2021 ASCO ANNUAL MEETING PROCEEDINGS ABSTRACTS

Letter From the Editor

The *2021 ASCO Annual Meeting Proceedings* (a supplement to *Journal of Clinical Oncology*) is an enduring record of the more than 2,400 abstracts selected by the ASCO Scientific Program Committee for presentation as part of the ASCO Annual Meeting. Publication-only abstracts are included in the online supplement to the May 20 issue of *Journal of Clinical Oncology* at JCO.org. Abstracts can be also accessed online through the ASCO.org. Online abstracts include the full list of abstract authors and their disclosure information.

All abstracts carry *Journal of Clinical Oncology* citations, for example:

J Clin Oncol 39:18s, 2021 (suppl; abstr 1)

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

Michael A. Carducci, MD, FACP, FASCO
Editor, *ASCO Annual Meeting Proceedings*

ASCO Abstracts Policy

Public Release of Abstracts

The abstracts published in the *2021 ASCO Annual Meeting Proceedings*, including those abstracts published but not presented at the Meeting, were publicly released by ASCO at 5:00 PM (EDT) on Wednesday, May 19, 2021. These abstracts are publicly available online through meetinglibrary.asco.org. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released at 5:00 p.m. (EDT) on Thursday, June 3, 2021.

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on am.asco.org.

Conflict of Interest Disclosure

As the CE provider for the Meeting, ASCO is committed to balance, objectivity, and scientific rigor in the management of financial interactions with for-profit health care companies that could create real or perceived conflicts of interest. Participants in the Meeting have disclosed their financial relationships in accordance with ASCO's Policy for Relationships with Companies; review the policy at asco.org/rwc.

ASCO offers a comprehensive disclosure management system, using one disclosure for all ASCO activities. Members and participants in activities use coi.asco.org to disclose all interactions with companies. Their disclosure is kept on file and can be confirmed or updated with each new activity.

Please email coi@asco.org with specific questions or concerns.

SPECIAL AWARD LECTURE ABSTRACTS

B.J. Kennedy Award and Lecture for Scientific Excellence in Geriatric Oncology

Treatment of advanced non-small cell lung cancer (NSCLC) in older patients: From best supportive care (BSC) to chemotherapy, targeted therapies, and immunotherapy.

Cesare Gridelli, MD, "S.G. Moscati" Hospital, Avellino, Italy

More than 50% of people with lung cancer are diagnosed over the age of 65 and about 40% over the age of 70. The majority of older patients tolerate chemotherapy poorly because of comorbidity and organ failure. At the end of the 1990s, considering the toxicity of cisplatin (CDDP)-based chemotherapy, best supportive care was considered the standard of care for advanced NSCLC in the elderly population. In a phase III trial (ELVIS-Elderly Lung Cancer Vinorelbine Italian Study), we showed that vinorelbine compared to BSC improved survival and quality of life in patients with advanced NSCLC age 70 or older. Then we ran a phase III trial (MILES-Multicenter Italian Lung Cancer in the Elderly Study) and demonstrated that gemcitabine and vinorelbine combination did not improve any outcome as compared to single-agent vinorelbine or gemcitabine. A French trial showed superiority of carboplatin plus paclitaxel chemotherapy, at doses usually used in younger patients, as compared to single-agent chemotherapy but with increased toxicity. Feasibility of CDDP-based polychemotherapy remained an open issue and was addressed by retrospective analyses of randomized trials without age limits, suggesting that advanced age alone should not preclude it to fit older patients. In a phase II randomized trial (MILES 02), we showed that CDDP-based regimens with reduced doses were feasible in older people. In the MILES 03-04, trial we demonstrated that CDDP plus gemcitabine or CDDP plus pemetrexed did not improve survival as compared to single-agent gemcitabine or pemetrexed but increased progression-free survival and response rate with higher toxicity. For patients with oncogene-addicted disease (EGFR or B-RAF mutations and ALK or ROS-1 rearrangements) the targeted therapies showed, in subset analyses of phase III randomized trials in general populations or dedicated phase II studies, similar tolerability and efficacy in older patients as compared to their younger counterparts. The same is for immunotherapy and for the chemotherapy plus immunotherapy combinations with no specific phase III trials in older patients.

Gianni Bonadonna Breast Cancer Award and Lecture

A Bronx tale: Pursuing progress, precision, and equity in cancer care.

Joseph A. Sparano, MD, FASCO, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY

Gianni Bonadonna ushered in the era of progress in cancer care through his pioneering work testing combination chemotherapy in rigorously conducted prospective clinical trials, both novel concepts at the time. His work provided a foundation for reducing mortality from breast cancer, Hodgkin lymphoma, and other cancers. For breast cancer, progress in reducing mortality has come with a price—broader use of adjuvant chemotherapy in those with early-stage disease who might have been adequately treated and perhaps cured without it. Moreover, declining cancer mortality rates have not been shared by all populations, even in circumstances where they may be equal access to care. This lecture will focus on three distinct challenges facing the field: 1) How can we continue to make progress? 2) How can biomarkers be used to more precisely guide the use of effective therapies? 3) How can we best address the inequities in outcomes?

LBA1 **Plenary Session**

OlympiA: A phase III, multicenter, randomized, placebo-controlled trial of adjuvant olaparib after (neo)adjuvant chemotherapy in patients with germline *BRCA1/2* mutations and high-risk HER2-negative early breast cancer. *First Author: Andrew Tutt, Breast Cancer Now, Toby Robins Research Centre, The Institute of Cancer Research, and The Breast Cancer Now Unit, Guy's Hospital Cancer Centre, King's College London, London, United Kingdom*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 PM ET on Thursday, June 3, 2021.

