Poster Session**

A phase 2 study of belinostat and SGI-110 (guadecitabine) for the treatment of unresectable and metastatic conventional chondrosarcoma. *First Author: Jay Oza, Columbia University Irving Medical Center, New York, NY*

Background: Conventional chondrosarcoma (cCS) accounts for ~25% of primary bone cancers and is the second most common primary bone tumor after osteosarcoma. Surgical resection is the primary treatment for localized disease. No FDA approved therapy exists for advanced disease and chemotherapy has marginal efficacy with ORR < 12%. IDH1/2 mutation is seen in 50% of cases. Epigenetic dysregulation is central to oncogenesis in both IDH1/2 mutant and wild-type CS. Pre-clinical studies from our group show that combination treatment with HDAC and DNMT inhibitors is significantly more effective at suppressing the growth of CS models in vitro and in vivo compared to either therapy alone. The combination regimen mediates anti-tumor effects on CS by induction of apoptosis, induction of tumor suppressor genes (eg. E-cadherin), the induction of interferon responsive genes (eg. IRF7, OASL, ISG15, DDX58) and reversal of global hypomethylated state. Based on these findings we have designed a phase 2 clinical trial with an HDAC inhibitor (belinostat) and a DNMT inhibitor (guadecitabine) in patients with advanced cCS. **Methods:** NCI # 10330 is a single-arm, multi-center, Simon 2-stage, phase 2 clinical trial evaluating belinostat and guadecitabine in patients with advanced cCS. Eligible patients will have biopsy proven cCS which is measurable by RECIST v1.1 and amenable to biopsy, ECOG PS ≤ 2, any number of prior treatments (including none). Patients will receive guadecitabine 45 mg/m^2 SC followed by belinostat 1000 mg/m^2 IV once daily on days 1-5 of a 28-day cycle. A safety lead-in and continuous toxicity monitoring rule will be applied. The primary endpoint will be ORR. Since chemotherapy is associated with an ORR of 8-12% and targeted agents have shown an ORR of 0% in cCS, we will consider an ORR of 8% as inactive while an ORR of 28% will suggest promising activity. A Simon 2-stage design is employed. The design calls for 26 patients. If ≥ 2 responses are observed among 13 patients in stage I, the study will proceed to full accrual. If ≥ 5 responses are seen among 26 patients, the study treatment is considered promising. This design has 85% power with α of 0.054 to test for a response rate of 8% vs 28%. Secondary objectives include safety, tolerability and PFS. All patients will undergo pre-treatment and on-treatment tumor biopsies. Paired tissue will be used for correlative analysis including: 1) whole exome sequencing/RNAseq to evaluate changes in gene expression in response to treatment, 2) multiplex IHC to interrogate the effect of combination therapy on tumor immune microenvironment and 3) a global DNA methylation assay to better understand the changes in epigenetic landscape in response to treatment. This study is open throughout the ETCTN (NCT04340843). Six of the planned 26 patients in the safety lead-in have been enrolled without DLT. Further accrual is on hold pending completion of the safety lead-in. Clinical trial information: 04340843. Research Sponsor: U.S. National Institutes of Health.

TPS11579 **Poster Session**

A multicenter, open-label, uncontrolled phase II study of ONO-4538 for cutaneous angiosarcoma (Angio Check study). *First Author: Yasuhiro Fujisawa, University of Tsukuba Hospital, Tsukuba, Japan*

Background: Cutaneous angiosarcoma (CAS) is a rare sarcoma and advanced cases face a complex treatment regimen and dismal prognosis. Several cytotoxic agents (anthracycline, taxane, and gemcitabine) and targeted therapies (bevacizumab and sorafenib) have been tested for advanced disease in clinical trials with poor results. Since CAS commonly develops in elderly patients, high-grade adverse events from treatment may not be ideal and thus therapies featuring durable response and low comorbidity are in great demand. Recent studies suggest that CAS has a distinct genomic profile, including higher tumor mutational burden (TMB), compared to angiosarcomas developed in other sites. Moreover, we have shown that CAS with higher PD-1/L1 in the tumor microenvironment had statistically better overall survival compared with those without, indicating CAS susceptibility to immune checkpoint blockade therapy. However, to date, reports of immune checkpoint inhibitors for CAS are nonexistent. **Methods:** The present study is a phase 2, multicenter, single-arm clinical trial of ONO-4538 (nivolumab, 480 mg IV every 4 weeks) for patients with unresectable or metastatic CAS refractory to first-line paclitaxel. Twenty-three patients with advanced CAS will be enrolled at 11 sites in Japan with a primary objective to assess the confirmed response rate (H0 p < 5%, H1: p > 20%) to nivolumab. Secondary endpoints include PFS, OS, time to response, and adverse events. A correlative aim includes assessing tissue biomarkers using whole-genome sequencing (1023 genes including interferon-gamma associated genes and other known factors associated with response to immune checkpoint inhibitors) for association with response to nivolumab. The study started in April 2020 and remains open with 7 patients enrolled at time of Clinical trial information: UMIN000043039. Research Sponsor: Ono pharmaceutical Co. Ltd.

TPS11580 **Poster Session**

A randomized phase II trial of second-line treatment for advanced soft tissue sarcoma comparing trabectedin, eribulin and pazopanib (2ND-STEP, JCOG1802). *First Author: Makoto Endo, Kyushu University Hospital, Fukuoka, Japan*

Background: Soft tissue sarcomas (STS) are a rare type of malignancy, which comprises of a variety of histologies. Chemotherapy is the standard treatment for patients with advanced STS. Doxorubicin alone or in combination with ifosfamide is widely accepted as the first-line chemotherapy for advanced STS. While a combination with gemcitabine and docetaxel is regarded as a standard regimen of the second-line chemotherapy after failure of doxorubicin-based first-line regimen, the efficacy is not sufficient. Trabectedin, eribulin, and pazopanib are the candidates of the second-line chemotherapy for advanced STS, although there is no clear evidence showing which is better among those agents. The purpose of this clinical trial conducted by Bone and Soft Tissue Tumor Study Group of Japan Clinical Oncology Group (JCOG) is to determine the most promising regimen among trabectedin, eribulin and pazopanib as the test arm regimen in the future phase III trial of the second-line treatment for patients with advanced STS. **Methods:** The study, JCOG1802, is a multicenter, selection design, randomized phase II trial comparing trabectedin (1.2 mg/m^2 IV, every 3 weeks), eribulin (1.4 mg/m^2 IV, days 1 and 8, every 3 weeks) and pazopanib (800 mg PO, everyday) for patients with unresectable or metastatic STS refractory to doxorubicin-based first-line chemotherapy. Eligibility criteria include 16 year-old or older, unresectable and/or metastatic STS, an exacerbation within 6 months prior to registration, histological diagnosis of STS other than Ewing sarcoma, well-differentiated liposarcoma and myxoid liposarcoma, a history of chemotherapy for STS other than doxorubicin-based regimen, ECOG (Eastern Cooperative Oncology Group) performance status 0 to 2, and sufficient organ function. Primary endpoint is progression-free survival (PFS), and secondary endpoints include overall survival, disease-control rate, response rate, and adverse events. To select the most promising regimen in median PFS (3 months in the worst regimen and 4 months in the best regimen) with a probability of at least 80%, a total of 120 patients will be enrolled from 37 institutions in Japan. After JCOG1802, a subsequent phase III trial comparing the winner of this study and a combination of gemcitabine and docetaxel will be planned. The study was activated at December 5, 2019 and 22 of planned 120 patients have been enrolled as of February 15, 2021. Clinical trial information: jRCTs031190152. Research Sponsor: Japan Agency for Medical Research and Development, Other Government Agency.

TPS11581 **Poster Session**

ENVASARC: A pivotal trial of envafolimab, and envafolimab in combination with ipilimumab, in patients with advanced or metastatic undifferentiated pleomorphic sarcoma or myxofibrosarcoma who have progressed on prior chemotherapy. *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Metastatic undifferentiated Pleomorphic Sarcoma (UPS) and the genetically related myxofibrosarcoma (MFS) are soft tissue sarcoma (STS) subtypes with poor prognoses. While responses to front line chemotherapy can approach 20%, efficacy remains limited in the 2nd line setting and beyond. Pazopanib, the only approved treatment in the refractory setting, has demonstrated an objective response rate (ORR) of 4%. Envafolimab is a single domain PD-L1 antibody administered rapidly by subcutaneous (SQ) injection that is being studied in two additional pivotal trials: microsatellite instability-high (MSI-H) cancer and biliary tract cancer. The activity of envafolimab appears to be similar to other PD-1 antibodies administered i.v. Envafolimab demonstrated a 32% objective response rate (ORR) in MSI-H colorectal cancer patients who failed three approved chemotherapeutics, similar to the ORR of 28% and 33% with nivolumab and pembrolizumab in these patient populations, respectively. The rationale for the ENVASARC trial is based on the previously reported activity of checkpoint inhibition in UPS/MFS. Single agent pembrolizumab demonstrated a 23% ORR, while the combination of nivolumab and ipilimumab demonstrated a 29% ORR in refractory UPS/MFS. **Methods:** ENVASARC (NCT 04480502) is a pivotal multicenter (at ~25 U.S. centers) open-label, randomized, non-comparative, parallel cohort study of treatment with envafolimab 300 mg every 3 weeks by SQ injection (cohort A; n = 80) or envafolimab 300 mg every 3 weeks by SQ injection combined with ipilimumab 1 mg/kg every 3 weeks i.v. for four doses (cohort B; n = 80) in patients with locally advanced, unresectable or metastatic UPS/MFS who have progressed on one or two lines of prior therapy. The primary objective of each of parallel cohort is to demonstrate an ORR with a lower limit of the 95% confidence interval that excludes 5.0% in each cohort. If ≥ 9 responders are observed of the 80 patients enrolled in each cohort, then the lower bound of the 95% confidence interval will exclude 5.0%. Secondary endpoints include duration of response (DOR), PFS and OS. Key inclusion criteria: ≤ 2 prior lines of therapy (neoadjuvant and adjuvant therapy excluded), ECOG ≤ 1. Clinical trial information: NCT 04480502. Research Sponsor: TRACON Pharmaceuticals.

TPS11582 **Poster Session**

IGNYTE-ESO: A master protocol to assess safety and activity of letetresgene autoleucel (lete-cel; GSK3377794) in HLA-A*02+ patients with synovial sarcoma or myxoid/round cell liposarcoma (Substudies 1 and 2). *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Letetresgene autoleucel (lete-cel; GSK3377794) is an autologous T-cell product using a genetically modified T-cell receptor to target cancer cells expressing the cancer testis antigen New-York esophageal squamous cell carcinoma 1 (NY-ESO-1). Lete-cel is currently being investigated alone and in combination in multiple tumor types [1,2]. NY-ESO-1 is expressed in 70–80% of synovial sarcoma (SS) and 80–90% of myxoid/round cell liposarcoma (MRCLS) tumors [3,4], suggesting these tumors may be prime lete-cel targets. This master protocol design (IGNYTE-ESO; NCT03967223) enables evaluation of multiple cell therapies in multiple tumor types and treatment stages in separate substudies, beginning with lete-cel in Substudies 1 and 2 for SS and MRCLS. **Methods:** Substudy 1 is a single-arm study assessing lete-cel in treatment-naïve patients (pts; ie, anthracycline therapy-naïve for metastatic disease) with advanced (metastatic/unresectable) NY-ESO-1+ SS or MRCLS as a first line of therapy (n=10 planned). Substudy 2 is a pivotal, single-arm study assessing lete-cel in pts with NY-ESO-1+ SS or MRCLS who progressed after anthracycline therapy (n=70 planned). Key eligibility criteria are age ≥10 y and NY-ESO-1 and HLA-A*02 positivity. Exclusion criteria include prior NY-ESO-1–specific/gene therapy, allogeneic stem cell transplant, and central nervous system metastases. Screened pts undergo leukapheresis for lete-cel manufacture, lymphodepletion, lete-cel infusion, and follow-up (FU). Long-term FU (15 y) may be done under a separate protocol. The Substudy 2 primary endpoint is overall response rate (ORR) per RECIST v1.1 assessed by central independent review. Substudy 1 is not testing any formal hypotheses; statistical analysis will be descriptive. Substudy 2 is comparing ORR with the historical control assuming at least 90% power with 0.025 one-sided type I error. Secondary endpoints include efficacy (time to/duration of response, disease control rate, progression-free survival), safety (adverse event [AE] frequency/severity, serious AEs, AEs of special interest), and pharmacokinetic (maximum transgene expansion [C_{max}], time to C_{max}, area under the time curve from zero to time *t* as data permit). Enrollment began in December 2019. References: 1. Reckamp KL, et al. *Ann Oncol* 2019;30(Suppl_5):v602–v660. 2. Rapoport A, et al. *J Clin Oncol* 2020 38:15_suppl, TPS8555. 3. TPS11583 **Poster Session**

A randomized phase II trial of cabozantinib combined with PD-1 and CTLA-4 inhibition in metastatic soft tissue sarcoma. *First Author: Vanessa Anne Eulo, Washington University in St. Louis, St. Louis, MO*

Background: Soft tissue sarcomas (STS) are rare malignancies with poor prognosis in the metastatic setting. Current standard therapy includes anthracycline based chemotherapy. Cabozantinib is a multikinase inhibitor that has demonstrated efficacy in solid tumors such as renal cell carcinoma (RCC) and hepatocellular carcinoma (HCC). A phase II study of cabozantinib in advanced STS is underway. Cabozantinib in combination with immune checkpoint blockade has shown clinical benefit in several tumor types including HCC, RCC, non-small cell lung cancer, and urothelial carcinoma. Since cabozantinib may alter PD-1 expression in regulatory T-cells and promote an immune permissive environment, we hypothesize that combining cabozantinib with immune checkpoint inhibition is a therapeutic strategy that will be more effective than cabozantinib alone. Additionally, the design of the trial will allow assessment of whether pretreatment with cabozantinib will enhance the efficacy of nivolumab and ipilimumab alone. **Methods:** This is an open label, multicenter, randomized phase II clinical trial of cabozantinib (60mg orally daily as a single agent, 40mg in combination) with or without combination Ipilimumab (ipi, 1mg/kg IV every 3 weeks for 4 doses) and Nivolumab (nivo, 3mg/kg IV every 3 weeks for four doses, then 480mg IV every 4 weeks) in patients (pts) with unresectable or metastatic STS refractory to up to two lines of chemotherapy. 105 pts with non-translocation driven sarcomas will be enrolled at three US sites and randomized 2:1 to the combination group. Pts will be stratified by prior pazopanib use and balanced for histologies. Patients who progress on arm A will cross over to combination therapy (arm B). The primary efficacy endpoint is objective response rate (ORR) by RECIST 1.1. 35 patients in Cohort A (cabozantinib alone) and 70 patients in Cohort B (cabozantinib plus ipi/nivo) will be required to detect an increase of the ORR from 10% in cohort A to 30% in cohort B with 81% power with a one-sided alpha level of 10%. Key eligibility criteria include: at least 18 years of age, ECOG performance status of 0 or 1, ≤2 prior lines of therapy and measurable disease. Exclusion criteria include: translocation-driven sarcoma except alveolar soft part sarcoma (ASPS), prior immunotherapy, and chronic use of corticosteroids or other immunosuppression. Secondary endpoints are safety, overall and progression free survival, disease control rate, and response rate to ipilimumab and nivolumab after cabozantinib pretreatment. Mandatory tumor biopsies pre-treatment and at 6 weeks will be obtained. Peripheral blood will be collected for circulating immune phenotyping. Enrollment will occur at 3 participating institutions and is expected to be completed in 2022. Clinical trial information: NCT04551430. Research Sponsor: Exelixis, Bristol Myers Squibb.

Randomized trial of remote cancer symptom monitoring during COVID-19: Impact on symptoms, QoL, and unplanned health care utilization. *First Author: Kathi Mooney, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Unplanned health care utilization due to poorly controlled cancer symptoms is common and important to avoid during the Covid-19 pandemic. In a randomized trial we evaluated whether remote symptom monitoring and management utilizing Symptom Care at Home (SCH), would reduce symptom burden, improve quality of life, and decrease unplanned health care use in cancer patients receiving active treatment. **Methods:** Patients (n = 252) receiving chemotherapy and/or radiation therapy were randomized to the SCH intervention (n = 128) or usual care (UC) (n = 124). Daily, those in the intervention group, utilized the SCH system to report the presence and severity of 9 common symptoms during treatment. For symptoms endorsed, SCH participants received immediate, tailored automated self-management coaching. Symptoms at moderate to severe levels were automatically reported to oncology nurse practitioners who called the SCH patients to improve symptom management based on a decision support dashboard. Participants from both groups were assessed at baseline and monthly for up to 5 months on symptom burden (MDASI), mental health well-being and social isolation (PROMIS; HADS) and Health-related Quality of Life (HRQoL) (Penedo Covid-19 HRQoL subscale). Unplanned health care use was extracted from the EHR. Descriptive statistics examined equivalency between groups. Mixed effects models with random intercepts were utilized to examine group differences over time with post-hoc analyses to determine specific timepoint differences. **Results:** Participants did not differ on demographic or baseline measures. On average participants were 61 years of age, predominantly female (61%) and white (93%). A variety of cancers were represented with colon, breast and ovarian most common and 60% had stage 3 or 4 disease. Longitudinal mixed effects models found significant effects for lower symptom burden (p = .018) and better HRQoL (p = .007) for SCH participants versus UC at months 1 and 2 with improvements subsiding over the remaining months. Mental health wellbeing and social isolation were not significantly different. There were a total of 71 unplanned health care episodes with 28 for SCH and 43 for UC. Unplanned episode types included: unplanned clinic visit- 3 SCH vs 2 UC; ED visit- 10 SCH vs 16 UC and unplanned hospitalizations-15 SCH vs 25 UC. More SCH participants had no unplanned health care episodes than UC participants ($\chi 2$ 4.08; p = .04). **Conclusions:** Remote monitoring and management of patients' cancer and treatment-related symptoms during the Covid-19 pandemic reduced symptom burden and improved quality of life during the first two months of monitoring. Unplanned health care utilization trended lower for those remotely monitored. Extending care to the home during the pandemic can decrease demand on the health care system and improve cancer patients' symptom experience. Clinical trial information: NCT04464486. Research Sponsor: U.S. National Institutes of Health.

I'm being forced to make decisions I have never had to make before': Oncologists and the conundrums created by COVID-19. *First Author: Chithra R. Perumalswami, University of Michigan, Ann Arbor, MI*

Background: The COVID-19 pandemic has created conundrums for physicians. This study examines the experiences of oncologists who engage in complex decision-making regarding the use of chemotherapy in seriously ill persons in the context of the COVID-19 pandemic. **Methods:** Between January 2020 and August 2020, the authors conducted semi-structured, in-depth individual interviews with 22 purposefully sampled oncologists from practices enrolled in the Michigan Oncology Quality Consortium. Transcripts were double-coded and reconciled by consensus using qualitative data analysis software for thematic analysis. **Results:** Among the thematic clusters we identified, one was related to conundrums created by the COVID-19 pandemic. In this presentation, we report the results pertaining to three themes within this cluster: (1) the ethical dilemmas faced by oncologists due to the COVID-19 pandemic, (2) the need for both patients and oncologists to manage uncertainty and emotions, and (3) the importance and complexity of integrating technology and communication for seriously ill persons. Oncologists grappled with several conundrums including resource scarcity, resource allocation, delays in care, a duty to promote equity and non-abandonment, high levels of uncertainty and fear, and the importance of advanced care directives and end-of-life care planning. Non-abandonment featured as a coping mechanism for increased stress, and integration of communication with telemedicine was frequent and necessary. **Conclusions:** This study offers an in-depth exploration of the conundrums faced by oncologists due to the COVID-19 pandemic and how they navigated them. Optimal decision-making for seriously ill persons with cancer during the COVID-19 pandemic must include open acknowledgement of the ethical dilemmas faced, the heightened emotions experienced by both patients and their oncologists, and the urgent need for integrating technology with compassionate communication in determining patient preferences. 12002 **Oral Abstract Session**

Feasibility of a virtual hybrid resistance and balance training program for older patients with cancer and its preliminary effects on lower body strength and balance. *First Author: Schroder Sattar, University of Saskatchewan, Regina, SK, Canada*

Background: Falls are a major issue among older patients with cancer and can lead to interruption in cancer treatment. Ample evidence shows resistance and balance training can prevent falls in older adults; however, there is a paucity of evidence regarding exercise on fall prevention in the older cancer population, who often have unique risk factors for falls. Given the new reality of the COVID-19 pandemic, minimizing group gatherings and its associated risks is imperative for older patients, who are a vulnerable population. This study sought to investigate the feasibility of an 8-week, virtual exercise program and its preliminary effects on lower body strength and balance in community-dwelling cancer patients. **Methods:** Study participants were recruited for this pretest-posttest intervention study using consecutive sampling over a one-year period from the Cross Cancer Institute in Edmonton, Alberta. The intervention entailed leg muscle strengthening and balance training exercises that progressed in difficulty as outlined by the Otago program, and involved a virtual component (facilitated live by a certified exercise physiologist via Zoom meeting platform once a week) and independent at-home training component (twice a week). Lower body strength and balance were assessed using the 5-times chair-stand and the 4-stage balance test, respectively, and were analyzed using the Wilcoxon Signed Rank test. **Results:** Twenty-seven older patients (mean age 70.1, range 65-76) participated. The most common cancer sites were breast (48%) and prostate (41%). One participant withdrew due to personal reasons unrelated to the program. The remaining 26 participants completed the intervention. Attendance rate for the virtual component was 97.6% and independent component 84.7%. Participants perceived the program as rewarding and enjoyable (100%), felt this program prepared them to exercise on their own (92%), were confident to continue exercising on their own (81%), and would recommend the program to other patients (100%). At baseline, 33% (n = 9) $\geq$1 fall over the past 6 months. A statistically significant improvement in lower body strength was detected post-intervention ($p = .001$), whereas no difference was detected in balance ($p = .059$). **Conclusions:** This virtual, hybrid resistance and balance training program was feasible, overwhelmingly accepted by our older participants, and appeared effective in improving lower body strength. Findings from this study may have potential to inform design of a larger, randomized multi-site study. Research Sponsor: CIHR Project Seed Grant.

Prospective validation of genetic predictors of aromatase inhibitor-associated musculoskeletal symptoms (AIMSS) in a racially diverse cohort: Results from ECOG-ACRIN E1Z11. *First Author: Vered Stearns, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins School of Medicine, Baltimore, MD*

Background: AIMSS are common and frequently lead to early discontinuation of adjuvant AI therapy. Single nucleotide polymorphisms (SNPs) in candidate genes have been associated with AIMSS and AI discontinuation. The primary objective of E1Z11 was to validate previously identified associations between 10 specific SNPs in candidate genes and AI discontinuation due to AIMSS in a community-based, racially diverse cohort. **Methods:** Postmenopausal women with hormone receptor-positive stage I-III breast cancer enrolled onto a prospective multi-site cohort study, the majority through the NCI Community Oncology Research Program (NCORP). Participants received anastrozole 1 mg oral daily, and completed patient-reported outcomes (PROs) at baseline, 3, 6, 9, and 12 months. AIMSS was defined as >20% increase in Stanford Health Assessment Questionnaire (HAQ) score over baseline occurring within 1 year of AI therapy. We projected 40% would develop AIMSS and 25% would discontinue AI treatment within 1 year, informing a planned enrollment of 1000 women with a fixed number per strata (600 Caucasian, 200 African-American [AA] & 200 Asian) to provide 80% power to detect an effect size of 1.5-4. SNPs include ESR1 (rs2234693, rs2347868, rs9340835), CYP19A1 (rs1062033, rs4646), TCL1A (rs11849538, rs2369049, rs7158782, rs7159713), and HTR2A (rs2296972). Hardy-Weinberg equilibrium (HWE) was evaluated within each racial subset. SNP genotypes were coded as additive effects on the log odds ratio by coding as 0, 1 or 2 for the count of the minor allele. A Cochran-Armitage trend test was used with a 1-sided alpha of 0.0025 (Bonferroni correction for 10 tests). **Results:** We enrolled 999 evaluable women (616 Caucasian, 184 AA, 199 Asian). Genotyping was successful in 974 (98%). AIMSS developed in 43%, and AI therapy was discontinued in 12% within 1 year. While more AA and Asians developed AIMSS compared to Caucasians (48% vs 38%, p=0.017; 50% vs 38%, p=0.004), AI discontinuation rates were similar across racial groups. HWE was satisfied for all SNPs at the 5% alpha level, except for TCL1A/rs11849538 (p=0.002) in the AA cohort. None of the 10 SNPs were significantly associated with AI discontinuation or development of AIMSS in the overall population, or in any of the 3 cohorts. **Conclusions:** Although AIMSS were more common in AA and Asians, AI discontinuation rates were similar in the 3 cohorts. We were unable to prospectively validate 10 SNPs in 4 genes previously associated with AI discontinuation due to AIMSS. Future analyses will include other predictors of AIMSS, PROs, and additional genetic markers for the entire cohort and by race. Pharmacogenomics of cisplatin-induced neurotoxicities: Hearing loss, tinnitus and peripheral sensory neuropathy. *First Author: Xindi Zhang, Department of Medicine, University of Chicago, Chicago, IL*

Background: Cisplatin is an essential component of first-line chemotherapy for many cancers, but causes neurotoxicity, including hearing loss (CisHL), tinnitus (CisTinn), and peripheral sensory neuropathy (CisPNeuro). However, few opportunities exist to identify risk factors and comorbidities for cisplatin-induced neurotoxicities among large numbers of homogenously treated patients without the confounding effect of cranial radiotherapy. **Methods:** Within a well-characterized clinical cohort of 1,680 cisplatin-treated testicular cancer survivors, linear and logistic regression analysis were utilized to analyze associations of CisHL (n = 1,258), CisTinn (n = 1,217), and CisPNeuro (n = 1,653) with non-genetic risk factors. Genome-wide association studies and gene-based analysis were performed on each phenotype. **Results:** Cisplatin-induced neurotoxicities (CisHL CisTinn, CisPNeuro), adjusting for age and cisplatin dose, were interdependent. Survivors with these neurotoxicities experienced more hypertension (CisTinn: OR = 2.62, $p < 0.0001$; CisHL: $\beta = 0.25$, $p = 8.5 \times 10^{-4}$; CisPNeuro: OR = 1.86, $p < 0.0001$) and were more likely to report their health as poor (CisTinn: OR = 0.54, $p < 0.0001$; CisHL: $\beta = -0.11$, $p < 0.0001$; CisPNeuro: OR = 0.61, $p < 0.0001$). Persistent vertigo was significantly associated with both CisTinn (OR = 7.18, $p < 0.0001$) and CisPNeuro (OR = 4.29, $p < 0.0001$). In addition, CisTinn was significantly associated with hypercholesterolemia (OR = 1.78, p = 0.01). Importantly, gene-based association analyses identified significant associations between CisTinn and *WNT8A* (n = 1,037, $p = 2.52 \times 10^{-6}$), encoding a signaling protein important in germ cell tumors; and marginal significance between CisHL and *TXNRD1* (n = 1,071, $p = 4.21 \times 10^{-6}$), thioredoxin reductase-1, which plays a key role in redox regulation. In silico analysis showed high expression levels of *TXNRD1* were significantly correlated with cellular resistance to cisplatin in central nervous system tumor cells (Spearman Rho = 0.35, p = 0.04; $R^2 = 0.14$, p = 0.03), indicating *TXNRD1* is protective for cisplatin-induced cytotoxicity. Previously, rs62283056 in *WFS1* found to be significantly associated with CisHL (n = 511; subset of current population), was marginally significant in an independent replication cohort (p = 0.06; n = 606; subset of current population). **Conclusions:** Cisplatin-induced neurotoxicities are significantly associated with multiple clinical characteristics, including hypertension and self-reported poor health. *WNT8A and TXNRD1* are notable risk factors for CisTinn and CisHL, respectively. Future studies should further investigate these genes and their potential impact on chemotherapy strategies. This study, based on the largest number of testicular cancer survivors investigated to date, highlights the clinical importance of these iatrogenic toxicities and their associated risk factors. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Polymorphisms rs4673 and rs28714259 as predictors of anthracycline-mediated cardiotoxicity in patients with breast cancer. *First Author: Dmitry Yu. Gvaldin, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Numerous pharmacogenetic studies have led to the identification of genetic polymorphisms associated not only with the development of cardiovascular disease, but also increase the risk of complications due to the use of anthracycline drugs, widely used in the treatment of cancer. The purpose of this study was to study the frequency of rs4673 and rs28714259 and possible associations with the risk of cardiovascular changes in patients with breast cancer during anthracycline therapy (anthracycline-mediated cardiotoxicity — AMC). **Methods:** The study included 256 Caucasian patients (median age - 55 years) with a diagnosis of breast cancer without diagnosed cardiovascular changes, who were treated with anthracyclines at the National Medical Research Center of Oncology in 2019-2020. For genotyping of rs4673 and rs28714259, DNA was extracted from blood using DNA-sorb-B (AmpliSens, Russia) and HRM-PCR was performed on a CFX96 amplifier (Bio-Rad, USA). The presence of polymorphisms was confirmed by Sanger sequencing on a Genetic Analyzer 3500 (ABI, USA). **Results:** During the follow-up period 21 (8.2%) patients were diagnosed with signs of subacute (changes developed within several weeks after the last course of therapy) or early chronic AMC (changes developed within a year after completion of anthracycline therapy). In the group of patients without AOC the allelic frequency of rs4673 (c.214T > C *CYBA*) was 0.38, the frequency of genotypes C/C – 0.4, C/T – 0.43, and T/T – 0.17. In the same group, the frequency of the A allele rs28714259 was 0.07, the frequency of the G/G genotypes – 0.87, G/A – 0.13, and A/A – 0. The prevalence of genotypes T/T rs4673 and allele G rs28714259 in a cohort of Russian patients differed from the European population (p = 0.014 and p = 0.05, respectively). The risk of cardiovascular changes on the background of anthracycline therapy increased in the presence of the rs4673 polymorphic allele by 6.49 times, in the case of the G/A and A/A rs28714259 genotypes - by 3.27 times. The results of the ROC-analysis suggested high quality of the tests based on the dominant models rs4673 and rs28714259 (AUC was 71.9% and 76.3% correspondingly). **Conclusions:** In this study the prognostic efficiency of the genetic markers rs4673 and rs28714259 was shown for the prompt detection of the risks of AMC development in the management of cancer patients. However, population characteristics should be taken into consideration for risk assessment. Research Sponsor: None.

Does early palliative care reduce end-of-life hospital costs? A propensity-score matched, population-based, cohort study. *First Author: Hsien Seow, McMaster University, Hamilton, ON, Canada*

Background: Few studies describe how early versus late palliative care affects end-of-life health services costs. The aim of this study was to investigate the impact of early vs not-early palliative care among cancer decedents on the combined costs of receiving aggressive care (ED/hospitalization) and supportive care (home care/physician home visit). **Methods:** Using linked administrative databases, we created a retrospective cohort of cancer decedents between 2004 -2014 in Ontario, Canada. We identified those who received early palliative care (palliative care service used in the hospital or community 12 to 6 months before death [exposure]). We used propensity score matching to identify a control group of not-early palliative care, hard matched on age, sex, cancer type and stage. The propensity score included region, year, treatment, etc. We examined differences in median costs (including hospital, ED, physician, and home care costs) between pairs in the last month of life. **Results:** We identified 144,306 cancer decedents, of which 37% received early palliative care in the exposure period. After propensity score matching, we created 36,238 pairs of decedents who received early and not-early palliative care. After matching the early and not-early groups had equal distributions of age, sex, cancer type (24% lung cancer) and stage (25% stage 3 or 4). Among those who received early palliative care, 56.3% used hospital in-patient care in the last month, whereas 66.7% of the control group (not-early palliative care) used in-patient care; considering only inpatient hospital costs, those receiving early palliative care used a median of $2,894 in the last month of life compared to the control group of $5,311 ($p < 0.001$). Overall median costs in the last month of life for patients in the early palliative care vs the control group was $11,129 vs. $10,598 ($p < 0.001$). **Conclusions:** In our population-based, propensity-score matched, cohort study of cancer decedents, receiving early palliative care reduced the median overall health system costs, especially via avoiding hospitalizations in the last month of life. Research Sponsor: Canadian Centre for Applied Research in Cancer Control (ARCC).

12007 **Oral Abstract Session**

Palliative care and coping in patients with acute myeloid leukemia receiving intensive induction therapy: A mediation analysis of data from a randomized trial. *First Author: Thomas William LeBlanc, Duke University School of Medicine, Durham, NC*

Background: Patients with acute myeloid leukemia (AML) receiving intensive induction chemotherapy experience significant symptoms, quality of life impairment, anxiety, and depression. We previously showed that integrated palliative care improves quality of life (QOL), anxiety and depression during induction, but the mechanism of these benefits is unexplained. **Methods:** We conducted a non-blinded, multi-site randomized trial of integrated palliative and oncology care (IPC) (n = 86) vs usual care (n = 74) for hospitalized patients with AML receiving induction therapy. IPC patients were seen by palliative care clinicians at least twice weekly while hospitalized. Patients completed the Functional Assessment of Cancer Therapy-Leukemia scale, the Hospital Anxiety and Depression Scale, and the Brief COPE questionnaire, to assess QOL, mood, and coping at baseline and weeks 2, 4, 12, and 24. To facilitate analysis, we categorized coping strategies into approach-oriented (active coping, positive reframing, and acceptance) or avoidant (denial, or self-blame), per prior studies. We used linear regression models adjusting for baseline scores to assess the effect of the intervention on coping at week 2. We used causal mediation regression models to examine whether changes in coping during the initial hospitalization mediated intervention effects on QOL, depression and anxiety symptoms at week 2, when patients feel worst during induction. **Results:** We enrolled 160 of 235 (68.1%) eligible patients. Those randomized to IPC reported more approach-oriented coping (B = 1.85, 95%CI 0.62-0.38, P = 0.004) and less avoidant-oriented coping (B = -0.70, 95%CI -1.28, -0.11, P = 0.020) at week 2. Intervention effects on approach-oriented coping were sustained up to week 24 (B = 0.36, 95%CI 0.68, 0.09, P = 0.010), but not on avoidant-oriented coping (B = -0.01, 95%CI -0.28-0.05, P = 0.163). Changes in approach-oriented coping and avoidant-oriented coping during hospitalization partially mediated the intervention effects on week 2 QOL (indirect effect = 6.58, 95%CI 2.14, 13.63), depression (indirect effect = -1.08, 95%CI -2.05, -0.27), and anxiety symptoms (indirect effect = -0.52, 95%CI -1.25, -0.04). Changes in approach- and avoidant-oriented coping accounted for 78% of the total palliative care intervention effect on QOL; 66% of the intervention effect on depression; and 35% of the intervention effect on anxiety. **Conclusions:** IPC as part of induction chemotherapy for AML facilitates active coping strategies for patients, while reducing avoidant coping. Improvement in coping skills accounts for a substantial proportion of the effect from a palliative care intervention on QOL, depression, and anxiety symptoms. These findings offer important insights into the mechanism by which palliative care may enhance patient-reported outcomes in patients with AML. Clinical trial information: NCT02975869. Research Sponsor: Cambia Health Foundation.

12008 **Oral Abstract Session**

Disparities in end-of-life inpatient care received by patients with metastatic cancer, 2010 to 2017. *First Author: Stephanie Deeb, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Many patients with metastatic cancer receive high-cost, low-value care near the end of life. We examined interventions during terminal hospitalizations for patients with metastatic cancer to identify those with high likelihood of receiving futile care. **Methods:** A retrospective population-based cohort analysis of encounter-level data from the National Inpatient Sample was conducted, including records from 2010-2017 for patients ages ≥18 with metastatic cancer who died during hospitalization. We fit multivariable binomial logistic regression models to examine associations between exposures, including patient demographics, and the main outcome of aggressive, low-value, and high-cost medical care (Table). **Results:** Out of 321,898 hospitalizations among patients with metastatic cancer, 21,335 (6.6%) were terminal. Of these, 65.9% were white, 14.1% Black, 7.5% Hispanic, 58.2% were insured by Medicare or Medicaid, and 33.2% were privately insured. Overall, 63.2% were admitted from the Emergency Department (ED), 4.6% received systemic therapy, and 19.2% received invasive ventilation. Median total charges were $43,681. Black patients and publicly insured patients had higher likelihoods of admission from the ED and receiving ventilation, as well as higher total charges; similar trends emerged among patients of Asian race and Hispanic ethnicity. Patients hospitalized at urban teaching hospitals had higher likelihoods of receiving systemic therapy, ventilation, and incurring higher total charges (Table). **Conclusions:** Metastatic cancer patients of racial and ethnic minority groups and those with Medicare or Medicaid were more likely to receive low-value, aggressive interventions at the end of life. Further studies are needed to determine the underlying causes of these disparities in order to implement prospective interventions and advance appropriate end-of-life care. Research Sponsor: U.S. National Institutes of Health, Icahn School of Medicine at Mount Sinai.

A symptom-adapted physical activity intervention during induction chemotherapy for older adults with acute myeloid leukemia (AML) to maintain physical function. *First Author: Heidi D. Klepin, Comprehensive Cancer Center, Wake Forest Baptist Health, Winston Salem, NC*

Background: Older adults are at risk for physical function decline during therapy for AML. Impaired physical function after induction therapy is associated with shorter survival Interventions designed to maintain function may improve treatment outcomes. We piloted a physical activity (PA) intervention among older adults receiving intensive chemotherapy for AML designed to prevent functional decline. **Methods:** Single institution randomized pilot study of PA vs. usual care. Eligibility included age ≥60 years, newly-diagnosed AML, ambulatory, planned intensive induction chemotherapy. Intervention participants were offered a PA session five days/week tailored daily to symptoms and conditions during the induction hospitalization. Session options were: 1) Standard (ward-based), walking + balance trahining + resistance exercises; 2) Intermediate (room-based), upper-body ergometer + balance training + resistance exercises; 3) Low-intensity (bed-based), upper-body ergometer + resistance exercises. Behavioral counseling sessions to establish PA goals and overcome barriers were conducted weekly during hospitalization and continued monthly by phone for 6 months. Assessment of physical function occurred at baseline, weekly during hospitalization (approximately 4-6 weeks), 3 months, and 6 months. The primary functional outcome of interest was the Short Physical Performance Battery (SPPB; 5 repeat chair stands, gait speed, balance tests; score 0-12 higher indicates better function). Clinically significant change in physical function was defined as ≥1.0 on the SPPB. Proportions of those that declined, remained stable, or improved on the SPPB were compared by group using an exact test for trend. **Results:** Among 96 eligible patients 70 enrolled (recruitment rate 73%, average participation 3 sessions/week). The mean age was 72.1±6.3 years, 70% were male. Mean baseline SPPB score was 7.0±3.8. In the surviving intention to treat population (N = 66), more intervention participants, compared to controls, maintained or improved their SPPB score (38% vs. 25%) during induction hospitalization (p = 0.278). Among those who achieved remission (N = 42), function was maintained or improved in a greater proportion of intervention participants (55%) compared to controls (23%), p = 0.047. Maintenance or improvement in SPPB from baseline to last follow-up (3 or 6 months post enrollment) was 62% vs 54% for intervention versus control among the intention to treat cohort (N = 50) and 67% vs. 55% among those who achieved remission (N = 40). **Conclusions:** A symptom adapted PA intervention with behavioral counseling during induction chemotherapy shows promise in preventing clinically meaningful decline in physical function among older adults with AML who achieve remission. Continued maintenance intervention may sustain benefits. Clinical trial information: NCT01519596. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

The effects of geriatric assessment on oncologist-patient communication regarding functional status and physical performance in older adults with cancer: A secondary analysis of a 541-subject nationwide URCC NCORP (NCI Community Oncology Research Program) cluster randomized trial. *First Author: Marielle Jensen-Battaglia, James P. Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: Despite high prevalence of functional status (FS) and physical performance (PP) impairments among older adults with cancer, standardized assessments and interventions are not routinely used in oncology care. This study characterized how oncologist knowledge of Geriatric Assessment (GA) results influenced conversations and GA-guided recommendations addressing FS and PP concerns. **Methods:** Data were from a NCORP funded (UG1CA189961) nationwide cluster randomized controlled trial (ClinicalTrials.gov: NCT02107443; PI: Mohile), with inclusion criteria: age ≥70, stage III/IV solid tumor or lymphoma with palliative treatment intent, and ≥1 GA domain impairment. All subjects underwent baseline GA including standardized FS ([instrumental] activities of daily living) and PP (Timed Up and Go, Short Physical Performance Battery, Older Americans Resources and Services Physical Health scale, falls in past 6 months) measures. Oncologists in Intervention arm practices received full GA results and validated recommendations for each patient, while those in the usual care (UC) arm were only notified of depression or severe cognitive impairment. One clinical encounter per patient within 4 weeks of GA was audio-recorded, transcribed and blind coded using a priori content-analysis scheme to categorize conversations and oncologist response (dismissed, acknowledged, or addressed with recommendation) by GA domain. Frequencies, raw and adjusted (for site using generalized linear mixed models) proportions were compared using the Chi square test. **Results:** 541 patients (mean age: 77, range 70-96) were included. More FS and PP conversations occurred in Intervention (PP=532, FS=164) than UC (PP=183, FS=87) arm (p<.0001). The adjusted proportion of all patients having one or more FS or PP conversations reached 85.8% in the Intervention arm but only 58.6% in UC (p<.0001). Intervention oncologists were more likely to address FS and PP concerns than UC oncologists (42.6% vs 16.5%, p=0.0003), and to use referrals (Intervention=23.5%, UC=5.0%, p<.0001) or information (Intervention=22.3%, UC=3.8%, p=0.0006) to address them. **Conclusions:** Providing oncologists a GA report with recommended interventions enhances oncologist-patient communication regarding FS and PP-related concerns in older adults with advanced cancer. FS and PP-related issues were more likely to be addressed by those oncologists receiving the GA report, demonstrating the utility of GA as a tool in creating tailored interventions for FS and PP concerns. Our findings support use of GA as an important tool in caring for patients with impairments in physical performance and function. Funding: NIH/NCI UG1CA189961, T32CA102618. Clinical trial information: NCT02107443. Research Sponsor: U.S. National Institutes of Health.

Comprehensive geriatric assessment and management for Canadian elders with Cancer: The 5C study. *First Author: Martine Puts, University of Toronto, Toronto, ON, Canada*

Background: Comprehensive Geriatric Assessment (CGA) is recommended by ASCO for older adults with cancer undergoing chemotherapy to identify issues that can interfere with treatment delivery and optimize functional status and quality of life. However, few randomized controlled trials have been completed so far. Our objective is to evaluate the effectiveness of CGA on improving quality of life for older adults receiving cancer treatment. **Methods:** Eligible patients were aged 70+, diagnosed with a solid tumour, lymphoma or myeloma, referred for first/second line chemotherapy, speaking English/French, and with an Eastern Collaborative Oncology Group Performance Status 0–2. The CGA was done by a nurse and geriatrician followed by monthly phone calls by the study nurse for 6 months. Patients were randomly assigned (1:1) to receive either the intervention (CGA plus follow-up by geriatric trained team in addition to usual oncology care) or usual care alone. All participants received a monthly healthy aging booklet for attention control. Randomization was stratified by center and treatment intent (curative/adjuvant versus palliative). Our primary outcome was health-related quality of life (HRQOL) assessed with the European Organisation for Research and Treatment of Cancer (EORTC) QLQ-C30 global health scale (items 29 and 30). Secondary outcomes include functional status (Instrumental Activities of Daily Living). Outcome data collection was completed monthly for the first 6 months, then at 9 and 12 months. For the primary outcome we used a pattern mixture model using an intent-to-treat approach (at 0, 3, and 6 months). The last data collection took place March 8 2021. **Results:** From May 2017 to March 2020, 351 participants from 8 hospitals across Canada were enrolled. All patients were seen on or after day 1 of treatment for the intervention per patient request. Patient characteristics at baseline were similar in both arms. The average age was 75.7 (SD = 4.8), 60.4% was male and 54.3% had treatment with palliative intent. Change in HRQOL scores did not differ by arm (p = .80). Neither group exceeded the MCID of 10 points. There was also no difference in IADL between the groups (p = 0.82). **Conclusion:** CGA was not effective in improving quality of life for older adults receiving cancer treatment in this study. CGA may need to be performed prior to treatment initiation to achieve benefits. Clinical trial information: NCT03154671. Research Sponsor: 705046.

Barriers and facilitators of geriatric assessment implementation in daily oncology practice: A qualitative study applying a theoretical implementation framework. *First Author: Ayumu Matsuoka, Division of Behavioral Sciences, Research Center for Public Health Sciences, National Cancer Center, Tokyo, Japan*

Background: Geriatric assessment (GA) is recommended in various guidelines for older adults with cancer, but is not widely used in daily practice. This study aims to identify multi-level barriers and facilitators of GA implementation in daily oncology practice, based on a theoretical implementation framework. **Methods:** We conducted 20 semi-structured interviews with healthcare providers and managers in 14 hospitals treating older adults with cancer in Japan. The Consolidated Framework for Implementation Research (CFIR) was used to guide the collection and analysis of interview data using a deductive approach. CFIR consists of 5 major domains (I. intervention characteristics, II. outer setting, inner setting, . individual characteristics, and V. process), including 39 constructs. Differences in the constructs influencing GA implementation between hospitals where GA is routinely performed (high implementation, HI) and hospitals where GA is not performed or performed only in clinical trials (low implementation, LI) were explored. **Results:** Among constructs identified as barriers or facilitators of GA implementation, 15 multi-level constructs greatly differed between 5HI and 5LI, including 4 constructs from intervention characteristics, 6 from inner setting, 1 from individual characteristics, and 4 from process. In HI, GA was self-administered (I. adaptability), or administered on a mobile app with interpretation (I. design quality and packaging). In HI, healthcare providers strongly perceived the need to change the practice for older adults (III. tension for change), and recognized GA as fitting in with existing workflow as part of their jobs (III. compatibility). In LI, they did not realize the need to change practice, and rejected GA as an extra burden on their heavy workload. In HI, the usefulness of GA was widely recognized by healthcare providers (IV. knowledge and beliefs about the intervention), GA was given high priority (III. relative priority), had strong support from hospital directors and nursing chiefs (V. leadership engagement), and multiple stakeholders were successfully engaged, such as healthcare providers, especially nurses (V. key stakeholders), directors and nursing chiefs (V. opinion leaders), and those who dedicated themselves to implementing GA (champions). **Conclusions:** This is the first study to reveal the multi-level barriers and facilitators of GA implementation in daily oncology practice. The findings highlight the need to focus not only on individual or intervention characteristics, but also on the inner setting and the process of implementing GA. Our findings suggest future strategies, such as devising the administration of GA using technology, conducting local needs assessment and consensus discussions about the usefulness and priority of GA, and engaging multiple stakeholders. Effects of metabolic syndrome on cognitive outcomes in long-term survivors of childhood cancer. *First Author: Tyler Alexander, St. Jude Children's Research Hospital, Memphis, TN*

Background: Childhood cancer therapy increases risk for cognitive impairment and other chronic conditions, which also may impact cognition. We assessed the unique impact of metabolic syndrome (MetS) on cognition in survivors participating in the St. Jude Lifetime Cohort Study. **Methods:** Participants included 4058 survivors of childhood cancer (53.9% female; mean [SD] age 30.1 [10.5] years at evaluation; 22.6 [10.1] years from diagnosis) who completed clinical evaluation and cognitive testing. MetS criteria followed Adult Treatment Panel III guidelines (at least 3 of: hypertension, high triglycerides, abdominal obesity, low high-density lipoprotein [HDL], high fasting glucose). Multivariable log-binomial regression models assessed risk of cognitive impairment associated with MetS stratified by survivors who did (n = 2301) or did not (n = 1757) receive central nervous system (CNS)-directed therapy. Mediation analysis assessed effects of MetS and physical activity in cranial radiotherapy (CRT)-associated cognitive impairment. Models were adjusted for age, sex, follow-up time and treatment exposures. **Results:** MetS was associated with increased risk of impaired attention (relative risk [RR] 1.34 95% confidence interval [CI] 1.07-1.66), processing speed (RR 1.25 CI 1.11-1.41) and executive function (RR 1.18 CI 1.01-1.37) in survivors with CNS-directed therapy and academic achievement (RR 1.84 CI 1.18-2.89), attention (RR 1.43 CI 1.10-1.87), and processing speed (RR 1.46 CI 1.21-1.75) in those without CNS-directed therapy. MetS components associated with cognitive impairment included abdominal obesity (memory RR 1.34 CI 1.13-1.59; processing speed RR 1.41 CI 1.24-1.59; executive function RR 1.21 CI 1.05-1.39) and low HDL (intelligence RR 1.26 CI 1.06-1.49; attention RR 1.27 CI 1.03-1.57; processing speed RR 1.17 CI 1.01-1.35; executive function RR 1.20 CI 1.05-1.37) in survivors with CNS-directed therapy. In survivors treated without CNS-directed therapy hypertension (academic achievement RR 1.49 CI 1.18-1.88; intelligence RR 1.34 CI 1.02-1.76; attention RR 1.42 CI 1.12-1.79; memory RR 1.45 CI 1.14-1.84; processing speed RR 1.30 CI 1.08-1.55; executive function RR 1.32 CI 1.08-1.62) and abdominal obesity (academic achievement RR 1.71 CI 1.07-2.72; processing speed RR 1.23 CI 1.02-1.49; executive function RR 1.38 CI 1.09-1.75) were associated with impairment. In mediation analyses, direct effects of CRT were identified, as were indirect effects through physical activity (processing speed $\beta = 0.035$ $p < 0.01$; attention $\beta = 0.03$ $p < 0.01$; executive function $\beta = 0.172$ $p < 0.01$). **Conclusions:** MetS increases risk of cognitive impairment in survivors, particularly abdominal obesity, hypertension and low HDL. Physical activity appears to partially mediate impact of CRT on cognitive outcomes and is an important target for interventions to lower impairment risk. Association between learning and memory problems and health outcomes after blood or marrow transplantation (BMT): A BMT survivor study (BMTSS) report. *First Author: Donna Murdaugh, University of Alabama at Birmingham, Birmingham, AL*

Background: Cognitive impairment after BMT for hematologic malignancies typically involves processing speed, attention and working memory. Survivors perceive these deficits as learning and/or memory problems. However, limited information exists regarding learning/memory problems experienced by survivors several years after BMT. We addressed this gap using the BMTSS. **Methods:** BMTSS is a retrospective cohort study examining long-term outcomes of individuals who survived ≥2y after BMT performed between 1974 and 2014 at three transplant centers. Study participants completed a 255-item questionnaire covering diagnosis by a healthcare provider of health conditions (including learning/memory problems), sociodemographic characteristics, and functional status. We used a nested matched case-control study design. Cases consisted of individuals with learning/memory problems developing after BMT (n = 543). Each case was matched to a BMTSS participant without memory problems (controls: n = 543) using the following criteria: cancer diagnosis, race/ethnicity, type of BMT (allogeneic or autologous), and time from BMT. Multivariable conditional logistic regression analysis was used to identify clinical factors (age at BMT, stem cell source, chronic graft vs. host disease [cGvHD], total body irradiation [TBI], fatigue, pain) and demographic factors (household income, education, sex) associated with learning/memory problems. We also examined the association between learning/memory problems and instrumental activities of daily living (IADL). Analyses were stratified by type of BMT. **Results:** For all survivors (n = 1,086), mean age at BMT was 40.7y and at study participation was 53.3y (18-85); 47% of the study population was females; 78% were non-Hispanic whites; 31% reported an annual household income < $50k. Primary diagnoses included leukemia (50%), lymphoma (36%), and other (14%); 55% received an allogeneic BMT (36% developed cGvHD); 54% received TBI; and 68% received peripheral blood stem cells. Allogeneic BMT survivors with fatigue (odds ratio [OR] = 2.2, 95% CI, 1.4-3.3; p = 0.001), significant pain (OR = 1.8, 95% CI, 1.1-2.9; p = 0.02) and < college education (OR = 1.6, 95% CI, 1.1-2.5; p = 0.02) had higher odds of reporting learning/memory problems. Autologous BMT survivors exposed to TBI (OR = 2.8, 95% CI, 1.4-5.4; p = 0.003) and reporting significant pain (OR = 1.7, 95% CI, 1.0-2.9; p = 0.05) had higher odds of reporting learning/memory problems. Learning/memory problems were associated with increased odds of impairments in IADL in both autologous (OR = 2.1, 95% CI, 1.1-4.0; p = 0.03) and allogeneic (OR = 2.0, 95% CI, 1.2-3.3; p = 0.01) BMT survivors. **Conclusions:** Modifiable risk factors, such as fatigue and pain, can be targeted to mitigate the learning/memory problems and improve the functional outcomes of BMT survivors. Research Sponsor: Leukemia and Lymphoma Society, U.S. National Institutes of Health.

Effect of physical exercise on cognitive function after chemotherapy in patients with breast cancer: A randomized controlled trial (PAM study). *First Author: Emmie W. Koevoets, Julius Center for Health Sciences and Primary Care, University Medical Center, Utrecht University, Utrecht, Netherlands*

Background: Chemotherapy is associated with cognitive problems. Physical exercise is a promising intervention. We investigated whether exercise improves cognition in chemotherapy-exposed breast cancer (BC) patients 2-4 years after diagnosis. **Methods:** In the PAM study, we randomized chemotherapy-exposed BC patients with self-reported and test-confirmed cognitive problems to an exercise or control group. The 6-month exercise intervention consisted of 2 hours of supervised aerobic and resistance training and two hours of Nordic/power walking. Memory function measured with the Hopkins Verbal Learning Test-Revised (HVLT-R) was our primary outcome. Further measurements included online neuropsychological tests (Amsterdam Cognition Scan; ACS), self-reported cognitive complaints (MDASI-MM, EORTC QLQ C-30 cognitive functioning), physical fitness (VO_{2peak}), fatigue (MFI, EORTC fatigue), quality of life (QoL; EORTC), anxiety (HADS) and depression (HADS, PHQ9). HVLT-R total recall was analyzed with a Fisher exact test for clinically relevant improvement of ≥5 words. Other outcomes were analyzed using multiple regression analyses adjusted for baseline and stratification factors. An hypothesis driven but not pre-specified analysis in patients with high baseline EORTC fatigue levels (≥39) was performed. **Results:** We randomized 181 patients to the exercise (n = 91) or control group (n = 90). Two-third of the patients attended ≥ 80% of the exercise program and physical fitness significantly improved compared to the control patients (VO_{2peak}1.4 ml/min/kg, 95% CI 0.6; 2.2). No difference in favor of the intervention group was seen on the primary cognitive outcome or other cognitive tests. However, significant beneficial intervention effects were found for self-reported cognition (MDASI-MM Severity (-0.7, -1.2;-0.1)), fatigue (general fatigue (-2.2, -3.3; -1.1), physical fatigue (-3.3, -4.4; -2.2), mental fatigue (-1.0, -2.0; 0.0), reduced motivation (-1.1, -2.0; -0.2) and reduced activity (-2.1, -3.2; -1.1)), QoL (summary score (4.0, 1.2; 6.7), global health status (5.8, 1.1; 10.6), role functioning (7.2, 1.3; 13.1) and social functioning (5.9, 0.2; 11.6)) and depression (PHQ9 (-1.16, -2.19; -0.13)). In high-fatigued patients, exercise did show significant positive effects on objective cognitive function (ACS Reaction Time (-26.8, -52.9; -0.6) and ACS Wordlist Learning (4.4, 0.5; 8.3)). **Conclusions:** A 6-month exercise intervention did not improve objectively measured cognitive function in chemotherapy-exposed BC patients with cognitive problems. However, self-reported cognitive function, physical fitness, fatigue, QoL and depression did improve. Unplanned analysis indicated a small positive effect of exercise on cognitive functioning in high-fatigued patients. Clinical trial information: NTR6104. Research Sponsor: KWF kankerbestrijding.

12016 **Clinical Science Symposium**

Phase II study of exercise and low-dose ibuprofen for cancer-related cognitive impairment (CRCI) during chemotherapy. *First Author: Michelle Christine Janelsins, University of Rochester Medical Center, Rochester, NY*

Background: CRCI is a debilitating consequence of cancer and its treatment, including difficulties in attention, memory, and executive function. Though CRCI can develop during the course of chemotherapy, interventions targeting CRCI during chemotherapy have not been investigated. Inflammation contributes to CRCI and thus reducing inflammation may ameliorate CRCI. Using a biobehavioral approach, we investigated 2 promising interventions that reduce inflammation: exercise and low-dose ibuprofen. **Methods:** This is a Phase II RCT with a 2:2 factorial design. Eligible participants were patients with cancer receiving chemotherapy who self-reported cognitive difficulties. Participants were stratified by disease type (breast cancer; gastrointestinal cancer; other) and were randomized to 1 of 4 groups for 6 weeks: exercise alone (+ placebo), ibuprofen alone, exercise + ibuprofen, or placebo only. The exercise intervention, delivered by an exercise physiologist, was Exercise for Cancer Patients (EXCAP), an individually tailored, home-based prescription of walking and resistance band training. Ibuprofen/placebo was over-encapsulated for blinding; 200mg was taken 2 times per day. Participants completed 7 cognitive assessments probing attention, memory, and executive function including the Trail Making Test (TMT) and self-report (FACT-Cog) at baseline and post-intervention. ANCOVA, controlling for baseline, assessed overall Arm effects at post-intervention. **Results:** Of the 110 who consented to the study, 86 participants (mean age=54; 88% female; 76% breast cancer, 21% GI; 73% Stage I-III) completed baseline assessments and were randomized to one of four study arms. Ninety percent (78/86) of those completed post-intervention. Average pill compliance across all 4 groups was balanced and averaged 90.8%. Participants in the exercise and exercise + ibuprofen arms increased 2,414 and 1,073 steps respectively compared to those in placebo and ibuprofen arms increased only 464 and 412 steps respectively from pre- to post-intervention. No study-related adverse events occurred. Intent to treat ANCOVA analyses revealed a significant improvement in attention (TMT) in exercise alone compared to placebo (21.57 seconds better; p=0.003), ibuprofen alone compared to placebo (11.27 seconds better; p=0.0475), and trend for exercise + ibuprofen (7.98 seconds better; p=0.122). Those participating in both exercise arms exhibited significant improvements in the FACT-Cog Comments from Others subdomain ($p<0.05$). **Conclusions:** Exercise and low-dose ibuprofen during chemotherapy improved attention in patients with cancer receiving chemotherapy. Exercise improved self-reported cognitive functioning. These results suggest possible treatment options for ameliorating CRCI during chemotherapy. Phase III trials are needed to confirm these findings. K07CA16888; DP2CA195765. Clinical trial information: NCT01238120. Research Sponsor: U.S. National Institutes of Health.

12017 **Poster Discussion Session**

Effects of yoga, cognitive behavioral therapy, and a behavioral placebo on sleep: A nationwide multicenter phase III RCT in cancer survivors. *First Author: Po-Ju Lin, University of Rochester Medical Center, Rochester, NY*

Background: Patients commonly experience impaired sleep throughout cancer treatment and for years into survivorship. Impaired sleep may mediate other cancer-related symptoms and can lead to the inability to complete daily activities and lower quality of life. More effective non-pharmacological treatment options for impaired sleep are needed. We conducted a nationwide, multicenter, phase III randomized controlled trial (RCT) comparing the effects of yoga (Yoga for Cancer Survivors; YOCAS), cognitive behavioral therapy for insomnia (CBT-I), and a behavioral placebo on impaired sleep in cancer survivors. **Methods:** This RCT was conducted via the URCC NCORP Research Base. Participants were cancer survivors 2-60 months post-treatment with insomnia. They were randomized to 1) YOCAS (75-min session biweekly for 4 wks), 2) CBT-I (90-min session weekly for 8 wks), and 3) behavioral placebo (survivorship health education per ASCO guidelines; 75-min session biweekly for 4 wks). Sleep efficiency, sleep duration, wake after sleep onset (WASO), and sleep latency were assessed via actigraphy at baseline and post-intervention. Actigraphs were worn on the non-dominant wrist 24 hours a day for 7 days. Linear mixed models were used to assess intervention effects on sleep outcomes. **Results:** 740 survivors were enrolled (93% female, mean age 56±11 years, 73% breast cancer). Results revealed significant group differences among survivors in the 3 arms in sleep efficiency, sleep duration, and WASO (all $p<0.05$), but not in sleep latency ($p>0.05$). YOCAS and CBT-I subjects maintained sleep efficiency (mean change= -0.8% and -0.03%, respectively, all $p>0.05$) while behavioral placebo subjects significantly reduced sleep efficiency (mean change= -3.4%, $p<0.01$). When controlling for baseline, YOCAS and CBT-I subjects demonstrated better sleep efficiency compared to behavioral placebo subjects at post-intervention (all $p<0.05$). YOCAS subjects also maintained sleep duration (mean change= -3.5 minutes, $p>0.05$) while CBT-I and behavioral placebo subjects significantly reduced sleep duration (mean change= -20.3 minutes and -26.6 minutes, respectively, all $p<0.01$). When controlling for baseline, YOCAS subjects demonstrated longer sleep duration compared to CBT-I and behavioral placebo subjects at post-intervention (all $p<0.05$). There were no significant within-group changes in WASO over time in the 3 arms. When controlling for baseline, CBT-I subjects demonstrated a trend toward lower WASO compared to YOCAS (p=0.07) and behavioral placebo (p=0.05) subjects at post-intervention. **Conclusions:** Both YOCAS and CBT-I maintained sleep efficiency and/or sleep duration among cancer survivors. Oncologists should consider prescribing yoga and CBT-I for treating impaired sleep in cancer survivors. Funding: NCI UG1CA189961, R01CA181064, T32CA102618. Clinical trial information: NCT02613364. 12018 **Poster Discussion Session**

Long-term results from a randomized blinded sham- and waitlist-controlled trial of acupuncture for joint symptoms related to aromatase inhibitors in early stage breast cancer (S1200). *First Author: Dawn L. Hershman, Columbia University Irving Medical Center, New York, NY*

Background: Musculoskeletal symptoms are the most common side effect of aromatase inhibitors (AIs) among breast cancer (BC) survivors. We previously reported that true acupuncture (TA) resulted in better pain outcomes than either sham acupuncture (SA) or wait-list controls (WC) at 6 weeks with durable effects through 24 weeks, with minimal toxicity. We now report the 52-week outcomes. **Methods:** We conducted a SWOG multicenter randomized controlled trial among postmenopausal women with early-stage BC. Patients taking an AI for ≥30 days and reporting a worst pain score of ≥3 out of 10 using the Brief Pain Inventory-Worst Pain (BPI-WP) were eligible. Subjects were randomized 2:1:1 to TA vs. SA vs. WC. Both the TA and SA protocols consisted of a 12-week intervention, with 2 sessions per week for 6 weeks, followed by 1 session per week for 6 additional weeks. At 24 weeks, all subjects remained blinded to intervention arm but were offered 10 sessions of true acupuncture. Endpoints included BPI scores, the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) for hips and knees, the Modified Score for the Assessment of Chronic Rheumatoid Affections of the Hands (M-SACRAH), PROMIS Pain Inventory Short Form (PI-SF), and Functional Assessment of Cancer therapy Endocrine Symptoms (FACT-ES). **Results:** Among 226 patients registered, 110 were randomized to TA, 59 to SA and 57 to WC. Baseline characteristics were similar among the arms. At 52 weeks, follow-up assessments were available for 91 (82.7%) TA, 53 (89.8%) SA, and 47 (82.5%) WC patients. In a linear regression adjusting for the baseline score and stratification factors, 52-week mean BPI-WP scores were 1.08 points lower (correlating with less pain) in the TA compared to SA arm (95% CI: 0.24-1.91, p = .01), and were 0.99 points lower in the TA compared to WC arm (95% CI: 0.12-1.86, p = .03). The proportion of patients experiencing a clinically meaningful (>2) reduction (i.e. improvement) in BPI-WP was 64% for TA compared to 45% on SA and 53% on WC. Patients randomized to TA had reduced BPI pain interference at 52 weeks compared to SA (adjusted difference = 0.58, 95% CI: 0.00-1.16, p = .05) but not compared to WC (adjusted difference = 0.33, 95% CI: -0.28-0.93, p = .29). Also, at 52 weeks, patients randomized to TA had improved PROMIS PI-SF T-scores compared to SA (adjusted difference = 2.35, 95% CI: 0.07-4.63, p = .04) but not compared to WC (adjusted difference = 1.28, 95% CI: -1.09-3.66, p = .29). No statistically significant differences were observed in other measures. **Conclusions:** Women with breast cancer receiving AI therapy and treated with 12 weeks of TA for joint symptoms had reduced levels of worst pain compared to control patients, an effect that was durable through one year despite completion of protocol acupuncture at 12 weeks, and the offering of acupuncture to all participants at 24 weeks. Clinical trial information: NCT01535066. Research Sponsor: U.S. National Institutes of Health.

12019 **Poster Discussion Session**

Complementary and alternative medicine (CAM) use in cancer patients of immigration background. *First Author: Alex Wu, Maimonides Cancer Center, Brooklyn, NY*

Background: Cancer patients are more likely to use complementary and alternative medicine (CAM) than non-cancer patients for immune enhancement and symptom relief. Cancer patients with immigration background may seek out CAM use more readily due to the influence from their cultural background. **Methods:** We carried out a prospective questionnaire study surveying the use of 21 CAM types to cancer patients between 10/23/2015 and 10/31/2020, to evaluate the association of CAM use with patients' age, sex, cancer types, stages, race/ethnicity, birthplace, immigration duration, first language, marital status, levels of poverty, education and anxiety. **Results:** 658 patients were included in this analysis. The median age was 62 years old. The prevalence of CAM use was 66.11%. CAM use was higher in females (71.98%) than the males (54.34%) ($p = 1.13 \times 10^{-5}$), and higher in patients ≥ 38 years old (67.09%) than < 38 years old (46.88%) (p = 0.0215). Patients of African American descent (both US born and foreign born) (n = 198) had statistically higher CAM use (72.73%) than the Caucasians and Others (including Middle-Eastern, Multi-Racial and Others) (n = 266) (63.53%) (p = 0.0371). There was no difference of CAM use between the US born patients (n = 301, CAM use 68.77%) and the immigrants (n = 347, CAM use 63.98%) as a whole; however, Asian born immigrants (n = 106) had statistically less CAM use (53.77%) than the US born and other non-Latin American born (n = 397, CAM use 66.50%) (p = 0.0161), while the Latin-American born had a trend towards higher CAM use (74.83%, P = 0.0608). The number of years living in the US by the immigrants did not have an association with CAM use. Among psychosocial economic factors, married patients had a lower CAM use (61.23%) than the unmarried group (defined as divorced, separated, widowed, or single status, 70.85%) (p = 0.0102). The levels of education, poverty and anxiety did not show a statistical difference in relation to CAM use. Earlier stages of disease had numerically higher CAM use than stage 4 patients, and patients with breast and GYN cancers had higher CAM use (72.30%, p = 0.00252), consistent with the data on the higher CAM use in females. Prayer and spirituality and Dietary medicine were the 2 most common CAM types used (25.91% and 16.12%, respectively). African Americans of the combined US and Non-US origin showed the highest rate of using Prayer and spirituality (84.72%), versus Hispanics (71.19%), Caucasians (53.85%), and Asians (40.32%). Chiropractic therapy was exclusively used by Caucasian CAM users (9.38%). **Conclusions:** Among cancer patients of multi-ethnic groups with immigration background served in a community hospital in Brooklyn, New York, CAM use appeared to be higher in the African American patients, and lower in the patients born in Eastern Asia, as compared to the US born, or to Caucasians. Cultural roots appeared to be a strong influencing factor among all the medical and socioeconomic factors. Research Sponsor: None.

The comparative effectiveness of direct oral anti-coagulants and low molecular weight heparins for prevention of recurrent venous thromboembolism in cancer: The CANVAS pragmatic randomized trial. *First Author: Deborah Schrag, Dana-Farber Cancer Institute, Boston, MA*

Background: Previous randomized trials in cancer patients suggest that DOACs are non-inferior to LMWH for preventing recurrent VTE but have higher risk of bleeding. However, the balance of benefits and burdens remains uncertain. Objective: The CANVAS pragmatic trial compared recurrent VTE, bleeding and death in cancer patients following an initial VTE treated with either DOAC or LMWH therapy. **Methods:** CANVAS was an unblinded hybrid comparative effectiveness non-inferiority trial, with randomized and preference cohorts. Between 12/16 and 4/20, 671 participants were randomized and followed for 6-months. Between 12/16 and 12/17, 140 participants declined randomization, chose their preferred anticoagulant and were followed for 6-months. The preference cohort was closed when predetermined stopping criteria were met. Final follow-up was 11/30/20. Randomized patients were assigned 1:1 to receive either a DOAC or a LMWH. If assigned to LMWH, transitions to warfarin were allowed. Physicians and patients could choose among any DOAC or LMWH. Doses were suggested based on FDA-approved labeling but not mandated. Patients from 67 practices in the US with any invasive solid tumor, lymphoma, multiple myeloma or CLL and a diagnosis of symptomatic or radiographically detected VTE within 30 days of enrollment were eligible. The 1° analysis was conducted in the randomized modified-into to treat popululation, (all subjects who received study drug). The 1° outcome was recurrent VTE. The aim was to establish noninferiority of anticoagulation with a DOAC as defined by the upper limit of the 2-sided 90% CI for the difference in the event rate at 6 months of $< 3\%$. Secondary outcomes included death and bleeding. Hypothesis testing included only the randomized cohort but propensity score adjusted results for the preference and combined cohorts are also shown. **Results:** The non-inferiority criteria for recurrent VTE was met. **Conclusions:** Among adult cancer patients with VTE, the use of a DOAC compared with a LMWH resulted in a noninferior risk of recurrent VTE with no differences in rates of bleeding or death in randomized patients. Clinical trial information: NCT02744092. Research Sponsor: PCORI CER-1503-29805.

CANVAS event rate at 6 months.

Incidence of venous thromboembolism in advanced lung cancer and efficacy and safety of direct oral anticoagulant: A multicenter, prospective, observational study (Rising-VTE/NEJ037 Study). *First Author: Yukari Tsubata, Department of Internal Medicine, Division of Medical Oncology & Respiratory Medicine, Shimane University Faculty of Medicine, Izumo, Japan*

Background: Venous thromboembolism (VTE) is a well-known kind of cancer-associated thrombosis and a common complication of malignancy. However, little is known about the incidence of VTE and the effectiveness of direct oral anticoagulants (DOACs) associated with lung cancer chemotherapy. **Methods:** The Rising-VTE/NEJ037 study was a multicenter, prospective, observational study with 40 participating Japanese institutions. A total of 1,021 patients diagnosed with lung cancer that was unsuitable for radical resection or radiation were enrolled and followed up for two years. The diagnosis of VTE was confirmed through a central review by two radiologists. Patients with VTE at the time of lung cancer diagnosis started treatment with edoxaban. The primary endpoint of this trial was the rate of newly diagnosed VTE after enrollment or the recurrence rate 6 months after the start of treatment with edoxaban. **Results:** Of the 1,021 enrolled patients, data were available for 1,008 patients. The median age was 70 years (range: 30-94 years), and 70.8% were males. Eighty-six percent of patients had non-small cell lung cancer, and 13.6% had small cell lung cancer. Histological types included adenocarcinoma (N = 641, 63.6%), squamous cell carcinoma (N = 187, 18.6%), and others (N = 42, 4.2%). Sixty-two patients (6.2%) had VTE at the time of lung cancer diagnosis, and 42 patients (4.2%) developed VTE during two years follow-up, making a total of 104 patients (10.3%). No cases of VTE recurrence were found 6 months after the start of treatment with edoxaban. Major and minor bleeding occurred in 95 patients (9.4%) and increased to 23% in the edoxaban treatment group. The two-year survival probability was 0.43 in the non-VTE group and 0.48 in the VTE with edoxaban treatment group, showing no difference. **Conclusions:** This study shows a high cumulative incidence of VTE, suggesting that attention should be paid to VTE during treatment for lung cancer. Treatment with edoxaban was highly effective in preventing recurrence of VTE, and there was no difference in survival with or without VTE, but treatment should be considered more carefully because of the high bleeding rate associated with DOAC. Clinical trial information: jRCTs061180025. Research Sponsor: Daiichi Sankyo Co., Ltd.

Assessing the risk of severe post-treatment (tx) cancer-related fatigue (CRF) among breast cancer survivors (BCS) in the CANcer TOxicity (CANTO) cohort. *First Author: Antonio Di Meglio, Gustave Roussy, Villejuif, France*

Background: CRF is among the most common and troublesome symptoms experienced by BCS. While preventing severe post-tx CRF is a major survivorship need, limited tools exist to predict this risk. We aimed to describe the long-term prevalence rates and to identify BCS that are more likely to develop severe CRF. **Methods:** CANTO is a multicenter, prospective clinical study of stage I-III BCS (NCT01993498). Longitudinal data were collected at diagnosis (dx), 0.5 (T1), 1 (T2) and 3 (T3) years post-tx. The primary outcome of interest was severe post-tx global CRF (score $\geq$ 40/100, EORTC QLQ-C30). Secondary outcomes were physical, emotional and cognitive dimensions of CRF (QLQ-FA12). Multivariable logistic regression models retained associations with severe CRF by bootstrapped Augmented Backwards Elimination, validated using 10-fold internal cross-validation and overoptimism-corrected AUC. **Results:** Among 6619 BCS, mean age at dx was 56.5 years (SD 11.5), mean BMI was 25.9 Kg/m^2 (SD 5.4), 53.3% and 80.8% received chemotherapy (CT) and hormonotherapy (HT), respectively. Prevalence rates of severe global CRF were 25.0% (dx), 35.6% (T1), 34.0% (T2) and 31.6% (T3). Severe post-tx global CRF was consistently associated with higher BMI, worse insomnia and pain, and severe pre-tx CRF. Receipt of CT increased odds of severe CRF at T1, whereas associations of HT with CRF emerged at T2 and T3 (Table). The estimated risk of severe CRF at T3 was 14% for a BCS with BMI 23.0 Kg/m^2 and no concomitant symptoms at dx, whereas it was 82% for a BCS with BMI 32.0 Kg/m^2, severe insomnia, pain and pre-tx CRF, receiving HT. Anxiety and depression at dx were consistently retained in models of severe post-tx emotional and cognitive CRF (all $p < .05$). **Conclusions:** Over 1/3 BCS endured persistent, severe global CRF, particularly those that were medically more fragile and reported heavier pre-tx symptom burden. A transient impact of CT on CRF was evident on the short aftermath of tx, whereas exposure to HT seemed to affect CRF on the longer run. Consistent factors flag BCS whose risk of severe CRF is high and who should be upfront targeted and aggressively helped. Dimension-specific risk factors can guide prevention of distinct CRF symptoms. Clinical trial information: NCT01993498. Research Sponsor: Career Catalyst Research grant from Susan G. Komen to Ines Vaz-Luis (CCR17483507), Conquer Cancer Foundation of the American Society of Clinical Oncology.

Health concerns in long-term survivors with ovarian cancer: Results of Expression VI–Carolin meets HANNA–Holistic Analysis of Long-term survival with Ovarian Cancer—The international NOGGO, ENGOT and GCIG survey. *First Author: Hannah Woopen, NOGGO and Department of Gynecology, European Competence Center for Ovarian Cancer, Charité, University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany*

Background: So-called long-term survivors (LTS) may be cured from cancer but still experience a wide range of long-term side effects. Aim was to analyze the main concerns in long-term survival to improve follow-up care. **Methods:** Within the study Carolin meets HANNA (www.carolinmeetshanna.com) long-term survivors with ovarian cancer (LTS) were recruited since 11/2016. Long-term survival was defined as an ovarian cancer diagnosis more than five years ago. **Results:** Until 02/2021 1,044 long-term survivors with ovarian cancer could be recruited. Median survival time at recruitment was 11 years (range 5-43 years). More than half had been diagnosed with advanced stage ovarian cancer (58.6% FIGO III/IV). Almost half have developed recurrent disease (43.4%). 26.0% were under cancer treatment at recruitment. Health status was rated very good or good by 52.0% while 20.3% report a bad or very bad health status. Almost half of the LTS have current concerns/long-term side effects (46.1%). Main concerns are fatigue (23.9%), pain (21.6%), polyneuropathy (16.9%), gastrointestinal symptoms (16.6%) and memory problems (15.5%). 42.8% still regard themselves as cancer patients. Health status and distress did not differ between LTS 5-10 years after diagnosis and $>$ 10 years after diagnosis ($p = 0.59$ and $p = 0.0843$ respectively). Patients with a history of recurrence and those under current treatment had a worse health status and more health concerns. LTS without recurrence reported fatigue in 18.4%, pain in 19.2%, polyneuropathy in 13.1%, gastrointestinal problems in 13.4% and memory problems in 14.4%. Fatigue, polyneuropathy, nausea and concentration problems improve with the time of survival. However, fatigue is still present in 21.1% after ten years survival time. There was no significant difference in pain between 5-10 (20.1%) and $>$ 10 years (22.0%) survival time. In this cohort 94.2% receive regular follow-up care including CA125 testing in 77.0%, clinical examination in 54.3%, transvaginal ultrasound in 55.1%, abdominal ultrasound in 43.9%, mammogram in 50.5% and further radiological examinations such as CT scans in 53.4%. **Conclusions:** Follow-up care in ovarian cancer is usually delivered within the first five years after diagnosis. However, our analyses show the high frequency of health concerns in LTS despite the high frequency of follow-up care in this cohort. Therefore, specialized survivorship care should be offered beyond the typical five years of follow-up care with a focus on long-term side effects. Simplifying survivorship care planning: A randomized controlled trial comparing three care plan delivery approaches. *First Author: Claire Frances Snyder, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Survivorship care plans (plans) have been promoted to smooth the transition from active cancer treatment to survivorship. However, the time and resources involved in plan completion and delivery have been barriers to implementation. This randomized controlled trial aimed to identify the simplest, most effective approach for implementing survivorship care planning. **Methods:** Stage 1-3 breast, colorectal, and prostate cancer patients aged 21+ who were completing acute treatment were recruited from one urban-academic and one rural-community cancer center. Participants were randomized, stratified by recruitment site and cancer type, 1:1:1 to (a) mailed plan (mail), (b) plan delivered during one-time transition visit (one-visit), or (c) plan delivered during transition visit plus a 6-month follow-up visit (two-visit). Health service use (visits, tests/procedures, non-oral medications) was collected from participants and medical records for 18 months and compared to the plan recommendations. Logistic regression, adjusting for cancer type and recruitment site, was used to evaluate the primary outcome of adherence to recommendations for all health service use categories by intervention arm. Descriptive analyses compared care receipt for each health service use category separately (i.e., visits, tests/procedures, non-oral medications). **Results:** Of 378 participants randomized (n = 126 mail; n = 125 one-visit; n = 127 two-visit), 316 (84%) were analyzable for the primary outcome (n = 107 mail; n = 105 one-visit; n = 104 two-visit): 164 (52%) recruited from the urban-academic and 152 (48%) from the rural-community site; 137 (43%) breast, 112 (35%) prostate, 67 (21%) colorectal cancer; mean age 62 years. For the primary outcome, there was no difference across arms in the proportion of participants who received all plan-recommended care: 45.2% mail, 50.5% one-visit, 42.7% two-visit (p = 0.60). We did not find significant interactions by recruitment site or cancer type. There were also no differences in receipt of recommended care by category of health service use. The proportion of participants who had the recommended number of visits was 53.4% mail, 54.8% one-visit, 53.7% two-visit (p = 0.99). The proportion undergoing recommended tests/procedures was 78.8% mail, 77.2% one-visit, 73.0% two-visit (p = 0.62). The proportion receiving recommended non-oral medications was 66.7% mail, 75.0% one-visit, 73.7% two-visit (p = 0.87). **Conclusions:** This study found no significant difference in receipt of recommended follow-up care by plan delivery approach. Across study arms, survivors were more likely to receive recommended tests/procedures and non-oral medications but less likely to have the recommended number of visits. Feasibility and other factors may determine the best survivorship care planning approach. Clinical trial information: NCT03035773. Research Sponsor: Patient-Centered Outcomes Research Institute.

12025 **Poster Discussion Session**

Racial disparities in follow-up care of early-stage lung cancer survivors. *First Author: Jyoti Malhotra, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Follow-up care and surveillance in lung cancer survivors is essential formanagement of treatment- and disease-related symptoms as well as for the early detection of cancer recurrence. To investigate if race impacts receipt of follow-up care in lung cancer survivors, we conducted a cross-sectional study in lung cancer survivors recruited through the New Jersey State Cancer Registry (NJSCR). **Methods:** Between May 2019 and December 2019, survivors of early-stage NSCLC were identified and recruited from the NJSCR. Participants were eligible if they had surgery for stage I or II NSCLC between 2014 and 2017 and, completed all treatment at least one year prior to enrollment. Eligible participants were asked to complete a paper survey questionnaire and medical record release form sent to them by mail. The survey had questions about demographics, smoking, cancer history and treatment, quality of life, follow-up care, barriers to care and informational needs. Study measures were compared between the groups using t-test or chi-square test as applicable. **Results:** Of the 482 survivors contacted, 23% (n = 114) mailed back the survey questionnaire. Of the 112 survivors who returned a completed survey; 78 (70%) were non-Hispanic (NH) Whites and 34 (30%) were NH Blacks. Mean age was 67 years, 61% were female, 92% had cancer in remission. 82% of participants reported receiving a surveillance scan (CT or PET) within one year of completing the study survey. More NH White survivors received a scan within a year compared to NH Black survivors (89% vs 64%; p = 0.006). Also, 88% of survivors reported that they were informed of the need for follow-up care by their provider with more NH White survivors reporting receiving this information (94%) compared to NH Blacks (71%; p = 0.002). About 57% of the survivors reported receiving a written treatment summary and 92% reported being seen by a physician within the past year; no racial differences in these measures were noted.There was also no racial difference in receipt of age-appropriate cancer screening; 66% and 80% reported receiving regular colon and breast cancer screening, respectively. A significantly higher percentage of NH Blacks reported currently smoking compared to NH Whites (16% vs 12%). The most significant barriers to care for both populations were concern for out-of-pocket costs (26% NH Whites, 19% NH Blacks), non-coverage of test (14% NH Whites, 10% NH Blacks) and lack of insurance (8% NH Whites, 16% NH Blacks). **Conclusions:** Significant racial disparity was identified between NH Blacks and NH Whites in receipt of surveillance scans, guidance about follow-up care and smoking cessation. The most significant barriers to follow-up care was lack of insurance in NH Blacks and financial concerns about cost and coverage of tests in NH Whites. Future interventions to increase survivorship care should target these specific needs in survivor populations. Research Sponsor: American Cancer Society.

Real-world outcomes in older adults treated with immunotherapy: A United Kingdom multicenter series of 2,049 patients. *First Author: Anna Claire Olsson-Brown, Clatterbridge Cancer Centre, Liverpool, United Kingdom*

Background: Immune checkpoint inhibitor (ICI) therapy is now commonly used in a range of tumours and settings. Most data relating to outcomes and rates of immune-related adverse events (irAE) is derived from clinical trial or registry populations and small case series. Limited data exist for patients aged > 75 years. Here we present a multi-centre, real-world analysis of the outcomes and incidence of irAEs in older adults managed within a single comprehensive public health service. We also compare these outcomes to younger patients in the same cohort. **Methods:** A retrospective analysis of 2049 patients treated with ICIs was undertaken across 12 centres. All patients were managed within the UK National Health Service outside of a trial setting between June 2016 and September 2018. Patients received either ICI monotherapy (MT) or duel combination ICI therapy (CT) for malignant melanoma (MM), non-small cell lung cancer (NSCLC) or renal cell cancer (RCC). Data were collected using a standardised, collection tool. IrAEs ≥ grade 2 or all-grade endocrinopathies were recorded as per the Common Terminology Criteria for Adverse Events (V5) (CTCAE). Statistical analyses were performed using T-tests, Mann-Whitney and Chi-squared. Kaplan-Meier analysis and log-rank test were used for overall survival (OS) analysis. **Results:** 409 (20%) of patients were aged > 75 years(a), 1413 (69%) aged 50-75(b) and 227 (11.1%) aged < 50(c). There was no difference in sex, ethnicity or PD-L1 status (in the NSCLC cohort) between groups. Older patients were less likely to receive combination therapy (3%(a) v 13%(b) v 34%(c), p < 0.001). There was no difference in median OS across age groups in the cohort as a whole (p = 0.822) or for the individual tumour groups when treated with single agent ICI. Across the total cohort patients aged > 75 had no increased risk of any irAE (35%(a) v 33%(b) v 41%(c),p = 0.074). However there was an increase in irAEs in older patients treated with MT (36%(a) v 26(b) v 25%(c), p = 0.011) However there was no difference in the > 75s with regard to severe (G3/4) toxicity, toxicity type, admission or discontinuation due to toxicity in the aPD-1 group. In the overall cohort younger patients were more likely to develop irAEs and be admitted. **Conclusions:** Patients aged > 75 years treated with anti-PD1 therapy in the standard of care setting derive similar survival benefit to younger patients. There was no increase in ≥G3 toxicity. Our data support the safety of single agent aPD-1 ICI therapy in older adults and provide reassurance relating to the impact of toxicity. Research Sponsor: None.

	< 50 years	50-75 years	> 75 years	p-value

Immunotherapy toxicity in patients over 65 years. *First Author: Miriam Mendez, Hospital Puerta de Hierro, Majadahonda, Spain*

Background: Cancer patients increasingly present an advanced age at diagnosis; 50% of the new cases are over 65 years old, being underrepresented in clinical trials. The safety of immunotherapy has not been adequately evaluated in the subgroup of elderly patient. In this population, with more comorbidities, adverse events may be less well tolerated and have more serious consequences. **Methods:** A retrospective observational study was developed, including all patients treated with immunotherapy at our center between January 2015 to February 2020. Of the total (279 patients), the analysis was performed with the 105 patients ≥65 years of age who had received at least one cycle (in routine clinical practice or within an unblinded clinical trial). All clinical and radiological data of the patients were collected. **Results:** From the total, the majority had a lung carcinoma or melanoma, treated with nivolumab or pembrolizumab either in first or second line. 63% had died at the time of the analysis. The frequency of toxicities: digestive (15%), pneumonitis (12%) and endocrine (9%). We divided the population into 65-75 years (76 patients) or > 75 years (29 patients), analyzing the frequency of toxicity and deaths secondary to it. Those > 75 years had more digestive toxicity (25% vs 11%), but less pneumonitis (3% vs 15%). There were 7 deaths (6%) related to treatment: 2 patients with ipilimumab-nivolumab (28%), 2 nivolumab (28%), 2 pembrolizumab (28%), and 1 ipilimumab (16%). 5 patients were > 75 years old (median 78 years) presenting a higher mortality rate in relation to toxicity (4% vs 20%, p 0.02) and a worse median survival (29 vs 23 months). The fatal toxicities were: 3 neurological (2 meningoencephalitis and 1 acute diffuse axonal denervation), 2 hepatic, 1 hemophagocytic syndrome and 1 myocarditis. **Conclusions:** The most frequent toxicity was digestive, but those that led to death were neurological, hepatic, hematological and cardiac. In our series, neurological and cardiac adverse events accounted for 57% of immunotherapy deaths in older patients. Our data warn that patients over 75 years have a higher risk of death from immune-mediated events. In addition, these would be mainly neurological and cardiac, which represents a diagnostic and treatment challenge for oncologists. Research Sponsor: None.

Can patients with advanced malignancy and poor performance status benefit from nivolumab plus ipilimumab as a palliative treatment? *First Author: Omar Khaled Abughanimeh, University of Nebraska Medical Center, Omaha, NE*

Background: Performance status (e.g. Eastern Cooperative Oncology Group [ECOG] score) is a predictive tool used to determine whether a patient may benefit from cytotoxic chemotherapy. The toxicity profile of immunotherapy is different, and less is known about whether performance status (PS) is similarly associated with toxicity and benefit. Nonetheless, most clinical trials for immune checkpoint inhibitors have excluded patients with poor PS. Emerging data by our group and others has linked poor PS with lack of response and decreased survival with anti-PD-1/L1 agents, but whether combination therapy abrogates the poor outcomes of PD1 only therapy is unknown. **Methods:** We conducted a retrospective cohort study of patients with metastatic cancer who received ipilimumab plus nivolumab at our institution between January 2014-December 2020. We compared outcomes between those with good PS (Group A, ECOG PS 0-1) and poor PS (Group B, ECOG PS $\geq$ 2). Our primary outcomes were overall survival (OS) and incidence of grade 3-4 immune-related adverse events (irAEs). Other outcomes included objective response rates and need for hospitalization. We utilized the Kaplan-Meyer method for time to survival analysis and exact Pearson Chi-squared testing for response, toxicity, and hospitalization analysis. **Results:** A total of 129 patients were identified with a mean age of 59.9 years. Among them were 73 males (57%) and 56 females (43%). Malignant melanoma was the most common malignancy (39%) followed by renal cell carcinoma (27%), small cell lung cancers (10%), non-small cell lung cancers (9%), and the rest with other histologies. 113 patients (87.6%) were in group A and 16 (12.4%) in group B. Across all tumor types, patients in Group B had significantly worse OS compared to group A (HR 0.24 [0.13-0.48], P = < 0.0001). Group B similarly had higher rates of hospitalization compared to group A (94% vs 56%, P = 0.0048). Interestingly, irAEs were not driving these hospitalizations, with a trend toward lower rates of irAEs in the poor PS group (19% vs 46% in Group A, P = 0.057). The overall response rate in group B was numerically lower (6% vs 26% in group A, p = 0.1). **Conclusions:** Our study showed that using ipilimumab plus nivolumab in patients with poor PS was associated with significantly poorer OS and higher rates of hospitalizations. irAEs were not increased in the poor PS group, suggesting a lack of treatment efficacy seemed to driving these poor outcomes. Extrapolation of clinical trial data for ipilimumab-nivolumab to a broader population including those with poor PS should be done with caution. Unfortunately, our data showed that most patients with poor PS were not adequately palliated with ipilimumab-nivolumab. Research Sponsor: None.