LBA2 **Plenary Session**

JUPITER-02: Randomized, double-blind, phase III study of toripalimab or placebo plus gemcitabine and cisplatin as first-line treatment for recurrent or metastatic nasopharyngeal carcinoma (NPC). *First Author: Rui-hua Xu, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 PM ET on Thursday, June 3, 2021.

LBA3 **Plenary Session**

Adjuvant chemotherapy following chemoradiation as primary treatment for locally advanced cervical cancer compared to chemoradiation alone: The randomized phase III OUTBACK Trial (ANZGOG 0902, RTOG 1174, NRG 0274). *First Author: Linda R. Mileshkin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 PM ET on Thursday, June 3, 2021.

LBA4 **Plenary Session**

Phase III study of lutetium-177-PSMA-617 in patients with metastatic castration-resistant prostate cancer (VISION). *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 PM ET on Thursday, June 3, 2021.

LBA5 **Plenary Session**

Pembrolizumab versus placebo as post-nephrectomy adjuvant therapy for patients with renal cell carcinoma: Randomized, double-blind, phase III KEYNOTE-564 study. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

The full, final text of this abstract will be available at abstracts.asco.org at 5:00 PM ET on Thursday, June 3, 2021.

Accrual of Black participants to cancer clinical trials following a five-year prospective initiative of community outreach and engagement. *First Author: Carmen E. Guerra, Abramson Cancer Center and Perelman School of Medicine, Philadelphia, PA*

Background: Accrual of Black participants to cancer clinical trials remains a major challenge across the country. Here, we report the outcomes of a five-year initiative of community outreach and engagement to improve enrollment of adult Black participants to clinical trials at the Abramson Cancer Center (ACC) at the University of Pennsylvania. **Methods**: Primary metrics were the percentage of Black patients among all cancer cases in our catchment area, the percentage of adult Black patients cared for at the ACC, and the percentage of adult Black participants enrolled on the three types of NCI-defined clinical trials. **Results**: In 2014, at baseline, Black residents comprised 19% of the population and 16.5% of cancer cases in our catchment area surrounding Philadelphia, but only 11.1% of ACC patients were Black. The percentages of Black participants accrued onto treatment, non-therapeutic interventional, and non-interventional trials were 12.2%, 8.3%, and 13.0%, respectively. We then established a center-wide program with community guidance to address these gaps. Key elements of the program included: 1) culturally tailored marketing strategies for cancer clinical trials; 2) plans for each protocol to facilitate Black participant enrollment; 3) new partnerships with faith-based organizations serving Black communities to conduct educational events about clinical trials; 4) pilot programs with Lyft and Ride Health to address transportation barriers; 5) patient education by nurse navigators regarding cancer and clinical trials; and 6) an improved informed consent process. These efforts reached more than 10,000 individuals in venues including churches, neighborhoods, community parks and centers, and health centers with formats ranging from educational forums to wellness fairs. Reassessing metrics in 2018, we found that the percentage of Black patients seen at ACC had increased to 16.2%, matching the percentage of Black cancer patients among all cancer cases in our catchment area (16.5%). Total cancer clinical trial accrual had increased from 9,308 participants in 2014 to 13,170 in 2018 (41.5% increase). The percentages of Black participants accrued onto treatment, non-therapeutic interventional, and non-interventional trials were 23.9%, 33.1%, and 22.5%, respectively – a 1.7- to 4.0-fold increase in five years and higher than the percentage of Black patients seen at the ACC. **Conclusions**: Our multifaceted, community-based engagement initiative to encourage clinical trial enrollment was associated with improved accrual of Black participants to cancer clinical trials. These findings also suggest that gaps in access to cancer centers are a key factor driving access to clinical trials. Medicaid expansion occurred concurrently in all states in our catchment area and its impact on accrual merits further research. Research Sponsor: U.S. National Institutes of Health.

Effect of an antiracism intervention on disparities in time to lung cancer surgery. *First Author: Jacob Newton Stein, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Racial disparities are well described in the management of early-stage lung cancer, with Black patients less likely to receive potentially curative surgery than non-Hispanic Whites. A multi-site pragmatic trial entitled Accountability for Cancer Care through Undoing Racism and Equity (ACCURE), designed in collaboration with community partners, eliminated racial disparities in lung cancer surgery through a multi-component intervention. The study involved real-time electronic health record (EHR) monitoring to identify patients not receiving recommended care, a nurse navigator who reviewed and addressed EHR alerts daily, and race-specific feedback provided to clinical teams. Timeliness of cancer care is an important quality metric. Delays can lead to disease progression, upstaging, and worse survival, and Black patients are more likely to experience longer wait times to lung cancer surgery. Yet interventions to reduce racial disparities in timely delivery of lung cancer surgery have not been well studied. We evaluated the effect of ACCURE on timely receipt of lung cancer surgery. **Methods:** We analyzed data of a retrospective cohort at five cancer centers gathered prior to the ACCURE intervention and compared results with prospective data collected during the intervention. We calculated mean time from clinical suspicion of lung cancer to surgery and evaluated the proportion of patients who received surgery within 60 days stratified by race. We performed a t-test to compare mean days to surgery and chi^2 for the delivery of surgery within 60 days. **Results:** 1320 patients underwent surgery in the retrospective arm, 160 were Black. 254 patients received surgery in the intervention arm, 85 were Black. Results are summarized in Table. Mean time to surgery in the retrospective cohort was 41.8 days, compared with 25.5 days in the intervention cohort ($p<0.01$). In the retrospective cohort, 68.8% of Black patients received surgery within 60 days versus 78.9% of White patients ($p<0.01$). In the intervention, the difference between Blacks and Whites with respect to surgery within 60 days was no longer significant (89.41% of Black patients vs 94.67% of White patients, p=0.12). **Conclusions:** Racial disparities exist in the delivery of timely lung cancer surgery. The ACCURE intervention improved time to surgery and timeliness of surgery for Black and White patients with early-stage lung cancer. A combination of real-time EHR monitoring, nurse navigation, and race-based feedback markedly reduced racial disparities in timely lung cancer care. Research Sponsor: U.S. National Institutes of Health.