The impact of advance care planning on hope among patients with advanced cancer. *First Author: Michael Cohen, UPMC Cancer Center - Magee-Womens Hospital, Pittsburgh, PA*

Background: Providers often cite a fear of giving up hope as a reason they defer advance care planning (ACP) among patients with advanced cancer. We sought to determine whether engagement in ACP impacts patient's hope. **Methods:** This is a secondary analysis of a randomized controlled trial of primary palliative care in advanced cancer. Patients who had not completed ACP at baseline were included in the analysis. ACP was assessed in the forms of an end of life conversation with one's oncologist (EOL conversation) and completion of a living will/advance directive (AD). Measurements were obtained at baseline and 3 months. Hope was measured using the Herth Hope Index (HHI, range 12-48, higher scores indicate higher hope). ACP was measured with patient responses to a validated ACP questionnaire that queried (1) if they had had an EOL conversation with their provider and (2) if they had completed a living will or advance directive. Multivariate regression was performed to control for baseline HHI score, study randomization and age, religious importance, education, marital status, socioeconomic status, time since cancer diagnosis, pain/symptom burden (ESAS), and anxiety/depression score (HADS)—all variables known to be associated with ACP and/or hope. **Results:** A total of 672 patients with advanced cancer were enrolled in the overall study. The mean age was 69±10, and the most common cancer types were lung (36%), GI (20%) and breast/GYN (16%). In this group, 378 (56%) had not had an EOL conversation at baseline, of whom 29% (111/378) reported having an EOL conversation by 3 months. Hope was not different between patients who had or did not have an EOL conversation over the study period (ΔHHI 0.20 ± 5.32 vs -0.53 ± 3.80, p=0.136). After multivariable adjustment, hope was significantly increased in patients who had engaged in an EOL conversation (adjusted mean difference in ΔHHI 0.95 (95%CI 0.08-1.82), p=0.032). Similarly, of 216 (32%) patients without an AD at baseline, 31% (67/216) patients had subsequently completed one. Unadjusted hope was not different between those who had and had not completed an AD (ΔHHI 0.20 ± 3.89 vs -0.91 ± 4.50, p=0.085). After adjustment, hope was significantly higher in those who completed an AD (adjusted mean difference in ΔHHI 1.31 (95%CI 0.13-2.49), p=0.030), (Table). **Conclusions:** Our results demonstrate that hope is not decreased after engagement in ACP and may, in fact, be increased. These findings may provide reassurance to providers who are apprehensive about having these important and difficult conversations. Unadjusted and adjusted change in hope for those patients who had and had not had completed an EOL conversation or AD. Research Sponsor: U.S. National Institutes of Health.

Predicting dying from lung cancer: Urine metabolites predict the last weeks and days of life. *First Author: Seamus Coyle, Waterford Regional Hospital, Waterford, Ireland*

Background: Recognising dying is difficult. We believe there is a predictable biological process to dying and previously demonstrated that urinary volatile organic compounds change in the last weeks and days of life of patients with lung cancer. We further analysed our urine samples using a different metabolomic platform, Liquid Chromatography QTOF Mass Spectrometry (LC-QTOF-MS). **Methods:** We prospectively collected urine samples from people with lung cancer many of whom were in the last 4 weeks of life. The samples were analysed using a LC-QTOF-MS. Volcano plots identified metabolites that changed 2 fold for different time periods (0-28 days, 0-14 days, 0-7days, 0-5 days and 0-3 days). All metabolites were also grouped into weeks. A One-way ANOVA between the groups identified metabolites that changed significantly. Cox regression with Least Absolute Shrinkage and Selection Operator (LASSO) logistic regression was used to analyse the data and create a statistical model. **Results:** 234 urine samples from 112 patients were analysed by LC-QTOF-MS. 90 metabolites were identified that increase or decrease in the last weeks or days. Pathway Analysis using MetaboAnalyst demonstrated a number of biochemical pathways affected during different time intervals; 0-2 weeks and 0-3 days before death. Cox LASSO regression analysis was performed for the last 28 days. A model using 21 metabolites, prognosticates for each day in the last 28 days with high AUC values (88-90%). Patients can be categorized into high, medium and low risk of death. A Kaplan-Meier survival analysis demonstrated the groups were well separated. **Conclusions:** The results confirm urine metabolites predict when people with lung cancer are in the last weeks and days of life. Our model, using 21 metabolites, prognosticates for each of the last 28 days of life and is approximately 88% -90% accurate. This is the only model able to prognosticate for the last week or days of life. Research Sponsor: Wellcome Trust UK, North West Cancer Research UK.

Outcomes among patients with cancer previously identified as being at risk for 30-day mortality using augmented intelligence. *First Author: Ajeet Gajra, Cardinal Health, Dublin, OH*

Background: An augmented intelligence (AI) tool using a machine learning algorithm was developed and validated to generate insights into risk for short-term mortality among patients with cancer. The algorithm, which scores patients every week as being at low, medium or high risk for death within 30 days, allowing providers to potentially intervene and modify care of those at medium to high risk based on established practice pathways. Deployment of the algorithm increased palliative care referrals in a large community hematology/oncology practice in the United States (Gajra et al, JCO 2020). The objective of this retrospective analysis was to evaluate the differences in survival and healthcare utilization (HCU) outcomes of patients previously scored as medium or high risk by the AI tool. **Methods:** Between 6/2018 – 10/2019, the AI tool scored patients on a weekly basis at the hematology/oncology practice. In 9/2020, a chart review was conducted for the 886 patients who had been identified by the algorithm as being at medium or high risk for 30-day mortality during the index period, to determine outcomes (including death, emergency department [ED] visits, and hospital admissions). Data are presented using descriptive statistics. **Results:** Of the 886 at-risk patients, 450 (50.8%) were deceased at the time of follow-up. Of these, 244 (54.2%) died within the first 180 days of scoring as at-risk, with median time to death 68 days (IQR 99). Among the 255 patients scored as high risk, 171 (67.1%) had died, vs. 279 (44.2%) of the 631 patients who were scored as medium risk ($p < 0.001$). Of the 601 patients who were scored more than once during the index period as medium or high risk, 342 (56.9%) had died, vs. 108 (37.9%) of the 285 who were scored as at risk only once ($p < 0.001$). A total of 363 patients (43.1%) had at least 1 ED visit, and 346 patients (41.1%) had at least 1 hospital admission. There was no difference in the proportion of patients scored as high risk compared with those scored as medium risk in ED visits (104 of 237 [43.9%] vs. 259 of 605 [42.8%], p = 0.778) or hospital admissions (100 of 237 [42.2%] vs. 246 of 605 [40.7%], p = 0.684, respectively). Compared with patients scored as medium or high risk only once during the index period, patients who were scored as at-risk more than once had more ED visits (282 of 593 [47.6%] vs. 81 of 249 [32.5%], $p < 0.001$) and hospital admissions (269 of 593 [45.4%] vs. 77 of 249 [30.9%], $p < 0.001$). **Conclusions:** This follow-up study found that half of the patients identified as at-risk for short-term mortality during the index period were deceased, with greater likelihood associated with high risk score and being scored more than once. Over 40% had visited an ED or were admitted to hospital. These findings have important implications for the use of the algorithm to guide treatment discussions, prevent acute HCU and to plan ahead for end of life care in patients with cancer. Intensity of end-of-life care for gynecologic cancer patients by primary oncologist specialty. *First Author: Katherine Hicks-Courant, University of Pennsylvania, Philadelphia, PA*

Background: The impact of primary oncologist specialty, medical oncology (MO) versus gynecologic oncology (GO), on intensity of care at the end of life (EOL) in elderly patients with gynecologic cancer is unclear. **Methods:** This retrospective cohort study used Surveillance, Epidemiology and End Results (SEER) Medicare data. Subjects were fee-for-service Medicare enrollees over 65 years old, who had seen a GO or MO in an outpatient setting in the last year of life and died of a gynecologic cancer between 2006 and 2015. The primary oncologist was defined as the provider with the majority of outpatient visits in the last year of life. The primary outcome was intensity of care at the EOL, a composite score defined by receipt of chemotherapy in the last 14 days of life, death in the hospital, enrollment in hospice for less than three days, more than one ED visit, more than one hospital admission, spending more than 14 days in the hospital, or any ICU admission in the last 30 days of life. Simple and multivariable linear regression analyses were conducted to evaluate for differences in EOL care outcomes by primary oncologist specialty. Linear regressions were repeated after creating a more similar control group through nearest-neighbor propensity score matching, with and without replacement. **Results:** Of 12,189 subjects, 63% were primarily treated by a MO and only 27% by a GO for EOL care. Most died of ovarian cancer (55.1%), followed by uterine (31.4%), cervical (6.9%), and other cancers (6.7%). Compared to GO patients, MO patients were younger, more likely to be white, married, not dual-eligible, higher stage, and to die of ovarian cancer. Overall, 55.4% (95% CI 54.73-56.49) received intense care at the EOL. Although both specialties engaged in high levels of intense EOL care, the adjusted rates for GO (54.03%; 95% CI 52.28-55.77) were significantly less compared to MO (56.53%; 95% CI 55.36-57.69; p=0.023) in unadjusted and adjusted analyses of the entire and propensity-matched cohorts (Table). **Conclusions:** Approximately 2/3 of women with gynecologic cancer will receive EOL care from a MO, compared to 1/3 from a GO. Both specialists engage in high levels of intense EOL care in over half of their patients, although GO less so. Future work should focus on identifying approaches to reduce high-intensity EOL care, which may include additional training or incorporation of palliative medicine into cancer care. Research Sponsor: None.

Personalized delirium sedation goal (PDSG): Balancing comfort and communication in the last days of life. *First Author: David Hui, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Management of patients with agitated terminal delirium is challenging as clinicians try to find a balance between adequate sedation to maximize comfort while retaining communication abilities. A novel approach to tailor care is to ask caregivers for a PDSG by setting an individualized target for sedation. In this study, we examined PDSG using (1) clinical vignettes and (2) as a clinical response criteria in patients enrolled onto a randomized clinical trial. **Methods:** This is a pre-planned secondary analysis of a double-blind randomized clinical trial examining the sedative effect of chlorpromazine and/or haloperidol in patients with agitated terminal delirium refractory to low dose haloperidol (clinicaltrials.gov: NCT03021486; *Lancet Oncol* 2020 21:7 989-998). At baseline, caregivers and bedside nurses were independently asked to select the PDSG for 6 patient vignettes that differed by level of agitation (high vs. moderate), ability to communicate (yes or no), and survival (days vs. weeks). There were 5 choices for PDSG, corresponding to RASS scores of 0 (no sedation), -1 to -2, -3, -4 and -5 (deep sedation). Respondents were also asked to select the PDSG for the enrolled study patient, which were assessed against actual RASS scores over the first 24 hours to determine a response. We examined the association between PDSG levels and various patient and respondent characteristics with multi-level cumulative logits models. **Results:** 68 patients were enrolled and 45 received the masked study interventions (median survival 73 h [95% CI 49,106 h]). 42 caregivers and 40 nurses provided PDSG data. For the case vignettes, 7-31% of caregivers and 20-55% of nurses chose RASS -4 or -5 as PDSG. PDSG was significantly lower for patients who were unable to communicate (odds ratio [OR] 3.1-4.4, $P < 0.0001$), patients with only days of survival vs. weeks (OR 1.7, 95% confidence interval [CI] 1.2-2.5; $P = 0.002$) and if the respondent was a bedside nurse (OR = 2.5, 95% CI 1.8-3.6; $P < 0.0001$). For study patients, 12 (29%) of caregivers and 13 (33%) of nurses selected RASS -4 or -5 as PDSG. After the first 2 hours, 40-61% of patients achieved RASS scores that were within ±1 point of caregiver's PDSG, with no significant difference detected among treatment groups ($P = 0.45$). PDSG for study patients was significantly lower if the respondent perceived severe distress related to agitation (OR = 4.4, 95% CI 1.1-17.2; $P = 0.03$), particularly if the respondent was a bedside nurse (OR = 4.8, 95% CI 1.4-16.2; $P = 0.01$). **Conclusions:** PDSG represents a novel response criterion to tailor care for patients with agitated terminal delirium. Lighter sedation was preferred by caregivers compared to nurses, particularly for patients with less agitation, ability to communicate, and longer expected survival. These findings may allow clinicians to better tailor the level of sedation for patients with restlessness/agitation in the last days of life. Clinical trial information: NCT03021486. Research Sponsor: U.S. National Institutes of Health.

Incidence and risk factors for euthanasia or physician-assisted suicide in oncology patients: A systematic review. *First Author: Wei Liu, Department of Radiation Oncology, London Health Sciences Centre, London, ON, Canada*

Background: In a growing number of jurisdictions, oncology patients may choose euthanasia or physician-assisted suicide (EPAS). A 2016 systematic review reported that 75% of U.S. and over 70% of Dutch and Belgian EPAS cases involved oncology patients. In the Netherlands and Belgium, the percentage of deaths among oncology patients via EPAS has been increasing. We investigated the incidence and risk factors for EPAS and EPAS requests in oncology patients. **Methods:** A systematic review was performed following PRISMA guidelines. PubMed, Embase and Cochrane databases were searched for articles from January 2000 to April 2020. Search terms were related to suicide, euthanasia, assisted dying, assisted death, right to die, mercy killing, and cancer. Eligible studies reported incidence and/or risk factors for EPAS/EPAS request based on at least 50 oncology patients. Eligibility for inclusion was independently reviewed by two authors, with discrepancies adjudicated by a third. Data obtained included: study type, country, cancer diagnosis, number of eligible patients, inclusion criteria, follow-up length, incidence of EPAS or EPAS request, and odds ratios (OR) for risk factors for EPAS and EPAS request. ORs and p values were extracted from studies whenever possible and were otherwise calculated based on the data provided using chi-squared test. **Results:** The search strategy identified 6519 results. 25 abstracts were selected for full-text review and 10 studies were included for analysis. All studies reported incidence of EPAS/EPAS request and 6 studies reported risk factors for EPAS/EPAS request. Six studies were from the Netherlands, 3 from Belgium, and 1 from Canada. Inclusion period for studies spanned from 1996 to 2018. Half of the included studies were prospectively conducted. Incidence of EPAS in cancer patients ranged from 7% to 15% and EPAS requests ranged from 8% to 27%. Factors significantly associated ($p<0.05$) with EPAS or EPAS request in any study are shown in the Table. **Conclusions:** Up to 15% of oncology patients choose euthanasia or physician-assisted suicide. Potentially modifiable symptoms including severe nausea, vomiting, and pain are significantly associated with EPAS in oncology patients. Research Sponsor: None.

Code status and outcomes in patients with cancer and COVID-19: A COVID-19 and cancer consortium (CCC19) registry analysis. *First Author: Elizabeth Trice Loggers, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: In-hospital mortality among patients with cancer (pts) and COVID-19 infection is high. The frequency of, and factors associated with, do-not-resuscitate (DNR) or do-not-intubate (DNI) orders at hospital admission (HA), and their correlation with care, has not been well studied. In November 2020, we began collecting this information for pts who were hospitalized at initial presentation in the CCC19 registry (NCT04354701). **Methods:** We investigated: 1. the frequency of, and factors associated with, DNR/DNI orders at HA; 2. change in code status during HA; and 3. the correlation between DNR/DNI orders and palliative care consultation (PC), mortality or length of stay (LOS). We included hospitalized, adult pts with cancer and COVID-19 from 57 participating sites. Reported characteristics include age, ECOG performance status (PS), and cancer status. Comparative statistics include 2-sided Wilcoxon rank sum and Fisher's exact tests. **Results:** 744 pts had known baseline and/or changed code status (CS); most (79%) maintained their baseline CS (Table). Those with DNR±DNI orders at HA were older (median age 79 vs 69 yrs, $p<0.001$) and more likely to have: ECOG PS 2+ vs 0-1 (45% vs 22%, OR 3.95, $p<0.001$), metastatic disease (45% vs 35%, OR 1.72, p=0.005) and progressing cancer (32% vs 16%, OR 2.69, $p<0.001$), but equally likely to have received systemic anticancer therapy in the prior 3 months (38% vs 45%, p=0.15). N=192 pts with a change in CS from full to DNR±DNI were younger (median age 73), had better PS (37% ECOG PS 2+), and were less likely to have progressing cancer (23%) than those with DNR±DNI orders at baseline. However, their LOS was significantly longer, median 9 vs 6 days, $p<0.001$. Compared to those with DNR±DNI orders at HA, pts whose CS changed to DNR±DNI were more likely to die, OR 2.94, 95% CI 1.76-4.97, $p<0.001$. PC was obtained in 106 (14%) pts and associated with transition to DNR±DNI in 47 (44%), affirmation of admission CS in 58 (55%), and reversal in 1 (1%). Median LOS for pts receiving PC was 11 vs 6 days, $p<0.001$. **Conclusions:** In our sample, the majority of patients with cancer and COVID-19 were full code at hospital admission. DNR±DNI status, whether at baseline or assigned during the hospital course, was associated with worse prognosis. Longer length of stay for patients changing code status and/or receiving palliative care consultation was observed likely suggesting earlier palliative care consultation is an important, but likely underutilized component in the care of patients with cancer and COVID-19. Research Sponsor: P30 CA068485.

Inequity in location and quality of death of advanced cancer patients by immigrant status. *First Author: Ana Isabel Tergas, Columbia University College of Physicians and Surgeons and New York-Presbyterian Hospital, New York, NY*

Background: Most cancer patients prefer to die at home, a location associated with better quality of death (QoD) and caregiver outcomes. A number of studies demonstrate disparities in end-of-life (EoL) care among immigrant vs non-immigrant populations in the U.S. This study aims to evaluate how immigrant status affects location and QoD among patients with advanced cancer in the U.S. **Methods:** Data were derived from Coping with Cancer, a federally funded multi-site prospective study of advanced cancer patients and caregivers. The analytic sample of patients who died during the study observation period was weighted (N_w=308) to reduce statistically significant sociodemographic differences between immigrant (N_w=49) and non-immigrant (N_w=259) groups. Immigrant status was determined by patient self-report. Primary outcomes were location of death (intensive care unit, hospital, nursing home, inpatient hospice, home), death at preferred location (yes/no, as per caregiver report in post-mortem interview), and poor QoD (composite score of post-mortem caregiver ratings for patient psychological distress, physical distress, and quality of life in the last week of life). **Results:** As compared to non-immigrants, immigrants were more likely to die in a hospital as opposed to home [AOR 3.33; 95% CI (1.65-6.71); p=0.001] and less likely to die where they preferred [AOR 0.42, 95% CI (0.20-0.90); p=0.026]. As shown in Table, values-inconsistent aggressive EoL care mediated the effect of immigrant status on death at the patient s preferred location. Further, immigrants were more likely to have poor QoD [AOR 5.47; 95% CI (2.70-11.08); p<0.001]. In particular, among patients who preferred symptom-directed, comfort EoL care, immigrants as opposed to non-immigrants were more likely to have poor QoD [AOR 9.53, 95%CI (4.05-22.40); p<0.001]. **Conclusions:** Immigrants, as compared to non-immigrants, are more likely to die in hospital settings, less likely to die at their preferred location, and more likely to have poor QoD. These findings are consistent with previously described inequities in EoL care of immigrants and highlight the importance of determining the potential causes and solutions to ensure immigrants receive values-congruent care. Research Sponsor: U.S. National Institutes of Health.

Values-inconsistent aggressive end-of-life (EoL) care as a mediator of the effect of immigrant status on death at preferred location (weighted sample; N_w=291).

	Values-Inconsistent Aggressive EoL Care, Y/N				Death at Preferred Location, Y/N (Model A)				Death at Preferred Location, Y/N (Model B)			
Predictor	AOR	(95% CI)		p	AOR	(95% CI)		p	AOR	(95% CI)		p

Prognostic understanding, hospitalization, and hospice use among older patients with advanced cancer. *First Author: Kah Poh Loh, University of Rochester Medical Center, Rochester, NY*

Background: Poor prognostic understanding of curability is associated with lower hospice use in patients with advanced cancer. Little is known if this holds true for older adults specifically. In addition, prognostic understanding are variably assessed and defined in prior studies. We evaluated the associations of poor prognostic understanding and patient-oncologist discordance in both curability and survival estimates with hospitalization and hospice use in older patients with advanced cancer. **Methods:** We utilized data from a national geriatric assessment cluster-randomized trial (URCC 13070: PI Mohile) that recruited 541 patients aged ≥70 with incurable solid tumor or lymphoma considering any line of cancer treatment and their oncologists. At enrollment, patients and oncologists were asked about their beliefs about cancer curability (options: 100%, > 50%, 50/50, < 50%, 0%, and uncertain) and estimates of patient's survival (options: 0-6 months, 7-12 months, 1-2 years, 2-5 years, and > 5 years). Non-0% options were considered poor understanding of curability (uncertain was removed from the analysis) and > 5 years was considered poor understanding of survival estimates. Any difference in response options was considered discordant. We used generalized estimating equations to estimate adjusted odds ratios (AOR) assessing associations of poor prognostic understanding and discordance with hospitalization and hospice use at 6 months, adjusting for covariates and practice clusters. **Results:** Poor prognostic understanding of curability and survival estimates occurred in 59% (206/348) and 41% (205/496) of patients, respectively. Approximately 60% (202/336) and 72% (356/492) of patient-oncologist dyads were discordant in curability and survival estimates, respectively. In the first 6 months after enrollment, 24% were hospitalized and 15% utilized hospice. Poor prognostic understanding of survival estimates was associated with lower odds of hospice use (AOR 0.30, 95% CI 0.16-0.59) (Table). Discordance in survival estimates was associated with greater odds of hospitalization (AOR 1.64, 95% CI 1.01-2.66). **Conclusions:** Prognostic understanding may be associated with hospitalization or hospice use depending on how patients were queried about their prognosis and whether oncologists' estimates were considered. Research Sponsor: U.S. National Institutes of Health.

	Adjusted Odds Ratio	95% Confidence Interval
Hospitalization		
Poor understanding of curability	0.77	0.49-1.21
Poor understanding of survival estimates	0.74	0.50-1.08
Discordance in curability	0.87	0.50-1.53
Discordance in survival estimates	1.64	1.01-2.66
Hospice Care		
Poor understanding of curability	0.76	0.51-1.12
Poor understanding of survival estimates	0.30	0.16-0.59
Discordance in curability	0.78	0.50-1.22
Discordance in survival estimates	1.27	0.73-2.20

Impact of the G8 score on the outcome of a cohort of elderly patients with solid or hematological malignancies. *First Author: Federica Biello, Division of Oncology, Department of Translational Medicine, University of Eastern Piedmont, Maggiore Hospital, Novara, Italy*

Background: Elderly cancer patients may have important benefits from innovative treatments. However, they are often barred from clinical trials because of highly selective eligibility criteria, or due to biased and subjective physician standpoints including reluctance to invite elderly patients and fear of excessive toxicity. Indeed, geriatric assessment has been increasingly recognized as predictive and prognostic instrument to detect frailty in older adults with cancer. In this perspective, the G8 score is a simple and reproducible instrument to identify elderly patients who should undergo full geriatric evaluation. The aim of our study was to evaluate the impact of frailty assessment by the G8 screening tool on the outcome of onco-hematological patients. **Methods:** Between January 2017 and December 2020 the G8 screening tool was administered to patients, aged >65 years, referred to our center for solid and hematological malignancies. G8 score was assessed at the time of first access. The primary endpoint was overall survival. Multivariate analysis was performed according to G8 score, age, tumor type, stage and treatment. **Results:** In the observation period, 430 patients were screened for frailty by G8; median age was 77 years (65-92); of these, 331 (77%) had a G8 score <14. Pts with solid tumors were 310 (72%), 175 (57%) of whom had metastatic diseases; 227 (73%) had a G8 score <14. Pts with hematological malignancies were 120 (28%), 100 (83%) of whom had a G8 score <14. Systemic therapy was administered to 336 patients (78%). At a median follow up of 7.2 months (range 1 to 52) 101 pts (24%) were dead. Median overall survival (mOS) was 27 months (1-52+).Patients with solid tumors, classified as frail by a G8 score <14 had a 3-fold risk of death compared with those with G8 > 14 (OR 3.26, CI 95 1.5-7.2, p = 0.003). Conversely, this increased risk was not observed in hematological malignancies (OR 1.4, CI 95 0.4-4.6, p = 0.57). By multivariate analysis, G8 score was associated with a worse prognosis only in patients with solid tumors. **Conclusions:** Our analysis suggest that elderly frail patients with solid tumors have a significantly increased risk of death as compared to elderly fit patients. Conversely, no impact of frailty, as assessed by a G8 score < 14, was evident in elderly patients with hematological malignancies. Research Sponsor: None.

Effect of a geriatric management unit on the outcomes of hospitalized older adults with cancer in Mexico. *First Author: Gretell Henriquez Santos, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

Background: Geriatric assessments and interventions improve the outcomes of hospitalized older adults with cancer, but their implementation in developing countries is limited. We studied the effect of a specialized geriatrician-led inpatient geriatric management unit compared with a conventional internal medicine ward on the outcomes of hospitalized Mexican older adults with cancer. **Methods:** This retrospective study included patients aged ≥65 with solid tumors who had a cancer-related hospitalization at a public academic center in Mexico City between March 2015 and October 2018. Patients hospitalized in the geriatric management unit (cases) were paired in a 1:2 fashion with those in internal medicine wards (controls). Pairing was done by age (+/- 5 years), tumor type, and admission date (+/- 3 months). We studied the effect of being hospitalized in the geriatric management unit on length of stay (LOS), incidence of delirium, hospital-acquired complications, and in-hospital mortality. Multivariate logistic regression models for each outcome were created using variables which were significant on univariate analysis. **Results:** 300 patients (100 cases, 200 controls, median age 75) were included. The most common tumors were gastrointestinal (GI) (53%) and genitourinary (25%). Both groups were comparable regarding baseline comorbidities (Charlson index 8.5 vs. 7.7, p = 0.99) and illness severity at admission (NEWS2 score 2.6 vs. 2.3, p = 0.82). No difference in median LOS was found between cases and controls (9.1 vs. 9.5 days, p = 0.34). Diagnosis of a GI tumor (OR 3.4, 95% CI 1.3-5.5), hospital-acquired complications (OR 4.9, 95% CI 2.5-7.3), and delirium (OR 5.5, 95% CI 2.3-8.7) were associated with longer LOS. 14% of patients in both groups had delirium. Hospitalization in the geriatric management unit reduced the risk of delirium (OR 0.35, 95% CI 0.1-0.9), while a higher Charlson index (OR 1.2, 95% CI 1.0-1.4), NEWS2 score (OR 1.2, 95% CI 1.1-1.4), and hospital-acquired complications (OR 7.3, 95% CI 2.9-18.5) increased it. 34% of patients developed hospital-acquired complications. Diagnosis of a GI tumor (OR 1.9, 95% CI 1.1-3.3) and higher NEWS2 score (OR 1.2, 95% CI 1.1-1.4) increased the risk of hospital-acquired complications. No differences in in-hospital mortality were seen between cases and controls (12% vs. 10%, p = 0.59). A higher NEWS2 score at admission (OR 1.4, 95% CI 1.2-1.7) and delirium (OR 10.7, 95% CI 3.2-36.3) increased the risk of death. **Conclusions:** Among older Mexican adults hospitalized for a cancer-related diagnosis, receiving care in a geriatric management unit led to a significant decrease in the risk of delirium. No improvements were seen in LOS, complications, or in-hospital mortality, which were associated with tumor and patient-related characteristics. Geriatric co-management can lead to improved geriatric outcomes in developing countries with limited resources. Research Sponsor: Fundación Carlos Slim.

12040 **Poster Session**

Characteristics of elderly-specific oncology trials registered in ClinicalTrials.gov. *First Author: Bian Wu, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: Clinical trials dedicated to the elderly cancer patients are essential to help to define optimal cancer therapy for this rapidly growing population. Our study aimed to analyze the characteristics and the evolution of elderly-specific oncology trials registered in ClinicalTrials.gov. **Methods:** A dataset of 61120 oncology trials registered in ClinicalTrials.gov between Jan 1th, 2000 and Dec 17th, 2019 was downloaded. Interventional trials were identified and systematically reviewed to validate classification into elderly-specific (at least using a chronological landmark to define the elderly) and age-unspecified trials. Cancer type and other registration information were extracted. Characteristics of elderly-specific trials were compared with characteristics of age-unspecified trials. Chronological shifts in elderly-specific trials between 2000 to 2009, and 2010 to 2019 were analyzed. **Results:** Of the 49273 trials eligible for analysis, only 791 (1.6%) were elderly-specific. The most frequently used threshold to define the old was 60 years (36%), followed by 70 years (28%) and 65 years (26%). More than half of the elderly-specific trials were phase 2 (56.8%) trials and enrolled 100 or fewer participants (59.4%). Compared with age-unspecified trials, elderly-specific trials were less likely to be funded by industry (28.3% vs 37.1%; $p < 0.001$), and more likely to be conducted in Europe (42.1% vs 24.5%, $p < 0.001$). During the two time periods between 2000 to 2009, and 2010 to 2019, the proportion of elderly-specific trials of all the oncology trials remained stable (1.57% vs 1.62%). The proportion of treatment-oriented trials decreased from 91.9% to 71.4% ($p < 0.001$) while supportive care-oriented trials increased from 1.9% to 13.2% ($p < 0.001$). Industry-funded elderly-specific trials decreased from 34.0% to 25.6% ($p = 0.014$). Concerningly, the use of clinically meaningful end points in elderly such as disease-specific survival, patient-reported outcomes (PROs) and functional status as a primary end point were uncommon (0.5%, 8.0%, and 6.9%, respectively). However, the use of PROs as a primary end point tended to increase in the second time period, from 2.4% to 10.5% ($p < 0.001$). There was no correlation between the number of trials for a given cancer type and relative incidence and mortality. 336/791 (42.5%) of the trials were conducted for patients with blood cancer, although the incidence and mortality of blood cancer were relatively low. The most common solid cancer types were breast cancer (13.9%), lung cancer (10.0%), and colorectal cancer (7.8%). **Conclusions:** Although the majority of all new cases of cancer occur in the elderly population, elderly-specific trials account for only a minority of all oncology trials. Our study helps us to better understand the current state of elderly-specific trials and provides insights for future development that can improve the care of elder patients with cancer. Research Sponsor: None.

Association between baseline geriatric domains and survival in older adults with chronic lymphocytic leukemia (CLL). *First Author: Julia Rice, Massachusetts General Hospital, Boston, MA*

Background: CLL is a disease that commonly affects older adults. Although the value of geriatric assessment is increasingly being recognized in older adults with cancer, few studies have examined the relationship between baseline geriatric domains and clinical outcomes in older adults with CLL. **Methods:** We conducted a secondary data analysis of 369 adults diagnosed with CLL and treated in a phase 3 randomized trial of patients age ≥65 with bendamustine plus rituximab versus ibrutinib plus rituximab versus ibrutinib alone. We evaluated geriatric domains of functional status (activities of daily living [ADL], instrumental activities of daily living [IADL], Timed Up and Go, and number of falls in last 6 months), psychological status (Mental Health Inventory), social activity (Medical Outcomes Study [MOS] Social Activity Survey), cognition (Blessed Orientation Memory Concentration Test), social support (MOS Social Support Tangible and Emotional/Informational subscales), and nutritional status (> 5% weight loss in the preceding 6 months). We examined associations among baseline geriatric domains with overall survival (OS) and progression-free survival (PFS) using multivariable Cox regression models. **Results:** The median age of patients was 71 years (range: 65-89). Most were male (67.1%) and had an ECOG performance status of 0 or 1 (96.9%). In multivariable models, the following geriatric domains were significantly associated with OS: better functional status (ADL score: HR 0.67, $p = 0.012$; IADL score: HR 0.98, $p = 0.007$); social activity score (HR 0.97, $p = 0.004$); and nutritional status (HR 2.58, $p = 0.008$). Similarly, functional status (ADL score: HR 0.77, $p = 0.028$; IADL score: HR 0.99, $p = 0.007$); social activity score (HR 0.97, $p < 0.001$); and nutritional status (HR 2.87, $p < 0.001$) were all associated with PFS. Additionally, the number of impaired geriatric domains was also associated with OS (HR 1.50, $p = 0.004$) and PFS (HR 1.45, $p < 0.001$). Timed Up and Go, number of falls in last 6 months, psychological status, cognition, and social support were not significantly associated with clinical outcomes. **Conclusions:** Geriatric domains of functional status, social activity, and nutritional status were associated with OS and PFS in this cohort of older adults with CLL. These findings highlight the importance of assessing geriatric domains to identify high-risk patients with CLL who may benefit from additional support during their treatment. Research Sponsor: None.

Concerns and difficulties associated with the COVID-19 pandemic among older adults with cancer in Mexico. *First Author: Sofia Sánchez-Román, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Delegacion Tlalpan, Mexico*

Background: The COVID-19 pandemic has impacted the well-being of people not only due to the disease but also because of stay-at-home orders, social distancing, unemployment, and different kinds of loses. Older adults have particularly suffered during the pandemic, with increased health-related concerns and anxiety leading to increased vulnerability. However, little is known about the effects of the pandemic on older adults with cancer living in developing countries. They are facing issues related to their diagnosis and treatment, as well as the effects of the pandemic on their care and on the well-being of their families. To improve care for this vulnerable population, we studied the concerns and difficulties associated with COVID-19 among older Mexican adults with cancer. **Methods:** We included patients age ≥65 with the 10 most common tumors in Mexico according to GLOBOCAN and within 3-24 months of cancer diagnosis at two public hospitals in Mexico City. Patients were contacted telephonically and asked to complete a survey reporting the difficulties encountered during the COVID-19 pandemic and to rate their concerns associated with cancer care management using a 0-10 Likert-type scale, with higher ratings meaning increased concerns. Focused interviews were used to describe the individual experience of selected patients and their relatives related to COVID-19 and cancer care. **Results:** Between April 20, 2020 and December 1, 2021, 67 patients (mean age 71.9, min 65, max 90; 35.8% female; 62.7% living with a partner) were included. The most common tumors were prostate (43%), colon (16%), and lung (12%). 46% had Stage IV disease, and 61% had a life expectancy of more than a year. Twenty-five percent of patients reported encountering at least one difficulty in obtaining cancer care due to the COVID-19 pandemic. 43% of the patients reported difficulties with accessing follow-up cancer care; 39% reported issues with obtaining medications, including chemotherapy; and 34% reported problems obtaining medical care in general, including oncology visits. Regarding concerns, 33% of the patients reported being very worried or extremely worried about the COVID-19 pandemic. The most relevant concerns were related to getting infected with COVID-19 (or having a family member who became infected) (mean rating 7.9, SD 2.9); not being able to pay for cancer treatments or medical care (mean rating 6.9, SD 3.5); and worsening of cancer due to delayed care during the pandemic (mean rating 6.6, SD 3.7). **Conclusions:** A significant proportion of older adults with cancer in Mexico faced difficulties obtaining cancer treatment and follow-up care during the COVID-19 pandemic. Their most relevant concerns included getting infected, financial losses, and progression of disease. Creating systems to provide continued cancer care for vulnerable populations in developing countries is essential to face the COVID-19 pandemic. Evaluating the role of baseline geriatric assessment in predicting adherence to oral targeted therapies and outcomes in older adults with non-Hodgkin lymphoma. *First Author: Othman Salim Akhtar, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Oral targeted therapies (OTT) have transformed the treatment landscape of Non-Hodgkin lymphoma (NHL). However, measuring, defining and optimizing adherence to OTT remains a challenge. Prior studies have reported variable adherence rates (12-100%) to OTT in cancer patients (pts), with suboptimal adherence associated with inferior outcomes. In older adults (OA), geriatric syndromes (GS) such as polypharmacy and cognitive impairment can impact adherence. While geriatric assessment (GA) can predict chemotherapy-related toxicity in OA, its utility in NHL pts on OTT is unknown. In this pilot study, we evaluate the role of GA in predicting adherence and outcomes in NHL pts on OTT. We also report the feasibility of using MEMS Cap, an electronic event monitoring system, to measure adherence in this population. **Methods:** Pts ≥70 years (yrs) with NHL, initiating/receiving OTT were included. A GA was performed at baseline; pt, disease, and OTT characteristics were recorded. Pts were followed monthly for the first 3 months (mos), then every 3 mos for 1 year. Primary endpoint was treatment adherence rate, measured using both subjective [brief adherence rating scale (BARS)] and objective (pill counts and MEMS cap) methods. Progression free survival (PFS) was measured from time of therapy initiation to disease progression or death. **Results:** Of the 54 pts screened, 25 were enrolled. Median age was 77 yrs (71-93 yrs), 21 pts had chronic lymphocytic leukemia, 3 had mantle cell lymphoma and 1 had marginal zone lymphoma. Most frequently used OTT were ibrutinib (n = 17) and venetoclax (n = 5). Most pts (72%) were on OTT at study entry. Median time on therapy was 16.4 mos (1.9-44.6 mos). GS included cognitive impairment (28%), depression (24%), polypharmacy (92%) and recent falls (12%); 48% pts had ≥2 GS. Nine pts (36%) had impaired 4-meter gait speed and/or timed-up-and-go; 20 pts (80%) had an adjusted CIRS-G score of ≥6. So far, pts have completed a median follow up of 3.3 mos. BARS was the most consistent measure of adherence used (63/63 visits, 100%). MEMS Cap and pill counts were used at 13% and 8% visits respectively. Only 5 pts used the MEMS Cap, mostly due to packaging incompatibility (44%-pill box, 32%-blister packs). Median adherence was 100% (range, 70%-100%) with no pts missing > 7 days of prescribed doses. Five pts (20%) required dose interruptions, mostly due to adverse events. Six pts discontinued therapy and 2 pts died of unrelated causes. Median PFS was not reached. Chronological age and presence of a GS were not associated with adherence rate or outcomes. **Conclusions:** Despite presence of ≥2 geriatric syndromes in 48% of older adults with NHL on OTT, self-reported adherence remains high (> 99%) in this group. The MEMS Cap device has poor applicability in measuring adherence to OTT due to pill package incompatibility and increasing use of virtual/tele visits. Research Sponsor: Roswell Park Alliance Foundation.

Pre-existing geriatric conditions in older adults with poor prognosis cancers. *First Author: Mazie Tsang, University of California San Francisco, San Francisco, CA*

Background: Older adults with poor prognosis cancers are more likely to experience toxicity from cancer-directed therapies. Although geriatric assessment (GA) reduces chemotherapy toxicity by detecting pre-existing conditions, GA can be difficult for oncologists to perform because of limited time and resources. We aim to determine the prevalence of pre-existing geriatric conditions that could be detected if GA were performed during routine oncology care. **Methods:** We used the Health and Retirement Study (HRS) linked with Medicare (1998-2016) to identify adults age >65 with poor prognosis cancers (median overall survival < 1 year). The HRS is a biennial nationally representative survey that asks about pre-existing geriatric conditions. Using the interview prior to the cancer diagnosis, we determined the presence of conditions included in GA: functional status (i.e. difficulty with climbing stairs, walking one block, getting up from a chair, bathing or showering, taking medications, and managing money), falls and injurious falls, unintentional weight loss, self-rated health, social support, mentation, advanced care planning, use of pain or sleep medications, and mobility. To identify groups with the highest prevalence of pre-existing geriatric conditions, we stratified results by age (adjusted for gender) and gender (adjusted for age). **Results:** Our study included 2,121 participants. At the time of cancer diagnosis, mean age was 76, 51% were female, 79% were non-Hispanic White, 26% had lung cancer, 14% had a GI cancer, and 60% had other metastatic cancers. Mean time between the HRS interview and cancer diagnosis was 12.7 months. The median overall survival of the entire cohort was 9.6 months with a 45% 1-year survival rate. The adjusted prevalence of pre-existing geriatric concerns were as follows: 65% had difficulty with climbing several flights of stairs, 27% had difficulty with walking one block, 47% had difficulty getting up from a chair after sitting down, 12% had difficulty in bathing or showering, 6% had difficulty taking medications, 11% had difficulty in managing money, 35% had a fall in the last 2 years with 12% of participants reporting injury after their fall. Those who were aged 85 +, vs those aged 65-74, had higher rates of conditions indicative of cognitive impairment (e.g. 12 vs 4% had difficulty taking medications, p = 0.000, 26% vs 6% had difficulty managing money, p = 0.000) and physical impairments (e.g. 54% vs 30% had falls, respectively, p = 0.000). Rates of geriatric conditions indicative of physical impairment were higher in women vs men (e.g. 72% vs 58% had difficulty climbing stairs, p = 0.000 and 52% vs 41% had difficulty getting up from a chair, p = 0.000). **Conclusions:** Patients with poor prognosis cancers have high rates of pre-existing geriatric conditions that can be detected by GA. Geriatric assessments could find important impairments that could be addressed prior to cancer therapy to reduce adverse effects. Research Sponsor: T32-AG000212.

Trajectories of functional status among older adults receiving treatment for gastrointestinal (GI) malignancies: A report from the CARE study. *First Author: Smith Giri, University of Alabama at Birmingham, Alabama, AL*

Background: Preservation of functional independence while undergoing treatment is of utmost importance to older adults with cancer, in addition to being associated with healthcare utilization and survival. Yet, such data are not readily available from published clinical trials. We sought to examine functional status trajectories and risk factors associated with functional decline among older adults receiving treatment for GI malignancies. **Methods:** This study included older adults (≥60y) treated at the UAB GI oncology clinic and enrolled in a prospective Cancer and Aging Resilience Evaluation (CARE) registry. All patients completed a geriatric assessment (GA) that included an assessment of activities of daily living (ADL) and instrumental activities of daily living (IADL). Participants were approached for a repeat assessment three months after baseline GA. Change in functional status was classified as one or more points decline or improvement in IADL and/or ADL from baseline to follow up. We measured the proportion with functional decline or improvement and constructed 95% confidence interval (95%CI) using binomial exact methods. We built multivariable logistic regression models to study the impact of baseline predictors on functional decline. Putative risk factors included age, sex, race/ethnicity, cancer type & stage, baseline CARE frailty index, fatigue, pain, malnutrition and CT-based muscle mass indices (Skeletal Muscle Index [SMI] and Skeletal Muscle Density [SMD]) at the time of diagnosis. **Results:** This study included 184 patients. The median age at first visit was 68y (IQR 64-74); 55% were males, 71% white. Primary cancer diagnoses included colorectal cancer (29%), pancreatic cancer (28%) and other GI cancers (43%); 73% presented with advanced stage disease (III/IV). Most patients were receiving first line therapy (91%), with systemic chemotherapy (95%). The median duration between the baseline and follow up assessment was 109 days (IQR 84-154 days). Overall, 38% (95%CI, 30-45%) experienced a functional decline, whereas functional improvement was seen in 22% (95%CI, 16-29%). In a multivariable analysis, baseline frailty (odds ratio [OR] = 2.37; 95%CI, 1.05-5.38; p =0.03) was associated with significantly increased odds of functional decline; a trend towards increased odds was seen for pancreatic cancer (OR = 2.23; 95%CI, 0.90-5.53; p= 0.08; reference group: colorectal cancer). **Conclusions:** One in three older adults with GI malignancies experienced functional decline while a quarter experienced functional improvement in the first 3 months following treatment. Baseline frailty was associated with higher odds of functional decline. Early identification of such patients may allow targeted interventions to preserve functional independence and optimize quality of life of older adults with cancer. Research Sponsor: U.S. National Institutes of Health.

12046 **Poster Session**

Impact of geriatric assessment (GA) based frailty index (CARE-Frailty Index) on mortality and treatment-related toxicity among older adults with gastrointestinal (GI) malignancies. *First Author: Smith Giri, University of Alabama at Birmingham, Alabama, AL*

Background: Older adults with cancer are at increased risk of treatment-related toxicity and mortality. A comprehensive geriatric assessment (GA) may uncover aging associated vulnerability and identify those at greatest risk of adverse outcomes. We studied the association between a novel frailty index and treatment-related morbidity and mortality among older adults with GI malignancies. **Methods:** Older adults (≥60y) referred for initial consultation at the UAB GI oncology clinic between 9/2017 to 12/2020 were enrolled in a prospective Cancer and Aging Resilience Evaluation (CARE) registry. All participants underwent a patient-reported GA at baseline as previously described *(Williams et al J Geriat Oncol 2020).* Using this information, we constructed a 44-item frailty index using a deficit accumulation approach. Vital status was acquired by linking with death records and chart review. In a subgroup of patients continuing care at UAB, we collected information on toxicity for the first 6 months of treatment via chart review using CTCAE v5.0. We used Kaplan Meier Methods and log-rank test to compare survival distributions, and a multivariate cox regression to adjust for potential confounders. We compared the toxicity rates across frailty subgroups using risk ratio (RR) calculated from general linear models. **Results:** Of 765 consecutive older adults referred to GI oncology clinic, 590 (77%) had available data to measure frailty index. Median age at enrollment was 68y; with 59% males and 72% White. Common cancer types included colorectal (30%) and pancreatic cancer (26%); mostly with advanced stage disease (stage III 28%; IV 46%). Overall, 168 (28%) were characterized as pre-frail and 230 (39.3%) as frail. As compared to non-frail, those who were frail were more likely to be Black (33% vs 20%; p < 0.01) and have pancreatic cancer (33.6% vs 21.8%; p < 0.01). Over a median follow up of 22 months, 212 (36%) patients had died. The 2y overall survival among non-frail, pre-frail and frail patients was 71%, 63% and 51%, respectively (log rank p value < 0.001). In a multivariate cox regression, as compared to non-frail patients, frailty was associated with worse OS (HR 1.75; 95% CI 1.13-2.70; p = 0.01) after adjusting for age, sex, race, cancer stage, cancer type, line of therapy and performance status. In a subset of 168 patients with available data, baseline frailty was associated with increased risk of ≥grade 3 non-hematologic toxicity (RR 2.23; 95% CI 1.27-3.92; p < 0.01) but not ≥grade 3 hematologic toxicity (RR 1.03; 95% CI 0.67-1.58; p = 0.90) as compared to non-frail patients **Conclusions:** The CARE-Frailty Index is a novel frailty index built on the principle of deficit accumulation using a patient-reported GA, and appears to be a robust predictor of survival and may predict treatment related toxicity among older adults with GI malignancies. Research Sponsor: U.S. National Institutes of Health.

The association between geriatric assessment, body composition measures, and treatment-related toxicity in elderly cancer patients: A prospective cohort study. *First Author: Shlomit Strulov Shachar, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Background: Treatment decisions in older adults with cancer are confounded by limited evidence due to their under-representation in clinical trials and as associations between geriatric assessment findings, body composition measures, treatment-related toxicity, and treatment effectiveness have yet to be fully elucidated. We investigated the relationship between geriatric assessment results, skeletal muscle measures, and treatment-related toxicity in older adults with cancer. **Methods:** This prospective single-center cohort study included patients with cancer > 65 years of age with advanced lung, breast, or genitourinary (GU) cancer who received systemic treatment (chemotherapy, biologic therapy, immunotherapy, or combination), and had available CT scans. Patients completed the Comprehensive Geriatric assessment (CGA) and 36-item Carolina Frailty Index (CFI) was calculated to classify them as robust (< 0.2), pre-frail (0.2-0.35), or frail (> 0.35). For each patient, skeletal muscle area (SMA) and density (SMD) were analyzed from CT scan L3 lumbar segments using Slice-O-Matic software. SMA and height (m^2) were used to calculate skeletal muscle index (SMI). Skeletal muscle gauge (SMG) was created by multiplying SMI x SMD. Sarcopenia was defined as having SMI < 41 cm^2/m^2 for males and < 38 cm^2/m^2 for females. The associations between study variables and the occurrence of at least one adverse event (AE) grade ≥2 were analyzed using the Pearson's chi-squared test. The study was approved by the IRB of Rambam Health Care Campus. All patients signed an informed consent. **Results:** Overall, 51 patients (recruited between 5/2015 and 1/2020) were included in the final analysis. Median (interquartile [IQR]) age was 72 (68-76) years; 59% were male; 51%, 28%, and 22% had lung, breast, and GU cancer respectively. The most common treatment received was doublet chemotherapy (49%). All patients except 3 (6%) completed the CGA and CFI was calculated; 29%, 26%, and 39% were classified as robust, pre-frail, and frail, respectively. Median (IQR) SMG was 1251 (1104-1497) AU; median (IQR) SMI was 42 (39-48) cm^2/m^2; 31% were defined as sarcopenic. Overall, 45% of patients experienced at least one AE grade ≥2; 24% experienced at least one AE grade≥3. No statistically significant association was found between treatment-related toxicity and sex, age, tumor type, treatment, or CFI category. Yet, having low SMG (categorically, by tertile) was significantly associated with having at least one AE grade≥2 (p = 0.03) as was being sarcopenic (p = 0.02). **Conclusions:** Low SMG and sarcopenia are associated with treatment-related toxicity in older patients with cancer. Further research and better understanding of this association could help optimize treatment decisions (e.g., choice of regimen, dosing) and interventions in this population. Change in the comprehensive geriatric assessment scores at day 30 post-cancer treatment in geriatric oncology patients. *First Author: Toufic Tannous, Roger Williams Medical Center/Boston University School of Medicine, Providence, RI*

Background: The comprehensive geriatric assessment (CGA) is a multidimensional tool for assessing the functional, cognitive, nutritional and frailty status of patients above 65 years of age with cancer. It includes several components: patient health questionnaire (PHQ-9), timed up and go (TUG), mini mental status exam (MMSE), mini nutritional assessment (MNA), Poly Pharmacy (PP), activities of daily living (ADL), instrumental activities of daily living (IADL) and comorbidities. Previous studies showed that some baseline CGA scores (pre-treatment) are predictors of mortality. However, to our knowledge, there has been no study evaluating the change of those scores in response to treatment at different time periods. We sought to evaluate the evolution of the CGA scores after 30 days post-treatment. **Methods:** We conducted a single institution, prospective cohort registry of patients with solid cancers aged 65 or older in Rhode Island from 2013-2018. All patients underwent a CGA before starting treatment (day 0) and post-treatment (day 30). Treatment included surgery, chemotherapy, radiation, or any combination. Baseline demographic characteristics as well as CGA components were abstracted. TUG, MMSE, PHQ-9, IADL, PP, BMI, MNA and ADL performed at day 0 and 30 were collected. The mean for each score was obtained at both days. Student T test was used to test for significance for nominal data and Chi square test for ordinal data. A P value of less than 0.05 was deemed statistically significant. **Results:** 283 patients were enrolled. The mean age was 76 (+-6.86) of which 54% were females. 92% of patients were white and 8% were black. Colorectal and lung cancer were among the most common. The mean Charleston comorbidity index was 12.3 (+-3.2). The mean BMI decreased from 26.92 (+-5.84) at day 0 to 26.1 (+-5.45) at day 30 ($p < 0.01$). The mean IADL decreased from 5.93 (+-2.03) to 5.2 (+-2.12) ($p < 0.01$). At day 0, one patient had impaired ADLs compared to 7 patients at day 30 ($p = 0.03$). PHQ-9, MMSE, MNA, TUG and PP scores did not significantly differ at day 30 post treatment (Table). **Conclusions:** The ADL, IADL and BMI scores showed a statistically significant change at Day 30, indicating deteriorating scores in those patients. Our study showed that ADL, IADL and BMI were the only variables that worsened at day 30 post-treatment compared to PHQ-9, MMSE, MNA, TUG and PP. This suggests that they may be used as early markers of clinical deterioration in geri-onc patients undergoing treatment. More studies are needed to assess their prognostic significance. Research Sponsor: None.

CGA variables	Day 0	Day 30	P
BM	26.92 (+-5.84)	26.1(+-5.45)	<0.01
IADL	5.93(+-2.03)	5.2(+-2.12)	<0.01
PHQ-9	5.02(+-4.3)	5.13(+-3.82)	0.72
MMSE	27.01(+-3.38)	26.91(+-3.11)	0.63
MNA	4.96(+-3.44)	5.23(+-2.81)	0.5
TUG	10.23(+-2.52)	10.11(+-1.78)	0.74

Associations of quality of social support and beliefs in curability among older adults with advanced cancer. *First Author: Lee Kehoe, University of Rochester Medical Center, Rochester, NY*

Background: Prior studies suggest that social support plays a role in disease understanding of older patients with advanced cancer. In this study, we examined the association of quantity and quality of social support with belief in curability among older patients with advanced incurable cancer. **Methods:** We performed a secondary analysis of a cluster-randomized geriatric assessment trial (URCC 13070: PI Mohile) that recruited older adults (≥70) with advanced incurable cancer and caregivers. At enrollment, patients completed the Older Americans Resources and Services (OARS) Medical Social Support form to measure both quantity (number of close friends and relatives) and quality of social support. Quality of social support was measured using twelve questions, each ranged from 1 (none of the time) to 5 (all of the time). Higher cumulative scores indicated greater quality of support. For beliefs in curability, patients were asked, What do you believe are the chances that your cancer will go away and never come back with treatment? Responses were 0%, <50%, 50/50, >50%, and 100%. Ordinal logistic regression was used to investigate the association of social support with beliefs in curability, adjusting for adjusting for age, gender, education, race, number of Geriatric Assessment (GA) impairments, cancer type, and locality (rural versus urban). **Results:** We included 347 patients; mean age was 76.4 years, 91% were white, 52% were male, 46% had household income <$50,000, and 55% had high school degree or higher. For every unit increase in OARS Medical Social Support score, the odds of believing in curability decreases by 36.4% [Adjusted Odds Ratio (AOR) 0.733, 95% Confidence Interval (CI): (0.555, 0.969)], after controlling for covariates. Quantity of social support was not associated with belief in curability [AOR 1.033 95% CI: (0.921, 1.156)]. **Conclusions:** Our study revealed that older patients with advanced cancer who felt more supported by their social network were more likely to report that their cancer was not curable. Interventions that improve quality of social support may also affect disease understanding. Perceived physical fatigability improves after an exercise intervention among breast cancer survivors: A pilot randomized clinical trial. *First Author: Yujia (Susanna) Qiao, University of Pittsburgh, Pittsburgh, PA*

Background: Among breast cancer populations, exercise interventions resulted in positive but relatively small improvements on fatigue, which may have been masked by using single-item, non-specific measures of global fatigue. Perceived fatigability – whole-body tiredness anchored to standardized tasks/activities of specific intensity and duration – accounts for self-pacing bias as an individual likely titrates their usual activities and exertion level to avoid exhaustion. We examined whether this novel fatigability measure could replace global fatigue in an exercise intervention trial in breast cancer survivors. **Methods:** This pilot single-center randomized clinical trial of 49 breast cancer survivors was conducted from 2015-17, among which 41 participants (exercise = 22, control = 19) completed the trial and reported their perceived physical fatigability and global fatigue at the first (V1) and the last visit (V3). Perceived physical fatigability was measured using the 10-item, self-administered Pittsburgh Fatigability Scale (PFS) scored 0-50, higher PFS Physical scores = greater fatigability. Global fatigue was assessed with a single question I have a lack of energy scored 0 not at all to 4 very much from the Functional Assessment of Cancer Therapy-Endocrine Subscale (FACT-ES). The exercise intervention consisted of three one-on-one training sessions over 6-14 weeks, plus two optional email/phone consultations. The trainer developed a personalized, home-based exercise program with a goal of achieving the recommended ≥150 minutes/week of moderate to vigorous exercise based on ACSM guidelines. Those randomized to the control group met the trainer for V1 and again 6-14 weeks later at V3, but no exercise prescription was provided. We computed mean differences in perceived physical fatigability and global fatigue between V3 and V1 and compared by intervention groups. **Results:** Among the 41 women in the study (mean age = 54.9±9.8 years; 80% white), sociodemographic and clinical characteristics were similar by intervention groups, except for antiestrogen use. Post-intervention changes (mean ± SE) in PFS Physical scores were -4.4±1.4 (-22.5%) in the exercise group and 0.2±1.4 (+1.0%) in the control group ($p = .022$), whereas change in global fatigue scores were -0.64±0.23 in the exercise group and 0.00±0.22 in the control group ($p = .054$). **Conclusions:** These findings add to mounting evidence that an exercise intervention reduces fatigue among breast cancer survivors. Importantly, the PFS showed a clinically meaningful reduction after the exercise intervention that was masked when using global fatigue as the measurement. Therefore, the PFS serves as a more sensitive instrument to measure perceived physical fatigability and can better evaluate patient-reported outcomes in future cancer trials, especially those focused on cancer survivorship. Clinical trial information: NCT 02770781. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Patient experience of early high grade symptomatic adverse events on early phase clinical trials using the PRO-CTCAE. *First Author: Geoffrey Alan Watson, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: There are limited data describing the patients' experience of symptomatic adverse events (syAEs) on early phase clinical trials. This information is critical to understand the tolerability of experimental agents. The patient reported outcome version of the CTCAE (PRO-CTCAE) evaluates syAE components such as severity and interference in daily life. The aim of this study was to correlate clinician reported early, high grade (grade 3-4) AEs with patients' reported experience of these toxicities. **Methods:** Advanced solid tumor patients (pts) enrolled on early phase clinical trials at Princess Margaret Cancer Centre were surveyed electronically using the full library of 78 items for PRO-CTCAE v1.0, which was administered at baseline (prior to therapy), mid-cycle 1, and mid-cycle 2. AEs on study were recorded by physicians using the CTCAE v4.0. Worst responses for severity items are severe' and very severe' and for interference items are quite a bit' and very much'. A logistic regression model was used to assess the association between CTCAE grade and PRO-CTCAE severity and interference. **Results:** A total of 292 pts were approached in phase 1 clinics from May 2017 to January 2019, and 219 pts were included in the analysis: median age 60 years (range 18-82), 111 (51%) were male; all were ECOG ≤1. A total of 140 pts (64%) received combination therapy (immunotherapy and targeted therapy), and 73 pts (33%) had received ≥3 previous lines of treatment. In terms of patient reported syAEs, a total of 114 pts (52%) reported a symptomatic AE as either severe or very severe at any timepoint and 79 pts (36%) reported a syAE with an interference that was either quite a bit' or very much'. With regards to clinician reported AEs, a total of 82 pts (37%) had a clinician reported grade 3 or 4 syAE, and of these 34 pts (41%) reported these as either severe or very severe; and 26 pts (32%) found these AEs interfered with daily life either quite a bit' or very much'. Additionally 137 pts (66%) had a clinician reported grade 1 or 2 syAE, and of these 39 pts (28%) reported these as either severe or very severe; and 19 (14%) found these AEs interfered with daily life either quite a bit' or very much'. Higher grade clinician reported syAEs (CTCAE grade 3-4 vs 1-2) was associated with higher patient reported severity levels (odds ratio, OR = 1.78, 95% CI 1-3.16, $p = 0.049$), and was associated with higher patient reported interference levels (OR = 2.88, 95% CI 1.47-5.64, $p = 0.002$). **Conclusions:** A majority of patients had a very negative experience of syAEs on a phase I trial. Higher grades of clinician reported AEs correlated with greater severity and interference with daily living. Future phase I studies could incorporate the PRO-CTCAE and other PRO tools which could inform the tolerability of experimental regimens and enhance the description of symptomatic AEs. Overall and progression-free survival in young breast cancer patients with low muscle mass and density. *First Author: Rebecca Sheaff Greiner, Atrium Health Levine Cancer Institute, Charlotte, NC*

Background: Low muscle mass (skeletal muscle index, SMI) and density (skeletal muscle density, SMD) are associated with chemotherapy toxicity and shorter survival in women with breast cancer. This has not been studied specifically in women ≤ 40 years at diagnosis. They have different body compositions and more aggressive cancers than older women. We compared pre-treatment muscle measures in survivors and non-survivors and investigated their association with overall survival (OS) and progression-free survival (PFS). **Methods:** This case-control study included 112 women aged ≤ 40 years at diagnosis. Women with pre-treatment CT scans from 2009-2018 were identified; non-survivors were matched with survivors by age, year of diagnosis and disease characteristics. Body composition was determined by CT analysis. Measures were compared between the groups using Kruskal-Wallis tests. Kaplan-Meier methods summarized OS and PFS and the associations of muscle characteristics with OS and PFS were examined by univariate Cox proportional hazard models. **Results:** Median age was 35 years; median follow-up was 8.2 years. 75% had Stage II or III disease and 21% Stage IV disease. 33% were sarcopenic (SMI < 40) and 16% had low SMD (HU <37.8). Non-survivors had more intermuscular fat (IMAT), reduced SMD, and reduced skeletal muscle gauge (SMG). Sarcopenia was not associated with OS; however, sarcopenia was associated with shorter PFS. The median skeletal muscle gauge was 1973; low skeletal muscle gauge (SMG <1973) was associated with both shorter OS and PFS. Median IMAT was 1.6, and high IMAT (≥1.6) was associated with shorter OS and PFS. **Conclusions:** Low muscle mass (sarcopenia) at breast cancer diagnosis was associated with shorter PFS and low muscle density (low SMG and higher IMAT) was associated with shorter OS and PFS in women ≤ 40 years. These sub-optimal muscle characteristics may indicate an overall reduced state of health and/or decreased ability to tolerate treatment, thus reducing survival. Future research should determine the significance of muscle changes throughout treatment and establish standards for improved muscle health. Research Sponsor: Atrium Health Foundation.

COVID-related anxiety is prevalent and accurately reflects serious COVID risks in breast cancer patients. *First Author: Marisa C. Weiss, Breastcancer.org, Ardmore, PA*

Background: A current cancer diagnosis is a risk factor for serious COVID-19 complications (CDC). In addition, the pandemic has caused major disruptions in medical care and support networks, resulting in treatment delays, limited access to doctors, worsening health disparities, social isolation; and driving higher utilization of telemedicine and online resources. Breastcancer.org has experienced a sustained surge of new and repeat users seeking urgent information and support. To better understand these unmet needs, we conducted a survey of the Breastcancer.org Community. **Methods:** Members of the Breastcancer.org Community were invited to complete a survey on the effects of the COVID-19 pandemic on their breast cancer care, including questions on demographics, comorbidities (including lung, heart, liver and kidney disease, asthma, diabetes, obesity, and other chronic health conditions); care delays, anxiety due to COVID-related care delays, use of telemedicine, and satisfaction with care during COVID. The survey was conducted between 4/27/2020-6/1/2020 using Survey Monkey. Results were tabulated and compared by chi square test. A p-value of 0.05 is considered significant. Data were analyzed using Stata 16.0 (Stata Corp., Inc, College Station, TX). **Results:** Our analysis included 568 breast cancer patients of whom 44% had ≥1 other comorbidities associated with serious COVID-19 complications (per CDC) and 37% had moderate to extreme anxiety about contracting COVID. This anxiety increased with the number of comorbidities (p=0.021), age (p=0.040), and with a current breast cancer diagnosis (p=0.011) (see table). Anxiety was significantly higher in those currently diagnosed, ≥65, or with ≥3 other comorbidities, compared to those diagnosed in the past, age <44, or without other comorbidities. **Conclusions:** Our survey reveals that COVID-related anxiety is prevalent at any age regardless of overall health status, but it increased with the number of other comorbidities, older age, and a current breast cancer diagnosis. Thus, reported anxiety is proportional to the risk of developing serious complications from COVID. Current breast cancer patients of all ages—especially with other comorbidities—require emotional support, safe access to their providers, and prioritization for vaccination. Research Sponsor: None.

High intensity interval training safety and efficacy in patients with advanced NSCLC receiving systemic treatment: Results of a prospective trial. *First Author: Myriam Nait Ajjou, CHUM, Montreal, QC, Canada*

Background: Patients with advanced NSCLC experience fatigue and physical deconditioning altering their quality of life. Safety and feasibility of high intensity exercise in advanced NSCLC has not been explored yet. **Methods:** We report the results of a single-center, prospective two-arm study. Patients with advanced NSCLC actively receiving systemic therapy or having completed treatment less than 2 months prior to enrollment were included. Patients were allocated to either an intervention arm consisting of kinesiologist supervised high intensity interval training (HIIT) at 2 sessions per week for a total of 12 weeks; or a control arm of home exercise guided by an informative pamphlet. All patients were evaluated at baseline, 6 and 12 weeks by a kinesiologist. Quality of life (QoL) exercise surveys and measurement of strength were measured. **Results:** Sixty patients were enrolled between January 2018 and March 2020. The study was interrupted due to COVID-19. Thirty-two patients were included in the exercise program and 28 patients in the control group. Both groups were balanced in respect to baseline characteristics. A total of 32 (53%) patients went off protocol, 13 (18%) patients stopped due to symptomatic disease progression which included 2 (3%) deaths, 2 (3%) stopped due to COVID-19 preoccupations and the remaining patients withdrew for other reasons. 42 (70%) patients were evaluated at 6-weeks and 28 (47%) completed the 12-week follow-up, with equal distribution in each group. There were no significant difference at 12 weeks in the physical assessment nor the overall QoL scores between both groups: FACT-L on 135 points (+4.1 vs +1.7, p = 0.342) and FACIT on 52 points (+3 vs -0.2, p = 0.832). Patients in the exercise group demonstrated a significant improvement at 12 weeks in the Lung Cancer Symptoms domain on 28 points (22.3 vs 19.8, p = 0.015) as well as the Physical Wellbeing domain on 28 points (23.6 vs 20.6, p = 0.056) compared to the control group, respectively. No significant exercise related complications were reported. After the study, 9 of the 14 patients (64%) who completed the HIIT program continued to exercise virtually with a kinesiologist in contrast to none in the control group. **Conclusions:** This study demonstrated the safety and potential benefit of a HIIT program on lung-specific and physical wellbeing in patients with advanced NSCLC on active treatment. This study provides further support on the role of supervised physical exercise in patients living with cancer. Clinical trial information: 16.229. Research Sponsor: None.

Predictors of receiving survivorship care plans and visits. *First Author: Christine M. Duffy, Lifespan Cancer Institute, Providence, RI*

Background: While the Commission on Cancer has eliminated strict quotas for accreditation, Survivorship Care Plans (SCPs) and/or Survivorship Care Visits (SCV) at treatment completion are encouraged. However, who receives a SCP or SCV, whether it impacts care, and impact of distress on care is unknown. We examined the provision of survivorship care at the Lifespan Cancer Institute (LCI) to determine (1) clinical and distress thermometer scores (DTS) association with SCPs and SCVs; (2) impact of SCV visits on specialty referrals, and (3) demographic and clinical predictors of receipt of SCP and SCV. **Methods:** We retrospectively reviewed EMR records on 1,960 patients at LCI between 2014-2017 for SCPs and SCVs and extracted demographics, treatment variables, and distress scores. We used T-test or Wilcoxon rank test and Chi-square tests for evaluating the bivariate associations of SCP and SCV with continuous and categorical factors respectively. We fit logistic regression models to assess the adjusted effect of these factors on receipt of SCP and SCV independently. All analyses were performed in R v4.0.2. **Results:** The mean age was 63.9 (SD=11.8), 67% were female, 51.2% were married or partnered. Breast (38.8%), lung (17.6%), and prostate (13.7%) were the most common cancers. DTS were recorded in 64% with mean of 3.88(SD=3.05): distress was higher in women (4.36, SD=3.01), breast cancer pts (4.53, SD=3.07), gyn (4.22, SD=3.07) , pancreatic (4.12, SD=3.41) and anal cancers (4.52, SD=3.47) and in those with Stage IV disease (5.33, SD=3.43). SCPs were completed in 740 (37.8%) patients and of those 65.9% had a SCV. SCV were associated with more specialty referrals for psychiatry, physical therapy, nutrition, and sexual health but not smoking cessation or fiscal services. DTS were associated with increased referral to psychiatry only. The adjusted models (table) showed odds of receiving a SCP were higher in those younger, and having breast cancer v all other cancers, with prostate having lowest odds. For receipt of SCV, odds were higher in those younger, female, and having breast cancer, with prostate and lung having the lowest odds. **Conclusions:** Gender, age and type of cancer are significant predictors of receipt of SCP and SCV. SCP and SCV patterns may represent patient preferences, but practice patterns and unconscious biases may also play a part suggesting areas for further research and outreach. Research Sponsor: None.

Weight management following endometrial cancer treatment: A pilot trial to evaluate the efficacy of the profile by Sanford program. *First Author: Maria Bell, Sanford Health, Sioux Falls, SD*

Background: Excess weight and weight gain are risk factors for endometrial cancer and cancer recurrence following treatment for women with endometrial cancer. Conversely, weight loss among women with obesity has been shown to reduce endometrial cancer risk. Intensive behavioral weight management programs may be an effective method to improve health and reduce weight following treatment. **Methods:** Twenty-two women following endometrial cancer treatment (age = 59.4 ± 11.5; weight = 241.3 ± 46.3; BMI = 40.5 ± 7.8; time since last treatment 19 ± 17.4 months) were enrolled in a behavioral weight management program and followed for 12 months and 28 matched controls (age = 58.4 ± 11.5; weight = 246.9 ± 60.3; BMI = 41.6 ± 8.6) were assessed over 12 months. The program consists of weekly health coaching meetings to discuss nutrition, activity, and behavior change topics. The nutrition plan targets ≥4 cups of vegetables per day, a lean and green' grocery meal, complimented with meal replacement foods to provide a nutritionally complete meal plan. Cost of participant membership, coaching, and meal replacements were covered for 6 months and available to purchase for months 7-12. **Results:** The treatment group completed 28.3 ± 14.1 appointments throughout 12 months resulting in an average weight change of -31.2 ± 17.3 pounds (-13.3 ± 7.4%) at 6 months and -36.1 ± 27.6 pounds (-15.3 ± 11.4%) at 12 months (all $p<0.001$). Controls had a weight change of -3.9 ± 18.4 pounds (-2.3 ± 7.6%) at 12 months which was significantly different than the treatment group ($p<0.001$). BMI was significantly reduced in the treatment group at 6 months (-4.8 ± 4.5, $p<0.001$) and 12 months (-5.2 ± 5.9, $p<0.001$) and significantly different than in the control group at 12 months (-0.9 ± 3.2, $p=0.007$). **Conclusions:** This behavioral weight management program with health coaching and structured nutrition provided clinically significant weight loss that was sustained to 12 months. Future research should examine long-term enrollment in the Profile by Sanford program with reduction in endometrial cancer recurrence. Research Sponsor: Profile by Sanford.

Predictors of early readmission to hospital and mortality in patients with malignant ascites: Analysis of the nationwide readmissions database. *First Author: Omid Yazdanpanah, Wayne State University, Detroit, MI*

Background: Malignant ascites accounts for 7 percent of ascites cases in the United States. It is a common manifestation of several solid tumors and is associated with poor prognosis with median survival of 3 months. Moreover, patients with malignant ascites are at risk of recurrent hospitalizations. Hospital readmissions are costly for health-care system and are regarded as a quality of care index. Nevertheless, predictive factors for hospital readmissions and mortality in patients with malignant ascites are limited. Understanding these factors can expedite development of strategies to reduce the readmission and health-care costs. **Methods:** Utilizing the Nationwide Readmissions Database (NRD), we conducted a retrospective cohort study on patients admitted with malignant ascites between 2016 and 2018 across the United States. We used multivariable logistic regression to determine the predictors of unplanned 30-days readmissions and mortality among patients with malignant ascites. **Results:** Out of 130,648 patients hospitalized with malignant ascites, 15,756 individuals (12.1%) were readmitted within next 30 days. Predictors of early readmission included pulmonary embolism (OR 2.40; 95% CI 1.55-3.74), complicated diabetes (OR 1.28; 95% CI 1.05-1.56) and having Medicaid insurance (OR 1.34; 95% CI 1.11-1.62). In-hospital mortality for patients with malignant ascites was 14.1%. The comorbidities associated with increased mortality were liver disease (OR 1.87; 95% CI 1.77-1.97), pulmonary embolism (OR 1.60; 95% CI 1.34-1.90), renal failure (OR 1.39; 95% CI 1.27-1.52), and congestive heart failure (OR 1.27; 95% CI 1.16-1.38). Patients with Medicaid insurance also had higher mortality (OR 1.21; 95% CI 1.12-1.32) among the payers. **Conclusions:** One in eight patients with malignant ascites was readmitted to the hospital within 30 days of discharge. By examining the risk factors leading to readmission, this study helped to identify the subpopulations of patients likely to become more ill. The strong association of pulmonary embolism with readmission and in hospital mortality suggests the benefit of prophylactic anticoagulation. Furthermore, higher readmission and mortality rate within Medicaid insurance population can open a new window in studying health care disparities. Research Sponsor: None.

The GET FIT trial (NCT01635413): A randomized controlled trial of strength training versus Tai Ji Quan for fall prevention among female cancer survivors. *First Author: Kerri M. Winters-Stone, Oregon Health & Science University, Portland, OR*

Background: Women with cancer are significantly more likely to fall than women without cancer but there are not yet any evidence-based fall prevention strategies that specifically target cancer survivors. The GET FIT trial compares the efficacy of two distinct types of exercise, strength training vs. tai ji quan, to prevent falls in women finished with chemotherapy. **Methods:** We conducted a 3 group, single-blind, parallel design, randomized controlled trial in older, inactive women cancer survivors treated with chemotherapy. Women were randomly assigned to 1 of 3 intervention groups: 1) strength training, 2) tai ji quan or 3) a placebo control group (stretching) that trained 2x/week for 6 months. Additional follow-up occurred 6 months after formal training stopped. The primary outcome was fall rate across 6-and 12 months; secondary outcomes, reflective of training fidelity, were maximal leg strength (by 1-repetition maximum) and dynamic postural control (by computerized dynamic posturography), collected at 0, 3, and 6 months. **Results:** 442 women (mean age 62.4 + 6.3 yrs.) were enrolled and randomly assigned to study groups. Over the 6 months prior to enrollment, 21% of the sample (n = 94) reported at least one fall (of which, 37% (n = 35) reported two or more falls)), and 12% (n = 51) reported at least one injurious fall. Retention across the 12 months study period was 88%, while adherence to the study interventions over 6 months averaged 73%, 71%, and 74% for the strength, tai ji quan and stretching (control) groups, respectively. 26% of the sample (n = 99 of 382) reported at least one fall during the intervention and 27% (n = 102) reported falls during follow up. Using regression models, there were no significant differences in the odds of having at least one fall during the intervention period (1-6 months) or across the entire follow-up period (1-12 months) between the control and either the strength or tai ji quan groups. At 6 months, the strength group showed a greater increase from baseline in maximal leg strength (+14.3 kg, 95% CI: 11.4-17.1) than the control group (+7.5 kg, 95% CI: 4.6-10.4, p = 0.002). Whereas, the tai ji quan group showed a greater increase in dynamic postural control (+2.42%, 95% CI: 1.36-3.48) compared to the control group (+0.35%, 95% CI: -0.69-1.38, p = 0.007). **Conclusions:** Despite evidence for fidelity of strength and tai ji quan training to improve muscle strength and postural control, respectively, neither program significantly lowered fall rates over a placebo control group. It is possible that the dose of exercise was too low and/or the sample was not at high risk of falls. The etiology of fall risk in women cancer survivors needs to be better understood as it may differ from risk factors in older adults. Future trials should consider patient-centered, tailored fall-prevention interventions for cancer survivors based on identified fall risk factors. Clinical trial information: NCT01635413. Complementary and alternative medicine use among cancer patients at two cancer centers in Brazil. *First Author: Eliza Dalsasso Ricardo, Hospital Alemão Oswaldo Cruz, São Paulo, Brazil*

Background: Complementary and alternative medicine (CAM) use is relatively common among cancer patients. Data regarding CAM use in Brazil is scarce. We sought to define CAM use among cancer patients and investigate factors that might influence it. **Methods:** We conducted a cross-sectional survey of adults diagnosed with any cancer type who came to appointments at two cancer centers in Brazil from January 2020 to January 2021. Unadjusted and adjusted analyses were conducted by using Logistic Regression models to determine the association of covariates with binary outcome. Statistical analyses were performed with SAS 9.4 (SAS Institute Inc, Cary, NC). All tests were 2-sided, and $P < 0.05$ was considered significant. **Results:** In total, 319 patients who consented to the face-to-face interview were included and all of them completed the questionnaires. Most patients (52.4%) were between 51 and 70 years-old, 59,6% were female, 85,2% were from the private service and 67% had college graduate/baccalaureate. Most cancer types were from gastrointestinal tract (31,4%), breast (20.4%), lung (12.3%) and genitourinary type. More than 85% of the participants were on any active cancer treatment. The prevalence of current CAM use was 34.2% and 50.2% of the patients did not believe CAM has anti-cancer properties. Two-thirds of the participants have never discussed about CAM with their oncologists. Only 4.1% of the respondents would abandon conventional cancer treatment in order to use just CAM. Among CAM users, 55% referred multiple therapies use. Of those therapies, spiritual surgery was the most prevalent one. There was a significant higher proportion of females reporting CAM use (p = 0,008) as well as a higher proportion of CAM use among private patients (p = 0,008). **Conclusions:** CAM use was common among our study population, especially spiritual surgery. Women and private patients were more prone to use CAM. Although most patients would not abandon conventional treatment, many of them have never discussed about CAM with their oncologists. Research Sponsor: None.

Brief relaxation training effects on long-term endocrine therapy adherence among women with breast cancer. *First Author: Molly Ream, University of Miami, Coral Gables, FL*

Background: Despite life-saving potential, many women struggle to adhere to adjuvant endocrine therapy (AET) for their early-stage, hormone receptor-positive breast cancer. Prior research has demonstrated that emotional distress is a barrier to AET adherence. The current study aimed to test the long-term effects of two 5-week post-surgical group-based stress management interventions, cognitive behavioral therapy (CBT) and relaxation training (RT), versus an attention-matched health education (HE) control on AET adherence at long-term follow-up. **Methods:** We conducted long-term follow-up (median = 8 years, range = 7-11 years) of a cohort of women who enrolled in a randomized controlled trial of CBT vs. RT vs. HE shortly after surgery for stage 0-3 breast cancer.We measuredadherence with the Endocrine Therapy Medication Usage Questionnaire (ETMUQ) given at long-term follow-up. First, we established adherence factors on the ETMUQ via confirmatory factor analysis. We then used structural equation modeling to regress these factors on study arm, controlling for patient age, stage of disease, and treatments received (chemotherapy/radiation). **Results:** The sample was predominately middle-aged (M= 54.81, SD= 10.19), White (41.5%) and Hispanic (42.2%), partnered (62.2%) with stage 1 (57.0%) or stage 2 (25.9%) disease. Of the women who completed long-term follow-up (N = 59, 44.7% of original sample); more than half (n = 30; 50.8%) reported having at least some problems with adherence. There was an effect of intervention group on adherence, such that women receiving RT (n = 15) had significantly better adherence than those receiving CBT (n = 20) on the factor measuring Forgetfulness/Inconsistency ($B(SE)$ = .57 (.34), p= .001), and marginally better adherence than those receiving CBT on the factor measuring Intentional Nonadherence ($B(SE)$ = .60 (.33), p = .062). There was no such effect when comparing RT or CBT to HE (n = 24). **Conclusions:** Women receiving RT were less likely to forget to take their AET and marginally less likely to intentionally miss doses of AET in the long-term compared to women receiving CBT. Future research could investigate the mechanism by which RT may improve adherence. For example, RT may reduce somatic symptoms related to AET or improve a patients' self-efficacy to cope with these symptoms thereby reducing intentional non-adherence. In addition, RT may improve patients' attention and awareness leading to less forgetfulness. Clinical trial information: NCT02103387. Research Sponsor: U.S. National Institutes of Health.

Multifactorial analysis of cancer patients' willingness for COVID-19 vaccination. *First Author: Paris A. Kosmidis, Care Across, London, United Kingdom*

Background: Public health authorities advocate vaccinations for the general population, including cancer patients and survivors. Since the onset of the COVID-19 pandemic, its vaccine has been eagerly awaited, but the extent of cancer patients' willingness to get vaccinated is not clear. As health promotion is crucial for these individuals, it is important to measure and analyze their willingness to receive the vaccine. **Methods:** A few days after the regulatory approval for the first COVID-19 vaccine, the CareAcross online interactive platforms were used to evaluate the willingness of patients to get vaccinated. Through an online survey, within a few hours, 1106 cancer patients selected either Yes, I plan to get the vaccine or No, I will not get the vaccine. The patients were from the UK, Germany, France, Spain or Italy; they had been diagnosed with breast, lung, prostate or colorectal cancer. Their responses were analyzed to determine how their cancer diagnosis (including date, metastatic status, and other aspects), and their country of origin, affected their reported willingness to get vaccinated. **Results:** Overall, 70.6% of patients indicated willingness to get the vaccine (WTV), and 29.4% reported the opposite (NWTV). The strongest determinant of WTV was the patient's country of origin: patients in the UK, Spain, Italy, Germany and France reported WTV of 84.1%, 64.2%, 58.7%, 47.4% and 38.3%, respectively. The next strongest determinant was the time elapsed since the patient's diagnosis: for the largest population with available diagnosis date (451 UK patients), the average time since diagnosis for patients with WTV vs NWTV was: breast, 3.5 vs 2.5 years; lung, 1.6 vs 1.4 years; prostate, 2.4 vs 3.3 years; colorectal, 1.9 vs 1.5 years. Among patients from other countries with available diagnosis date: as the time since diagnosis increased, among 148 Italian patients WTV gradually increased; among 94 Spanish patients, WTV substantially decreased; among 85 French patients, WTV gradually decreased; among 50 German patients, WTV substantially increased. There was no significant correlation of WTV percentages with cancer type; metastatic status; triple negative vs non-triple negative among breast cancer patients; non-small cell vs small cell among lung cancer patients. **Conclusions:** Despite long-standing efforts of the scientific community for health promotion through the COVID-19 vaccine, a substantial percentage of cancer patients reported no willingness to get vaccinated. This appeared to depend on each patient's country of origin, and the time elapsed since their diagnosis. This patient input was collected shortly after the first vaccine's approval. With increasing evidence of efficacy and safety through more vaccinations of citizens and patients, willingness is expected to increase. We are in the process of conducting a follow-up survey to track these changes and update the results to be reportable during ASCO. Research Sponsor: None.

Integration of a polygenic risk score of kidney function with cumulative cisplatin dose and time variables for the prediction of serum platinum levels. *First Author: Megan Shuey, Vanderbilt University Medical Center, Nashville, TN*

Background: Platinum levels are measurable in the serum for decades after cisplatin therapy and higher levels may be related to chemotherapy-induced toxicities. Since cisplatin is cleared exclusively by the kidney, we hypothesized that a genetic predictor of kidney function, an estimated glomerular filtration rate polygenic risk score (eGFR PRS), would significantly associate with serum platinum levels and could improve prediction models. **Methods:** Within a large well-characterized, multicenter clinical cohort of cisplatin-treated testicular cancer survivors (TCS), we conducted analyses on all patients with genetic data and serum platinum levels. Genotyping was performed on the HumanOmniExpressExome chip and standard QC measures were included. Serum platinum concentrations were quantified by inductively coupled plasma mass spectrometry. For all TCS, time since therapy (TIME) and cumulative cisplatin dose were collected. The eGFR PRS was developed from the Chronic Kidney Disease Genetics (CKDGen) consortium meta-analysis summary statistics using PRS-CS. Using principal component analysis, we restricted the analysis to TCS of genetically determined European ancestry, then calculated the genome-wide PRS for all participants. We performed Cox regression analyses to evaluate prediction models of serum platinum that included cumulative dose and TIME, as well as a model including eGFR PRS. Data are presented as median (interquartile range). **Results:** 901 patients were included in our analysis with a median diagnosis age of 31 (26 - 38) years, cumulative cisplatin dose of 400 (300-400) mg/m^2, and time since first cisplatin dose of 4.6 (2.3-9.5) years. The median serum platinum level for all TCS was 305 (121-981) ng/L. When stratified into quartiles by eGFR PRS, TCS in the lowest quartile had a median serum platinum level of 316 (139-1014) ng/L while TCS in the highest had a median of 268 (106-731) ng/L. Comparison of two Cox regression models for serum platinum prediction, one including only cumulative dose and TIME as predictors and a second including dose, TIME, eGFR PRS, and an eGFR PRS*TIME interaction term, we determined the model including eGFR PRS had a lower AIC (14350 vs 16180) suggesting a more parsimonious model. Further, eGFR PRS was a significant independent predictor of serum platinum levels (p = 0.02) and the impact of eGFR PRS varies over time (eGFR PRS*TIME, p = 0.05). **Conclusions:** The genetic predictor of kidney function circumvents the use of renal function measures that may have been impaired by initial cisplatin administration. It is a significant independent predictor of serum platinum levels and consistent with expectation: TCS with higher genetically predicted kidney function had lower serum platinum levels. Our results suggest kidney function inferred by genetics may improve the prediction of serum platinum levels. Research Sponsor: U.S. National Institutes of Health.

Patient preferences for cancer survivorship care: Results of an online survey. *First Author: Deanna J. Attai, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Nearly 17 million cancer survivors live in the United States. Workforce shortages are projected to diminish the number of available medical oncologists (MOs) to care for newly diagnosed patients with cancer and for the growing number of cancer survivors. Models of survivorship care include oncologist-led, primary care-led, and shared care approaches. Recent proposals recommend a risk-stratified approach to care, guided by individual and cancer-specific factors, but there is little evidence regarding patient preferences for non-oncologist survivorship care. **Methods:** We developed a survey in partnership with patient advocates. The primary endpoints were patient-reported comfort with survivorship care by a primary care provider (PCP) or in a dedicated survivorship clinic. We distributed the survey to online, cancer-specific patient communities from June to August 2020. Logistic regression analyses were adjusted for patient age, race and ethnicity, insurance, and cancer type and stage. **Results:** Of 1166 responses, 975 surveys were complete and available for analysis. Respondents were primarily women (91%), white (92%), and US residents (73%); 78% had a college or graduate degree. Two-thirds had private insurance. Thirty-six different cancer types were reported; 61% of respondents had breast cancer, and 25% were treated for more than one type of cancer. Most respondents (83%) had nonmetastatic disease, 74% reported experiencing late effects of cancer therapy, and almost all (93%) had a PCP. Only 21% of respondents were comfortable seeing a PCP (versus MO) for survivorship care, including cancer follow-up, side effect management, and monitoring for recurrence or progression. About half (55%) were comfortable with follow-up in a survivorship clinic instead of with their MO. Multivariable analyses showed no significant associations between age, race or ethnicity, insurance, cancer type, or stage at diagnosis and comfort with follow-up care from a PCP or in a survivorship clinic. In analyses restricted to the 439 respondents with a history of early-stage breast cancer, the 239 (54%) who were within 1 to 5 years of diagnosis were less comfortable with PCP versus MO follow-up, compared with the 52 (12%) who were $>$ 15 years from diagnosis (OR 0.40; 95% CI 0.20–0.75; p= 0.004). In this sub-analysis, time from diagnosis was not associated with comfort being seen in a survivorship clinic. **Conclusions:** In our study, most patients with a history of cancer were not comfortable receiving follow-up care from their PCP. It is often recommended that survivors of early-stage breast cancer transition to primary care for follow-up and surveillance, but our study revealed comfort with this approach only many years after diagnosis. While both PCP survivorship training and patient confidence in PCP follow up is needed, preferences of cancer survivors should be considered in designing new models of survivorship care. The rate and risk of secondary pelvic malignancies (SPM) in patients treated with definitive radiation for locally advanced rectal cancer. *First Author: Kathryn Ries Tringale, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: With a rising incidence of younger patients diagnosed with rectal cancer, the long-term toxicity of cancer-related therapy is becoming even more relevant. Risk of SPM is a known potential consequence of both chemotherapy (chemo) and radiation therapy (RT), yet the rate of SPM in patients with rectal cancer is still not defined. We sought to further investigate factors associated with and outcomes of SPM after RT for rectal cancer. **Methods:** Patients diagnosed with stage II-III rectal cancer treated with chemo and/or RT from 1995-2019 were included in a retrospective study. Patients treated with palliative intent and those who survived < 5 years from treatment were excluded. RT-associated SPM was defined as a cancer occurring $^{3}5$ years after RT completion. Cumulative incidence (CI) of SPM was analyzed using a landmark analysis at 5 years with death as a competing risk. For patients with CT simulation scans available, dosimetric analyses evaluated doses to the organs developing SPM. Kaplan Meier analysis was used to evaluate overall survival among patients who developed an SPM. **Results:** A total of 2,700 patients were included (RT = 978; chemo = 1722). Demographic characteristics were equivalent apart from age, which was higher in the RT group (61 vs 59 years, $p < 0.001$). Five (0.3%) chemo patients developed an SPM, all within 5-10 years after treatment for rectal cancer, vs 48 (4.9%) RT patients. The 8-year CI of developing an SPM in the RT group was 4% (95% CI 2.4-6.2) and increased to 17% at 15 years (95% CI 12.1-21.8) and 21% at 20 years (95% CI 14.8-27.7). Most (89%) RT patients had received chemotherapy (most commonly 5-FU or FOLFOX). The median time to SPM was 108 months (interquartile range [IQR], 84-140). After pelvic RT, the most common SPM histology was endometrial (38%), followed by prostate (31%), bladder (23%), sarcoma (4.2%), and other gynecologic cancers (4.2%). Seven patients had CT simulations for dosimetric analyses: median of maximum dose to the organ with SPM was 5301cGy (IQR, 4928-5427), median of mean dose was 4551 cGy (IQR, 4476-4751). None of the patients who developed endometrial cancer had Lynch syndrome. Median OS for patients with SPM after RT was 5.1 years with 5-yr OS of 58% (95% CI 43-77); 44 out of 48 patients needed at least one treatment modality for their SPM, and 8 received trimodality treatment [surgery, chemo and RT]. **Conclusions:** The CI of SPM increased from 4% at 8 years to 17% at 15 years and 21% at 20 years following pelvic RT for rectal cancer. Endometrial cancer was the most common SPM and survival following treatment of SPM was favorable. These data serve as a foundation for future prospective studies evaluating ways to reduce SPM such as proton therapy. Research Sponsor: None.