Impact of the VA opioid safety initiative on pain management for cancer patients. *First Author: Mallika Marar, Department of Radiation Oncology, Stanford University, Stanford, CA*

Background: Limited research exists on how risk reduction policies in response to the opioid epidemic have impacted pain management among cancer patients. This study investigated the impact of the Veteran's Health Administration (VHA) Opioid Safety Initiative (OSI) on opioid prescribing patterns and opioid-related toxicity among patients undergoing definitive cancer treatment. **Methods:** This retrospective cohort study included 42,064 opioid-naïve patients receiving definitive local therapy for prostate, lung, breast, and colorectal cancer at the VHA from 2011-2016. Interrupted time series analysis with segmented regression was used to evaluate the impact of the OSI, which launched October 2013. The primary outcome was the incidence of new opioid prescriptions with diagnosis or treatment. Secondary outcomes included rates of high daily dose opioid (≥ 100 morphine milligram equivalent) and concomitant benzodiazepine prescriptions. Additional long-term outcomes included persistent opioid use, opioid abuse diagnoses, pain-related ED visits, and opioid-related admissions. **Results:** Prior to OSI implementation, the incidence of opioid prescriptions among new cancer patients increased from 26.7% (95% CI 25.0 – 28.4) in the first quarter (Q1) of 2011 to 50.6% (95% CI 48.3 – 53.0) in Q3 2013. There was a monthly increase in opioid prescription rate pre-OSI followed by a monthly decrease post-OSI (Table). High-dose opioid prescriptions were rare, and the monthly rate was stable before and after the OSI. Monthly incidence of concomitant benzodiazepine prescriptions was stable pre-OSI and decreased post-OSI. Persistent opioid use increased pre-OSI and decreased post-OSI. Pain-related ED visits had an incidence of 0.8% (95% CI 0.4 – 1.0) in Q1 2011, 0.3% (95% CI 0.1 – 0.6) in Q3 2013, and 1.8% (95% CI 0.9 – 2.7) in Q4 2016, with an increasing monthly rate after the OSI. At three years, the cumulative incidence of opioid abuse was 1.2% for both the pre- and post-OSI groups but opioid-related admissions were greater in the pre-OSI cohort than the post-OSI cohort (0.9% vs. 0.5%, $p < 0.001$). **Conclusions:** The OSI was associated with a decrease in new, persistent, and certain high-risk opioid prescribing as well as an increase in pain-related ED visits. Further research on patient-centered outcomes is required to optimize opioid prescribing policies for patients with cancer. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology., U.S. National Institutes of Health.

103 **Clinical Science Symposium**

Less is more: Postoperative pain management using restrictive opioid protocols in all surgical services in a comprehensive cancer center. *First Author: Jason Ricciuti, Department of Gynecologic Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Opioids are routinely given for postoperative pain management with limited evidence on the amount needed to be dispensed. Prescribed opioids increase the risk of chronic use, abuse, and diversion, which contribute to the opioid epidemic. We sought to demonstrate that postsurgical acute pain can be effectively managed across different surgical specialties with a markedly reduced number of opioids. **Methods:** A prospective case-control study of restrictive opioid prescription protocol (ROPP) was implemented in all surgical services from February 2019 through July 2019 at a tertiary comprehensive cancer center for all patients undergoing a surgery for which opioids would be routinely prescribed at discharge (n = 2,015). Data from surgeries performed by the same services from August 2018 through January 2019 were used for comparison (n = 2,051). At discharge, patients did not routinely receive opioids unless they had a maximally invasive procedure or if they required multiple doses of opioids during hospitalization (maximum 3-day supply). Compliance with the protocol was tracked by pharmacists daily. Patient demographics and surgical details were collected. State-run opioid prescription database was used to determine the number of opioids prescribed to all surgical patients within a 120-day surgical window. Validated patient satisfaction surveys were used at postoperative visits to assess patient experience. **Results:** After implementation of the ROPP, 45% less opioids were prescribed after surgery for all participating patients (323,674 morphine milligram equivalents (MME) vs 179,458 MME, $p < 0.001$). The majority of services complied with the ROPP in more than 95% of cases. There was no difference in postsurgical pain intensity between cohorts. Patients in the ROPP cohort had less refill requests compared to the control group (20.9% vs 17.9%, p value = 0.016). Surveys were completed by 338 patients in the control group (16.5%) and 360 in the ROPP group (17.9%). There was no significant difference in patient reported satisfaction with postoperative pain control or on the impact of pain on daily activities between the cohorts. **Conclusions:** Implementation of a ROPP by multiple surgical services at a tertiary cancer center was feasible and resulted in substantial decrease in the number of opioids prescribed while not compromising patient experience. Patients did not require more prescription refills despite being provided no opioids or a limited supply. This study provides evidence to support reducing the number of opioids routinely prescribed after surgery. Research Sponsor: Roswell Park Alliance Foundation.