Impact of using volumetric dosimetry to screen childhood cancer survivors for radiation-related late effects. *First Author: Sally Cohen-Cutler, Children's Hospital Los Angeles, Los Angeles, CA*

Background: Late effects screening guidelines for survivors of childhood cancer treated with radiation therapy currently use irradiated regions (IR) rather than volumetric dosimetry (VD), which more precisely identifies organs-at-risk (OAR). We recently showed that VD reduced mean number of recommended screening diagnostic imaging studies and procedures by 37.0% per patient ($p<0.001$).[1] Here we have incorporated chemotherapy and refined volumetric dosimetry dose thresholds. **Methods:** This was a cross-sectional cohort study of patients (n=132) treated for cancer using computerized tomography-planned irradiation at Children's Hospital Los Angeles from 2000-2016. For each patient, both VD and IR methods were used to determine radiation exposure to the cochlea, heart, lung, breast, and colon. Dose thresholds for VD were based on those supplied in the Children's Oncology Group (COG) Long-Term Follow-Up Guidelines. Relevant chemotherapy exposures were recorded. Under each method, COG Long-Term Follow-Up Guidelines were applied to determine potential chemotherapy- and radiation-related late effects and their correlative screening practices (complete audiologic evaluation, pure tone audiometry, mammogram, breast MRI, echocardiogram, pulmonary functions test, and/or colonoscopy). Identified OAR were compared using Exact McNemar's test. Total numbers of screening practices were computed using VD and IR and compared. **Results:** Median age at end of treatment was 10.6 years (range 1.4-20.4). The most frequent cancer type was brain tumor (45%), followed by bone and soft tissue tumor (39%) and leukemia/lymphoma (16%). Head/brain was the most commonly irradiated region (61%), followed by abdomen (22%). Anthracyclines were received by 25% of patients at < 250 mg/m^2 and by 16% at ≥ 250 mg/m^2. With use of VD, fewer patients were flagged for screening for each organ of interest: cochlea (-21.3%, $p<0.001$), heart (-22.5%, $p<0.001$), lung (-13.8%, p=0.219), breast (-25%, p=0.625), colon (-51.9%, $p<0.001$). Over the lifetime of this cohort, use of VD resulted in recommendations for 1,333 fewer pure tone audiometric tests (-21.5%), 9 fewer complete audiologic evaluations (-16.1%), 4 fewer pulmonary function tests (-13.8%), 112 fewer mammograms (-25.0%) and breast MRIs (-25.0%), 349 fewer echocardiograms (-16.1%), and 275 fewer colonoscopies (-51.9%). **Conclusions:** Use of VD rather than IR significantly reduces guideline-based screening for radiation-related late effects in long-term childhood cancer survivors. This work forms the basis for a comparative cost-effectiveness analysis of these two approaches. (1) Cohen-Cutler et al, Cancer Medicine, 2020. Safety of using hormone replacement therapy in breast cancer survivors: A systematic review and metanalysis. *First Author: Francesca Poggio, Breast Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy*

Background: Improvements in breast cancer (BC) care have led to increased survival of patients; hence, more attention to long-term treatment-related adverse events and quality of life (QoL) is required. Symptoms of spontaneous and treatment-induced menopause significantly affect the QoL and adherence to endocrine therapy among BC survivors, with potential negative implications on outcome. Use of systemic hormone replacement therapy (HRT) to mitigate menopause-associated symptoms is not recommended to reduce the burden of these side effects being historically associated with an increased risk of disease recurrence. This systematic review and metanalysis aimed to estimate the effect of HRT on risk of disease recurrence in BC survivors. **Methods:** A systematic search of Pubmed and Embase libraries up to January 15, 2021, was conducted in order to identify randomized controlled trials (RCTs) investigating the risk of disease recurrence with the use of HRT in BC survivors. We used the random-effect model to calculate the overall risk of recurrence, reported as pooled hazard ratio (HR) with 95% confidence intervals (CI). Moreover, we performed a subgroup analysis to estimate the risk of recurrence according to hormone receptor status. The Higgins I^2 index was computed to assess the heterogeneity between studies. The likelihood of publication bias was assessed by Egger's test. **Results:** Four RCTs were found and three were included in the metanalysis (n = 3.973 patients); one study (n = 100 patients) was excluded due to the impossibility to extract the HR for disease recurrence. Overall, 1.990 patients were randomized to receive HRT (estrogen-progesteron combination or tibolone), while 1.983 patients were included in control groups (placebo or no HRT). As compared to control group, HRT significantly increased the risk of BC recurrence (HR 1.49, 95% CI 1.15-1.93, $p = 0.002$). The heterogeneity between the studies was low (39%, $p = 0.194$), and no publication bias was found ($p = 0.537$). Two studies reported the HR according to hormone receptor status. At the subgroups analysis, the risk of BC recurrence with the use of HRT was significantly increased in hormone receptor-positive patients (HR 1.8, 95% CI 1.15-2.82, $p = 0.010$) but not in those with hormone receptor-negative tumors (HR 1.25, 95% CI 0.83-1.88, $p = 0.290$). **Conclusions:** Use of HRT significantly increases the risk of recurrence in BC survivors, particularly in those with hormone receptor-positive disease. Therefore, this approach remains contraindicated in this setting. Alternative interventions to mitigate menopause-related symptoms should be proposed to these patients. Research Sponsor: None.

Associations between preexisting nociplastic pain and early discontinuation of aromatase inhibitor therapy in breast cancer. *First Author: Elizabeth Joyce, University of Michigan Health System, Ann Arbor, MI*

Background: Aromatase inhibitors (AI) are recommended for at least five years to reduce risk of breast cancer recurrence in postmenopausal women with hormone receptor-positive disease. Despite the potential benefit, up to 50% of patients discontinue AI early, primarily because of musculoskeletal side effects. Some patients, including those with fibromyalgia and other chronic pain conditions, have preexisting pain that arises from altered nociception without clear evidence of tissue or peripheral nerve damage, called nociplastic or centralized pain. We hypothesized that preexisting nociplastic pain is associated with early discontinuation of AI therapy due to toxicity. **Methods:** Patients diagnosed with breast cancer between 2012-19 and who enrolled in the Michigan Genomics Initiative (MGI) were identified. Patients who were female, had hormone receptor-positive breast cancer, had not received neoadjuvant therapy, and who initiated adjuvant AI therapy were included in the analysis. Prior to breast cancer surgery patients completed surveys about pain in the affected breast and overall worst pain (Brief Pain Inventory [BPI]), nociplastic pain (2011 Fibromyalgia Survey [FS], which assesses widespread pain plus somatic symptom severity), and anxiety (PROMIS Anxiety 4a v.1). Demographics, cancer characteristics, and treatment history, including date and reason for discontinuation of AI therapy, were abstracted from the medical record. Patients were censored at date of last oncology follow-up. Univariate and multivariable analyses were conducted to assess relationship between age, BMI, surgical site pain, overall worst pain, FS score, anxiety, and time to discontinuation of initial AI medication. **Results:** Of 207 analyzed patients, the average age was 61 years, average BMI was 30.3 kg/m^2, 181 (87%) were postmenopausal at the time of breast cancer diagnosis, and 31% received chemotherapy. The majority were prescribed anastrozole (n=196); 6 took letrozole and 5 took exemestane. Average scores prior to surgery were 1.5/10 for worst pain, 0.2/10 for surgical site pain, 4.2/31 for FS score, and 54.1/100 for anxiety. On univariate analysis, only use of exemestane (HR 5.55, $p<.001$) and use of letrozole (HR 3.11, $p<.001$) were associated with shorter time to ET discontinuation; age, BMI, surgical site pain, worst pain, FS score, and anxiety were not statistically significantly associated with time to AI discontinuation. On multivariable analysis, only higher FS score was statistically significantly associated with time to AI discontinuation (HR 1.11, p=.021). **Conclusions:** Greater pre-existing nociplastic pain was associated with early discontinuation of AI therapy. For these patients, early interventions that target centralized pain, or treatment with tamoxifen instead of AI therapy, may be appropriate in order to reduce risk of nonpersistence with AI therapy. Prevalence and predictors of peripheral neuropathy after chemotherapy: Outcomes from the Detroit Research on Cancer Survivorship (ROCS) cohort. *First Author: Kalyan Sreeram, Ascension St. Vincent Hospital, Indianapolis, IN*

Background: Increased life expectancy for cancer survivors following advances in treatment has led to a greater likelihood of developing long-term complications. Among them is chemotherapy-induced peripheral neuropathy (CIPN), which adversely impacts the functional capacity of survivors. We assessed prevalence and predictors of CIPN in a cohort of African-American (AA) cancer survivors. **Methods:** The study population included 633 breast, colorectal, prostate and lung cancer survivors who received chemotherapy and participated in the Detroit Research on Cancer Survivorship (ROCS) study. Presence of CIPN was based on self-reported pain, numbness or tingling in the hands or feet, occurring either for the first time or worsening after chemotherapy. If participants reported continued CIPN at the time of survey, their symptoms were reported as persistent. CIPN severity was self-reported as mild, moderate or severe. Logistic regression analysis was used to evaluate socio-demographic and clinical factors (including 12 common comorbid conditions) associated with CIPN prevalence, persistence and severity. **Results:** Overall, 67% of the cohort reported CIPN at a mean time of 25.3 months (range 2-74 months) after cancer diagnosis, and 51% reported persistent CIPN. The distribution of CIPN severity consisted of 32.2% with mild, 30.8% with moderate, and 36.9% with moderate to severe symptoms. Diagnosis of primary breast (OR 3.99, 95% CI 1.52-10.46) or colorectal cancers (OR 5.24, 95% CI 2.17-12.69) conferred greater CIPN prevalence relative to a diagnosis of prostate cancer. The presence of each additional comorbid condition among those outlined in the survey also conferred a 20% greater prevalence of CIPN (OR 1.2, 95% CI 1.03-1.39). Similar trends were seen among those who reported persistent CIPN. Using age $>$ 65 at diagnosis as the reference group, age $<$ 50 (OR 2.64, 95% CI 1.43-4.88) and age 51-64 (OR 1.96, 95% CI 1.14-3.35) resulted in an increased risk of moderate or severe compared to mild CIPN. **Conclusions:** In the Detroit ROCS cohort, CIPN was reported in two-thirds of cancer survivors receiving chemotherapy. Out of them, more than one-third reported moderate to severe symptoms, more commonly seen among those age $<$ 65. Consideration of CIPN as a prominent long-term complication of cancer treatment should play a role in treatment decisions and development of new chemotherapy regimens. Research Sponsor: None.

Late cardiac events and their impact on overall survival in patients receiving an allogeneic stem cell transplant. *First Author: Christine Auberle, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: There is limited data on the impact of cardiac disease on long term outcomes of allogeneic stem cell transplant (alloSCT). We sought to describe the importance of adverse cardiac events on long term outcomes of alloSCT. **Methods:** We performed a retrospective analysis of pts who underwent alloSCT from 2007 to 2017 and survived at least one year after transplantation. Late cardiac events were defined as occurring at least one year after transplant. Data was obtained through electronic medical records and the transplant database at Siteman Cancer Center. Univariate Cox proportional hazards model was used to assess the effect of baseline characteristics on cardiac events and overall survival. Time-dependent Cox model was used to determine the effect of cardiac events on overall survival. Gray's sub-distribution methods, while accounting for death as a competing risk, were used to calculate the incidence of cardiac events. **Results:** 804 pts met our criteria (58.7% male, average age 49.7 years). Median duration of follow up was 59.3 months. Most pts were transplanted for acute myeloid leukemia (49.9%) and had a match-related or unrelated donor (56.1%). The majority received myeloablative conditioning (74.4%), and 34.6% received total body irradiation (TBI). The most common late cardiac events were an elevated troponin (20.9%), elevated brain natriuretic peptide (BNP) or N-terminal pro-BNP (16.9%), shock (15.3%), and reduced left ventricular ejection fraction (LVEF) defined as $<$ 45% (10.4%). Pts were at significantly increased hazard of developing late cardiac events if they were of male sex (HR 1.29, P = 0.026), had pre-existing diabetes (HR 1.45, P = 0.022), pre-existing atrial fibrillation or flutter (HR 1.77, P = 0.008), history of congestive heart failure (HR 1.82, P = 0.032) or increasing age at time of transplant (HR 1.02, P $<$ 0.001). Primary disease for alloSCT, donor type, TBI and myeloablative conditioning regimen had no significant association with late cardiac events. The cumulative incidence of developing any cardiac event in the period 1-5 years after transplant was 28.2% with a cumulative incidence of shock at 13.6%, reduced ejection fraction at 8.7% and an atrial arrythmia at 7.1%. Most cardiac events were associated with an increased risk of death (Table). **Conclusions:** Cardiac events after alloSCT have a substantial impact on overall survival. Efforts to optimally manage cardiac disease after alloSCT are likely to have a major benefit, and cardiac protection should be a major focus for post-alloSCT follow up. Research Sponsor: Mentors in Medicine Program, Division of Medical Education, Department of Internal Medicine at the Washington University School of Medicine.

The effect of cardiac events on risk of death.

Cardiac event	Hazard Ratio (HR)	95% CI
Troponin elevation	10.7*	8.4-13.5
Percutaneous coronary intervention	1.6	0.7-3.7
Atrial arrythmia	10.6*	7.7-14.6
LVEF < 45%	5.8*	4.3-7.9
Elevated NT pro-BNP	5.2*	3.7-7.3
Shock	19.0*	14.7-24.4

Feasibility and first results of digital patient-reported outcomes measures (PROMs) data collection for patients with localized prostate cancer at diagnosis. *First Author: Geraldine Pignot, Institut Paoli-Calmettes, Marseille, France*

Background: Patient-reported outcomes measures (PROMs) allow optimal evaluation of side effects of treatments and their impact on quality of life. In localized prostate cancer, these PROMs are an interesting tool for comparing the impact of different treatments. The objective of our study was to evaluate the feasibility of a PROMs assessment using a digital application and to analyze the functional outcomes at 1, 3 and 6 months for urinary continence and sexuality. **Methods:** Since May 2019, patients treated for localized prostate cancer in our center, regardless of the treatment choice, have been offered inclusion in a digital prospective program. PROMs questionnaires (EPIC-26, Q50 PR25, EQ- 5D and PRO-CTCAE) were sent via a dedicated digital application, before treatment (T0), at 1 month (M1), 3 months (M3), 6 months (M6) and 1 year. Program adherence was assessed by the proportion of patients who logged in to the app and the proportion of patients who responded to questionnaires. The first results, at T0, M1, M3 and M6, were analyzed for urinary continence and erectile function, and compared according to age, baseline characteristics and treatment strategy. **Results:** Between May 2019 and December 2020, 324 patients were included in the program. Thirty patients (9.3%) did not log into the app and 29 (8.9%) logged in but did not respond to the PROMs questionnaires sent out. The adherence rate was not related to age or treatment strategy. In the end, 265 patients (81.8%) answered the PROMs questionnaires, including 185 patients treated by surgery, 11 by brachytherapy, 15 by radiotherapy, 24 by radio-hormonotherapy and 30 under active surveillance. Before treatment (T0), 15.8% (42/265) of patients reported having urine leakage (at least once a week) and 41.5% (110/265) having poor or no erections. At M1, M3, and M6, the incontinence rate was 50.8%, 37.8% and 28.7% respectively, and the erectile dysfunction rate was 73.3%, 74.1% and 70.1% respectively. Sexual recovery was strongly associated with baseline erectile function (T0); patients with good sexual function at diagnosis had an erectile dysfunction rate of 53.8% at 1 month (versus 89.9% for patients with pre-existing sexual dysfunction, p $<$ 0.001), and 51.1% at 3 months (versus 84.0%, p $<$ 0.001). Age was not associated with continence or sexuality recovery. Patients treated with surgery had significantly poorer functional outcomes in terms of continence (p $<$ 0.001) and sexuality (p $<$ 0.001) compared to other strategies. **Conclusions:** The implementation of PROMs using a digital application achieves an adherence rate of over 80%. The incontinence rate decreases rapidly over the 6 months following treatment, while erectile dysfunction rate remains stable over time. Early side effects are more common after surgery, requiring appropriate supportive strategies. Research Sponsor: ARS (AAP Pertinence des Soins).

Treatment-specific risk of second malignancies in five-year survivors of diffuse large B-cell lymphoma. *First Author: Yvonne M. Geurts, Department of Epidemiology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Due to the historically less favorable prognosis of diffuse large B cell lymphoma (DLBCL), the burden of second malignant neoplasms (SMNs) has been rarely studied in DLBCL survivors. However, radiotherapy and chemotherapy may increase SMN risk among DLBCL patients. Anthracyclines may increase the risk of hematological malignancies, but it is not clear whether they also increase solid cancer risk. **Methods:** We established a multicenter cohort of 2,384 5-year DLBCL survivors treated at ages 15-60 years with radiotherapy and/or immunochemotherapy between 1989 and 2012. Observed numbers of SMNs were compared with expected cancer incidence in the general population to compute standardized incidence ratios (SIRs), absolute excess risks (AERs, per 10.000 person-years) and cumulative incidence. Treatment specific incidence was compared with general population rates and assessed within the cohort using Cox regression. **Results:** Most DLBCL patients received alkylating agents (95%), anthracycline-containing chemotherapy (95%) or radiotherapy (61%); 46% received rituximab. Median follow-up was 13.3 years; 17% of patients was followed ≥20 years. In total, 308 5-year survivors developed an invasive SMN (SIR 1.6; 95% confidence interval (CI), 1.4 to 1.8), translating into 56.2 excess cancers per 10.000 person-years (see Table for specific sites). In 20-year survivors of DLBCL, the SIR was 1.8 (95% CI 1.3-2.6). The 20-year cumulative incidence of any SMN was 18.7% (95% CI 16.5-21.0%). The SIR for any SMN was higher in patients $<$40 years at first treatment (SIR ≤40 years: 2.8, SIR $>$40 years: 1.4; p$<$0.001). Treatment specific results will be presented at ASCO21. **Conclusions:** DLBCL survivors experience higher risk of SMNs than the general population. Identification of patients at increased risk could improve follow-up care. Research Sponsor: Dutch Cancer Society.

SIRs, AERs and 20-year cumulative incidence of selected SMNs*.

Second malignancy site	Number of patients	SIR (95% CI)	AER 10.000 person-years	20-year cumulative incidence (95% CI)
Any cancer	308	1.6 (1.4-1.8)	56.2	18.7 (16.5-21.0)

Overall and cardiac-specific mortality following serious cardiovascular events in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Wendy Bottinor, Virginia Commonwealth University, Richmond, VA*

Background: The direct impact of a major cardiovascular (CV) event on mortality among childhood cancer survivors is not well described. We hypothesized that mortality following a major CV event would be higher among survivors compared with siblings and that mortality would be influenced by primary cancer treatment. **Methods:** The CCSS cohort has conducted longitudinal follow-up of 25,658 survivors of childhood cancer and 5,051 siblings. All-cause and CV-cause specific mortality after a first event of heart failure (HF), coronary artery disease (CAD), or stroke occurring at least 5 years after cancer diagnosis, was estimated using the Kaplan-Meier method. The relative hazards (HR) and 95% confidence intervals (CI) between survivors and siblings as well as the influence of demographic (sex, age, race/ethnicity) and cancer treatment factors were estimated via Cox regression. **Results:** In total, 1780 survivors and 91 siblings experienced a serious CV event. Total deaths included 706 survivors (271 cardiac causes, 381 non-cardiac causes, 54 unknown causes) and 14 siblings. Survivors were a median age of 31.5 years (range 6.5-61.5) and 20.0 years (range 5.0-44.6) since cancer diagnosis at time of CV event. After a CV event, estimated 10- and 20-y all-cause mortality was significantly higher among survivors than siblings (Table). The HR for all-cause mortality was significantly higher among survivors than siblings after HF (HR 5.2, CI 2.1-13.0), CAD (HR 4.2, CI 2.0-9.0), and stroke (HR 4.6, CI 1.5-14.6). HF and stroke-specific mortality were not significantly increased among survivors versus siblings, in contrast to CAD-specific mortality (HR 3.5, CI 1.1-11.0). Among survivors, heart dose from radiotherapy (per 10 Gy) was associated with increased all-cause and cause-specific mortality after HF (HR 1.2, CI 1.0-1.3; HR 1.3, CI 1.0-1.7), all-cause mortality after CAD (HR 1.2, CI 1.0-1.3), and cause-specific mortality after stroke (HR 2.5, CI 1.2-4.9). Brain dose from radiotherapy was associated with increased all-cause mortality (HR 1.1, CI, 1.0-1.2, per 10 Gy) after stroke. Anthracycline dose was not associated with increased overall or cause-specific mortality risk after a CV event. **Conclusions:** After a CV event, mortality is higher among survivors than siblings. In survivors, mortality is primarily driven by non-cardiac causes. CAD and prior radiotherapy exposure to the heart and brain also influenced mortality. Research Sponsor: Childhood Cancer Survivor Study.

Kaplan-Meier estimates of all-cause mortality probability after a CV event.

		HF	CI	CAD	CI	Stroke	CI
10-y mortality	Survivors	30%	0.26-0.33	36%	0.31-0.40	29%	0.25-0.33
	Siblings	14%	0.00-0.25	14%	0.02-0.25	4%	0.00-0.11
20-y mortality	Survivors	48%	0.44-0.53	63%	0.56-0.69	41%	0.35-0.45
	Siblings	14%	0.00-0.25	14%	0.02-0.25	19%	0.00-0.38

Log-rank tests comparing survivor and sibling survival curves all had P<0.001.

Anthracycline exposure and breast cancer risk in female Hodgkin lymphoma survivors. *First Author: Suzanne I.M. Neppelenbroek, Department of Epidemiology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Female Hodgkin lymphoma (HL) survivors treated with chest radiotherapy (RT) at a young age have a strongly increased risk of breast cancer (BC). Recently concern has been raised that anthracyclines may also increase BC risk, based on studies in childhood cancer survivors with/without a history of chest RT. So far, the association between anthracyclines and BC risk has not been examined in cancer survivors treated at adolescent/adult ages. Now that RT dose and volumes are decreasing, the potential contribution of anthracyclines to BC risk is an important issue. **Methods:** We assessed BC risk in a cohort of 2314 female 5-year HL survivors, treated at ages 15-50 years and diagnosed between 1965 and 2008 in 20 Dutch hospitals. Treatment factors were time-dependently included in the analysis, focusing on the effect of anthracycline exposure on BC risk. **Results:** After a median follow-up of 18.8 years, 258 women developed invasive BC or ductal carcinoma in situ as a subsequent malignancy. The 30-year cumulative incidence was 15.0% (95% Confidence Interval (CI) 12.8-17.4%). Mantle field RT (or other RT involving both axillae) was associated with increased risk of BC (Hazard ratio (HR) 1.9; 95% CI 1.2-2.8) compared to no supradiaphragmatic RT or RT to the neck only (Table 1). Gonadotoxic treatment (>4.2 g/m^2 procarbazine or pelvic RT) significantly decreased this risk. In a multivariable analysis, anthracycline exposure was associated with increased BC risk (HR 1.8; 95% CI 1.3-2.5) in patients who received a cumulative dose of >200 mg/m^2. Among patients exposed to gonadotoxic treatment, the HR of BC associated with >200mg/m^2 anthracyclines was 3.8 (95% CI 2.0-7.2), with a trend for higher risk with higher anthracycline dose (HR 1.58 per 100mg/m^2 anthracycline, p<0.001). **Conclusions:** Our results suggest an association of anthracyclines with BC risk in HL survivors. Also when accounting for the protective effect of gonadotoxic treatment on RT-associated BC risk, anthracyclines significantly contributed to a higher BC risk. Research Sponsor: KWF Dutch Cancer Society.

Cox PH regression model of anthracycline exposure and breast cancer risk.

	Number of patients N=2314	Events (%) N=258	Hazard ratio (95% CI)
Anthracyclines			
No anthracyclines	994	172 (17.3%)	1.0
35-200 mg/m^2 (median: 150 mg/m^2)	471	21 (4.5%)	1.5 (0.9-2.5)
>200 mg/m^2 (median: 245 mg/m^2)	793	64 (8.1%)	1.8 (1.3-2.5)
Unknown	56	1 (1.8%)	0.3 (0.0-2.0)

Predictors of falls after starting an exercise program: A secondary analysis in inactive, female cancer survivors participating in the GET FIT trial. *First Author: Deanne Tibbitts, Oregon Health & Science University, Portland, OR*

Background: Women treated for cancer are more likely to fall than women without a cancer history. Exercise is a fall prevention strategy for older adults that we are testing in the GET FIT trial as a fall prevention approach in women cancer survivors. Increasing physical activity, though, could acutely increase the risk of falls in inactive survivors with known fall risk related to treatment. Knowing who might be at risk prior to beginning an exercise program would inform additional safety precautions during exercise. **Methods:** We conducted a secondary analysis of baseline data from the GET FIT trial that enrolled inactive, older women who had completed chemotherapy for cancer. Women completed objective (muscle strength, static postural control, range of motion, physical functioning) and self-report (fall history, comorbidities, presence of neuropathy symptoms, pain severity, depressive symptoms, cognitive functioning, perceptions of lower extremity functioning, disability, fear of falling, demographic, and clinical characteristics) measures at baseline. Falls were prospectively collected during the 6 month intervention using monthly self report. Potential predictors of falls were included if univariate tests revealed significant differences between fallers and non-fallers. To identify the strongest predictors of falls, we used an automated model selection and multimodel inference approach to perform an exhaustive model search. **Results:** Baseline data were available for 415 participants with known faller status at the end of the intervention, of whom 31.3% (n = 130) reported at least one fall. The average age of the sample was 62.1±6.4 years and consisted mostly of non-Hispanic white, married, highly educated, overweight or obese women treated for breast cancer. Fallers (1+ falls) and non-fallers significantly differed on measures of fall history, comorbidities, pain, neuropathy, fear of falling, disability, perceived lower extremity functioning, cognitive functioning, depression, and postural control. The best model of faller status (per BIC) included postural control (p = 0.004), perceived lower extremity functioning (p = 0.072), and fear of falling (p = 0.030). Odds of ≥1 fall during the intervention increased by 1.72 (95% CI: 1.05-2.83) times for a 0.1-point decrease in postural control, 1.11 (1.04-1.19) times for a 0.1-point increase in fear of falling, and 1.02 (1.00-1.03) times for a 1-point decrease in perceived lower extremity functioning. **Conclusions:** Women cancer survivors with poor balance, poor self-rated functioning, and a fear of falling may need to take additional fall precautions when starting an exercise program. Clinical trial information: NCT01635413. Research Sponsor: U.S. National Institutes of Health.

Factors associated with weight gain during endocrine therapy for breast cancer. *First Author: Anna-Carson Uhelski, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Weight gain is common after a breast cancer diagnosis. The incidence of and risk factors for weight gain during adjuvant endocrine therapy (ET) are poorly described. Limited data support an association between emergent symptoms and weight gain after a breast cancer diagnosis. **Methods:** We enrolled women with stage 0-III breast cancer initiating ET in a prospective clinic-based cohort. We assessed symptoms with the FACT-ES and PROMIS pain interference, depression, anxiety, fatigue, sleep disturbance and physical function measures at baseline (BL), 3, 6, 12, 24, 36, 48 and 60 months (mo). We defined emergent symptoms at 3 and/or 6 mo as worsening of 4 points from BL on PROMIS measures and 5 points from BL on the FACT-ES. We abstracted weight and menopausal status from charts. The primary outcome of this secondary analysis was weight gain (dichotomized as ≥5% vs < 5% of body weight compared to BL) through 60 mo. We evaluated the association between weight gain during ET and menopausal status. We also evaluated the associations between clinicodemographic factors and emergent symptoms with weight gain and if these associations differed by menopausal status. We performed logistic regression modeling with GEE to account for the longitudinal design. We identified a multivariable model for the set of factors associated with weight gain among pre-menopausal women taking ET. **Results:** 309 of 321 participants with BL and ≥1 follow-up (FU) weight were included. 263 (85%) had stage I-II disease, 99 (32%) were pre-menopausal, 259 (84%) were White and 32 (10%) were Black. Prior to ET, 45% had mastectomy, 66% had radiation, and 28% received chemotherapy. 4% of pre- and 82% of post-menopausal participants initiated an aromatase inhibitor (AI); all others initiated tamoxifen (Tam). 17% of pre-menopausal participants received ovarian suppression. At BL, 75% of Black and 59% of White participants were overweight/obese. With a median FU of 56 mo, 51% of pre- and 34% of post-menopausal participants gained ≥5% body weight (OR 1.09, 95% CI 1.07-1.13, p < 0.001). For each PRO measure, > 20% of participants had emergent symptoms. Worsening of physical function and pain interference scores at 3 and/or 6 mo were differentially associated with weight gain according to menopausal status (interaction p-values ≤0.05). On multivariate analysis, factors associated with weight gain among pre-menopausal participants were ET (AI vs Tam) (OR 2.8, 95% CI 0.90- 8.77, p = 0.08), prior mastectomy (OR 2.06, 95% CI 0.89-4.77, p = 0.09), emergent pain interference (OR 2.49, 95% CI 0.99-6.24, p = 0.05) and race (White vs other) (OR 7.13, 95% CI 1.29-39.4], p = 0.02). **Conclusions:** Weight gain during ET for breast cancer is more frequent among pre-menopausal than post-menopausal women. Worsening pain soon after ET initiation, receipt of AI, prior mastectomy and race may identify pre-menopausal women at risk for weight gain for whom prevention strategies are a priority. Long-term quality of life of cancer survivors: A case-control study. *First Author: Joaquin Ponce-Zepeda, UC Irvine Douglas Hospital, Orange, CA*

Background: There were extensive reports in literature about the debilitating health experienced by cancer patients during treatment. This study examined how the quality of life of cancer survivors changed over time. **Methods:** The National Health and Nutrition Examination Survey (NHANES) is a program of studies designed to assess the health and nutritional status of adults and children in the U.S. This study involved participants in NHANES from 2000-2020. Participants who reported having had a cancer diagnosis were matched one to one with participants who reported no cancer diagnosis by age, gender, race, year of recruitment into NHANES, and comorbidities. Quality of life measures including self-reported general/physical/mental health, examinations, and laboratory tests were compared between cancer cases and matched controls using paired t tests. **Results:** This study included 5,166 pairs of cancer cases and matched controls. Mean age was 66 (± 15 years). Male 47% and female 53%. White 69%, Black 14%, Hispanic 12%, others 5%. Most common comorbidities were hypertension (56%), arthritis (50%), diabetes (19%), and thyroid (18%). About 38% of cancer cases had survived in 1-5 years; 22% in 6-10 years; 39% in 10+ years. Most prevalent cancers were skin (28%), breast (15%), and prostate (15%). Compared to controls, cancer cases who had survived in 1-5 years reported higher rates of poor general health (38% vs. 27%, $p < .0001$), hospitalizations (31% vs. 17%, $p < .0001$), mental health visits (9% vs. 7%, $p = .0204$). There were no significant differences in general health and healthcare utilization between cancer cases who survived > 5 years and controls. There were no clinically meaningful differences in laboratory tests and examinations between cancer cases and controls regardless of survival time. **Conclusions:** During the first 5 years after cancer diagnosis, survivors reported worse health than controls. As survival time extended, there was no difference between cancer cases and controls. The debilitating health reported during the first 5 years could not be explained by examinations and laboratory tests alone. Future research should explore neurochemical and hormonal markers to investigate adverse effects of cancer treatment on long-term quality of life. Research Sponsor: None.

Investigating the prevalence and risk of chemotherapy-induced neuropathy among cancer patients. *First Author: Philip Jordache, University of Chicago, Chicago, IL*

Background: Neuropathy is a common side effect of some chemotherapies. Clinical and other factors may confer neuropathy risk, but rates and risk factors across neuropathy-causing chemotherapies are incompletely understood. **Methods:** We examined 15 chemotherapy drugs known to confer neuropathy. Within a broad population of cancer patients who underwent treatment with these agents at the University of Chicago Medicine between 2012-2018, we determined prevalence of chemotherapy-induced neuropathy, defined as patients with initiation of a neuropathy treatment medication (amitriptyline, carbamazepine, duloxetine, gabapentin, or pregabalin) after starting chemotherapy. We then analyzed chemotherapy-induced neuropathy risk for different drugs and based on clinical demographic factors. **Results:** We analyzed 7,866 patients (65.3% White, 53.7% Female, 27.6% Black/African-American, 5.6% Hispanic or Latino, 3.1% Asian/Mideast Indian, 2.4% More than one Race, 0.2% American Indian or Alaska Native, 0.2% Native Hawaiian/Other Pacific Islander). The overall prevalence of chemotherapy-induced neuropathy was 24.3% across our patient population. Black/African-American patients had an increased risk of chemotherapy-induced neuropathy compared to the rest of the patient cohort (OR 1.4, 95% CI 1.3-1.6, $P = 1.6e-10$). Females also exhibited an increased risk of chemotherapy-induced neuropathy compared to males (OR 1.2, 95% CI 1.1-1.3, $P = 1.5e-3$). **Conclusions:** Certain chemotherapy agents confer substantial risk of chemotherapy-induced neuropathy, and risk is increased in Blacks and females. Future work will investigate additional risk-modifying factors including the potential role of germline polymorphisms on chemotherapy neuropathy risk. Research Sponsor: None.

Chemotherapy drug	Total patients taking chemotherapy drug*	Patients initiated on at least 1 neuropathy treatment-related medication after chemotherapy start	Proportion initiated on neuropathy treatment-related medication after chemotherapy start out of total patients taking chemotherapy drug
Vincristine	473	106	106/473 = 22.4%

Effect of an e-home based symptom management and mindfulness training program on quality of life in breast cancer survivors: A randomized clinical trial. *First Author: Karis Kin-Fong Cheng, National University of Singapore, Singapore, Singapore*

Background: The first five years post-treatment for breast cancer are a critical phase, when the survivors may face a multitude of physical and psychosocial problems. We aimed to develop an e-home based symptom management and mindfulness training program to support women with breast cancer in transition to survivorship and to determine its effect on the endpoints including quality of life, symptom distress, psychosocial adjustment, and psychological morbidity. **Methods:** This parallel 4-arm, superiority randomized clinical trial together with a process evaluation using semi-structured interview recruited women who had completed cancer treatment for stage 0 to 3 breast cancer between 6 months to 5 years previously, from November 2016 through March 2020 at two tertiary hospitals. A total of 593 women were eligible, of these, 402 refused to participate and 191 women were randomized. However, 19 subjects withdrew from the study without completion of baseline assessments. Hence, 172 subjects were included in the intention-to-treat analysis (e-home based breast cancer survivorship program, experimental group; n = 44), comparison group 1 (online symptom management program only; n = 41), comparison group 2 (online mindfulness training program only; n = 44) or the usual care group (n = 43). The e-home based breast cancer survivorship program involved 5 weekly online education module regarding self-management strategies of common symptoms + various online self-administered mindfulness exercises. The primary endpoint included change of Quality of Life-Cancer Survivor Scale (QoL-CS) score measured at 8, 12 and 24 weeks from baseline. Secondary endpoints were changes of Social Support Questionnaire, Breast Cancer Survivor Self-Efficacy Scale, Memorial Symptom Assessment Scale, Psychosocial Adjustment to Illness Scale, Fear of Recurrence Scale, Hospital and anxiety Depression Scale, and Five Facet Mindfulness Questionnaire scores. **Results:** Of 172 subjects, mean ± SD age was 51.2 ± 9.4 years; 118 (77.7%) were in the first two years of cancer treatment completion; 165 (98.2%) underwent surgery; and 111 (73.5%) treated with adjuvant chemotherapy. All demographic and clinical characteristics were comparable among the four groups ($p > .05$). There was no between-group difference in the primary endpoint; QoL-CS scores among groups at 8, 12 and 24 weeks from baseline ($p > .05$). Secondary endpoints were also not different among groups ($p > .05$). Two main themes; positive impact and gap/barrier, emerged from process evaluation data. **Conclusions:** In women who were in the first five years post-breast cancer treatment, an e-home based multidimensional cancer survivorship program did not affect outcomes. Nevertheless, the interview data revealed a positive experience in regards to the home-based approach in cancer survivorship care program. Clinical trial information: NCT02931864. Research Sponsor: Singapore Cancer Society Cancer Research Grant.

Association of cancer treatment with excess heart age among young breast cancer survivors. *First Author: Jacqueline B Vo, National Cancer Institute, Rockville, MD*

Background: Young women with breast cancer may be at increased risk for premature development of cardiovascular disease (CVD) in part due to their cancer treatment. Limited data are available on CVD risk among young breast cancer survivors. **Methods:** Women aged 30-40 years at diagnosis with stage 0-III breast cancer enrolled in a prospective cohort study of women diagnosed with breast cancer at ≤40 were eligible for inclusion in this analysis. Data were obtained from serial surveys and electronic medical records at breast cancer diagnosis and 5-year follow-up. We calculated excess heart age, which incorporates a CVD risk-based score (calculated using age, systolic blood pressure, blood pressure medication, diabetes, smoking, body mass index) to estimate the difference in years between an individual's chronological age and their CVD-risk adjusted age. Multivariable logistic regression models (adjusting for age at diagnosis, stage, and race) were fitted to evaluate associations between treatment (radiation, endocrine therapy, anthracyclines, and trastuzumab) and having a change in excess heart age ≥2 years from baseline to 5 years. **Results:** Among 372 young breast cancer survivors, mean age at diagnosis was 36.6 (SD 2.89), 93% were white, and 79% were diagnosed with stage I or II breast cancer. Mean excess heart age was .32 (SD: 6.16) years at baseline, which declined to -.07 (SD 6.64) at 5-year follow-up (p=.17). At 5 years, 31% (n=114) of women experienced an increase of at least 2 years in their excess heart age since diagnosis, and their mean excess heart age was 4.34 years (range -9 to 30). In multivariable analyses, receipt of trastuzumab was associated with higher odds (OR: 1.68, 95% CI: 1.02-2.77) of experiencing an increase of ≥2 years in excess heart age between diagnosis and 5 years of follow-up. Endocrine therapy, anthracyclines, and radiation were not significantly associated with a change in excess heart age of ≥2 years at 5 years post-diagnosis. **Conclusions:** At 5 years post-diagnosis, approximately 1/3 of young breast cancer survivors experienced a change from baseline in their excess heart age of ≥2 years. Further research is warranted to confirm findings regarding trastuzumab and excess heart age, and potential effects on longer-term cardiac outcomes in this population. Extended follow-up of this cohort may further quantify CVD risk over time. Research Sponsor: Breast Cancer Research Foundation/Susan G. Komen.

Association of treatment with change in excess heart age of ≥2 years from diagnosis to 5-year follow-up.

Cancer Treatment	Odds Ratio	95% CI Lower	95% CI Upper	Standard Error	P
Anthracyclines	1.31	.74	2.35	.39	.354
Trastuzumab	1.68	1.02	2.77	.43	**.040**
Radiation therapy	.75	.44	1.28	.20	.296
Endocrine therapy	.86	.52	1.40	.21	.532

Perceptions of prognosis in caregivers of multiple myeloma (MM) patients. *First Author: Yael N. Shapiro, Massachusetts General Hospital, Boston, MA*

Background: Caregivers of patients with cancer play a critical role in supporting patients when making informed decisions about their medical care. Although MM patients and their caregivers face an incurable illness, data describing caregiver perceptions of the patient's prognosis and factors associated with accurate prognostic perceptions are lacking. **Methods:** We conducted a cross-sectional, multisite study of caregivers of MM patients between 6/2020-1/2021. Eligible caregivers were identified by the patient as the primary caregiver and enrolled in 1 of 3 cohorts based on lines of therapy: 1) caregivers of newly diagnosed patients receiving first-line therapy; 2) 2-3 lines; 3) ≥4 lines. Caregivers completed the Perception of Treatment and Prognosis Questionnaire to assess their perceptions of the illness and prognosis. We also used the CareGiver Oncology Quality of Life (QOL) questionnaire, the Hospital Anxiety and Depression Scale, the Post-Traumatic Stress Disorder Checklist–Civilian Version, and the Brief COPE to assess caregiver QOL, psychological distress, and coping strategies. We used a multivariate logistic regression analysis to examine whether caregiver factors (i.e. demographics), line of therapy, QOL, psychological distress, or coping were associated with caregiver perceptions of the patient's prognosis. **Results:** We enrolled 113 caregivers of MM patients (newly diagnosed (n=39), 2-3 lines (n=37), and ≥ 4 lines (n=37)). Overall, 89.2% (99/111) of caregivers reported that it is extremely' or very' important to know about the patient's prognosis and the majority (58.0%, 65/112) stated that they had received adequate information regarding the patient's prognosis. Caregivers reported that prognostic information was extremely' or very' helpful in making decisions about treatment (93.3%, 97/104), preparing for the future (88.2%, 90/102), and coping with the disease (85.6%, 89/104). Most caregivers (84.7%, 94/111) reported that the oncologist told them the patient's cancer was incurable. In contrast, only 53.6% (59/110) of caregivers reported that they thought the patient's cancer was incurable and 48.6% (52/107) acknowledged that the patient is terminally ill. In a multivariate analysis, we found that the use of positive reframing coping (OR=0.71, 95%CI=0.52-0.97, P=0.033) was associated with lower odds of reporting an accurate perception of prognosis. Caregiver demographics, line of therapy, QOL, and psychological distress were not associated with their perceptions of the patient's prognosis. **Conclusions:** Although the majority of caregivers of MM patients report that knowing the patient's prognosis is extremely important, a substantial minority still have significant misperceptions of the patient's prognosis. Interventions are needed to promote effective coping and enhance caregiver perceptions of the patient's prognosis to facilitate informed decision-making in this population. Research Sponsor: None.

The moderating role of informal caregiver's involvement on the relationship between patient activation and adherence to treatment: Implications for self-management intervention in cancer care. *First Author: Chiara Acquati, University of Houston, Houston, TX*

Background: With increasing demands for a more active role on the part of individuals with cancer and their families in cancer care, patient activation (PA) is emerging as a key factor to promote self-management, adherence to treatment, and satisfaction with treatment planning. The present work investigated the relationship between patient activation and treatment decision making. Given the role informal caregivers play on patient-reported outcomes, it was additionally assessed whether caregiver involvement acted as a moderator of this relationship. **Methods:** Survey data collected from 504 cancer survivors recruited through online consumer panels were utilized. The survey contained questions concerning treatment options, quality of life, adherence to treatment, next to presence and involvement of informal caregivers. Additionally, the Patient Activation Measure (PAM), sociodemographic and clinical questions were included. A path analysis Structural Equation Modeling (SEM) controlling for covariates was used to examine the relationship between Patient Activation Measure (PAM), caregiver involvement, and the identified outcomes. Moderator analysis was conducted using multiple group SEM. **Results:** Respondents were mostly women (57.1%), non-Hispanic white (72.9%), middle aged or older adults (68% ≥ 55 y.o.) The four largest cancer type groups were prostate (16.3%), early stage breast (9.7%), gynecological (8.9%), and colorectal cancer (8.3%). Most of the respondents were diagnosed more than 4 years earlier (52.0%). Participants were evenly split between those who received care at an academic cancer center (29.4%) and those treated at community hospital (31.7%). Patient activation was significantly associated with treatment planning being reflective of survivors 'goals and values ($p < 0.001$); adherence to treatment ($p = 0.011$); and satisfaction ($p < 0.001$). Caregiver's involvement significantly moderated the association between activation and adherence to treatment. **Conclusions:** Patient activation was positively associated with all three selected outcomes. However, for cancer survivors reporting low rates of caregiver involvement, patient activation was not associated with treatment adherence. Research is needed to deliver and test patient activation interventions inclusive of informal caregivers to improve self-management. Research Sponsor: In collaboration with CancerCare.