Explainable prediction of survival using clinical, molecular, and radiomic profiles in recurrent high-grade glioma patients treated with CAR T-cell therapy. *First Author: Chi Wah Wong, City of Hope National Medical Center, Duarte, CA*

Background: High-grade glioma (HGG) is an aggressive heterogeneous primary CNS neoplasm with high recurrence rate and poor survival. Multiple ongoing clinical trials are leveraging targeted molecular and immunologic therapeutics (e.g., pembrolizumab, Chimeric Antigen Receptor [CAR] T-cell therapy) in effort to improve survival. Explainable predictive models have shown value in identifying biomarkers predictive of treatment response as well as informing prognosis. In this study, we developed an explainable machine learning model leveraging clinical, molecular and radiomic (imaging) features to predict overall survival in patients suffering from HGG treated with CAR T-cell therapy. **Methods:** In this IRB-approved phase 1 clinical trial, 60 patients (39 males, median age = 49) suffering from HGG underwent surgical resection and CAR T-cell therapy[1]. All patients underwent baseline MRI scans prior to both surgical resection and CAR T-cell administration in the resection cavity. Using contrast-enhanced T1-weighted MRIs, we segmented the enhancing tumor (ET) and generated radiomic features. For predictive modeling, we incorporated the following features: Age, gender, race, ethnicity, histology, tumor grade (WHO), IL-13 receptor alpha 2 (IL-13Rα2) expression (H score), unifocal or multifocal lesions, tumor location (lobe), shape-based radiomics (tumor volume, surface area, and sphericity). We utilized gradient-boosted tree models to classify whether survival is above or below 180 days with two-loop nested cross-validation. For the inner validation loop, we optimized the model with hyper-parameter tuning. For the outer validation loop, we tested the optimal model on the hold-out data and the predictions were used as survival scores (0 – 1). Larger scores imply better predicted survival. For prediction explanations, we adopted the Shapley additive explanation (SHAP) framework. **Results:** The outer validation loop Area Under the Receiver Operating Characteristic Curve and Area under the Precision-Recall Curve were 0.76 and 0.81, respectively. Among the top five most important features calculated from SHAP; patients with larger tumor surface area, tumor volume and age have reduced survival scores while patients with larger IL-13Rα2 and tumor sphericity have increased survival scores. We stratified the patients into two distinct prognostic sub-groups (30 patients each group) using the survival scores obtained from the outer loop, with a log-rank test $p < 0.01$. **Conclusions:** In patients with HGG treated with CAR T-cell therapy, we found that tumor surface area/volume and age are inversely related to survival while increased IL-13Rα2 expression and tumor sphericity were positive predictor of survival. Our model can potentially be used to optimize clinical trial enrollment through more precise patient screening and treatment planning. Research Sponsor: None.

105 **Clinical Science Symposium**

Imaging-based patient inclusion model for clinical trial performance optimization. *First Author: Michal R Tomaszewski, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: In the era of precision medicine, development of new cancer therapies relies strongly on effective selection of target patient population. We hypothesize that computational analysis of imaging data can be used for development of a quantitative population enrichment strategy in clinical trials and thus we aim to establish an appropriate framework for this analysis. **Methods:** This hypothesis was tested among soft-tissue sarcoma (STS) patients accrued into a randomized Phase III clinical trial (SARC021) that evaluated the efficacy of evofosfamide (Evo), a hypoxia activated prodrug, in combination with doxorubicin (Dox). Notably, SARC021 failed to meet its survival objective (PMC7771354). We tested whether an inclusion/exclusion model based on radiomic analysis and relevant clinical covariates could have been employed to result in a significant treatment benefit of the Evo+Dox combination compared to the standard Dox monotherapy. A total of 163 radiomics features were extracted from lung metastases of 303 patients from the SARC021 trial, divided into demographically matched training and test sets. Stability analysis identified the most reproducible features. Univariable and multivariable models were utilized to discriminate OS in the two treatment groups. **Results:** A bespoke enrichment framework was established for individualized patient selection, based on model-derived risk score threshold. A radiomic feature, Short Run Emphasis, was identified as the most informative. When combined with tumor histology and smoking history information, an enriched subset (42%) of patients had longer OS in Evo+Dox vs. Dox groups [p = 0.01, Hazard Ratio (HR) = 0.57 (0.36-0.90)], overperforming a clinical-only approach. Application of the same model and threshold value in an independent test set confirmed the significant survival difference (p = 0.002, HR = 0.29 (0.13-0.63), 38% patients included). The breakdown of Dox+Evo treatment benefit depending on proportion of patients included based on the model is shown in the Table. Notably, this process also identified patients most likely to benefit from doxorubicin alone. **Conclusions:** The study presents a first of its kind radiomic approach for patient enrichment in clinical trials based on a quantitative score. In particular, we have shown that had the novel model been used for selective patient inclusion into the SARC021 trial, it would have met its primary survival objective for patients with metastatic STS. Research Sponsor: U.S. National Institutes of Health., Dr. Fan was partially supported by funds from the Dept. Radiology, Tianjin Medical University, Tianjin, China.

Artificial intelligence (AI)–powered pathologic response (PathR) assessment of resection specimens after neoadjuvant atezolizumab in patients with non-small cell lung cancer: Results from the LCMC3 study. *First Author: Sanja Dacic, Department of Pathology, University of Pittsburgh and UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: PathR is an efficacy endpoint in Phase II and III neoadjuvant trials and is proposed as a surrogate for disease-free survival (DFS) and overall survival. Machine learning (ML)–based, automated approaches standardize quantification of areas of tumor bed and residual viable tumor. Here we show that automation may provide a scalable alternative to or complementary tool for manual assessment. **Methods:** We determined inter-reader variability for PathR among pathologists in the LCMC3 (NCT02927301) study and developed an AI-powered digital PathR assessment tool in line with manual consensus recommendations. Study cases were reviewed for PathR by a local site pathologist and 3 central expert pathologists (n = 127). When determined manually, major PathR (MPR) was defined as ≤10% viable tumor averaged per case. ML models were trained and validated by the PathAI research platform using digitized H&E-stained tumor sections. The digital PathR model predicted percent viable tumor for each case as the sum of the cancer epithelium area from each slide divided by the sum of tumor bed area for each slide. DFS (clinical cutoff: Oct 23, 2020) was reported for patients with manual and digital PathR assessment (n = 135). For digital MPR, we used a prevalence-matched cutoff that maintained the same proportion of patients as manual MPR. **Results:** Inter-reader agreement among 1 local and 3 central pathologists for manual PathR was good (n = 127; ICC = 0.87; 95% CI: 0.84-0.90). Agreement was 91% (κ = 0.82) on manual MPR and 98% (κ = 0.88) on pathologic complete response (pCR). 6 patients had unanimous pCR. Digital and manual PathR were strongly correlated (n = 135, Pearson r = 0.78) and digital PathR demonstrated an outstanding predictability for manual MPR (AUROC = 0.975). The range was 0%-60% for digital PathR and 0%-100% for manual PathR with a regression line slope < 1.0 (m = 0.303) indicating systematic differences between the methods, consistent with digital PathR using a high-resolution segmentation of cancer epithelium from stroma across each slide. Longer DFS was observed for MPR yes vs no with both digital and manual assessment (Table). **Conclusions:** This analysis showed good inter-reader agreement for manual and strong correlation of AI-powered digital and manual PathR. Comparable DFS rates for manual MPR and digital MPR are encouraging in the preliminary data. These data support further studies of digital PathR as a standardized and scalable tool to determine PathR. Clinical trial information: NCT02927301. Research Sponsor: F. Hoffmann-La Roche.

HPV associated cancers in the United States over the last 15 years: Has screening or vaccination made any difference? *First Author: Cheng-I Liao, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*

Background: Human papillomavirus is a causative agent of many human cancers. This study aims to determine the incidence and trends of HPV-related cancers in the United States. **Methods:** HPV-associated cancers as classified by the CDC were included: oropharyngeal squamous cell carcinoma (SCC), anal & rectal SCC, vulvar SCC, vaginal SCC, cervical carcinoma, and penile SCC. Data were obtained from the United States Cancer Statistics program from 2001-2017. SEER*Stat 8.3.8 and Joinpoint regression program 4.8.0.1 were used to calculate incidence trends of HPV-associated cancers per 100,000. **Results:** The overall incidence of HPV related cancers for women was 13.68/100,000, more than half of which (52%) were cervical cancer, at 7.12/100,000 in the year 2017. Over the last 16 years, the incidence of cervical cancer has decreased at an annual percent change (APC) of 1.03% ($p < 0.001$). In contrast, oropharyngeal (APC = 0.77%, $p < 0.001$), anal & rectal (APC = 2.75%, $p < 0.001$), and vulvar SCC all increased significantly (APC = 1.27%, $p < 0.001$). For older women, the incidence of anal & rectal cancer approached that of cervical cancer. In those over 80, the incidence of cervical cancer was 6.95 (-2.90% APC, $p < 0.001$), compared to 6.36 for anal & rectal cancer (1.23% APC, $p < 0.001$). Using a projection model, incidence of anal & rectal cancer is expected to surpass that of cervical cancer by year 2025 for every age group over 55. For men, the incidence of all HPV-related cancers was 11.0/100,000 in the year 2017, 81% were associated with oropharyngeal cancer. Over the last 16 years, there was an overall annual increase in HPV related cancers at 2.36% per year ($p < 0.001$) with the highest increase in oropharyngeal (APC = 2.71%, $p < 0.001$) and anal & rectal SCC (APC = 1.71%, $p < 0.001$). Those at greatest risk of oropharyngeal cancer were older men aged 65-69 years with an incidence of 36.5/100,000 and annual percent increase of 4.24% ($p < 0.001$). The intersectionality of age and race showed that White men age 65-69 years had the highest incidence of oropharyngeal at 41.6/100,000. **Conclusions:** Overall, there was a decrease in cervical cancer incidence likely due to screening or vaccination. However, over 80% of men with HPV related cancers had oropharyngeal cancer, a nearly fivefold higher incidence compared to women. In contrast, there was a significant increase in non-screenable HPV-related cancers and anal & rectal SCC incidence is projected to surpass that of cervical cancer within 5 years for certain at-risk groups. Further resources and research should be conducted to address the lack of screening or vaccination in these preventable cancers. Research Sponsor: Fisher Foundation and Denise Cobb Hale.

Finding the missing millions: Integrating automated viral hepatitis screening in a hospital with care and treatment in a primary care setting. *First Author: Ruth Brogden, Saint Barnabas Medical Center, Florham Park, NJ*