Dermatologic diagnoses in oncology patients of color on anticancer therapy: Five-year retrospective review of outpatient dermatology consultations. *First Author: Britney N. Wilson, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Dermatologic toxicities from cancer treatments affecting patients from racial and ethnic minority backgrounds or skin of color (SOC) patients is an understudied area of research. These patients are also significantly underrepresented in therapeutic clinical trials, limiting complete understanding of toxicities associated with cancer therapies. Current treatment algorithms for dermatological adverse events (dAE) also do not take into account possible biologic differences in different skin types affecting toxicity presentation and treatment response. In this study we summarize the demographic, clinical, and treatment characteristics of oncology patients from racial and ethnic minority backgrounds who developed dermatologic adverse events related to cancer therapies. **Methods:** We performed a retrospective review of all SOC patients (Asian, Black, Hispanic) on active cancer therapy who received outpatient dermatology consultation at Memorial Sloan Kettering Cancer Center from January 1, 2014 to December 31, 2019. Electronic health record information for 2917 patients was obtained. A computational keyword-based text analysis of medical chart text, developed in consultation with a board-certified dermatologist, was performed to determine dermatologic diagnoses categories for each patient. All analyses were conducted using R statistical programming software, version 4.2.06. **Results:** There were 2917 outpatient dermatology consultations. Our population consisted of 1992 (68.29%) females and 925 (31.71%) males with a mean age of 53 (range 0-97). There were 35.55% Black, 41.28% Asian, 1.02% (30) Native American or Alaskan Native, 0.17% (5) Native Hawaiian or Other Pacific Islander. 729 were Hispanic ethnicity of which 641 were Caucasian. A total of 4,026 dermatologic diagnoses occurred in the study population. Bacterial infections were the most commonly observed, occurring in 15% of patients. Nail disorders were the second most common dAE, occurring in 14% of the study population, followed by eczema/eczematous reactions at 9%. In all racial groups, eczema/eczematous reactions, nail disorders, and dermatomyositis were in the top five most common observed dAEs. Asian patients made up the largest proportion of those who had morbilliform rash dAEs (55%) while Black patients made up the largest proportion of those with hyperpigmentation dAEs (54%) and vascular insufficiency dAEs (47%). **Conclusions:** The findings from our study indicate that pigmentary changes, bacterial infections, eczema/eczematous reactions, and nail disorders are the most common dAE types that occurred in our group of SOC patients. We hope to use this information to aid in the development of specific management strategies within the field of supportive oncodermatology to meet the needs of minority patient populations. Depression, chronic pain, and high-impact chronic pain among cancer survivors. *First Author: Nosayaba Osazuwa-Peters, Duke University School of Medicine, Durham, NC*

Background: The majority of the 17 million individuals living with a cancer diagnosis in the United States have experienced pain, either from the disease itself or from its treatment. Pain negatively impacts psychosocial quality of life and is associated with poorer overall outcome. However, the impact of pain on daily living differ among cancer survivors, and there is a paucity of research on chronic pain, especially high-impact chronic pain (HICP) in this growing population. We estimated the prevalence of chronic pain, and HICP among cancer survivors, and described the association between depression and these outcomes. **Methods:** This study used data from the 2015-2017 National Health Interview Survey. Outcomes of interest were chronic pain, defined as pain on most days or every day in the past six months, and HICP, defined as chronic pain that limited life or work activities on most days or every day during the past six months. Weighted, adjusted multivariable logistic regressions estimated association between depression and chronic pain and HICP among cancer survivors, while controlling for age, gender, marital status, education, employment, health insurance, smoking status, number of doctor's visit, general health, and comorbidities. **Results:** Among 49,326 survey respondents, 11.7% (n = 5,335) had a cancer diagnosis. An estimated 43.6% of cancer survivors reported chronic pain; and 19.2% reported HICP. We found an association between depression and both chronic pain and HICP in unadjusted analyses. In the adjusted models, cancer survivors depressed within the last month had more than double the odds of reporting both chronic pain (aOR = 2.32; 95% CI 1.75, 3.07) and HICP (aOR = 2.12; 95% CI 1.50, 3.01). Other factors associated with both chronic pain and HICP among cancer survivors included being a current smoker ($aOR_{chronic\ pain}$ = 1.63; 95% CI 1.14, 2.34; aOR_{HICP} = 1.83; 95% CI 1.18, 2.84) and being unemployed ($aOR_{chronic\ pain}$ = 1.44; 95% CI 1.10,1.90; aOR_{HICP} = 3.10; 95% CI: 2.00−4.81). Cancer survivors with ≥2 comorbidities also had 55% increased odds of reporting chronic pain (aOR = 1.55; 95% CI 1.17,2.04) compared with those without comorbidities. **Conclusions:** Over 40% of cancer survivors may have a history of chronic pain, and survivors reporting being depressed are significantly more likely to report both chronic pain and HICP. The association between depression and pain in cancer survivors calls for personalized management of chronic pain, especially in cancer survivors with a history of depression. Radiofrequency ablation for palliative treatment of osseous metastases results in rapid, significant, and durable improvements in pain relief and quality of life: Results from the OPuS One trial. *First Author: Jason Levy, Northside Hospital, Atlanta, GA*

Background: Patients with bone metastases may experience pain and decreased quality of life. Standard of care therapies such as radiation therapy could take weeks for pain relief and carry a risk of radiation induced fracture. Minimally invasive percutaneous radiofrequency ablation (RFA) have been shown in small observational studies to be an alternative treatment for bone metastases. We report the results of the OPuS One trial evaluating RFA for the palliative treatment of patients with painful bone metastases. **Methods:** OPuS One (NCT03249584) was a multicenter prospective trial. 218 subjects with painful bone metastases ($\geq$ 4/10 worst pain scores, Brief Pain Inventory [BPI], at target treated site) were enrolled from 15 sites. RFA was performed under image guidance at one or two locations. Vertebral augmentation was followed based on physician's discretion. Subjects' pain (BPI) and quality of life (EQ-5D) scores were calculated in subjects at three days, one week, and one, three, six, and 12 months post RFA. Rate of complete (0 pain score at treated site with no concomitant analgesic increase) and partial responders ($\geq$ 2 pain score reduction without analgesic increase or analgesic reduction of $\geq$ 25% from baseline) were calculated. Device-, procedure-, and/or therapy-related adverse events (AEs) were collected. **Results:** 206 subjects, 113 (55%) female and 93 (45%) males (mean age was 63.7 years) were treated with RFA. Most common primary cancers were breast (23%), lung (23%), and kidney (10%). 184 (89%) subjects were treated for metastatic lesions involving the thoracolumbar spine and 22 (11%) subjects were treated for iliac crest, periacetabulum, sacrum or mixed vertebral and pelvic location. 99% (262/264) of RFA procedures were technically successful and 97% were followed by vertebral augmentation. Subjects reported significant improvement in worst pain from baseline at 7.8 to 5.5, 4.7, 3.6, 3.2, 2.4, and 2.6 at three days, one week and one, three, six, and 12 months post RFA, respectively ($p < 0.0001$ for all visits). Significant improvements were also seen in average pain ($p < 0.0001$ for all visits), pain interference ($p < 0.0001$ for all visits), and quality of life scores ($p < 0.0001$ for all visits). Overall response rates were 53%, 58%, 61%, 63%, 70%, and 75% at three days, one week, one month, three months, six months, and twelve months post RFA, respectively. Six AEs were reported with three as serious: intra-abdominal fluid collection, pneumonia and respiratory failure. 82 deaths were reported during the study, none were related to the device, therapy, and/or procedure. No skeletal related events were reported. **Conclusions:** In a large prospective multicenter trial, OPuS One, RFA provided rapid, significant, and durable improvements in pain relief and quality of life up to 12 months. Clinical trial information: NCT03249584. Research Sponsor: Medtronic.

Receipt of palliative care (PC) in acute myeloid leukemia (AML) using data from the National Cancer Database (NCDB). *First Author: Bryan Chan, Georgetown University Medical Center, Lombardi Comprehensive Cancer Center, Washington, DC*

Background: AML is an aggressive disease with high mortality and significant impact on quality of life. Palliative care (PC) services have become integral in managing patient's symptoms during treatment as well as at the end of life. We hypothesize that socioeconomic factors such as achieving higher levels of education, and higher incomes, increases the odds of receiving PC. **Methods:** This is a retrospective analysis using NCDB data of 124,988 newly diagnosed non-M3 AML patients over 18 yrs from 2004-2016. Unadjusted and multivariate adjusted logistic regression analysis (MVA) evaluated the impact of socioeconomic variables on the receipt of PC. In the MVA, we adjusted for demographic variables and facility characteristics including facility type, facility volume, age, sex, race, Hispanic origin, income, education, urban/rural residence, Charlson-Deyo score, great circle distance, Medicaid expansion status state group, and insurance status. Patients with Medicaid expansion $<$ 39yrs were excluded due to low patient numbers. **Results:** For the 124,988 patients, median age was 63 years (range 18-90) with 54% males and 86% White. 25% of patients lived in regions with the highest education level defined as $<$ 6.3% of adults over 25 without a high school diploma. 35% of patients had a household income bracket of $\geq$ $63,333. A total of 3% of patients received PC. MVA showed that patients within the highest income bracket of $\geq$ $63,333 were less likely to have used PC services (OR 0.82, $p < 0.01$). More educated patients residing in regions with $<$ 6.3% of adults without a high school diploma had higher odds of receiving PC treatment compared with patients with less education (OR 1.23, $p < 0.01$). Residence in states with Medicaid expansion in January 2014 or later was associated with greater utilization of PC services (Jan 2014 expansion states: OR 1.33 and late expansion states/after Jan 2014: OR 1.43, $p < 0.01$) compared to residence in non-expansion states. No difference was seen across races; except Hispanics with decreased use of PC services(OR 0.8, $p = 0.022$). **Conclusions:** In this large cohort, a small percentage of patients received PC. Higher education was associated with higher likelihood of using PC, while, surprisingly, higher income was associated with a lower likelihood of PC. Additionally, the higher use of PC services with Medicaid expansion suggests a broad impact of public health insurance in providing increased access to PC services. Research Sponsor: None.

Marijuana use among US adults with cancer: Findings from the 2018-2019 Behavioral Risk Factor Surveillance System. *First Author: Min Jee Lee, Southern Illinois University School of Medicine, Springfield, IL*

Background: Cancer survivors experiencing adverse effects from their cancer and treatment report decreased symptom burden with marijuana use. An increasing number of U.S. states have legalized marijuana use for both medical and recreational purposes. This study aimed to assess the prevalence of current marijuana use and to identify the factors associated with its use among US adults with cancer living in 17 U.S. states and territories. **Methods:** Data from the 2018-2019 Behavioral Risk Factor Surveillance System Marijuana Use module were analyzed. In 2018, 13 states (California, Florida, Idaho, Maryland, Minnesota, Montana, New Hampshire, North Dakota, Ohio, South Carolina, Tennessee, West Virginia, and Wyoming) and 2 territories (Guam and Puerto Rico) participated in the optional marijuana use module. In 2019, 12 states (California, Idaho, Illinois, Maryland, Minnesota, New Hampshire, North Dakota, South Carolina, Tennessee, Utah, West Virginia, and Wyoming) and 1 territory (Guam) participated in the optional marijuana use module. The analytic sample included 13,174 adults with cancer. The analysis was weighted to account for BRFSS's complex survey design. The primary outcome was current marijuana use (in the past 30-days). Multivariable logistic regression was used to identify demographic, socioeconomic, clinical, and behavioral factors associated with marijuana use among US adults with cancer. **Results:** Overall, 9.2% of adult cancer survivors (n = 13,174; weighted 5.7 million; 37.9% men) reported marijuana recently current use, 51.3% of whom used it for medical reasons only, with 65.2% reporting smoking as the main method of administration. Adult cancer survivors were significantly more like to use marijuana if they were younger (odds ratio [OR] for 55-64 versus 18-44 years old: 0.60; 95% CI: 0.38-0.93; $P < 0.01$); male (OR for female versus male: 0.65; 95% CI: 0.48-0.87; $P < 0.01$); non-Hispanic Black race/ethnicity (OR: 2.00; 95% CI: 1.21-3.33; $P < 0.01$); having depression (OR: 1.58; 95% CI: 1.17-2.14; $P < 0.01$) and current (OR: 3.23; 95% CI: 2.20-4.74; $P < 0.01$) or former tobacco smoker (OR: 2.40; 95% CI: 1.70-3.38; $P < 0.01$) and binge drinker (OR: 2.25; 95% CI: 1.53-3.29; $P < 0.01$). **Conclusions:** Among a large cohort of US adults with cancer, marijuana use was commonly reported and certain subgroups were at higher risk for marijuana use. Health professionals should identify the risk factors for elevated marijuana use, especially as more states legalize medical and recreational marijuana use despite uncertain health risks. Research Sponsor: None.

Exploration of optimal paracentesis volume for terminally ill patients with malignant ascites. *First Author: Tetsuya Ito, Department of Palliative Care, Japanese Red Cross Medical Center, Tokyo, Japan*

Background: Malignant ascites (MA) often causes distressing symptoms especially for terminally ill cancer patients. Control of such symptoms is generally difficult when it becomes refractory to standard antitumor therapies. Paracentesis is the most common treatment modality which provides rapid and temporary symptom relief, while it requires frequently repeated treatment to maintain symptom control. The optimal procedure is often a balance between the potential for symptom improvement and the known risks of adverse events such as hypotension and renal impairment. However, there are limited data regarding the optimal amount of fluid to be removed. The aim of this study was to explore the efficacy (paracentesis interval and symptom relief) and safety (adverse events) of paracentesis by the drainage volume. **Methods:** This is part of a multicenter prospective observational study (EASED study). Consecutive adult patients with advanced cancer admitted to 23 participating palliative care units were eligible. We analyzed patients with MA who received paracentesis. We compared paracentesis-free survival (PFS) using Cox regression among 3 groups with different paracentesis volumes: minimum: $<$ = 1500 mL, small: 1500-2500 mL, and moderate: $>$ 2500 mL, with adjustment for potential confounders: age, sex, the Karnofsky Performance Status, and variables of which P-values were $<$ 0.1 in univariate analysis. Trend of the difference in abdominal distention numerical rating scale (NRS) before and after paracentesis and adverse events were compared among 3 groups. Under missing at random assumption, missing values were imputed using multiple imputation. **Results:** A total of 1926 patients were enrolled and 673 patients developed MA at admission. Of these, 586 patients never received paracentesis during their PCU stay. Thus, the population for analysis consisted of 87 patients. Median PFS was 7 days. Compared with a moderate volume, small-volume paracentesis was not a significant risk for shorter PFS (HR: 1.14, 95%CI: 0.69-1.93), while a minimum volume was a significant risk for shorter PFS (HR: 2.34, 95%CI: 1.25-4.39). The spline-based hazard ratio curve indicated that a dose-response of the ascites drainage volume to PFS was not likely when more than 2,000 mL of ascites was removed. Abdominal distension NRS significantly decreased after paracentesis (median: 7.5 to 4.0, $p < 0.0001$), while the difference did not significantly increase as the volume of paracentesis rose ($p = 0.61$). No severe adverse event was observed. **Conclusions:** Even small-volume paracentesis could alleviate abdominal distension of terminally ill cancer patients with MA without shortening the paracentesis interval compared with moderate-volume paracentesis. Small-volume paracentesis was an effective and safe treatment for such patients. Our findings may help physicians estimate an optimal volume of paracentesis for each patient with MA. Neuropathy severity at the time of oxaliplatin treatment alteration in patients with colon cancer (Alliance A151912). *First Author: Daniel Louis Hertz, University of Michigan College of Pharmacy, Ann Arbor, MI*

Background: Clinical guidelines recommend altering chemotherapy treatment by decreasing, delaying, or discontinuing dosing in patients (pts) experiencing chemotherapy-induced peripheral neuropathy (CIPN). There are few data available on clinical use of treatment alteration including the severity of CIPN at the time of alteration. Our objective was to investigate the incidence of oxaliplatin treatment alterations and CIPN severity at that time. **Methods:** This was a retrospective analysis of pts with colon cancer scheduled to receive oxaliplatin-containing combination chemotherapy on the N08CB trial of intravenous calcium and magnesium for prevention of CIPN. Dose alterations were not mandated by the N08CB protocol. Clinicians assessed CIPN using NCI-CTCAE V.4.0; pts used the sensory subscale of the EORTC-QLQ Chemotherapy-Induced Peripheral Neuropathy 20 (CIPN8). Pts were classified as 1) completed oxaliplatin treatment without alteration, 2) dose reduction or delay due to CIPN, 3) discontinuation due to CIPN, 4) discontinuation due to other AE, or 5) discontinuation for another reason. Comparisons focused primarily on pts with alteration due to CIPN (groups 2 and/or 3) compared with pts completing treatment without alteration (group 1) using chi-squared and Kruskal-Wallis tests. **Results:** In this analysis of 350 N08CB pts, 135 (39%) completed oxaliplatin without treatment alteration, 70 (20%) had a dose reduction (n=66) or delay (n=4) due to CIPN and 35 (10%) discontinued early due to CIPN. Pts who experienced alterations due to CIPN were younger (p=0.0249) and more likely to be female (p=0.008). Clinician-assessed CIPN severity was greater in pts at the time of dose reduction or delay compared with CIPN severity at the end of treatment in pts with no alteration ($p<0.0001$). Pt-assessed CIPN severity was not different in pts who completed treatment without alteration compared to pts who had a dose reduction or delay (p=0.88) or a discontinuation (p=0.37). CIPN8 scores at cycle 4 were higher (worse) in pts who eventually had any alteration (i.e., reduction, delay, or discontinuation) compared to pts who completed treatment without any alteration (median CIPN8 11.5 vs. 7.7, p=0.023). **Conclusions:** Treatment alterations due to CIPN are relatively common in pts receiving adjuvant oxaliplatin for colon cancer and are associated with clinician-assessed but not pt-reported CIPN severity. Rapid CIPN8 increases early in treatment are indicative of increased likelihood of a future oxaliplatin treatment alteration, indicating a potential use of early monitoring and intervention. Assessing duration of breakthrough chemotherapy-induced nausea and vomiting (CINV): A pooled study analysis of NEPA versus aprepitant. *First Author: Rudolph M. Navari, World Health Organization Cancer Care Program, Birmingham, AL*

Background: The historical standard clinical trial endpoint for preventing chemotherapy-induced nausea and vomiting (CINV) has been assessment of complete response (CR: no emesis and no rescue medication use) over five days. Recent evaluations focused on the duration of breakthrough CINV suggest that long duration of CINV results in more lost work time and impaired activity and is also a strong predictor for CINV in subsequent cycles. A recent pooled analysis of three similarly designed registration trials of NEPA, a fixed oral combination NK_1 receptor antagonist (RA) (netupitant)/5-HT_3RA (palonosetron), showed significantly higher CR rates during the delayed phase (≥24-120h) for NEPA compared to an aprepitant (APR) regimen. In this post-hoc analysis, we evaluated the extent and duration of breakthrough CINV in these pooled studies. **Methods:** Chemotherapy-nave patients who received cisplatin-based chemotherapy and antiemetic prophylaxis of either a single dose of NEPA plus dexamethasone (DEX) or a 3-day APR/5-HT_3 RA/DEX regimen from three randomized, double-blind pivotal trials were included. Patients without a CR were defined as treatment failures. Extent of CINV was evaluated using proportions of patients with treatment failure, emesis, and significant nausea (defined as >25 mm on a 100 mm visual analog scale). Over the 5-day overall phase, duration was categorized as 1-2, and ≥3 days. Pearson s chi-square test was employed to compare risks between treatments for each duration category in each of the previously mentioned endpoints. **Results:** Among all 621 NEPA and 576 APR patients, a significantly greater proportion of APR patients experienced treatment failure, emesis, and significant nausea for ≥3 days. Specifically, among patients with treatment failure, 31% (41/134) who received NEPA and 43% (61/143) who received APR experienced breakthrough CINV for ≥3 days. **Conclusions:** Expanding on data suggesting single-day NEPA is more effective than 3-day APR in preventing delayed CINV, NEPA is also more effective in minimizing the extent and duration of CINV in patients with breakthrough emesis and nausea. Research Sponsor: Helsinn Healthcare.

CINV Extent and Duration	NEPA + DEX (N = 621)	APR/5-HT_3 RA + DEX (N = 576)	P-value
TREATMENT FAILURE			
1-2 days	93 (15%)	82 (14.3%)	0.736
≥3 days	41 (6.6%)	61 (10.6%)	**0.013**
EMESIS			
1-2 days	85 (13.7%)	79 (13.8%)	0.969
≥3 days	40 (6.5%)	55 (9.6%)	**0.045**
SIGNIFICANT NAUSEA			
1-2 days	73 (11.8%)	76 (13.2%)	0.437
≥3 days	54 (8.7%)	71 (12.4%)	**0.038**

Province-wide analysis of patient reported outcomes for stage IV non-small cell lung cancer. *First Author: Michael Chandra Tjong, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Stage IV NSCLC patients have significant disease and treatment-related morbidity. In Ontario, Canada, cancer patients complete Edmonton Symptom Assessment System (ESAS) questionnaires, a tool that elicits patients' self-reported severity of common cancer-associated symptoms at clinical encounters. ESAS domains are: anxiety, depression, drowsiness, appetite, nausea, pain, shortness of breath, tiredness and well-being. The purpose of this study is to examine moderate-to-severe symptom burden in the 12 months following a diagnosis of stage IV NSCLC. **Methods:** Using administrative databases and unique encoded identifiers, stage IV NSCLC diagnosed between January 2007 and September 2018 were evaluated for symptom screening with ESAS in the 12 months following diagnosis. Proportion of patients reporting moderate-to-severe score (i.e. ESAS ≥4) in each domain within 12 months were calculated. Patients reporting moderate-to-severe within the different ESAS domains of were plotted over time. Multivariable (MV) Poisson regression models with potential covariates such as age, sex, Elixhauser comorbidity index, income quintiles, and lung cancer treatments received were constructed to identify factors associated with moderate-to-severe symptoms. **Results:** Of 22,799 stage IV NSCLC patients, 13,289 (58.3%) had completed ESAS (84,373 unique assessments) in the year following diagnosis. Patients with older age, high comorbidity, and not receiving active cancer therapy were less likely to complete ESAS. Most (94.4%) reported at least 1 moderate-to-severe score. Most prevalent moderate-to-severe ESAS symptoms within 12 months after diagnosis were tiredness (84.1%), lack of wellbeing (80.7%), low appetite (71.7%), and shortness of breath (67.8%); nausea was the least prevalent (34.6%). Most symptoms peaked at diagnosis and persisted in the year after diagnosis. On adjusted MV analyses, patients with high comorbidity, low income, and urban residency were associated with increased moderate-to-severe symptoms. Moderate-to-severe scores in all ESAS symptoms were associated with delivery of radiotherapy within 2 weeks prior, while moderate-to-severe nausea, drowsiness, tiredness, low appetite, and lack of wellbeing were associated with delivery of systemic therapy within preceding 2 weeks. **Conclusions:** In this population-based analysis of stage IV NSCLC PROs in the year following diagnosis, moderate-to-severe symptoms were highly prevalent and persistently high, underscoring the need to address supportive requirements in this at-risk population. Research Sponsor: Ontario Institute of Cancer Research Grant.

Noninferiority study evaluating dexamethasone (DEX)-sparing regimens administered with NEPA, a fixed combination of netupitant and palonosetron, for the prevention of chemotherapy-induced nausea and vomiting (CINV) caused by high-dose cisplatin. *First Author: Luigi Celio, Oncology Unit, ASST del Garda, Desenzano del Garda Hospital, Brescia, Italy*

Background: Corticosteroids such as DEX continue to play a key role for the prevention of CINV. Although they are generally considered safe when used in combination with other anti-emetic agents, corticosteroids can cause a range of side effects. To reduce the overall exposure to DEX in patients receiving cisplatin-based chemotherapy, we evaluated the non-inferiority of DEX on day 1, with or without low-dose DEX on days 2 and 3, combined with oral NEPA, a fixed combination of the NK_1 receptor antagonist (RA), netupitant and 5-HT_3 RA, palonosetron, compared with NEPA plus the guideline-recommended use of 4-day DEX (reference arm). Non-inferiority was met for both DEX-sparing regimens and the reference arm for the primary endpoint of complete response (CR: no emesis and no rescue use) during the overall (0-120h) phase post-chemotherapy. In this analysis secondary efficacy endpoints were evaluated for the single-dose DEX-sparing group versus the 4-day DEX arm. **Methods:** In this analysis from an open-label, multicenter study (ClinicalTrials.gov NCT04201769) chemotherapy-nave patients undergoing high-dose cisplatin (≥70 mg/m^2) received either NEPA and DEX (12 mg) on day 1 only or NEPA and DEX [12 mg on day 1 plus 4 mg twice daily on days 2-4 (DEX4)]. Efficacy endpoints included complete protection (CR plus no significant nausea), no emesis, and no significant nausea (<25 mm on a 100 mm visual analog scale) during the acute (0-24h), delayed (>24-120h) and overall phases. The non-inferiority margin was set at -15% difference (DEX1 minus DEX4). **Results:** One-hundred fifty-two patients, 76 in each arm, were included. Non-inferiority was met for the DEX1 arm and the DEX4 reference arm for all efficacy endpoints (Table). **Conclusions:** A simplified regimen of NEPA plus single-dose DEX offers comparable CINV prevention throughout 5 days post-chemotherapy with the advantage of sparing patients additional doses of DEX in the high emetic risk setting of cisplatin-based chemotherapy. Clinical trial information: NCT04201769. Research Sponsor: None.

Endpoint time period post-chemotherapy	NEPA + DEX1 (N = 76) % of patients	NEPA + DEX4 (N = 76) % of patients	Risk Difference (DEX1 minue DEX4) %	95% CI
Complete protection				
Acute (0-24h)	90.8	89.5	1.3	-8.2 to 10.8
Delayed (>24-120h)	73.7	67.1	6.6	-7.9 to 21.1
Overall (0-120h)	73.7	67.1	6.6	-7.9 to 21.1
No emetic episodes				
Acute	96.1	98.7	-2.6	-7.7 to 2.4
Delayed	92.1	97.4	-5.3	-12.3 to 1.8
Overall	92.1	97.4	-5.3	-12.3 to 1.8
No significant nausea				
Acute	93.4	97.3	-3.9	-10.6 to 2.7
Delayed	77.6	76.3	1.3	-12.1 to 14.7
Overall	77.6	76.3	1.3	-12.1 to 14.7

12094 **Poster Session**

A randomized, double-blind, multicenter, phase III study of fosnetupitant for the prevention of chemotherapy-induced nausea and vomiting (CINV) in patients receiving doxorubicin-cyclophosphamide/epirubicin-cyclophosphamide (AC/EC) based highly emetogenic chemotherapy: CONSOLE-BC. *First Author: Junji Tsurutani, Showa University, Tokyo, Japan*

Background: Fosnetupitant (FN) is a phosphorylated pro-drug of netupitant that has high binding affinity and selectivity for the neurokinin 1 receptor and a long half-life of 70 h. Recent studies have reported that fosaprepitant (FA) has a risk for developing injection site reactions (ISRs) in patients with breast cancer who receive doxorubicin-cyclophosphamide/epirubicin-cyclophosphamide (AC/EC)-based treatments. Previous studies have shown that FN may have a low risk of ISRs and could potentially address this unmet medical need. The present study (JapicCTI-194691) was intended to evaluate the safety profile, including ISRs, of FN in patients receiving AC/EC treatment. For exploratory purposes, we set the FA group as the exploratory arm. A separate pivotal phase 3 study (JapicCTI-194611) was conducted to verify the efficacy and safety of FN compared with FA in patients receiving cisplatin-based chemotherapy. **Methods:** Patients scheduled to receive AC/EC were randomly assigned 1:1 to receive FN 235 mg or FA 150 mg in a double-blind manner, in combination with intravenous palonosetron (PALO) 0.75 mg and dexamethasone (DEX) 9.9 mg on day 1. The stratification factors were age class ($<$ 55 years vs. $\geq$55 years) and site. The primary endpoint was the incidence of treatment-related adverse events (TRAEs) of FN. In addition, the ISRs were investigated as secondary endpoints. Efficacy outcomes were also evaluated as secondary endpoint. **Results:** Between April 2019 and March 2020, total 102 patients were enrolled in the study. Fifty-two patients were randomized to the FN group and 50 to the FA group, and all of them were treated with the study drug and evaluated for safety. The baseline characteristics were generally balanced, except for the history of motion sickness (54.9% vs. 44.9%) and non-smokers (78.4% vs. 63.3%) in the FN and FA groups, respectively, which are considered as risk factors for chemotherapy-induced nausea and vomiting. The primary endpoint, the incidence of TRAEs was 21.2% (n = 11) (95% CI 11.1% – 34.7%) in the FN group, which was similar to that in the FA group [22.0% (n = 11) (95% CI 11.5% - 36.0%)]. Any cause or treatment-related ISRs were observed in 5.8% (n = 3) and 0% (n = 0), respectively, in the FN group and 26.0% (n = 13) and 10.0% (n = 5), respectively, in the FA group. The overall (0–120 h) complete response (no emetic event and no rescue medication) rate standardized by age category was 45.9% (n = 23) in the FN group and 51.3% (n = 25) in the FA group. **Conclusions:** The safety of FN in combination with PALO and DEX was favorable. Risk of ISR by FN was quite low in the AC/EC setting. Clinical trial information: JapicCTI-194691. Research Sponsor: Taiho pharmaceutial Co., Ltd.

The PROVIEW+ tool: Developing and validating a tool to predict risk of poor performance status and severe symptoms in cancer patients over time. *First Author: Hsien Seow, McMaster University, Hamilton, ON, Canada*

Background: There are numerous predictive cancer tools that focus on survival. However, no tools predict risk of low performance status or severe symptoms, which are important for patient decision-making and early integration of palliative care. The aim of this study was to develop and validate a model for all cancer types that predicts the risk for having low performance status and severe symptoms. **Methods:** A retrospective, population-based, predictive study using linked administrative data from cancer patients from 2008-2015 in Ontario, Canada. Patients were randomly selected for model derivation (60%) and validation (40%). The derivation cohort was used to develop a multivariable logistic regression model to predict the risk of having the reported outcomes in the subsequent 6 months. Model performance was assessed using discrimination and calibration plots. The main outcome was low performance status using the Palliative Performance Scale. Secondary outcomes included severe pain, dyspnea, well-being, and depression using the Edmonton Symptom Assessment System. Outcomes were recalculated after each of 4 annual survivor marks. **Results:** We identified 255,494 cancer patients (57% female; median age of 64; common cancers were breast (24%) and lung (13%)). At diagnosis, the risk of having low performance status, severe pain, well-being, dyspnea, and depression in 6-months is 1%, 3%, 6%, 13% and 4%, respectively for the reference case (i.e. male, lung cancer, stage I, no symptoms). Generally these covariates increased the outcome risk by $>$ 10% across all models: obstructive lung disease, dementia, diabetes; radiation treatment; hospital admission; high pain; depression; Palliative Performance Scale score of 60-10; issues with appetite; or homecare. Model discrimination was high across all models. **Conclusions:** The model accurately predicted changing cancer risk for low performance status and severe symptoms over time. Providing accurate predictions of future performance status and symptom severity can support decision-making and earlier initiation of palliative care, even alongside disease modifying therapies. 12096 **Poster Session**

Cannabidiol (CBD) use among cancer survivors. *First Author: Chasse Margot Bailey-Dorton, Atrium Health Levine Cancer Institute, Charlotte, NC*

Background: Cannabidiol (CBD) is a non-psychoactive component of cannabis touted for various therapeutic effects. The Federal Drug Agency has only approved one prescription CBD product for treatment of severe epilepsy. On December 17, 2020 the Federal Trade Commission announced legal consequences for deceptively marketed CBD products in the rapidly expanding market of various CBD products; the products' unsupported claims included CBD as a cancer treatment. Little is known about survivors use of CBD. This study explores the prevalence and nature of CBD use by cancer survivors. **Methods:** A link to an anonymous, electronic survey was posted on the Levine Cancer Institute and SherryStrong (Martin Truex Jr. Foundation: philanthropy for ovarian cancer) Twitter and Facebook social media platforms. Data were managed in REDCap, a secure, web-based, electronic data capture tool. Survey responses were summarized and described with frequencies and compared using Fisher's Exact tests; $p < 0.1$ was considered statistically significant. **Results:** N = 295 self-selected respondents were White (95%), female (86%), middle aged (45-64 years) (58%) and in the US (95%). Ninety percent indicated current (85%) or past (15%) use of CBD product; a third of these participants (N = 102) identified as cancer survivors. Gynecologic (31%) and breast (30%) cancers were the most recorded malignancies, and 38% report active treatment. Most survivors indicated using CBD products daily (77%) for a year or less (79%) and spent @$30 a week on products (70%). Common uses for CBD were easing pain (66%), anxiety (50%), and sleep (50%)—14% reported treating or preventing cancer. 41% learned about CBD from family/friends, fewer learned from the Internet (21%) or local store (11%). Only 12% received information from a physician. Liquid drops (58%) and topicals (19%) were popular products and reported side effects were sparse—sedation and/or euphoria were indicated by 10% and 2%, respectively. Over 82% of cancer survivors indicated that CBD product helped their conditions. CBD use to ease anxiety and stress declined with age; 71% of young survivors (aged 18-44) sought anxiety relief versus 45% and 36% of middle age (aged 45-64) and seniors (aged 65+), respectively (p = 0.05), and 58% of young survivors pursued stress relief versus 39% of middle age and 21% of seniors (p = 0.08). More young (25%) and middle age (37%) survivors indicated spending over $30 on products weekly than seniors (7%) (p = 0.08). No differences were seen in CBD use between cancer survivors by gender or treatment status. **Conclusions:** Cancer survivors commonly use CBD, yet infrequently under the guidance of a physician. Survivors largely rely on word of mouth and internet information about CBD. Despite lack of standardization of production and labeling of CBD products, the majority of patients reported positive improvements in symptoms. Future research should explore strategies to educate cancer patients and providers in safe CBD use. Research Sponsor: None.

Effectiveness of a nurse-led, screening-triggered, early specialized palliative care intervention program for patients with advanced lung cancer: A multicenter randomized controlled trial. *First Author: Yoshihisa Matsumoto, Department of Palliative Medicine, National Cancer Center Hospital East, Kashiwa, Japan*

Background: The integration of palliative care into standard cancer treatment during the early phase of the disease can improve cancer patients' quality of life (QOL). The current study examined the effectiveness of a nurse-led, screening-triggered, early specialized palliative care intervention program for patients (pts) with advanced lung cancer. **Methods:** Pts with advanced lung cancer undergoing initial chemotherapy were randomized (1:1) to the intervention group (IG) or the usual care group (UG) between January 2017 and September 2019. The intervention, which was triggered using by a brief, self-administered screening tool, comprised comprehensive need assessments, counseling, and service coordination by advanced-leveled nurses. The primary endpoint was the change from baseline of the Functional Assessment of Cancer Therapy -Lung Trial Outcome Index (TOI) at week 12, and the secondary endpoints were TOI at week 20, depression (Patient Health Questionnaire-9), anxiety (Generalized Anxiety Disorder-7), and survival. **Results:** Pts were randomly allocated (102 for each group). The median age was 69 y (range, 27-91) and 77.5% were male. Seventy-two pts had extensive disease small-cell lung carcinoma and 132 Pts had stage IV non-small cell lung carcinoma. Because there was not a significant time-by-group interaction, we estimated main effects and the IG did not show a significant improvement in TOI from the baseline at week 12 and 20 compared to the UG (Mean group difference [the same applies hereafter] 2.13; 90% CI: -0.70, 4.95; P = .107, one-tailed). However, when we considered time-by-group interaction effects exploratorily, the IG did show significant improvement in TOI from baseline at week 20 compared to the UG (3.58; 90% CI: 0.15, 7.00; P = 0.043). There was no significant difference in change from baseline depression and anxiety between the two groups either at week 12 (depression −0.38; 95% CI: -1.81, 1.05; $P = 0.60$, anxiety -0.18; 95% CI: -1.45, 1.09; $P = 0.78$) or at week 20 (depression -1.27; 95% CI: -2.79, 0.25; $P = .10$, 1.26; 95% CI: -2.61, 0.09; $P = .067$). The 1-year survival rates were 49.5% (95% CI: 39.3, 58.9) in the IG and 43.4% (95% CI: 33.6, 52.8) in the UG. **Conclusions:** This trial failed to show statistical superiority of nurse-led, screening-triggered, early specialized palliative care intervention program over usual care, however, it's possible delayed clinical benefits of improvement in QOL (TOI), depression and anxiety were suggested. The study design that some pts in the IG received later or no intervention, may dilute the difference of intervention between group differences. Further investigation, including the mixed method approach adopted in this study, is needed to uncover mediating factors for the effect of this low-cost, novel model of early palliative care. Efficacy of olanzapine combined with the standard triplet antiemetic therapy for cisplatin-based chemotherapy: A sub-analysis of a randomized, double-blind, placebo-controlled trial (J-FORCE). *First Author: Yukiyoshi Fujita, Division of Pharmacy, Gunma Prefectural Cancer Center, Gunma, Japan*

Background: In a randomized, double-blind, placebo-controlled trial (J-FORCE), we previously reported the efficacy of olanzapine (OLZ) 5 mg plus triplet antiemetic therapy for cisplatin (CDDP)-based chemotherapy-induced nausea and vomiting (CINV) in the delayed phase (24–120 h after CDDP treatment). Here, we report the results of a pre-planned subgroup analysis of this trial (in which risk factors were used as the allocation factors). This analysis was designed to determine which patients benefit more from OLZ. **Methods:** Subgroup analysis was performed on complete response (CR: no emesis and no rescue medication) in the acute (within 24 h of CDDP treatment) and delayed phase and time to treatment failure (TTF: time from CDDP treatment to the first vomiting or use of rescue medication). Data from 705 patients in the efficacy analysis population (354 in the OLZ group and 351 in the placebo (PLA) group) were analyzed by sex (male/female), age (≥55 years/ < 55 years), and CDDP dose (≥70 mg/m^2/ < 70 mg/m^2). For CR, we calculated point estimates of differences between groups and 95% confidence intervals and performed a Mantel-Haenszel test. We used the Kaplan-Meier method for the analysis of TTF, and comparisons between groups were made using a log-rank test. **Results:** Delayed CR (OLZ versus PLA) and risk difference (RD) of delayed CR following OLZ treatment were significantly greater than following PLA in the following subgroups: male (83.1% versus 70.5%, RD 12.6%, p = 0.001), female (70.9% versus 56.4%, RD 14.5%, p = 0.021), age ≥55 years (78.7% versus 67.6%, RD 11.1%, p = 0.003), age < 55 years (81.0% versus 57.4%, RD 23.6%, p = 0.005), and CDDP ≥70 mg/m^2 (78.8% versus 65.3%, RD 13.5%, p < 0.001). TTF of all subgroups (male/female, ≥55 years/ < 55 years, and ≥70 mg/m^2/ < 70 mg/m^2) was significantly longer in the OLZ group than in the PLA group (HR 0.493, p < 0.001; HR 0.612, p = 0.022; HR 0.586, p < 0.001; HR 0.401, p = 0.005; HR 0.546, p < 0.001; HR 0.543, p = 0.031, respectively). **Conclusions:** Our results suggest a benefit of OLZ 5 mg plus triplet therapy regardless of risk factors for CDDP-based CINV. Clinical trial information: UMIN000024676. Research Sponsor: Japan Agency for Medical Research and Development.

A phase III, randomized, double-blind, multicenter, active control study of fosnetupitant for the prevention of chemotherapy-induced nausea and vomiting (CINV) in patients receiving cisplatin-based highly emetogenic chemotherapy (HEC): CONSOLE. *First Author: Yoshimasa Shiraishi, Research Institute for Diseases of the Chest, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan*

Background: Fosnetupitant (FN) is a phosphorylated pro-drug of netupitant that has high binding affinity for the neurokinin-1 (NK-1) receptor and a long half-life of 70 h. This phase 3 study is the first head-to-head study to compare two NK-1 receptor antagonists, FN and fosaprepitant (FA), in combination with palonosetron and dexamethasone for the prevention of chemotherapy-induced nausea and vomiting (CINV) in patients receiving highly emetogenic chemotherapy (JapicCTI-194611). **Methods:** Patients scheduled to receive cisplatin (≥70 mg/m^2) -based chemotherapy were randomly assigned 1:1 to receive FN 235 mg or FA 150 mg, in combination with palonosetron 0.75 mg and dexamethasone (9.9 mg on day 1, 6.6 mg on days 2-4). The stratification factors were sex, age category (<55 vs. ≥55 years), and site. The primary endpoint was the complete response (CR; no emetic events and no rescue medication) rate, stratified by sex and age category, during the overall phase (0-120 h) to show the non-inferiority (margin, -10%) of FN to FA. The secondary endpoints were: CR rate, complete protection rate, total control rate, no nausea rate, no emetic events rate in each period [i.e., acute (0-24 h), delayed (24-120 h), overall, 0-168 h and 120-168 h], time to treatment failure, and safety, including injection site reactions (ISRs). Assessment of efficacy was continued until 168 h after the initiation of cisplatin. Some eligible patients were evaluated for safety and efficacy of FN for up to four cycles. **Results:** Between February 2019 and March 2020, total 795 patients were enrolled in the study. The study drug was administered to 785 patients (n=392 in FN vs. n=393 in FA), and all of them were evaluated for efficacy and safety. Baseline characteristics were generally balanced between the two groups. The adjusted overall CR rate was 75.2% in FN vs. 71.0% in FA [MH common risk difference, 4.1%; 95% CI, -2.1% to 10.3%), thus demonstrating non-inferiority of FN to FA. Regarding the other secondary endpoints of efficacy until 168 h, FN was favorable against FA, especially the CR rate during 0-168 h (73.2% in FN vs. 66.9% in FA) (Table). The incidence rates of treatment-related adverse events were 22.2% in FN vs. 25.4% in FA, whereas those of ISRs with any cause or with treatment-related were 11.0% or 0.3% in FN vs 20.6% or 3.6% in FA, respectively (p<0.001). **Conclusions:** FN demonstrated non-inferiority to FA, with a favorable safety profile and lower risk for ISRs. For the period beyond 120 h after initiation of chemotherapy, FN may have the potential to improve the prevention of beyond delayed CINV. Clinical trial information: JapicCTI-194611. Research Sponsor: Taiho Pharmaceutical Co., Ltd.

CR rate by period.

	FN (n=392)	FA (n=393)
Acute (0-24 h)	93.9%	92.6%
Delayed (24-120 h)	76.8%	72.8%
Overall (0-120 h)*	75.2%	71.0%
0-168 h	73.2%	66.9%
120-168 h	86.5%	81.4%

The equivalency study of novel current standard 3-drugs combination regimen (ondansetron, dexamethasone and olanzapine) to netupitant containing regimen for preventing high dose cisplatin induce nausea and vomiting treatment, double blind placebo control trial. *First Author: Chalermchai Lertanansit, Division of Medical Oncology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*

Background: Prevention of chemotherapy-induced nausea and vomiting (CINV) is vital in cancer treatment. Here, we compared the efficacy of netupitant-containing regimen; composed of NEPA, dexamethasone, and olanzapine (NEPAs), which is recommended for preventing CINV from high-emetogenic chemotherapy (HEC) to standard 3-drugs; ondansetron, dexamethasone, olanzapine for preventing CINV from high-dose cisplatin (≥75 mg/m^2). **Methods:** This randomized, double-blind, placebo-control trial randomly assigned untreated patients who were received high-dose cisplatin in a 1:1 ratio to either NEPAs or standard 3-drugs combination regimen. Dose of dexamethasone in NEPAs regimen was modified after preplanned interim safety analysis to increase from 4 to 8 mg per day on days 2-4. The stratification factors were concurrent treatment with radiation and sex. The primary endpoint was the overall complete response (CR) rate defined as no vomiting and no use of rescue antiemetic drugs. The protocol allowed crossover to NEPAs for those who received standard 3-drugs and did not reach CR in the first cycle. We collected outcome in the first 2-cycle of treatment. **Results:** Between January 2019 and December 2020, hundred patients were randomly assigned to either NEPAs (n = 51) or in-house standard 3-drugs (n = 49). Demographic characteristics were well-balanced in both arms. Total events in both arms were 101 events for NEPAs and 78 events for standard 3-drug. Overall CR rate were 70% and 69% in NEPAs and standard 3-drugs, (p-value 0.87) respectively. According to emesis phase, CR in acute (0-24 hrs.) and delay phase (24-120 hrs.) were not different in both arms; 91% vs. 89% and 72% vs. 71% in NEPAs and standard 3-drugs respectively. However, mean nausea VAS score was significantly lower in NEPAs (1.63 vs. 2.02, p-value = 0.001). The ad hoc subgroup analysis shown similar efficacy between before and after protocol amendment of NEPAs regimen in term of delay emesis CR rate; 70.9% vs. 73.9% (p-value 0.73). **Conclusions:** The NEPA-containing regimen did not show superiority compare to standard 3-drug in terms of complete response rate for CINV prevention among patients receiving high-dose cisplatin. Furthermore, the dexamethasone dosage of 4 vs. 8 mg per day might not affect the efficacy of delay emesis of the NEPAs regimen. Clinical trial information: TCTR20190508001. The effectiveness of a provincial symptom assessment program in reaching adolescents and young adults with cancer: A population-based cohort study. *First Author: Sumit Gupta, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Symptom control is prioritized by cancer patients and may improve overall survival. Several jurisdictions have thus launched population-wide initiatives to assess symptoms at regular intervals. In Ontario, Canada, for example, all cancer patients are screened using the Edmonton Symptom Assessment System (ESAS) at every outpatient visit. Few studies have examined symptom burdens in adolescents and young adults (AYA). Previous work suggests that AYA symptoms differ from those in older patients, and that general screening tools may not be appropriate. Despite this, whether current symptom screening initiatives reach AYA with cancer are unknown. We therefore determined 1) Whether AYA with cancer were participating in ESAS screening, and 2) Which AYA were at highest risk of not being screened. **Methods:** We identified all Ontario AYA diagnosed with cancer at age 15-29 years between 2010-2018 and treated in adult centers. Patients were linked to population-based databases to identify all cancer-related outpatient visits in the year following diagnosis and whether visits involved completion of an ESAS form. Each patient's first year was divided into two-week periods. For each period, AYA were considered either unscreened if they had a cancer-related visit but no ESAS score, or screened if they had a cancer-related visit with at least one ESAS score. Periods without cancer-related visits were not considered, given no potential for ESAS screening during such periods. Covariates included age at diagnosis, sex, cancer type, neighbourhood income quintile, and institution type [regional cancer centre (RCC) vs. community]. Multivariable logistic regression models were implemented under a generalized estimating equations approach to account for individual-level correlation. **Results:** The final cohort included 5,435 AYA. Within any given two-week period, only 36-45% of AYA attending cancer-related outpatient visits were screened. In adjusted analyses, age and sex were not associated with being screened. However, AYA living in the lowest income quintile neighbourhood were less likely to be screened [odds ratio (OR) 0.86, 95th confidence interval (95CI) 0.77-0.97; p = 0.01] compared to those in the highest. Patients with hematologic malignancies were least likely to be screened (OR 0.77, 95CI 0.67-0.88; p < 0.001), as were AYA attending community centers (OR 0.48, 95CI 0.42-0.55; p < 0.001). **Conclusions:** Despite a population-wide symptom assessment program, only a minority of AYA are screened. Though patients with hematologic cancers suffer from particularly high symptom burdens, they were less likely to be screened. Interventions targeting AYA are required to increase uptake, particularly among those in disadvantaged neighborhoods or attending community hospitals. Studies of AYA-specific symptom assessment tools are also warranted. Research Sponsor: Terry Fox Research Institute.