Background: Rates of hepatocellular carcinoma (HCC) are rising in the US. Patients at Saint Barnabas Medical Cancer Center (SBMC) present with late-stage HCC at higher rates (29%) compared to the national (16%). Chronic Hepatitis C (HCV) and Hepatitis B (HBV) are major drivers of liver cancer, yet screening rates are low. Finding these missing millions is important to reducing rates of HCC. An automated emergency department (ED) viral hepatitis (VH) screening program was initiated in 2018 at SBMC. In January 2020, it was expanded to the inpatient setting and HCV screening was modified from cohort screening (those born in 1945-65) to a one time test for anybody 18 years or over, per updated Centers for Disease Control (CDC) and USPSTF (US Preventive Services Taskforce) recommendations. **Methods:** The electronic medical record (EMR) was modified to automate screening. HBV testing is triggered by a patient's country of birth or race, and HCV testing is triggered by age over 18 and no previous testing. The automated HCV (HCV Ab with reflex to HCV RNA) or HBV (HBsAg) lab orders lead to an EMR notification to the nurses of patient eligibility and education is provided to patients. Alerts of positive results are sent to nursing staff, physicians, and the patient navigator (PN). The PN is sent a real-time secure text message and works individually with patients to arrange linkage-to-care (LTC) for evaluation and treatment. **Results:** From March 2018 - December 2020, 44,002 patients were screened for HCV and 884 (2.0%) were HCVAb+ and 242 (0.55%) HCV RNA+. For HBV, 21,328 patients were screened and 212 (0.99%) were HBsAg+. The expanded screenings accounted for 8,716 (19.8%) of the total HCV screenings. Individuals born outside the 1945-65 birth cohort (younger and older) made up 76.2% of those screened and 41% of the infected. The top 3 countries for HBV screenings were Haiti, Jamaica, and Ecuador. LTC rates, defined as attending first medical appointment or already in care, were 86.8% for HCV and 85.4% for HBV. Of those linked to care, 43 HCV+ patients were seen at a outpatient primary care practice part of SBMC, and of those, 39 initiated HCV cure therapy and 33 were cured (confirmed sustained virologic response at 12 weeks), and 35 HBV+ patients were seen and 6 initiated treatment. **Conclusions:** This automated program for VH has led to a significant scale up of screening with successful LTC and treatment of patients. Expansion to universal screening of all adults and to the inpatient setting found additional viral hepatitis patients who would have otherwise been missed. In addition to the automated screening, a multidisciplinary team including internists, pharmacists, and patient navigators were part of creating a primary care based program. Integration of viral hepatitis screening and care in a hospital system can be initial steps towards establishing liver cancer prevention program. Research Sponsor: Gilead Sciences.

Identification of good and poor prognosis HPV associated oropharyngeal cancer based on CD103 immune cell expression in patients treated with cetuximab and radiotherapy on TROG 12.01 and De-ESCALaTE randomized trials. *First Author: Danny Rischin, Department of Medical Oncology, Peter MacCallum Cancer Centre and the Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia*

Background: Trials in human papilloma virus associated oropharyngeal squamous cell carcinoma (HPVOPSCC), substituting cetuximab (CETUX) for cisplatin (CIS) with radiotherapy (RT), resulted in decreased efficacy without improved toxicity or symptom burden. We reported that high intratumoral immune cell (ITIC) CD103 expression (> 30%), a marker of tissue-resident memory T cells, is associated with better prognosis in unselected patients with HPVOPSCC treated with CIS/RT. In this study our aim was to determine whether low risk HPVOPSCC patients treated with CETUX/RT with high CD103 have a superior prognosis. **Methods:** TROG 12.01 and De-ESCALaTE are randomised multicentre trials that compared 70Gy RT/CETUX with 70Gy RT/CIS (weekly in TROG 12.01, 3-weekly in De-ESCALaTE) in patients with HPVOPSCC, low risk by Ang criteria: AJCC 7^{th} Stage III (excluding T1-2N1) or stage IV (excluding N2b-c if smoking history > 10 pack years and/or distant metastases). In TROG 12.01 T4 and/or N3 patients were also excluded. Eligible patients required tumor samples available for immune cell quantification on immunohistochemistry. Data from the two trials were pooled, with analyses performed in eligible randomised patients who commenced treatment. The primary endpoint was failure-free survival (FFS) in patients receiving CETUX/ RT comparing CD103 ITIC > 30% (high) vs. < 30% (low). High/low CD103 were compared using Cox model adjusting for age, stage and trial. **Results:** Samples for CD103 testing were available in 159/182 patients on TROG 12.01 and 145/334 on De-ESCALaTE. ITIC CD103 expression was high in 26% of patients. The median follow-up was 3.2 years. The 3 -year failure-free survival rates in patients treated with CETUX/RT were 92% (95% CI: 78-97%) in high CD103 and 74% (95% CI: 64-82%) in low CD103, adjusted HR 0.25 (95% CI: 0.14-0.44); $p < 0.001$. The 3 -year overall survival (OS) in patients treated with CETUX/RT were 100% in high CD103 and 86% (95% CI: 76-92%) in low CD103, $p < 0.001$. Superior FFS in the high CD103 group was independent of stage. In patients treated with CIS/RT there was no significant difference in FFS (3-year 86% in high CD103 and 90% in low CD103; $p = 0.55$) or in OS (3-year 100% in high CD103 and 95% in low CD103; $p = 0.14$). The increase in failures in the low CD103 patients treated with CETUX/RT was evenly split between distant and locoregional failures. **Conclusions:** ITIC CD103 separates CETUX/RT treated low risk HPVOPSCC into excellent and poor prognosis subgroups. In a low risk population CIS/RT achieves excellent outcomes in both high and low ITIC CD103 groups. The high ITIC CD103 population is a rational target for future de-intensification trials. Research Sponsor: National Health and Medical Research Council (Investigator Grant GNT1175929).

De-intensified chemoradiotherapy for locoregionally advanced nasopharyngeal carcinoma based on plasma EBV DNA: A phase 2 randomized noninferiority trial. *First Author: Hai-Qiang Mai, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The cisplatin-based chemoradiotherapy (CCRT), given at a dose of 100 mg/m^2 for 3 cycles during radiotherapy, is the major treatment for locoregionally advanced nasopharyngeal carcinoma (NPC). As several retrospective studies showed that receiving a cumulative cisplatin dose of 200 mg/m^2 can bring survival benefits to NPC patients, we sought to test the non-inferiority of 2-cycle concurrent cisplatin over 3-cycle in locoregionally advanced NPC with Epstein-barr virus (EBV) DNA levels < 4000 copies/ml. **Methods:** We did a non-inferiority, phase 2, randomised controlled trial. Patients were enrolled with stage III–IVB NPC, EBV DNA levels < 4000 copies/ml, aged 18–70 and adequate haematological, renal, and hepatic function. Eligible patients were randomly assigned (1:1) to receive 2 or 3 cycles of cisplatin-based CCRT. Patients in the 2-cycle group were scheduled to receive 100 mg/m^2 cisplatin given every 3 weeks concurrently with radiotherapy, and patients in the 3-cycle group received 100 mg/m^2 cisplatin given every 3 weeks for 3 cycles. Randomization was done by a computer-generated random number code with a block size of six, stratified by clinical stage III or IV. The primary endpoint was 3-year progression-free survival (PFS), with a non-inferiority margin of 10%. This study was registered with ClinicalTrials.gov, ID. NCT02871518. **Results:** Between September 2016 and October 2018, 342 patients were enrolled, of whom 332 were randomly assigned to receive 2 or 3 cycles of cisplatin. 314 (94.6%) patients completed protocol-defined cycles of chemotherapy. After median follow-up of 33.6 months, 20 (12.0%) patients in the 2-cycle group and 17 (10.2%) patients in the 3-cycle group had tumor progression, and the 3-year PFS rates were 88.0% and 90.4% respectively, with a difference of 2.4% (95%CI -4.3 to 9.1, $P_{non\text{-}inferiority} < 0.001$). In the per-protocol analysis, 3-year PFS was 88.5% in the 2-cycle group and 90.6% in the 3-cycle group, with a difference of 2.1% (95% CI –4.7 to 8.9; $P_{non\text{-}inferiority} = 0.001$). No significant difference was observed concerning OS, LRRFS and DMFS. The grade 3 or 4 acute adverse events were recorded in 113 (68.1%) patients in the 2-cycle group and 116 (69.9%) patients in the 3-cycle group. Patients in the 3-cycle group was observed to have significantly more hyponatremia. Besides, patients in the 3-cycle group presented with more grade 1 or 2 dry mouth, dysphagia, weight loss, fatigue, constipation, fever, mucositis and dermatitis. More grade 3 or 4 anorexia, mucositis and dermatitis were also recorded in the 3-cycle group. No patients died from treatment-related toxicities. **Conclusions:** IMRT plus 2 cycles of concurrent 100 mg/m^2 cisplatin could be an alternative option for patients with low-risk locoregionally advanced NPC. Further phase III studies are needed to validate the findings of this study. Clinical trial information: NCT02871518. Research Sponsor: None.

Outcome of patients with an ultralow risk 70-gene signature in the MINDACT trial.

First Author: Josephine Lopes Cardozo, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Gene signatures have proven successful in identifying patients with a low risk of distant recurrence who could forego chemotherapy (CT) and are currently included in international treatment guidelines for breast cancer. For the 70-gene signature (MammaPrint) an additional threshold was established within the low risk category to identify patients with an ultralow risk of distant recurrence. In independent cohorts, these patients had excellent breast cancer specific survival at 15 years, suggesting that ultralow risk cancers represent indolent disease (Esserman, JAMA Oncol 2017, Delahaye, BC Res Treat 2017). Here we evaluate survival of patients with an ultralow risk 70-gene signature who participated in the randomized phase 3 MINDACT trial (Piccart, Lancet Oncol 2021). **Methods:** Of the 6,693 patients enrolled in the MINDACT trial (EORTC 10041/BIG 3-04) between 2007-2011, profiling revealed an ultralow risk 70-gene signature in 1,000 patients (15%). We assessed 5- and 8-year distant metastasis free interval (DMFI) and breast cancer specific survival (BCSS) in patients stratified by 70-gene signature result (high, low, ultralow), and within the ultralow risk group stratified by clinical risk. For these exploratory analyses, we used Kaplan-Meier estimates for time to event endpoints and Cox-regression models to calculate hazard ratio's (HR). **Results:** Median follow-up was 8.7 years. Among the ultralow risk patients (n = 1,000), 67% were ≥50 years, 81% had tumors < 2cm, 80% were lymph node negative, 96% had grade 1 or 2 tumors and 99% were ER-positive. Systemic therapy was received by 83% of patients (69% endocrine therapy (ET), 14% ET + CT) and 16% received no adjuvant systemic treatment (AST). Survival estimates for all endpoints are shown in the table; 8-year DMFI was 97.0% (95% CI 95.8-98.1) for ultralow risk. The 8-year DMFI in ultralow risk patients who received no AST or ET only was 97.8% (95% CI 95.3-100) and 97.4% (95% CI 96.1-98.7), respectively. The HR for DMFI was 0.66 (95% CI 0.46-0.95) for ultralow vs low risk, after adjusting for tumor and treatment characteristics (preliminary results). **Conclusions:** In this prospective study, patients with an ultralow risk 70-gene signature have an excellent prognosis with 8-year BCSS above 99% regardless of clinical risk status, and with an 8-year DMFI of 95-98%. Research Sponsor: This research was supported by a grant from the EORTC Breast Group and from the Netherlands Cancer Institute.

70-gene signature	Events (N)	5-year DMFI (95% CI)	8-year DMFI (95% CI)	8-year BCSS (95% CI)
Ultralow risk (n = 1000)	36	98.1% (97.2-99.0)	97.0% (95.8-98.1)	99.6% (99.1-100)
Low risk* (n = 3295)	192	97.5% (97.0-98.1)	94.5% (93.6-95.3)	98.2% (97.7-98.7)
High risk (n = 2398)	273	92.5% (91.4-93.6)	89.2% (87.9-90.5)	93.7% (92.6-94.7)
Ultralow risk				
Clinical low risk (n = 741)	21	98.7% (97.8-99.5)	97.6% (96.4-98.8)	99.7% (99.3-100)
Clinical high risk (n = 259)	15	96.3% (94.0-98.7)	95.0% (92.3-97.8)	99.2% (98.0-100)

Breast Cancer Index (BCI) and prediction of benefit from extended aromatase inhibitor (AI) therapy (tx) in HR+ breast cancer: NRG oncology/NSABP B-42.