Association between allostatic load, symptom burden and mortality in E1A11 trial for myeloma. *First Author: Samilia Obeng-Gyasi, The Ohio State University, Columbus, OH*

Background: Allostatic load (AL) conceptualizes the effects of chronic psychosocial adversity on physiologic dysregulation. To date, studies have shown an association between elevated AL and higher disease-specific and overall mortality among cancer patients; however, none have focused on multiple myeloma (MM) patients. We aim to understand the relationship between baseline AL, symptom burden, and mortality among patients enrolled in the E1A11 therapeutic trial in MM. **Methods:** ECOG-ACRIN E1A11 was a phase III RCT comparing induction with Bortezomib (Arm A) versus Carfilzomib (Arm B) in conjunction with Lenalidomide +Dexamethasone. AL included 7 biomarkers: BMI, alkaline phosphatase, creatinine, C-reactive protein, white blood cell count, albumin and creatinine clearance. AL7 was a composite summary score with a point was assigned for each biomarker value in the highest quartile, except for albumin and creatinine clearance, where a point was assigned for values in the lowest quartile. Endpoints included symptom burden at baseline and ~1 month, non-completion of induction therapy, and overall survival (OS). Functional Assessment of Cancer Therapy Multiple Myeloma (FACT-MM) items assessed patient-reported symptom burden, including fatigue (item HI7), pain (GP4), and bother by side effects of treatment (GP5) on a 5-point Likert scale. Multivariable logistic regressions assessed the effect of AL7 (ranging 0-7) on high-pain, -fatigue, and -bother (QOL score $>=3$ vs <3), and non-completion of induction therapy. The effect of AL7 on OS was assessed using multivariable Cox regression. Regression covariates included study arm, age, sex, race, ECOG performance status, and the target symptom burden score at baseline. **Results:** The study cohort included 1087 patients. Mean baseline AL7 was 1.8 (±1.4). In adjusted analysis, a unit increase in AL7 was associated with a greater odds of high pain (OR 1.15, 95%CI [1.04-1.27]) and high fatigue (OR 1.19, 95%CI [1.07-1.32]) at baseline, which did not persist at ~1 month (pain OR 0.96, 95%CI [0.84-1.10]; fatigue OR 1.03, 95%CI [0.91-1.16]). There was no association between AL7 and high side effect bother at baseline (OR 1.06, 95% CI [0.83-1.35]) or at ~1 month (OR 1.06, 95%CI [0.90-1.24]). There was no association between AL7 and induction non-completion (OR 1.07, 95%CI [0.96-1.18]). Notably, each unit increase in AL7 was associated with higher mortality (HR 1.26, 95%CI [1.14-1.39]). **Conclusions:** Despite its association with fatigue and pain at baseline, AL7 was not associated with these symptoms at ~1 month nor induction non-completion. However, elevated baseline AL7 was associated with poorer OS. AL composite score at baseline, which we interpret as a measure of physiological dysregulation associated with adverse social factors, may have implications on clinical outcomes within clinical trials despite presumed equal treatment access. Implementation of electronic patient-reported outcomes for symptom monitoring in a large multi-site community oncology practice. *First Author: Debra A. Patt, Texas Oncology, Dallas, TX*

Background: Among patients receiving chemotherapy, symptomatic adverse event monitoring with electronic patient-reported outcomes (ePRO) is associated with improved clinical outcomes, satisfaction, and compliance with therapy. Standard approaches for ePRO implementation are not established warranting evaluation in community cancer practices. Objective: Evaluate implementation of ePRO symptom monitoring across a large multi-site community oncology practice network. **Methods:** Patients initiating a new systemic therapy at one of 210 practice sites in the Texas Oncology Practice were invited to use in the Navigating Cancer ePRO platform, with rolling implementation from July-December 2020. Participating patients received a weekly prompt by text message or email (patient choice) to self-report common symptoms and well-being via web or smartphone. Severe self-reported symptoms triggered a real-time notification alert to nursing triage to address the symptom. Enrollment and compliance were systematically tracked weekly with evaluation of barriers and facilitators to adoption and sustainability. **Results:** 4375 patients planning systemic treatment enrolled and participated, with baseline characteristics are shown in Table 1. 73% (1841/2522) of enrolled patients with follow up completed at least one ePRO assessment, and among these individuals, 65% (8762/25061) of all available weekly ePRO assessments were completed. Over a 10-week period, compliance with weekly symptom reporting declined from 72% to 52%. Patients on oral therapy had higher compliance rates overall. Barriers currently being addressed include lack of a second reminder text/email prompt, inconsistent discussion of reported ePROs by clinicians at visits, and COVID-related changes in workflow. Facilitators included patient and staff engagement on the importance of PROs for symptom management. **Conclusions:** ePROs can be effectively implemented in community oncology practice. Utilization of ePROs is high, but diminishes over time without attention to barriers. Ongoing work to address barriers and optimize compliance are underway. Research Sponsor: None.

CD4+ T-cell count eligibility by HIV status among participants receiving immunotherapy for cancer diagnoses. *First Author: Thomas A Odeny, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: The Food and Drug Administration recommends that patients living with HIV (PLWH) with a CD4+ T cell count (CD4) ≥350 cells/μL should generally be eligible for any cancer clinical trial, but there has been a reluctance to enter patients with lower CD4 counts. Patients with relapsed or refractory cancers may also have low CD4 due to initial cancer therapies, irrespective of HIV status. Immune checkpoint inhibitors (ICI) are safe among PLWH with advanced cancer receiving antiretroviral therapy and CD4 >100 cells/μL. We examined the outcomes of immunotherapy trials by HIV and CD4 status among patients receiving ICI for relapsed/refractory cancers. **Methods:** We conducted a retrospective cohort study of participants who received ICI for relapsed/refractory cancers in 2 trials (1 specifically in PLWH with CD4 >100 only) from the National Cancer Institute. Primary outcomes were to assess relationship between HIV status and baseline CD4 (<350 vs ≥350 cells/μL) and other characteristics. We stratified 3-year survival by CD4 in PLWH and HIV-negative participants with HPV-related cancers. The Kaplan-Meier method was used to estimate survival rates. **Results:** Eighty-three participants were included: 26 (31.3%) were HIV-positive and received pembrolizumab and 57 (68.7%) were HIV-negative and received bintrafusp alfa. HIV-negative participants had relapsed HPV related malignancies (cervix, anal, head and neck) whereas participants with HIV had both viral and non-viral associated cancers (Table). While the median screening CD4 was significantly lower among PLWH than HIV-negative participants, there was no difference in the proportion with CD4 <350 (p=0.1). When restricted to HPV related malignancies, 3-year survival rates were 32.2% for CD4 <350 and 21.2% for CD4 ≥350 (p=0.7). **Conclusions:** In this retrospective study of ICI clinical trials in relapsed and refractory malignancies, there was no significant difference in baseline CD4 (<350 vs ≥350 cells/μL) by HIV status; 50% of HIV-negative participants had CD4<350 cells/μL. Patients with HIV should be included in ICI studies, and CD4 thresholds lower than 350 cells/μL should be considered as to not unfairly exclude PLWH with cancer. Research Sponsor: U.S. National Institutes of Health.

A multicenter analysis of the outcome of cancer patients with neutropenia and COVID-19 infection optionally treated with granulocyte colony-stimulating factor (G-CSF). *First Author: Ana M. Jimenez-Gordo, Medical Oncology Department, Hospital Universitario Infanta Sofía, San Sebastián De Los Reyes, Spain*

Background: Infection by SARS-CoV-2 can turn into an acute respiratory infection. Approximately 15% of patients will develop a distress syndrome responsible in most cases of mortality. A host hyperinflammatory response induced by a cytokine storm, is the main cause of this severe complication. Chemotherapy myelosuppression is associated with higher risk of infections and mortality in cancer patients. There have been no previous reports about the clinical management of patients with neutropenia and concomitant COVID-19. Herein, we present a multicenter experience in several hospitals during COVID-19 outbreak in neutropenic cancer patients infected by SARS-Cov-2. **Methods:** Retrospective clinical data were collected from clinical reports. Protocol was approved by a Clinical Research Ethics Committee (HULP: PI-4194). Inclusion criteria were cancer patients with neutropenia (<1500 cells/mm3) and concomitant COVID-19 infection. Comorbidities, tumor type and stage, treatment, neutropenia severity, filgrastim (G-CSF), COVID-19 parameters and mortality were analyzed. Exploratory analysis included a description of all data collected and bivariate analyses among different pairs of variables, including their impact in mortality in this cohort. In addition, multivariable logistic regression was used to predict respiratory failure and death as a function of multiple variables. **Results:** Among 943 patients with cancer screened in 14 hospitals in Spain, eighty-three patients (8%) had a febrile neutropenia and COVID-19 infection**.** Lung (26%), breast (22%), colorectal (13%) and digestive non-colorectal (17%) cancers were the main locations and most patients had advanced disease (67%). Fifty-three (63%) of patients included died because respiratory failure. Neumonia was presented in 76% of patients, bilateral in 47% and 12% of all patients had thrombotic events. The median of neutrophils was 650cls/mm3 and 49% received G-CSF with a median of days on treatment around 4,5 days. Among all variables related with mortality in neutropenic cancer patients with COVID-19 infection, we found that the number of days with G-CSF showed a significant trend toward worse outcome and higher mortality. In particular, a logistic regression model was developed to predict respiratory failure, as a function of the number of days of G-CSF treatment. As adjusting covariates, sex, age, treatment purpose (palliative vs curative, to adjust for patient status), tumor type, and the lowest level of neutrophils in the patient (to adjust for neutropenic status) were used. A significant effect was obtained for the days of G-CSF treatment (OR = 1.4, 95% CI [1.03, 1.92], p-value = 0.01). **Conclusions:** Our findings suggest that a prolonged G-CSF treatment could be disadvantageous for these cancer patients with COVID-19, with a higher probability of worse outcome. The impact of a web-based prognostic intervention on physicians' prognostic confidence. *First Author: David Hui, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Clinicians often hesitate to discuss prognosis with patients because of prognostic uncertainty. The use of validated prognostic models may enhance prognostic confidence and/or prognostic accuracy. Prognostic confidence is a novel concept that has not been well studied and may support prognosis-based decision making. We examined the impact of a web-based prognostic intervention on physicians' prognostic confidence. **Methods:** In this prospective study, palliative care specialists estimated the prognosis of patients with advanced cancer seen at an outpatient supportive care clinic using the temporal, surprise and probabilistic questions for 6 m, 3 m, 2 m, 1 m, 2 w, 1 w and 3 d survival. They then reviewed information from a web-based prognostic calculator (www.predictsurvival.com) that provided survival predictions from 7 validated prognostic scores, including the Palliative Prognostic Score, Palliative Prognostic Index, and Palliative Performance Status. The clinicians then provided their prognostic estimates post-intervention. The primary outcome was prognostic confidence (0-10 numeric rating scale, where 0 = not at all, 10 = most confident) before vs. after the study intervention. Secondary outcomes included (1) confidence to share the prognosis with patients, (2) confidence to make prognosis-based care recommendations (agreement = strongly agree or agree) and (3) prognostic accuracy. With 220 patients, we had 80% power to detect an effect size of 0.66 with 2-sided α 0.05. We compared the pre-post data using the Wilcoxon signed-rank test for the primary outcome and McNemar test for secondary outcomes. **Results:** 216 patients with advanced cancer (mean age 61, 50% female) were included and 154 (71%) died. The median (IQR) actual survival was 90 (39, 178) days; the median (IQR) predicted survival before and after intervention were 90 (60, 90) and 80 (60, 90) days, respectively. Prognostic confidence significantly increased after the intervention (pre vs. post: median 6 vs. 7, $P < 0.001$). A significantly greater proportion of clinicians reported that they felt confident enough about their prognostic estimate to share it with patients (44% vs. 74%, $P < 0.001$) and to formulate care recommendations (80% vs. 94%, $P < 0.001$) after the intervention. Prognostic accuracy did not differ significantly before and after the intervention, ranging from 72-100% for the temporal question, 45-97% for the surprise questions and 38%-100% for the probabilistic questions ($P > 0.05$). **Conclusions:** Among patients with advanced cancer seen at a supportive care clinic, the web-based prognostic intervention was associated with greater prognostic confidence and willingness to discuss prognosis, despite not significantly altering clinicians' prognostic estimate or prognostic accuracy. Further research is needed to examine how prognostic tools may be able to augment prognostic discussions and clinical decision making. Research Sponsor: None.

Cancer inpatient malnutrition risk, documentation, and ICD-10 coding in an academic medical center. *First Author: Aynur Aktas, Levine Cancer Institute, The Center for Supportive Oncology, Charlotte, NC*

Background: Malnutrition (MN) is common in hospitalized cancer patients but often underdiagnosed. We evaluated the prevalence of MN risk, dietitian documented MN (DDMN), and physician coded malnutrition (PCMN) in a consecutive cohort of cancer inpatients in an academic, community-based medical center. **Methods:** Electronic medical records (EMR) were reviewed for inpatients with a solid tumor diagnosis staged I-IV and admitted to Atrium Health Carolinas Medical Center at least once between 1/1/2016 to 5/21/2019. All data were collected from the first admission EMR encounter closest to the cancer diagnosis date. High MN risk was a score ≥2 on the Malnutrition Screening Tool (MST) completed by an RN at admission. Registered Dietitian (RD) assessments were reviewed for DDMN and grade (mild, moderate, severe). PCMN diagnosis was based on MN ICD-10 codes extracted from the medical coder's discharge summary. Multivariate logistic regression models identified associations between clinic-demographic factors and the prevalence of DDMN and PCMN with stepwise selection. **Results:** N=5,143; 48% females. Median age 63 (range 18-102) years. 70% White; 24% Black, 3% Latino. Most common cancers: thoracic 19% and digestive system (14% other, 11% colorectal). 28% had known stage IV disease. The MST was completed in 79%. Among those with MST ≥2 (N=1,005; 25%), DDMN and PCMN prevalence was 30% and 22%, respectively. In the entire cohort, 8% had DDMN; 7% PCMN; 4% both. Prevalence of MN risk, DDMN, and PCMN by cancer site are in the Table. DDMN (N=420) was mild 2%, moderate 16%; severe 66%; unspecified 16%. On discharge, PCMN (N=360) was mild 10%; moderate 0%; severe 69%; unspecified 21%. Male gender (OR 1.27 [1.01, 1.59]), Black race (OR 1.57 [1.25, 1.98]), stage IV disease (v. I-III) (OR 3.08 [2.49, 3.82]), and primary site were all independent predictors of DDMN (all $p<0.05$); Black race (OR 1.46 [1.14, 1.87]), stage IV disease (OR 2.70 [2.15, 3.39]), and primary site were independent predictors of PCMN (all $p<0.05$). **Conclusions:** 25% of cancer inpatients were at high risk for MN. Primary site, disease stage, and race were independent predictors of a greater risk. MN appears to be under-diagnosed compared to population studies. This is the first study to report the prevalence of MN in a large cancer inpatient database with a representative population. Research Sponsor: None.

Randomized study of electric hand warmer (EHW) versus observation to avoid discomfort during scalp cooling for chemotherapy-induced alopecia (CIA) prevention. *First Author: Luciana Castro G. Landeiro, Núcleo de Oncologia da Bahia-Grupo Oncoclínicas, Salvador, Brazil*

Background: CIA has been reported as the most disturbing adverse event of cancer treatment by most women receiving chemotherapy. Many strategies have been tested to minimize CIA, among which scalp cooling has proven high effectiveness. However, discontinuation rates of this technology vary from 3% to 13%, mostly due to headache, cold sensation and pain. EHW could be used to mitigate these side effects, produce heat on demand and a warming sensation. The primary objective of this study is to evaluated the impact of EHW device on the general comfort of breast cancer patients while on scalp cooling during chemotherapy treatment. **Methods:** Patients were randomly assigned to EHW use or observation. Thermal, sensory and general comfort were measured with pragmatic questionnaires after each chemotherapy infusion: neutral or hot as favorable thermal responses; comfortable and very comfortable as favorable sensory responses; finally, favorable outcomes in both thermal and sensory comfort questionnaires defined a positive result on the general comfort. We evaluated the impact of age (≤ or > 50 years), alopecia (grade 0 or 1/2), chemotherapy regimen (with or without taxanes) and EHW use (yes or no) in the different comfort scales using Logistic Regression (LR) models. **Results:** Forty women with early or locally advanced breast cancer were assigned to EHW (n = 20) or observation (n = 20) during neo(adjuvant) chemotherapy. Median age was 53 years, 67.5% concluded university education, 52.5% had comorbidities. Most patients had stage II disease (55%), largely ER/PR+ HER2- disease (67.5%), followed by triple negative (22.5%), and HER2+ (10%). Most frequent regimen was ACdd-Tdd (42.5%). Thirty-one patients (77.5%) continued scalp cooling during entire chemotherapy regimen (alopecia < grade 3). A favorable thermal response was seen in 79% of EHW applications as compared to 50% in control arm (odds ratio [OR] 3.79, $P < .001$). Sensory comfort was satisfactory in 82% of EHW applications as compared to 74% with control (OR 1.62, $P = .1$). General comfort was favorable in 73% of EHW applications as compared to 44% in control arm (OR 3.4, $P < .001$). Age, alopecia grade and taxane use did not significantly impact on comfort measures. **Conclusions:** Our study suggests that an EHW has a consistent favorable impact on thermal and general comfort of breast cancer patients under scalp cooling technology to prevent CIA. This simple device can improve patient's quality of life and eventually avoid scalp cooling discontinuation due to discomfort. Research Sponsor: Grupo Oncoclinicas.

A 10-hour time-restricted eating intervention to address cancer-related fatigue among cancer survivors. *First Author: Amber Kleckner, University of Rochester Medical Center, Rochester, NY*

Background: Cancer-related fatigue is a common, debilitating condition that can persist for months or years after cancer treatment. Time-restricted eating has been shown to improve circadian rhythm and strengthen rest and activity patterns, and therefore could help reduce persistent fatigue. Herein, we evaluated the feasibility of recruiting cancer survivors to a two-week, single-arm, time-restricted eating intervention with a 10-h eating window, assessed safety of the intervention, monitored adherence, and obtained initial estimates of within-group change in patient-reported fatigue. **Methods:** We recruited adults 4-60 months post-cancer treatment who had a fatigue level ≥3 on a scale from 0-10 and who did not already consume food within a 10-h window. Participants were asked to consume all food and beverages within a self-selected 10-h eating window for 14 days; water was allowed at all times. Participants completed a daily diary indicating when they began and stopped eating each day. To assess fatigue, participants completed the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) and the Brief Fatigue Inventory (BFI) at pre- and post-intervention. We report mean±standard deviation and used a t-test to assess differences in pre- vs. post-intervention scores. **Results:** A total of 21 participants consented (20 breast cancer, 1 prostate cancer; 20 female; age 57.7±11.4 years; 1.6±1.1 years post-primary treatment). The study was feasible: 19/21 (90.5%) completed pre- and post-intervention assessments and daily diaries. It was also safe: there were two mild adverse events—one unlikely (insomnia) and one possibly related to the intervention (acute headache) and no severe adverse events. Most of the participants adhered to the intervention; 14/19 (73.7%) ate all of their food within a 10-h window at least 80% of the days, and 16/19 (84.2%) reported an average eating window ≤10 h. Fatigue scores improved a clinically meaningful degree for FACIT-F total score, FACIT-F fatigue subscale, and the BFI total score from pre- to post-intervention per established cutoffs (Table). **Conclusions:** Cancer survivors were willing and able to adhere to a two-week time-restricted eating intervention, and the intervention was safe. Also, fatigue was reduced with moderate to large effect sizes after two weeks of time-restricted eating. Based on our results, a follow-up randomized controlled trial to investigate time-restricted eating to alleviate cancer-related fatigue among cancer survivors is indicated. Funding: NIH/NCI UG1CA189961, T32CA102618. Clinical trial information: NCT04243512. Research Sponsor: U.S. National Institutes of Health.

	Range	Direction	Baseline	Post-intervention	Change	p-value	Effect size
FACIT-F total score	0-160	Higher is better	106.9±14.5	118.2±16.2	11.4±11.3	<0.001	0.79
FACIT-F fatigue subscale	0-52	Higher is better	30.6±7.9	35.5±8.1	4.9±7.5	0.011	0.62

Improving cancer pain management in the emergency department: An EMR-based solution. *First Author: Christopher John Coyne, University of California San Diego, San Diego, CA*

Background: Pain is common reason for patients with cancer to seek care in the emergency department (ED). Unfortunately, these patients frequently receive inadequate doses of pain medication, partially due to opioid reduction efforts in the ED, as well as opioid tolerance among those with chronic cancer pain. The purpose of this study was to investigate the effectiveness of an electronic medical record (EMR) based best practice advisory (BPA) at improving analgesic dosing for cancer patients in the ED. **Methods:** We performed a retrospective cohort study on cancer pain at two academic medical centers from 05/18/20 to 10/27/20. The BPA algorithm identified ED patients with cancer that were taking prescription opioids with a morphine equivalent daily dose (MEDD) of at least 100, as calculated by the EMR. If the ED provider ordered opioids for these patients, a BPA alert appeared with a recommended opioid dose based on the patient's individual MEDD. This alert also included pre-set safety orders for O_2 and end tidal CO_2 monitoring as well as naloxone. We compared outcomes based on whether an ED provider accepted or cancelled the BPA recommendation. These outcomes included the change in opioid dose and ED disposition. Continuous variables were compared using the students t-test, while categorical variables were compared with the chi-squared test with an alpha of 0.05. **Results:** Our BPA identified 92 patients that met our criteria, representing 143 BPA alerts. The mean age was 52, 43.5% were female, 54.3% had metastatic disease, and 56.5% presented with a painful chief complaint. Of the ED providers that accepted the BPA, 57.5% increased their dose of opioid medication. BPA usage led to a 33.3% mean increase in medication dosage ($p < .001$). Patients that presented with a painful chief complaint, whose providers utilized the BPA were admitted at a rate of 60.5%, verses a 77.8% admission rate among those whose providers did not utilize the BPA ($p < .01$). No patients required an opioid reversal agent. **Conclusions:** Among cancer patients on chronic opioids presenting to the ED, use of an EMR-based BPA led to more appropriate opioid dosing without the need for opioid reversal agents, and was associated with an overall decrease in hospital admissions. Research Sponsor: None.

The impact of cancer-related diarrhea on changes in cancer therapy patterns. *First Author: Pablo C Okhuysen, UT MD Anderson Cancer Center, Houston, TX*

Background: We studied the impact that cancer related diarrhea (CRD) has on cancer therapy and treatment patterns, including persistence, discontinuation, adherence, and switching of chemotherapy and targeted therapies in patients with and without CRD. **Methods:** We performed a longitudinal observational study among adult (> 18 yrs) patients with CRD identified by diagnosis codes or pharmacy claims compared to matched (1:1) non-CRD patients using claims data derived from the IQVIA PharMetrics Plus database. Index date was defined as the date of the first cancer claim, and we re-indexed patients based on CRD claims. Each patient had a 6-month pre-index period and a minimum 3-month follow-up post-index period. To adjust for selection bias and baseline differences, we directly matched the CRD patients to non-CRD patients. Treatment patterns were evaluated and stratified for the first cancer therapy with or without CRD (chemotherapy vs targeted therapy vs both targeted and chemotherapy). Discontinuation was defined as a 30-day gap for chemotherapy and a 14-day gap for targeted therapies from index therapy; switching was a new chemotherapy or targeted therapy prescription within 30 days following discontinuation of index therapy. We computed adherence as the proportion of days covered over the 12-month post-index period and persistence as mean number of days on index therapy. A Cox proportional hazards model was used to estimate the difference in risk of discontinuation of index therapy between CRD and non-CRD cohorts. **Results:** We evaluated a total of 104,135 matched pairs of CRD and non-CRD adult patients with solid or hematologic cancer; each group further grouped by those receiving either chemotherapy (n = 47,220), targeted therapy (n = 2,427), or both treatments (n = 5,313). Patients with CRD discontinued the index therapy more frequently than non-CRD patients for chemotherapy (81.5% vs 62.3%), targeted therapy (69.2% vs 64.3%) or both (96.0% vs 85.5%) ($p < 0.0001$). Also, the overall percentage of discontinuation (82.4% vs. 64.6%) was significantly higher among patients with CRD. The mean time to discontinuation (59.6±54.1 vs. 68.3±76.6 days) was significantly lower ($p < 0.0001$) in patients with CRD. The mean time to switch (72.0± 48.6 vs. 96.9±84.0 days), mean persistence (95.1±98.1 vs. 154.3±142.7 days), and mean adherence (25.5%±37.2 vs. 47.9±41%) were significantly lower (all $p < 0.0001$) among patients with CRD compared to non-CRD. The percentage of patients requiring a dose titration for their index cancer therapy was significantly higher (21.8%) for the CRD cohort versus 8.5% for non-CRD patients ($p < 0.0001$). **Conclusions:** Patients with CRD were 40% (adjusted) more likely to discontinue the index therapy than patients without CRD. The persistence of index cancer therapy and time to switch were also lower for patients with CRD. Strategies to control CRD and continue cancer therapy are urgently needed. Research Sponsor: Napo Pharmaceuticals.

Patient-reported benefits and burdens of direct oral-anticoagulants (DOACs) and low molecular weight heparins (LMWHs): The CANVAS pragmatic randomized trial (AFT-28). *First Author: Deborah Schrag, Dana-Farber Cancer Institute, Boston, MA*

Background: Previous randomized trials in cancer patients suggest that DOACs are non-inferior to LMWHs for preventing recurrent venous thromboembolism (VTE). However, patients' perspectives have not been reported. Objective**:** CANVAS compared LMWHs to DOACs for preventing recurrent VTE in cancer patients. Key 2° endpoints were: 1) health-related quality of life (QOL); and, 2) treatment satisfaction. **Methods:** CANVAS was an unblinded hybrid comparative effectiveness non-inferiority trial. Between 12/2016 and 4/2020, 671 participants were randomized and followed for 6-months. Patients were assigned 1:1 to receive either a DOAC or a LMWH. Physicians could select any DOAC or LMWH at standard dosing, and patients assigned to LMWH were allowed to transition to Warfarin. Patients from 67 US practices with any invasive solid tumor, lymphoma, multiple myeloma or CLL and a diagnosis of VTE within 30 days of enrollment were eligible. The 1° analysis was conducted in the randomized modified intent-to-treat population, (all subjects who received assigned treatment). Key 2° endpoints were to establish: 1) non-inferior change in HR-QOL; 2) greater perception of benefit; and 3) lower perception of burden for participants receiving DOACs versus LMWHs. Participants reported QOL at 0, 3 and 6 months on the SF-12 survey. At 3 and 6 months, they also reported satisfaction via the Anti-Clot Treatment Scale (ACTS), which includes a burden and a benefit scale. A 2-point change was pre-specified as significant. **Results:** Neither QOL nor patients' perceptions of treatment benefits differed between groups. However, patients on DOACs reported lower treatment burden compared to those assigned LMWHs. **Conclusions:** Among adult cancer patients with VTE, the use of a DOAC compared with a LMWH resulted in no difference in QOL but higher patient-reported satisfaction stemming from decreased perception of the burden of treatment. Clinical trial information: NCT02744092. Research Sponsor: PCORI CER-1503-29805.

Development and validation of a novel patient-reported outcomes (PRO) measure for symptom burden in patients with cancer and COVID-19 infection. *First Author: Loretta A. Williams, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The symptom burden experienced by patients with cancer who contract the COVID-19 (C19) infection remains to be fully understood. To accurately assess this symptom burden, we developed a valid, reliable patient-reported outcome (PRO) measure of C19 symptoms combined with a known measure of cancer symptom burden. **Methods:** Within the institutional initiative on COVID-19 and cancer named Data-Driven Determinants for COVID-19 Oncology Discovery Effort (D3CODE), patients with cancer and PCR-positive C19 tests were invited to participate in this longitudinal study after providing consent. Pts completed the EQ-5D-5L and the 13 symptom severity and 6 interference items of the core MD Anderson Symptom Inventory (MDASI) plus 14 COVID-specific symptom items generated from literature and expert review. Items were measured on a 0-10 scale, 0 = none to 10 = worst imaginable symptom or interference. Demographic and disease information was collected. Psychometric procedures determined validity and reliability of the MDASI-COVID. **Results:** 600 pts enrolled, mean age 56.5y (range 20 to 91y). 59% female, 80% white. 78% solid tumors, 19% heme cancers. 12.5% required hospitalization for C19. Median number of days between positive C19 test and PRO completion was 17 days. Mean overall health rating on EQ-5D-5L was 78.3 (SD 19.6), best being 100. Highest mean (M) severity symptoms on the MDASI-COVID were fatigue (M 3.45, SD 2.17), drowsiness (M 2.50, SD 2.89), sleep disturbance (M 2.44, SD 2.99), malaise (M 2.37, SD 3.05), and distress (M 2.27, SD 2.90). Most severe ($\geq$ 7) symptoms) reported were fatigue (21.3% of pts), change in taste (14.8%), change in smell (14.4%), malaise (14.3%), sleep disturbance (14.3%), and drowsiness (14%). Internal consistency (Cronbach α) of the 27 symptom items was 0.957, of the 6 interference items was 0.937. Mean severity of the 27 symptom items was significantly correlated with overall EQ-5D-5L health rating (correlation = -0.45, $P < 0.0005$), demonstrating concurrent validity. Mean symptom severity and interference showed known-group validity between patients who required C19 hospitalization (symptom M 2.32, SD 2.09; interference M 3.29, SD 3.02) and those who did not (symptom M 1.69, SD 1.85; interference M 2.20, SD 2.64) (symptom P *0.007*; interference P *0.004*). **Conclusions:** We have validated a novel PRO, the MDASI-COVID, to quantify the combined symptom burden in patients with cancer and COVID-19. This measure allows longitudinal evaluation of COVID-19 on cancer symptom burden and provide clinicians with an accurate tool for ongoing symptom assessment and management. Longitudinal analysis on long-term symptoms related to COVID-19 and cancer are ongoing. Research Sponsor: American Cancer Society.

Immune cell counts and perceived cognitive impairment before and after chemotherapy among 544 women with breast cancer. *First Author: Elizabeth Belcher, University of Rochester Medical Center, Rochester, NY*

Background: In a nationwide prospective study, we found that patients with breast cancer had greater perceived cognitive impairment (PCI) before and after chemotherapy compared to controls without cancer. To gain further insight into the role that inflammation plays in cognitive function, we evaluated relationships between immune cell counts and lymphocyte:monocyte ratio with PCI at pre- and post- chemotherapy. **Methods:** Data were collected as part of longitudinal cohort study conducted through the National Cancer Institute Community Oncology Research Program network (NCT01382082). Self-reported PCI was scored at pre-chemotherapy (0-7 days before first chemotherapy) and post-chemotherapy (0-30 days after last chemotherapy) from the PCI sub-scale of the Functional Assessment of Cancer Therapy: Cognitive Function (possible score range 0-72). Immune cell counts were measured by complete blood count with differential at pre- and post- chemotherapy. Lymphocyte:monocyte ratio (LMR) was calculated. Separate linear regression models evaluated the association of immune cell counts and LMR with 1) pre-chemotherapy PCI and 2) post-chemotherapy PCI. Models were adjusted for age, cognitive reserve (reading score), anxiety, and depression. **Results:** PCI and immune cell data were available for 544 patients at pre-chemotherapy and 532 at post-chemotherapy. Subjects had a mean age of 53.1 (SD=10.8). At pre-chemotherapy, higher basophil count and higher LMR were significantly associated with worse PCI (β=5.73, SE=2.37, p<0.05; β=0.047, SE=0.02, p<0.05, respectively). Higher basophil count and higher LMR were also significantly associated with worse PCI at post-chemotherapy (β=5.84, SE=2.92, p<0.05; β=1.01, SE=0.48, p<0.05). **Conclusions:** These data support the hypothesis that inflammation is associated with perceived cognitive function before and after chemotherapy in adults with breast cancer. Targeting inflammatory processes may be beneficial for reducing cancer-related cognitive impairment. Funding: NCI UG1CA289961, T32CA102618, R01CA231014, DP2CA195765. Comparison of inpatient outcomes of pathological fractures in metastatic breast cancer and osteoporosis. *First Author: Kriti Ahuja, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: In the United States, an estimated 1 in 8 women will be diagnosed with breast cancer during her lifetime. Of those with metastasis, over half have bone metastases leading to risk for pathological fractures. Further, approximately 1 in 4 women over 65 years have osteoporosis of the femur neck or lumbar spine. We performed a retrospective analysis on outcomes in pathological fractures secondary to breast cancer metastasis in comparison to osteoporosis, including disposition at discharge. **Methods:** The Nationwide Inpatient Sample (NIS) database was queried to include all adult women admitted with osteoporotic fractures and pathological fractures due to metastatic breast cancer between 2016 and 2018. T-test was used to compare means of continuous variables and chi-square test to compare proportions of categorical variables. Multivariate analysis of predictors of pathological fractures in women with breast cancer metastatic to bone, as well as mortality, resource utilization and disposition in this group were performed. **Results:** A total of 91,494 fractures, combining osteoporosis and pathological fractures secondary to metastatic breast cancer were identified, of which the latter accounted for 4.9%. Patients with pathologic fractures secondary to metastatic breast cancer were younger (mean age 62.8 vs 79.5 years, $p < 0.0001$) and were more likely to be black (14.6% vs 3.1%, $p < 0.0001$) or Hispanic (8.3% vs 4.7%, $p < 0.0001$). Adjusting for demographic variables and comorbidity burden, pathological fractures secondary to metastatic breast cancer were not associated with a significant increase in inpatient mortality (aOR 1.57, 95% CI 0.84-2.95, p = 0.16), but were independently associated with increased length of hospital stay by 0.7 days per admission (p = 0.01) and higher hospitalization costs by $3,381 USD per admission ($p < 0.01$). Regarding disposition, patients with pathological fractures secondary to breast cancer were less likely to be discharged to a nursing facility (aOR 0.57, 95% CI 0.48-0.68, $p < 0.001$) and were more likely to be transitioned to home health care (aOR 1.46, 95% CI 1.20-1.78, $p < 0.001$). **Conclusions:** In adult women, pathological fractures secondary to breast cancer are less frequent than osteoporotic fractures and were not independent predictors of inpatient mortality. They do however prolong length of stay and increase healthcare costs. Further efforts should focus on risk prediction and prophylactic management of high risk bone lesions in order to enhance patient's quality of life, decrease hospitalization admissions, stay and cost. The impact of early palliative care on the quality of life of patients with advanced pancreatic cancer: The IMPERATIVE study. *First Author: Christina Kim, Research Institute of Oncology and Hematology, CancerCare Manitoba, Winnipeg, MB, Canada*

Background: Pancreatic cancer (PDAC) is an aggressive, deadly disease. Chemotherapy (CT) can improve survival by months, but symptom burden is heavy and quality of life (QOL) is poor. Early palliative care (EPC) alongside standard oncologic care improves QOL and survival in other types of cancer; however, the impact on QOL and symptom burden in advanced PDAC is not known. The primary objective of this study was to test for improvement in QOL between baseline (BL) and 16 weeks (wks) among patients receiving EPC. A secondary objective was to test for decreased symptom burden between BL and 16 wk. **Methods:** In this prospective case-crossover study, patients >18 years with advanced PDAC received EPC provided by a subspecialist palliative care physician and advanced practice nurse plus standard oncologic care. Ambulatory EPC visits occurred every 2 wks for the first month, then every 4 wks until wk 16, and then as needed. The Functional Assessment of Cancer Therapy – hepatobiliary (FACT-hep) and Edmonton Symptom Assessment System (ESAS) questionnaires were completed at enrollment and every 4 wks until wk 16. Least square means and 95% confidence intervals were computed. A generalized linear mixed model was used to test for statistically significant change in scores between BL and wk 16. A sample size of 20 patients provides 80% power after controlling for covariates; 40 patients were enrolled to account for anticipated attrition and missing data. **Results:** Of 40 patients, 25 (62.5%) were male, 28 (70%) had metastatic disease, 31 (77.5%) had an ECOG performance status of 0-1, 17 (42.5%) had a body mass index (BMI) >25, 35 (89.7%) had an elevated CA19-9 and 31 (77.5%) received CT. Median age was 70.2 (range 63.0-77.5). BL and wk 16 questionnaires were completed by 100% and 70% of patients, respectively. The mean FACT-hep score at BL was 118.8, compared to 125.7 at wk 16, for a mean change of 6.89, [95%CI (-1.69-15.6); p = 0.11]. The mean change from BL to wk 16 for FACT-hep was statistically significant in patients receiving CT, 10.1 [95%CI (0.32-19.8); p = 0.04], patients with metastatic disease, 14.7 [95%CI (5.30-24.1); p = 0.0030] and patients with a BMI >25, 12.5 [95%CI (1.29-23.7); p = 0.03]. The mean ESAS total symptom score at BL was 25.3, compared to 22.7 at wk 16 (p = 0.28). In those with metastatic disease the mean change was statistically significant, -5.73 [95%CI (-11.21 to -0.24); p = 0.04]. **Conclusions:** EPC resulted in improved QOL in pts with PDAC receiving CT and those with a BMI >25, and improved QOL and symptom burden in patients with metastatic disease. Given minimal attrition and high rates of questionnaire completion, our sample size was robust, resulting in strong power. Providing palliative care alongside standard oncologic care results in clinically meaningful improvements. Access to palliative care, shortly after diagnosis, should be available for patients with advanced PDAC. Clinical trial information: NCT03837132. Research Sponsor: CancerCare Manitoba Foundation, Pharmaceutical/Biotech Company.

The enduring negative effects of financial toxicity in young adult cancer survivors. *First Author: Bridgette Thom, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Due to disruptions in education, workforce entry, and career development caused by cancer and its treatment, young adult (YA) cancer survivors face financial toxicity (i.e., cancer-related financial distress) at rates higher than older survivors. Financial toxicity in YA survivors is associated with avoiding care and diminished psychosocial well-being, but enduring effects on employment, personal finances, and healthcare use and the association with YA's financial capability are not well studied. **Methods:** This was a cross-sectional survey of a national sample of YAs with cancer (n = 214) recruited online and via mailing lists. It included the Comprehensive Score for Financial Toxicity (COST), demographic/clinical self-report, and questions on medical cost-coping and healthcare use. Financial capability questions considered respondents' knowledge about finances, self-efficacy for managing health expenses, and attitudes and behaviors regarding tracking expenses, budgeting, saving, investing, and bill paying. Multiple linear regression assessed associations among financial toxicity, financial capability, and cost-coping. **Results:** Mean respondent age was 35.4 years (*sd*= 5.40) at survey and 27.5 years (*sd*= 7.23) at diagnosis. Breast cancer (28%) and lymphoma (17%) were the most common diagnoses; most respondents were white (79%) women (87%) with college degrees (74%). Financial toxicity, as measured by COST, was high (mean = 13.9, *sd*= 9.3; possible range 0-44, scores < 26 indicate severe financial toxicity). Nearly all of the sample (96%) had health insurance, but 30% said their insurance does not meet their needs. One-half of the sample lacked confidence to manage health expenses. Cost-coping strategies included skipping/delaying: treatment (23%), survivorship care (35%), or medications (39%); 65% relied on a family member to pay for some/all medical bills. Negative events related to medical expenses included using money from savings (58%), taking on credit card debt (45%), post-cancer credit score decrease (44%), borrowing money to pay bills (42%), debt collection contact (37%), lacking money to pay for basic necessities (23%), loan denial (20%), and thoughts about and/or filing for bankruptcy (15%). In multivariate analyses, greater financial toxicity was associated with lower self-efficacy for managing health expenses (β = -0.88, p = .01), poorer financial behaviors (β = -0.54, p = .001), lower income (β = -5.27, p = .001), and skipping/delaying: treatment (e^{β}= 1.16, p < .001), survivorship care (e^{β}= 1.13, p < .001), or prescribed medication (e^{β}= 1.10, p = .001). **Conclusions:** Our findings illustrate the profound enduring impact of financial toxicity among YAs after cancer treatment. Multilevel interventions are needed to provide YAs the tools to navigate financial aspects of the healthcare system and connect them with resources toward gaining financial independence. Neuropsychiatric disorders in hospitalized patients undergoing chimeric antigen receptor T-cell therapy for aggressive lymphomas and acute lymphoblastic leukemia: A national study. *First Author: Josephine Emole, Stem Cell Transplantation and Cellular Therapy, Henry Ford Hospital, Detroit, MI*

Background: Chimeric antigen receptor T cell therapy (CART) has shown efficacy in acute lymphoblastic leukemia (ALL), diffuse large B cell lymphoma (DLBCL), and primary mediastinal B cell lymphoma (PMBCL). While neurological toxicities of CART are known, neuropsychiatric disorders (NPD) in patients undergoing CART has not been well described. Our study assessed the prevalence of NPD in hospitalized patients (pts) undergoing CART, and explored association of NPD with clinical variables. **Methods:** Using the National Inpatient Sample database, we conducted a retrospective study of pts with ALL, DLBCL and PMLCL aged ≥ 18 years who underwent CART in 2018. Hospitalizations were selected using International Classification of Disease, Tenth Revision (ICD-10) codes. NPD of interest included anxiety, depression, adjustment disorder, insomnia, psychosis, dementia, bipolar disorder. Delirium was not included in the inventory of NPD since delirium is a neurotoxicity of CART, and inclusion of delirium as NPD would confound results. Patient, disease, and CART complications were extracted from hospitalization records. Regression analyses were used to assess association of NPD with clinical variables. **Results:** 945 CART procedures met the inclusion criteria (56 % males and 60% Caucasians). Majority of CART (88%) were performed for DLBCL and PMBCL. NPD was diagnosed in 31 % of pts. Anxiety was the most common NPD, followed by insomnia and depression. ALL pts were more likely to have NPD compared to pts with lymphoma (52% versus 28%, $p<0.05$). More females had NPD compared to males (40% versus 25%, $p<0.05$). Univariable analysis showed association of NPD with female gender [Odds ratio (OR)=2.03, 95% CI = 1.05-3.93] and ALL (OR=2.76, 95% CI = 1.03-7.43). In a multivariable model, NPD was associated with ALL (OR =3.57, 95% CI= 1.01-12.55), while the association of NPD with female gender was less certain (OR =1.41, 95% CI=0.73 - 2.74). There was no association between NPD and mortality, neurotoxicity, systemic inflammatory response syndrome or hemophagocytic lymphohistiocytosis. **Conclusions:** One in every 3 pts who underwent in-hospital CART for ALL or aggressive B cell lymphoma in 2018 had comorbid NPD. Females and ALL pts were at higher risk for NPD. As CART pts transition into longer follow up and survivorship, ours and similar results should inform the planning and allocation of psychosocial services. Research Sponsor: None.

A randomized controlled trial with a cluster of oncologists evaluating of an integrated communication support program for oncologists, caregivers, and patients with rapidly progressing advanced cancer on patient-centered conversation: J-SUPPORT 1704 study. *First Author: Maiko Fujimori, Division of Behavioral Sciences, Research Center for Public Health Sciences, National Cancer Center, Tokyo, Japan*

Background: Communication is an essential aspect of care for patients with progressive serious illnesses. Earlier discussion about patients' values and priorities may lead to empathic communication and more goal-concordant care, and improved quality of life (QOL). This study aims to evaluate the efficacy of a newly developed integrated communication support program for oncologists, patients with rapidly progressing advanced cancer and their caregivers. **Methods:** Oncologists are randomly assigned to the intervention group (IG) or control group (CG). Patients with advanced pancreatic cancer after the start of first-line chemotherapy and their caregivers are allocated to the same group as their oncologists. The IG oncologists receive a 2.5-hour individual communication skills training, and patients and caregivers receive a half-hour coaching intervention to facilitate prioritizing and discussing questions and concerns about care after standard chemotherapy; the CG participants do not receive any training. Conversations during the post-intervention consultation between oncologists, patients and caregivers were audio-recorded, and were assessed on their empathic communication and information sharing performance as primary outcome. Secondary outcomes included the patient psychological distress (HADS), QOL (CoQOLo), satisfaction with communication (CSQ) and trust in oncologist (TiOS) were assessed baseline and after the consultation. **Results:** A total of 26 oncologists (12 intervention; 13 control; 1 excluded before randomization), 230 patients (115 intervention; 115 control), and 127 caregivers (65 intervention; 62 control) in 4 teaching hospitals are enrolled. The intervention resulted statistically significant improvements in the empathetic communication (IG: Mean = 23.4, Standard Error = 0.8; CG: M = 20.3, SE = 0.7; effect, 3.1; 95%CI, 1.0-5.3; P = 0.0063) and in the information sharing (IG: M = 17.6, SE = 0.8; CG: M = 13.2, SE = 0.5; effect, 4.4; 95% CI, 2.5-6.2; $P < 0.0001$). Patients in IG rated more satisfaction with communication using CSQ (effect, 2.4; 95%CI, 1.3, 3.5; P = 0.00023) than those in the CG. There were no differences in HADS total score (effect, 0.1; 95%CI, -1.0, 1.1; P = 0.90), CoQOLo score (effect, 0.4; 95%CI, -0.7, 1.4; P = 0.46) and TiOS score (effect, 0.2; 95% CI, -0.1, 0.6; P = 0.15) between patients in the IG and the CG. **Conclusions:** The program for oncologist and patients with rapidly progressing advanced cancer was effective in improving empathic communication and information sharing about care after standard chemotherapy, and patients' reported satisfaction with communication without increasing psychological distress, but did not affect QOL and trust in oncologists immediately after the consultation. Clinical trial information: UMIN000033612. Research Sponsor: Practical Research for Innovative Cancer Control.

Associations between patient-centered communication and quality of life in patients with ovarian cancer. *First Author: Rachel A. Pozzar, Dana-Farber Cancer Institute, Boston, MA*

Background: Patient-centered communication (PCC) occurs when clinicians respond to patients' needs, preferences, concerns, and emotions. The National Cancer Institute (NCI) Framework for PCC in Cancer Care highlights the potential of PCC to improve health-related quality of life (HRQoL), but to date few studies have empirically examined associations between PCC and HRQoL in patients with ovarian cancer. We assessed associations between perceived PCC and HRQoL in patients with ovarian cancer. **Methods:** Cross-sectional, descriptive survey of English-speaking adults with ovarian cancer recruited both online and from one NCI-designated cancer center. We assessed perceived PCC with the Patient-Centered Communication in Cancer Care (PCC-Ca)-36 and HRQoL with the Functional Assessment of Cancer Therapy: General (FACT-G). We used simple linear regression to identify univariate associations between participant characteristics, PCC-Ca-36 total, FACT-G total, and FACT-G subscale (physical, social and family, emotional, and functional well-being) scores. We identified significant predictors of FACT-G total and subscale scores by entering variables associated with each outcome at $p \leq 0.25$ into a multiple linear regression model and using backward elimination. **Results:** One hundred seventy-six participants completed the survey. In multivariable analyses, older age, working (vs. not working), no current treatment (vs. any current treatment), and greater perceived PCC were associated with better overall HRQoL. Working and no current treatment were associated with better physical well-being. Older age, not being cared for by a gynecologic oncologist (vs. being cared for by a gynecologic oncologist), and greater perceived PCC were associated with better social and family well-being. Older age, being recruited online (vs. in clinic), and greater perceived PCC were associated with better emotional well-being. Older age, working, rural residence (vs. not), no current treatment, and greater perceived PCC were associated with better functional well-being (all $p \leq 0.05$). **Conclusions:** Greater perceived PCC was significantly associated with better overall HRQoL and better social, emotional, and functional well-being in this cross-sectional study of patients with ovarian cancer. The NCI Framework for PCC in Cancer Care posits that PCC promotes HRQoL by strengthening the therapeutic alliance, enhancing social support, and improving patient knowledge. Although PCC is theorized to promote patient self-management, PCC was not significantly associated with physical well-being in this sample. Future research should (a) identify mediators of the associations between PCC and HRQoL; (b) examine inter-individual variability in characteristics that may compromise HRQoL; (c) and examine associations between PCC and HRQoL over time. A randomized controlled trial of cognitive behavior therapy for reducing anxiety and depressive symptoms in patients with locoregional advanced nasopharyngeal carcinoma. *First Author: Feng Liu, Hunan Cancer Hospital and The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China*

Background: The purpose of this randomized trial was to compare the efficacy of cognitive behavioral therapy (CBT) versus treatment as usual (TAU) on anxiety and depression, response rates and acute adverse events in patients with locoregional advanced nasopharyngeal carcinoma (NPC) receiving chemoradiotherapy. To the best of our knowledge, this is the first randomized trial evaluating the effect of CBT for depression and anxiety in patients with locoregional advanced NPC treated with chemoradiotherapy. **Methods:** A total of 202 patients with diagnosis of stage III-IVa (8^{th} AJCC) NPC were randomly assigned to receive CBT plus chemoradiotherapy (CBT group, n = 101) or treatment as usual (TAU) plus chemoradiotherapy (TAU group, n = 101). Patients in the CBT group received a series of six CBT sessions for 6 weeks during concurrent chemoradiotherapy. Depression and anxiety were assessed using the Hospital Anxiety and Depression Scale (HADS) score at baseline, the completion of chemoradiotherapy, 1 and 3 months after chemoradiotherapy. Response rates and adverse events were also evaluated. This trial is registered with chictr.org.cn, number ChiCTR2000034701. **Results:** Patients in the CBT group showed significantly less depression and anxiety than patients in the TAU group after the completion of CBT ($P < 0.01$). Complete response (CR) rate was significantly higher in CBT group than in TAU group (100% vs. 93.1% P = 0.014). Compared with the TAU group, the CBT group showed a significantly lower incidence of acute adverse events including anemia, fatigue, mucositis, insomnia and weight losing ($P < 0.05$). **Conclusions:** The addition of CBT to chemoradiotherapy significantly reduced depressive and anxiety symptoms. CBT combined with chemoradiotherapy is associated with improved response rates, with reduced incidence of acute toxic effects in patients with locoregional advanced nasopharyngeal carcinoma. Clinical trial information: ChiCTR2000034701. The association between the coronavirus disease 2019 (COVID-19) pandemic and quality of life and depression symptoms in patients with advanced lung cancer. *First Author: Lauren Heuer, Massachusetts General Hospital, Boston, MA*

Background: It is unclear whether patients with cancer experience greater distress as a result of the COVID-19 pandemic. Thus, we assessed the relationship of the COVID-19 pandemic with quality of life (QOL) and depression symptoms in patients newly diagnosed with advanced lung cancer. **Methods:** We conducted a cross-sectional study of patients with advanced lung cancer enrolled in two multisite randomized supportive care trials. We enrolled adult patients within 12 weeks of diagnosis of advanced lung cancer and an Eastern Cooperative Oncology Group (ECOG) Performance Status from 0 to 3 across 23 institutions in the United States. At the time of enrollment, participants completed the Functional Assessment of Cancer Therapy-Lung (FACT-L), which includes four wellbeing subscales (i.e., physical, social, emotional, and functional) as well as lung cancer symptoms, and the Patient Health Questionnaire-9 (PHQ-9) to assess their QOL and depression symptoms, respectively. We compared QOL and depression symptoms between participants enrolled prior to COVID-19 (i.e., those enrolled in the following time periods: March 2018 to January 2019 and March 2019 to January 2020) and during the COVID-19 pandemic (March 2020 to January 2021). We used linear regression models adjusting for age, race, gender, and time since diagnosis of advanced cancer to examine the relationship between the period of enrollment and patients' QOL and depression symptoms. **Results:** A total of 860 patients were included in this analysis (665 participants enrolled prior to COVID-19 and 195 participants during COVID-19). The two cohorts did not differ significantly with respect to baseline demographic factors [Mean age 65.4 (SD = 11.4), 51.9% female]. In multivariate regression models, enrollment during COVID-19 was not associated with physical (B = -0.16, SE = 0.52, P = 0.763), social (B = -0.48, SE = 0.39, P = 0.217), emotional (B = -0.16, SE = 0.41, P = 0.693), functional (B = -0.83, SE = 0.55, P = 0.128) wellbeing, or lung cancer symptoms (B = -0.11, SE = 0.44, P = 0.806). Enrollment during COVID-19 was not associated with overall QOL (FACT-L: B = -1.32, SE = 1.69, P = 0.436) or depression symptoms (PHQ-9: B = -0.02, SE = 0.45, P = 0.973). **Conclusions:** Despite the prevailing belief that COVID-19 has negatively impacted QOL and distress in patients with cancer, we found no differences in QOL or depression symptoms in patients newly diagnosed with advanced lung cancer during the COVID-19 pandemic compared to those diagnosed prior to the pandemic. These findings suggest that factors other than the COVID-19 pandemic, such as patients' experience with their cancer, contribute to their QOL and depression symptoms. Evolution of post-traumatic stress disorder and patient reported-outcomes during the COVID-19 pandemic among cancer patients of the French longitudinal COVIPACT study. *First Author: Florence Joly, Department of Medical Oncology, Centre Francois Baclesse, Caen, France*

Background: Sudden COVID-19 pandemic has enforced social restrictions across the globe, including social distancing, curfews and total lockdowns, which persist in many parts of the world. Beyond these measures, cancer patients have faced up to the threat of the risk of severe COVID-19 infections and the adaptations of medical oncology practices, with potential impact on their psychological well-being. We aimed to follow Post-Traumatic Stress Disorder (PTSD) symptoms and other Patient-Reported Outcomes (PROs) over this period among cancer patients from the French COVIPACT study. **Methods:** The COVIPACT study (NCT04366154) included patients with solid/hematologic malignancy receiving medical treatment during the first lockdown in outpatient departments of two cancer centers. Patients were asked to fulfill validated questionnaires on PTSD symptoms (IES-R), insomnia (ISI), quality of life (FACT-G) and cognition (FACT-Cog) at baseline (M0, first lockdown, Apr/May 2020), 3 months (M3, post-lockdown, Jul/Aug 2020) and 6 months (M6, second lockdown, Oct/Nov 2020). PTSD was defined as an IES-R score $\geq$33 and moderate/severe insomnia as an ISI score $\geq$15. Higher values on the FACT-G (range 0-108) and FACT-Cog (PCI subscale range 0-72) indicated better quality of life and cognition, respectively. Changes in PROs over time were assessed using mixed models for repeated measures. **Results:** Among the 734 patients included in COVIPACT, 579, 347 and 328 completed the questionnaires at M0, M3 and M6, respectively: median age, 64 years, 72% women, 59% metastatic status. Patients were mostly treated for breast (44%), lung, head and neck (20%), digestive (16%) and gynecologic cancers (11%). We observed a J-shaped evolution of PTSD over time, affecting 21.2% of patients during the first lockdown, 13.6% the post-lockdown and 23.6% during the second lockdown (p for time $<$ 0.001). Moreover, patients reported linear deterioration of cognitive function over follow-up (p $<$ 0.001). No change was observed in any dimension of quality of life (p for time = 0.06). 24.3%, 27.1% and 28.1% of the patients reported insomnia at M0,M3 and M6 (p for time = 0.35). At each time, PTSD was associated with more insomnia, worst quality of life and cognitive complain. At all the times, $\geq$50% of patients with PTSD reported insomnia compared to $\leq$23% in non-PTSD patients (p $<$ 0.001). In addition, there was a clinically significant difference of $\geq$16 points on the FACT-G and $\geq$8 points on the FACT-Cog PCI between PTSD and non-PTSD patients (p $<$ 0.001) at the all times. **Conclusions:** More than 20% of patients have developed PTSD during the different periods of lockdown, with strong association with poor quality of life, cognitive complain and insomnia. Psychosocial support promoting emotional resilience should be largely offered to cancer patients to prevent and/or reduce PTSD. Clinical trial information: NCT04366154. Research Sponsor: ARC foundation.

Development and validation of the self-efficacy for medical communication scale. *First Author: David B. Feldman, Santa Clara University, Santa Clara, CA*

Background: Most studies of clinician-patient communication use scales created *ad hoc* with unknown validity. To provide a standard measure for future studies, we developed and validated a new scale of clinician-reported skills in communicating difficult news: the Self-Efficacy for Medical Communication (SEMC) scale. **Methods:** Using evidence-based scale development guidelines, we created 16 items sampling a range of communication skills, including Disclose difficult news in manageable chunks, so the patient is not overwhelmed, and Determine how to present information based on the patient's emotional state. Items are rated on Likert scales from 1 (*cannot do at all*) to 10 (*highly certain can do*). We constructed two forms—one assessing communication with patients and one with family—using identical items but replacing patient with family/caregiver. We examined the convergent and discriminant validity of the SEMC (correlations with similar and dissimilar measures) as well as its reliability and factor structure. A total of 221 clinicians working in oncology settings (physicians, nurses, medical students) completed measures online. Convergent measures included medical communication items from past studies; the Self-Perceived Communication Competence Scale to measure communication ability outside the medical realm; and the General Self-Efficacy and Occupational Self-Efficacy scales to measure overall self-efficacy/confidence. Discriminant measures included the Ten Item Personality Inventory to measure personality factors; the Maslach Burnout Inventory to measure job burnout; and the Satisfaction with Life Scale to measure well-being. Finally, the Marlowe-Crowne Social Desirability (MCSD) scale measured motivation to look good in responding to survey questions. **Results:** Mean scores were similar for the patient (126.36) and family (127.09) forms (max score 160), both with excellent reliability (*alphas* = .94, .96, respectively). Because these forms were almost perfectly correlated (r = .95, p $<$ .001), we used only the patient form in subsequent analyses. Factor analysis demonstrated that the SEMC measures a unitary construct (*eigenvalue* = 9.0). Its mean correlation was higher with convergent (r = .46) than discriminant measures (r = .22), supporting its validity. Moreover, its correlation with the MCSD was small (r = .28) and no larger than between the MCSD and other measures, indicating minimal social-desirability effects. Finally, no differences emerged for gender or profession; higher scores did correlate with age (r = .29, p $<$ .001) and years working in oncology (r = .18, p = .01). **Conclusions:** Our findings support the SEMC's validity and reliability. Scores on the patient and family forms were similar, indicating that either may be used. The SEMC provides a useful tool for measuring clinician-rated communication skills in future research, ultimately allowing standardization across studies. Research Sponsor: None.

12125 **Poster Session**

Screened social risk factors & screening acceptability among oncology patients in Philadelphia. *First Author: Jessica Davis, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: This pilot study describes the cancer-specific social risk factors (SRFs) of oncology patients on active treatment and the acceptability of using SRF screening to inform care and bolster support during cancer treatment. **Methods:** This is an ongoing cross-sectional survey of adult cancer patients on active treatment at two outpatient cancer centers in the University of Pennsylvania Health System. Since October 2019, 176 patients have completed our two-part, 19-item social risk screening tool (44% response rate; 49% age $>$ 65yo; 45% female; 35% non-white). Survey questions were adapted from other social screening measures (e.g., AHC-HRSN tool, PRAPARE), then pre-tested and modified for our cancer-specific population. Part 1 of our tool covers 12 SRFs in four core domains: technology (e.g., internet accessibility challenges), environmental (e.g., housing instability), emotional (e.g., social isolation), and financial (e.g., ongoing financial toxicity). In part 2, seven acceptability questions cover patients' perceived appropriateness of and comfort with screening, expectations of clinical staff to act on identified SRFs, prior SRF assistance received, interest in receiving SRF assistance (i.e., a proxy for patients' most pressing unmet social needs), willingness to add SRF data to electronic health records (EHR), and comfort sharing findings with other clinicians (e.g., oncologists, primary care physicians, nurses). **Results:** We identified an average of 2.48 SRFs per patient. The five most commonly reported SRFs were ongoing financial toxicity (57%), internet accessibility challenges (46%), social isolation (40%), housing instability (34%), and insufficient internet for telemedicine (29%). The majority of patients thought that SRF screening was appropriate (56%) and many felt comfortable being screened (63%). Half of patients expected cancer center staff to connect them to social resources (50%), fewer wanted staff to just be aware of their SRFs (43%), and a minority did not want staff to know about their SRFs (7%). Many patients had received prior SRF assistance (49%) or were interested in receiving future help (51%). Most patients felt discomfort toward listing SRF results in their EHR (63%) and some felt uncomfortable giving other clinicians access to this data (38%). **Conclusions:** Our study shows that oncology patients contend with SRFs while undergoing treatment and find SRF screening acceptable. These findings support clinical implementation of a cancer-specific social screening tool into routine cancer care, but also bring attention to privacy preferences and limited acceptability of EHR documentation of SRFs. Cancer centers adopting this approach may gain insights into where interventions or resources could be targeted to meaningfully address SRFs, potentially improving clinical outcomes for vulnerable populations. Oncologist phenotypes and associations with response to a behavioral intervention to increase serious illness conversations. *First Author: Eric Li, University of Pennsylvania, Philadelphia, PA*

Background: Interventions to increase serious illness conversations (SICs) between oncologists and patients may improve goal-concordant care, patient mood and quality of life. Randomized studies suggest that behavioral nudges to oncologists may prompt more and earlier SICs. Identifying characteristics of oncologists associated with response to such interventions may clarify barriers to SIC adoption. **Methods:** This was a secondary analysis of a randomized trial showing that machine learning (ML)-based behavioral nudges among 42 oncologist-advanced practice provider (APP) dyads (79 total oncology clinicians total) caring for 14,607 patients in a large academic health system led to a quadrupling of SIC rates (NCT03984773). Latent profile analysis identified oncologist phenotypes based on oncologist, patient, and practice data. We used difference-in-differences analyses among patients with predicted 180-day mortality risk ≥10% (n=2695 [12.6% of cohort]) to test the association between oncologist phenotype and response to the nudge, adjusted for patient and oncologist demographic and practice characteristics. **Results:** Three oncologist phenotypes were identified: 1) Higher-volume specialists 2) Lower-volume specialists; and 3) Higher-volume generalists. Compared with higher-volume specialists and higher-volume generalists, lower-volume specialists had fewer patients per week (9.2 vs 24.3 vs 53.2), fewer days in clinic per week (1.6 vs 2.5 vs 4.4), a higher proportion of new patients per week (34.9% vs 21.0% vs 17.6%), and higher baseline SIC rates (3.9% vs 1.6% vs 0.8%). Lower-volume specialists had a significantly greater response to the intervention than higher-volume specialists and generalists (see Table), demonstrating a nearly six-fold increase in SIC rate from baseline. **Conclusions:** Response to an ML-based behavioral nudge to prompt SICs was driven by specialist oncologists with lower patient volume and greater SIC adoption at baseline, although the nudge was associated with significantly higher SIC rates among all phenotypes. While effective among lower-volume oncologists, nudges to prompt supportive care interventions may have limited impact among higher-volume oncologists. Other strategies, including default involvement of specialty palliative care, may be more effective for higher-volume oncologists. Research Sponsor: National Palliative Care Research Center.

Association between oncologist phenotype and response to nudges.

Phenotype	Oncologists, n (%)	Patients, n (%)	Adjusted probability of SIC, pre-intervention	Adjusted probability of SIC, post-intervention	Difference-in-differences vs higher-volume specialists, absolute percentage points (95% CI)	p-value
Higher-volume specialists	28 (67%)	5755 (66%)	2.3%	7.6%	—	Ref
Lower-volume specialists	5 (12%)	320 (4%)	3.1%	20.7%	12.3 (4.3, 20.3)	0.003
Higher-volume generalists	9 (21%)	3006 (31%)	1.9%	10.7%	3.6 (1.0, 6.1)	0.006

Comparing adult child and spousal caregiver burden and potential causes. *First Author: Anny THR Fenton, Dana Farber/Harvard Cancer Center, Boston, MA*

Background: Adult children caring for a parent with cancer comprise a significant segment of caregivers. Demographic trends indicate this caregiving population will grow as the baby boomer generation ages. Yet little is known about adult child caregivers' needs and experiences and how they differ from the well-studied spousal caregiver. This knowledge gap may hinder efforts to ameliorate adult children's caregiver burden and its impact on patients. **Methods:** We analyzed adult child and spousal/partner caregivers' surveys from the Cancer Care Outcomes Research and Surveillance consortium, a multi-regional population-based study of approximately 10,000 persons with newly diagnosed colorectal and lung cancer. We used t-tests and a series of multivariate regression models to assess whether adult child and spousal caregivers' caregiving responsibilities, social/emotional burden, and financial burden (scaled 0-10) differed and examined patient and caregiver characteristics' mediation of variation in burden. **Results:** Compared to spouses/partners (N=1029), adult children (N=230) completed similar levels of caregiving tasks but spent less time (14 vs. 24 hours/week; $p<0.001$). However, adult children experienced higher social/emotional burden (2.9 vs. 2.4; $p<0.01$). In baseline models controlling for patient clinical factors, caregiving characteristics, and caregiver demographics, adult children's average social/emotional and financial burdens were statistically higher than spouses/partners. Additional adjustment for caregivers' childcare responsibilities and employment eliminated social/emotional and financial burden disparities. Additional adjustment to the baseline model for caregiver-patient gender concordance eliminated the social/emotional burden gap. Communication quality was a large and statistically significant predictor of both burdens ($p<0.001$). **Conclusions:** Adult children spend less time caregiving than spouses/partners but experience higher caregiving burden. Adult children's childcare and career responsibilities help explain this increased burden. Gender concordance between caregiver and patient may also contribute to social/emotional burden, adding important context to prior research indicating female caregivers experience the greatest burden. Interventions to improve communication between caregivers and patients have the potential to reduce both adult child and spouses/partners caregiver burden. Research Sponsor: U.S. National Institutes of Health.

Adjusted average caregiver burden for adult child and spousal caregivers.

	Social/emotional burden			Financial burden		
Adjustment	Adult child	Spousal	P	Adult child	Spousal	P
Unadjusted	2.9	2.4	<0.01	3.7	3.4	0.20
Baseline (patient clinical factors, caregiving characteristics, caregiver demographics)	2.8	2.4	0.03	4.0	3.3	<0.01
Baseline + childcare + employment	2.6	2.5	0.54	3.8	3.4	0.10
Baseline + caregiver-patient gender concordance	2.6	2.5	0.56	4.1	3.3	0.01

Patient reported sexual concerns in routine cancer care. *First Author: Brittany Lees, Atrium Health, Charlotte, NC*

Background: Sexual health is an important component of overall well-being and can be adversely impacted by chemotherapy, surgery, radiation, in addition to the psychological effects of cancer treatments. Sexual health is challenging to discuss and may be overlooked or avoided during cancer care. **Methods:** Patients presenting for consultation in an outpatient multisite cancer center completed electronic distress screening (EDS) between January 2017 and December 2020. The EDS contains 42 questions; demographic information, cancer symptoms and side effects, and psychosocial factors. The EDS is completed by patients before a clinical encounter for early symptom identification and intervention. We conducted a retrospective data analysis of sexual health concerns (>5; scale 0-10) and evaluated patient characteristics and clinically relevant distress (>4; NCCN Distress Tool), depression risk (>3; PhQ2), and anxiety risk (>3; GAD2). Our primary aim was to identify the prevalence of sexual health concerns. The secondary aim was to examine the relationship between sexual health and emotional well-being. **Results:** 57,375 EDS screens were completed. 13,950 patients (24%) reported sexual concerns or lack of interest in sex (>5) within the last 2 weeks. The frequency of these concerns at specific clinics ranged from 12% to 48%, with the highest rates at Palliative care (39%) and Psycho-Oncology (48%) clinics. Genitourinary (30%), Gynecologic (27%) and Gastroenterology (26%) reported the highest frequency of sexual concerns from cancer site specific clinics. Males reported a higher rate of sexual problems compared to females (30% vs 21%, $p < 0.001$), but a lower rate of relationship concern distress (12% vs 13%, $p < 0.05$). Patients with a risk for depression (n = 9,126) or anxiety (n = 10,809) had higher rates of self-reported sexual concerns than those with a negative screen (44% vs 21% depression, $p < 0.001$; 40% vs 21% anxiety, $p < 0.001$). **Conclusions:** Sexual health is a concern for approximately one-quarter of patients presenting for cancer care. Sexual health concerns were prevalent across cancer sites. Patients with positive screens for anxiety and/or depression have nearly double the rates of reported sexual health concerns. Sexual health is a current unmet need that impacts cancer patients and warrants attention. Research Sponsor: None.

The impact of the COVID-19 pandemic on African American cancer survivors living in metropolitan Detroit. *First Author: Jennifer Lynn Beebe-Dimmer, Barbara Ann Karmanos Cancer Institute/Wayne State University, Detroit, MI*

Background: COVID-19 has had profound direct and indirect effects on population health to date and long-term effects are anticipated. Vulnerabilities to the most serious consequences of infection include older age, obesity, African American race and the presence of comorbid conditions. African American cancer survivors represent a particularly high-risk group, therefore understanding the impact of the virus and our strategies to prevent its spread on this patient population is important. **Methods:** The Detroit Research on Cancer Survivors (ROCS) cohort is a unique effort to understand the determinants of poor outcomes in African American cancer survivors. Eligible participants were diagnosed with breast, prostate, colorectal, or lung cancer on or after 1/1/2013, or with endometrial or any other cancer before age 50 on or after 01/01/2016 and were identified through the Metropolitan Detroit Cancer Surveillance System cancer registry. To date, we have enrolled 4173 survivors. Full participation includes completion of a baseline survey, and collection of biospecimens, medical records and tumor tissue, if available. Participants are also followed annually for outcomes and changes in history. A supplemental survey focused on the impact of COVID-19 was offered to enrolled participants beginning in the spring of 2020. The results presented here include data from 890 survivors who also completed the ROCS COVID survey. **Results:** Nearly all (> 99%) survivors reported some change in their daily activities in an effort to reduce the risk of infection. At the time of survey, just over 1/3 of participants reported being tested for the virus and among those, 12% reported positive results. More than 40% of survivors reported some disruption in their access to medical care. A substantial (> 40%) proportion of survivors reported feeling anxious, depressed and/or isolated during the COVID-19 pandemic. Approximately 40% of patients reported changes in health behaviors as a direct result of the pandemic that are known to negatively affect survivorship outcomes (physical inactivity, smoking, alcohol use). Notably, 30% of survivors reported declines in physical activity and these declines were significantly associated with increased anxiety ($p = 0.008$), depression ($p = 0.005$) and poorer health-related quality of life ($p < 0.001$). **Conclusions:** The influence of the COVID-19 pandemic on African American cancer survivors has been substantial, affecting both their physical and mental health and access to needed medical care. Coupled with changes in health behaviors as a direct result of the pandemic, these factors will likely affect outcomes in this high-risk patient population making further study and interventions necessary to mitigate the long-term impact of the pandemic on cancer outcomes. Research Sponsor: U.S. National Institutes of Health.

Suicide risk following a new cancer diagnosis among veterans in Veterans Health Administration care. *First Author: Kallisse R. Dent, Serious Mental Illness Treatment Research and Evaluation Center (VHA), Ann Arbor, MI*

Background: Patients diagnosed with cancer are at an increased risk of adverse mental health outcomes including suicidal behavior. Suicide rates among Veterans are 50 percent greater than for non-Veteran US adults. To inform Veterans Affairs (VA) suicide prevention initiatives, it is important to understand associations between cancer and suicide risk among Veterans receiving VA healthcare from the Veterans Health Administration (VHA). Study aims were to assess associations between new cancer diagnoses and suicide among Veterans in VHA care to identify high risk diagnostic subgroups and risk-periods. **Methods:** We used a cohort study design, identifying 4,926,373 Veterans with VHA use in 2011 and either 2012 or 2013 and without a VHA cancer diagnosis in 2011. Incident cancer diagnoses, assessed between first VHA use in 2012-2013 and 12/31/2018, were characterized by subtype and stage using the VHA Oncology Raw Data. Data from the VA/Department of Defense Mortality Data Repository identified date and cause of death. Cox proportional hazards regression, accounting for time-varying cancer diagnosis, was used to evaluate associations between a new cancer diagnosis and suicide risk. An initial model adjusted for VHA regional network and patient age and sex. Cancer subtypes with significant associations with suicide were further assessed using a model that also adjusted for suicide attempts and mental health, tobacco use disorder, and other substance use disorder diagnoses in the prior year. Crude suicide rates following a new cancer diagnoses were calculated among Veterans with new diagnoses, 2012-2018 (N = 240,410). Rates were assessed up to 84 months following diagnosis. **Results:** On average, Veteran VHA users were followed for 6.0 years after their first VHA use in 2012-2013 and for 2.7 years following a new cancer diagnosis. Receipt of a new cancer diagnosis corresponded to a 43% (Adjusted Hazard Ratio [AHR] = 1.43, 95% CI: 1.29, 1.58) higher suicide risk, adjusting for covariates. The cancer subtype associated with the highest suicide risk was esophageal cancer (AHR = 5.93, 95% CI: 4.05, 10.51) and other significant subtypes included head and neck (AHR = 3.44, 95% CI: 2.65, 4.46) and lung cancer (AHR = 2.28, 95% CI: 1.79, 2.90). Cancer stages 3 (AHR = 2.29, 95% CI: 1.75, 3.01) and 4 (AHR = 3.45, 95% CI: 2.75, 4.34) at diagnosis were also positively associated with suicide risk. Suicide rates were highest in the first three months following a diagnosis (Rate = 128.3 per 100,000 person-years, 95% CI: 100.4, 161.6) and remained elevated through the first 12 months. **Conclusions:** Among Veteran VHA users, suicide risk was elevated following a new cancer diagnosis and was especially high in the initial 3 months. Additional screening and suicide prevention efforts may be warranted for VHA Veterans newly diagnosed with cancer, particularly among those diagnosed with esophageal, head and neck, or lung cancer or at stages 3 or 4. Research Sponsor: Department of Veterans Affairs.

Family members' attitudes towards disclosure of cancer diagnosis to patients in China. *First Author: Xi Rao, University Medical Center, University of Freiburg, Freiburg, Germany*

Background: Informed consent is very important aspect of treatment, in western countries, a diagnosis of malignancy should be delivered the paient directly. It was the decision of the patient for further disclosure. However, in China, people are always family centered decision making, a diagnosis of cancer is traditionally delivered to the family members, with a protective assumption. We used anonymized questionnaire to investigate the attitude of Chinese people towards to cancer diagnosis disclosure and correlated factors. **Methods:** This is a survey study conducted by a web system named Wenjuan Xing. The study questionnaires were designed in dual English and Chinese. answered by the same person. The regarding questions that answered by the same person are as following: If your close family member is diagnosed with a malignant tumor, would you like to tell him the truth?, If yes/no, what's your reason?. Demographic information include gender, age, economic status, education level, health condition, residential region, occupation, nationality and major reasons. The survey link was placed on Wechat contact of these investigators, social media and also distributed in Oncology Center of a general hospital in Mainland China. The answers of the questions were captured directly online, data can also be exported into excel format for compiled analysis. **Results:** A total of 1470 people completed the survey questions from January to July 2020. The potential factors which influence disclosing diagnosis were registered, 1041 (70.8%) family members are in favor of informing the diagnosis to patients, 429 (29.2%) are not. The main reasons for disclosure diagnosis are it is his or her life, he/she has to be in control' (N=832) and she or he can plan his/her remaining life and leave the world with no regret (N=588). The famliy member who hide the diagnosis worry that paitents could not handle the stress would have poor quality of life (N=295) and die faster(N=323). 1425 (96.9%) people want to know the diagnosis if they have a malignanti tumor, while 45 (3.1%) don't want to know.The univariate analysis revealed educational level, health condition and residential region are correlated to disclosing diagnosis. The logistic regression anaylsis show a significant effort to disclosing diagnosis(OR= 1.9, 95% CI (1.4, 2.7) $P<0.001$) .Interaction and stratified analyses were conducted according to education level and redidential region (P interaction= 0.0406). In the high education level group, people who live in other countries(America, Europe) (P=0.009 OR=29.7 CI 2.3-375.7) more likely to disclose the diagnosis compared to mainland in China. **Conclusions:** The majority of Chinese people want to know the diagnosis. People who have higher education level and live in western countries more likely prefer disclosure of diagnosis to patients. Research Sponsor: None.

TPS12132 **Poster Session**

A phase II study to evaluate the safety and efficacy of OQL011 on VEGFR inhibitor-associated hand-foot-skin reaction in cancer patients. *First Author: Mario E. Lacouture, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Hand-Foot Skin Reaction (HFSR) is frequently associated with the use of multi-targeted tyrosine kinase inhibitors of the vascular endothelial growth factor receptor (VEGFRi) such as cabozantinib, regorafenib, sunitinib, and lenvatinib. HFSR affects the skin on the palms and soles and is manifested as edema, erythema, hyperkeratosis, and bullae, leading to a decrease in quality of life and interruptions in dosing. The incidence of HFSR differs among VEGFRi, ranging from 5-60% (all grades) and 1-18% (grade 3). To date, there is no FDA approved treatment for HFSR, and marginal benefit has been shown with topical urea or steroids. Although not fully elucidated, the pathogenesis of HFSR has been associated with impaired vascular repair mechanisms, caused by inhibition of VEGF signaling pathways. We hypothesize that topical stimulation of VEGFR through OQL011 will decrease the severity of HFSR symptoms via local upregulation of the VEGF/VEGFR related signaling pathways. **Methods:** NCT04088318 is a phase 2, double-blind, randomized controlled trial to evaluate the safety and efficacy of OQL011 compared to vehicle control in the treatment of moderate to severe HFSR in patients on VEGFRi therapy. Eligible patients will have $\geq$ grade 2 palmar plantar erythrodysesthesia (PPE). The study is expected to enroll 112 patients in two parts. In the first part, 42 patients will apply 0.2% OQL011 topical ointment or vehicle control (2:1 randomization) TID for six weeks. In Part 2, 70 subjects will be randomized into two additional dose levels or vehicle control in a 2:2:1 ratio. The two dose levels selected will be based on the efficacy and safety results of Part 1. The primary efficacy endpoint is improvement of NCI CTCAE v5.0 PPE to grade $\leq$1 by week 3. Photographs of the affected areas will be taken at Day 0, 7, 14, 21 and 42 timepoints. Superiority test will be performed to compare treatment groups, and the exposure-response relationship will be explored. In addition, an investigator global assessment (IGA) for HFSR will be used in this trial to specifically assess skin recovery and is proposed to be a new evaluation tool. The validity of IGA criteria will be evaluated by assessing the inter-rater and intra-rater reliability. The correlation between IGA, NCI CTCAE v5.0 for PPE, and patient reported outcomes including Visual Analog Scale of Pain, Hand-foot Quality of Life questionnaire will also be evaluated. This study began enrolling patients in December 2019 and is ongoing. Clinical trial information: NCT04088318. Research Sponsor: OnQuality Pharmaceuticals (USA) LLC.

TPS12133 **Poster Session**

Olanzapine or dexamethasone, with 5-HT3 receptor antagonist and NK-1 receptor antagonist, to prevent nausea and vomiting induced by cisplatin-based doublet chemotherapy: A non-inferiority, prospective, multi-centered, randomized, controlled, phase III clinical trial. *First Author: Zhigang Liu, The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai, China*

Background: Chemotherapy-induced nausea and vomiting (CINV) is a common side effect of cancer treatments, and dexamethasone offers an advantage over placebo for protection against chemotherapy-induced emesis in both acute and delayed phases. However, its side effects are diverse including moderate to severe insomnia, hyperglycemia, dyspepsia and so on, which are gathering increasing concerns. What's more, dexamethasone is not applicable to all cancer patients. The incidence of diabetes mellitus varies in different cancer which can reach up to 55.3%, and dexamethasone might not be a proper anti-emesis choice for them. Besides, dexamethasone delivery is always on debating when patients are receiving immunotherapy. However, all anti-emesis regimen recommended in guidelines are dexamethasone based. Alternative anti-emesis regimen are required. Studies have shown that olanzapine plays an important role in treating delayed, refractory, breakthrough nausea and vomiting. Thus, we initiated this prospective, multi-center, phase III study to validate the dexamethasone-free protocol: the non-inferiority role of applying olanzapine to prevent CINV instead of dexamethasone. **Methods:** This clinical trial started on February 3, 2020 is being conducted in 23 centres. All patients eligible are chemotherapy nave and plan to receive cisplatin-containing regimen. Based on a 70% complete remission rate of previous study, to demonstrate a non-inferiority margin of 10%, 548 patients are required for two arms with the consideration of 5% of drop out and lost to follow-up (80% power,α = 0.05). Study design: Enrolled patients are randomized 1:1 into 2 arms to receive olanzapine or dexamethasone combined with 5-HT3 receptor antagonist (palonosetron, granisetron or ondansetron) and NK-1 receptor antagonist (aprepitant or fosaprepitant) from the first day of chemotherapy. Olanzapine (5mg) is delivered orally per night from day 1 to day 4. Dexamethasone (12 mg) is given orally or intravenously within 30 minutes before cisplatin administrated on day 1; on day 2-4, the orally or intravenously given dose of dexamethasone is 8 mg. The primary endpoint is complete remission rate of vomiting during the whole observation period (0-120 hours from the starting of first course chemotherapy delivery). The secondary endpoints are complete remission rate of vomiting during 25-120 hours from the starting of first course chemotherapy delivery and no nausea rate during the whole observation period. Besides, side effects will be recorded according protocol. Clinical trial information: NCT04437017. Research Sponsor: Beijing Xisike Clinical Oncology Research Foundation.

TPS12134 **Poster Session**

Effect of multimodal intervention care on cachexia in patients with advanced cancer compared to conventional management (MIRACLE): An open-label, phase 2 trial. *First Author: Chi Hoon Maeng, Department of Medicine, Division of Medical Oncology-Hematology, Kyung Hee University Hospital, Seoul, South Korea*

Background: Cancer Cachexia (CC) is a multi-factorial process characterized by progressive weight loss, muscle mass and fat tissue wasting, and adversely affecting the quality of life and survival in patients with advanced stage of cancer. CC has a complex and multi-factorial pathophysiology, and there is no established standard treatment. Once it occurs, it is often irreversible and also difficult to suppress the its progression with any single treatment modality. We are conducting an open-label, parallel, randomized phase 2 trial to investigate the effect on preventing or alleviating cancer cachexia and safety of a multi-modal intervention including anti-inflammation, omega-3-fatty acids, nutritional supplement with counselling, physical exercise, psychiatric intervention as well as bojungikki-tang, which mediates immune-modulation and reverse inflammation-related chronic consumptive wasting condition as a complementary and alternative medicine compared to patients receiving best supportive care. **Methods:** Eligible criteria included patients with recurrent or metastatic gastrointestinal (gastric, colorectal and pancreaticobiliary) as well as lung cancer undergoing active palliative chemotherapy. Patients who have already developed refractory cachexia (ie, low performance status, difficult to take medications orally or visit the hospital to exercise) are excluded. Patients are randomized into experimental arm (Multi-modal intervention care: MIC) versus control arm (Conventional Palliative Care, CPC). MIC are comprised of 1) daily oral medications; ibuprofen 400 mg three times a day, omega-3-fatty acid 1 g twice a day, Bojungikki-tang 3.75g twice a day, oral nutritional supplement (HAMONILAN SOLN) 200 ml twice a day, and 2) clinical interventions; weekly physical exercise (60 minutes per visit), psychiatric assessment on every other week, and nutritional counselling total four times during the study period. CPC included basic nutritional counselling for two times provided by National Health Insurance Service, and megestrol acetate as needed (ie, anorexia $\geq$ Grade 2). All interventions were provided during 12 weeks per subject. Co-primary outcomes are change of total lean body mass and handgrip strength from the baseline. Secondary outcomes included change of fat mass and total body mass, lean body mass, Functional Assessment of Anorexia/Cachexia Treatment (FAACT) score, quality of life assessed by EORTC QLQ-C30, Spleen Qi Deficiency questionnaire (SQDQ), and overall survival. Total 112 patients will be assigned in the two arms (56 in each group). We have started the study in October 2020. At the time of submission, 26 patients were enrolled. Planned period of enrollment is 18 months. Clinical trial information: Clinical Research information Service, CRIS (KCT0004967). Clinical trial information: KCT0004967. Research Sponsor: National Research Foundation of Korea (NRF).

Randomized double-blind, placebo-controlled study of topical diclofenac in prevention of hand-foot syndrome in patients receiving capecitabine. *First Author: Atul Batra, All India Institute of Medical Sciences, New Delhi, India*

Background: The pathophysiology of capecitabine induced hand-foot syndrome (HFS) includes activation of cyclooxygenase (COX)-2, leading to an upregulation of the inflammatory cascade. Prophylaxis with oral celecoxib was previously reported to be associated with a significantly lower frequency of HFS (grade 1 [29.0% vs. 72.0%, $p < 0.001$] and grade 2 [11.8% vs. 30.0%, p=0.024]) (1). The findings were confirmed in a phase III trial (2). However, the associated systemic adverse events limit routine prophylactic use. Till date, no clinical trials have assessed the role of topical non-steroidal anti-inflammatory drugs (NSAIDs) in preventing HFS. **Methods:** In this investigator-initiated randomised phase III double-blind, placebo controlled, parallel group trial, a total of 264 patients with any stage breast or gastrointestinal cancer planned to receive capecitabine as a single agent or in combination with other chemotherapy will be randomised (1:1) to 1% topical diclofenac or placebo (base for 1% topical diclofenac) arm at a single tertiary care cancer centre in India. Randomization will be done by stratified (male vs female, and capecitabine mono therapy vs combination) permuted block method using a computer generated random sequence and allocation concealment will be done by using sealed opaque envelopes. In both the arms, patients will be asked to apply 1 fingertip unit (FTU) of topical medication on both surfaces of bilateral hands twice daily for a total duration of 12 weeks or till development of grade 2 or higher HFS, whichever is earlier. The primary objective is to compare the effect of topical diclofenac with placebo in preventing clinically significant HFS (incidence of the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) version 5.0 grade 2 or higher HFS). The secondary objectives include comparison of topical diclofenac with placebo on (i) incidence of NCI CTCv5.0 all grade HFS, (ii) time to develop grade $\geq$2 HFS from start of capecitabine, (iii) patient-reported outcomes using HFS-14 questionnaire (iv) adherence with topical application using self-reported adherence diary, (v) capecitabine dose reductions, delays and cessation due to HFS and (vi) safety profile (NCICTCv5.0). The tertiary correlative endpoint is to correlate the occurrence and severity of HFS with serum COX-2 levels and polymorphism of dihydropyrimidine dehydrogenase (DPPD) enzyme. The trial is registered at the Clinical Trial Registry of India (CTRI/2021/01/030592). Till date, we have enrolled 12/264 patients. (1) Zhang RX et al. *J Cancer Res Clin Oncol*. 2011;137(6):953-957. TPS12136 **Poster Session**

Technology-enhanced palliative care for patients with cancer on phase 1 clinical trials. *First Author: Ishwaria Mohan Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients w advanced cancer participating in Phase I trials carry a high symptom burden from cancer and prior therapies. Our prior work shows patients on phase I trials w multiple active symptoms impacting their immediate quality of life with implications on toxicities and clinical outcomes on subsequent therapy. To identify an effective scalable approach to comprehensive symptom management for patients w adv cancer on phase I trials, we leveraged the increased technology use to design a technology-enhanced symptom management and palliative care intervention (TEC). **Methods:** Patients w adv cancer seen in the phase I clinic will be given the Edmonton Symptom Assessment System (ESAS), a validated patient-reported outcomes (PRO) tool of common cancer symptoms to identify those with a high symptom burden defined as $\geq$4 out of 10 on $>$1 ESAS symptom and a Global Distress Score (GDS) of $\geq$20. The GDS, a validated score of overall symptom intensity derived from the ESAS, is comprised of 6 physical (pain, fatigue, nausea, drowsiness, appetite, shortness of breath) & 2 psychosocial symptoms (depression, anxiety), and overall wellbeing. TEC is an innovative patient-centered care program of strategic vigorous symptom management where standard-of-care clinic visits are complemented by proactive symptom monitoring between clinic visits remotely and through provider-initiated calls. In this pilot randomized study, we will determine the effect sizes of High-Intensity TEC (HI-TEC; q3day remote PRO assessments w preset provider-initiated call bw visits), Low-Intensity TEC (LO-TEC; q5day remote PRO assessments w preset provider-initiated call bw visits), and Standard Palliative Care (no preset provider contact bw visits). Our guiding hypothesis is that a comprehensive, proactive, technology-enhanced symptom management program led by a Palliative Care team can mitigate the high symptom burden of patients with advanced cancers enrolling in phase I trials. The primary objective assesses the effect size of each TEC intervention on the GDS measure of symptom burden prior to C1D1 on phase I trial. Our working hypothesis is that HI-TEC and LO-TEC will be associated with a lower overall symptom burden signifying symptom optimization prior to starting on a phase I trial. Secondary objectives aim to estimate the effect size of TEC on the following: Symptom burden over 12 weeks on a phase I trial using ESAS, quality of life using FACIT-Sp, PRO-CTCAE and patient satisfaction using FAMCARE-P13. clinical outcomes at 6 months including OS, treatment outcomes (interruptions, dose reductions, discontinuation, time on trial) and quality metrics for end-of-life (EOL) (chemotherapy in the last 14 days of life, ICU admit in last 30 days of life, death without hospice or $<$ 3d of hospice). Qualitatively assessment of patients' + caregivers' perceptions of receiving TEC-based cancer care. Clinical trial information: NCI-2020-07465. Research Sponsor: American Cancer Society.

TPS12137 **Poster Session**

Investigating bacterial decolonization for the prevention of radiation dermatitis: A randomized controlled trial and quality of life assessment. *First Author: Karolina Mieczkowska, Department of Medicine, Division of Dermatology, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY*

Background: Radiation dermatitis (RD) can be therapy-limiting and detrimental to quality of life for cancer patients receiving radiation therapy (RT). Bacteria play an important role in many inflammatory dermatoses. In an observational clinical study, our group discovered that nasal colonization with bacteria, specifically with *Staphylococcus aureus* (SA), prior to RT was an independent predictor of higher-grade RD (grade $\geq$2). Higher-grade RD patients were also found to have more SA on the irradiated skin after treatment. If successful, bacterial decolonization could be a safe and cost-effective method to prevent RD. **Methods:** This is a randomized controlled trial assessing the efficacy of universal bacterial decolonization in preventing RD. Subject inclusion criteria include patients who are aged $\geq$ 18 years with a diagnosis of a solid tumor of the breast or head and neck with plans for fractionated RT ($\geq$ 15 fractions) with curative intent. Based on previous studies and power analyses, we plan to recruit a total of 80 patients. Patients in the control arm will be treated according to standard of care, including daily application of emollients and gentle bathing. In addition to standard of care, patients in the intervention arm will receive a decolonization regimen consisting of intranasal mupirocin ointment used twice daily and chlorhexidine wash used daily for 5 days prior to the initiation of RT and repeated for 5 days every other week throughout RT. Study evaluations for both groups will include bacterial cultures obtained via superficial swab from the nares, irradiated skin, and contralateral non-radiated skin performed at the beginning, middle, and end of RT. Additionally, standardized photographs of the skin at the radiated site will be performed prior to and at the completion of RT, which will be graded by a dermatologist blinded to study arm. Lastly, at identical timepoints, each patient will complete the SKINDEX-16 questionnaire, a validated quality of life (QoL) assessment. The primary endpoint is development of grade $\geq$ 2 RD, as compared to low-grade RD (grade 0-1), during RT. The secondary endpoint includes the impact of bacterial decolonization on QoL. Pearson's chi square or Fisher's exact tests will be used to compare the incidence rates of higher-grade RD between the interventional arm and control arm to assess if the intervention is associated with a lower incidence rate of higher-grade RD. Paired t-tests will be used to compare the QoL score change from baseline to after RT between the two arms. Linear regression models will be used in both analyses to adjust for covariates. Clinical trial information: NCT03883828. Research Sponsor: Beth N. McLellan MD.