First Author: Eleftherios P. Mamounas, NSABP/NRG Oncology, and The Orlando Health Cancer Institute, Orlando, FL

Background: The BCI HOXB13/IL17BR ratio (BCI-H/I) has been shown to predict endocrine tx (ET) and extended ET (EET) benefit. We examined the effect of BCI-H/I for EET benefit prediction in NSABP B-42, evaluating extended letrozole tx (ELT) in HR+ breast cancer patients (pts) who completed 5 yrs of ET. **Methods:** All pts with available primary tumor tissue were eligible. Primary endpoint was recurrence-free interval (RFI). Secondary endpoints were distant recurrence (DR), breast cancer-free interval (BCFI), and disease-free survival (DFS). Stratified Cox proportional hazards model was used. Due to a non-proportional effect of ELT on DR, time-dependent secondary analyses (≤4y, >4y) were performed. Likelihood ratio test evaluated treatment by BCI-H/I interaction. **Results:** In 2,179 pts analyzed (60% N0; 62% AI only; 80% HER2-), 45% were BCI-H/I-High and 55% BCI-H/I-Low. ELT showed an absolute 10y benefit of 1.6% for RFI (HR=0.77, 95% CI 0.57-1.05, p=0.10) (BCI-H/I-Low: 1.1% [HR=0.69, 0.43-1.11, p=0.13]; BCI-H/I-High: 2.4% [HR=0.83, 0.55-1.26, p=0.38]; interaction p=0.55). There was no statistically significant ELT by BCI-H/I interaction for BCFI (BCI-H/I-Low: HR=0.53, 0.36-0.78, p=0.001; BCI-H/I-High: HR=0.85, 0.60-1.21, p=0.36; interaction p=0.07) or for DFS (BCI-H/I-Low: HR=0.75, 0.58-0.95, p=0.017; BCI-H/I-High: HR=0.81, 0.64-1.04, p=0.09; interaction p=0.62). Before 4y, there was no statistically significant ELT benefit on DR in either BCI-H/I group. After 4y, BCI-H/I-High pts had statistically significant ELT benefit on DR (HR: 0.29, 0.12-0.69, p=0.003), while BCI-H/I-Low pts were less likely to benefit (HR: 0.68, 0.33-1.39, p=0.28) (interaction p=0.14). **Conclusions:** BCI-H/I prediction of ELT benefit on RFI was not confirmed. In time-dependent DR analyses, BCI-H/I-High pts had statistically significant benefit from ELT after 4y, while BCI-H/I-Low pts did not. Observed ELT benefit on BCFI in BCI-H/I-Low pts was primarily driven by second primary breast cancers. Additional follow-up is needed to further characterize BCI-H/I predictive ability in this study. Support: U10CA180868, -180822, U24CA196067; Novartis; Biotheranostics. Clinical trial information: NCT00382070. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Utility of the 70-gene MammaPrint assay for prediction of benefit from extended letrozole therapy (ELT) in the NRG Oncology/NSABP B-42 trial.

First Author: Priya Rastogi, NSABP/NRG Oncology and the UPMC Hillman Cancer Center, Pittsburgh, PA

Background: The 70-gene MammaPrint (MP) assay predicts risk of distant recurrence (DR) in hormone-receptor positive early-stage breast cancer and classifies cancers as Low Risk or High Risk. NSABP B-42 evaluated ELT in patients (pts) who had completed 5 yrs of adjuvant endocrine therapy (tx). The primary objective was to determine the utility of MP to identify pts enrolled in NSABP B-42 who are likely to benefit from ELT. **Methods:** A total of 1,866 pts from B-42 had available MP results. Primary endpoint is DR. Secondary endpoints are disease-free survival (DFS) and breast cancer-free interval (BCFI). For the primary analysis, pts were classified as High Risk (MP-H) (MP score ≤0.000) or Low Risk (MP-L) (MP score > 0.000). Exploratory analyses were performed for MP-L subcategories: MP Ultralow Risk (MP-UL) (MP score > 0.355) and MP-L but not MP-UL (MP-LNUL) (MP score > 0.000, ≤0.355). Likelihood ratio test based on stratified Cox proportional hazards (PH) model was used for treatment by risk group interaction. Stratified log-rank test was used to compare treatment groups. Hazard ratios and 95% CI were computed based on the stratified Cox PH model. **Results**: Among 1,866 pts, 706 (38%) were MP-H and 1,160 (62%) were MP-L. Of the MP-L, 252 (22%) were MP-UL. There were no significant differences in the distribution of patient and tumor characteristics between the MP group and the rest of the B-42 cohort, except for HER2 status. ELT effect was more pronounced in the MP cohort than in the overall B-42 population. For DR, there was statistically significant ELT benefit in MP-L (HR = 0.43, 95% CI 0.25-0.74, p = 0.002), but not MP-H (HR = 0.65, 0.34-1.24, p = 0.19) (interaction p = 0.38). For DFS, there was statistically significant ELT benefit in MP-L, but not MP-H (interaction p = 0.015). Similar findings were observed for BCFI (interaction p = 0.006). Within subcategories of MP-L, there was statistically significant ELT benefit in MP-LNUL, but not in MP-UL for all three endpoints, however the power in MP-UL was limited due to low number of pts (Table). Clinical trial information: 00382070. **Conclusions:** Statistically significant ELT benefit was observed for MP-L, but not MP-H. The treatment by risk group interaction was not statistically significant for DR, but it was for DFS and BCFI. The benefit appears to be stronger in MP-LNUL than in MP-UL. NCT: 00382070. De-escalated neoadjuvant pertuzumab+trastuzumab with or without paclitaxel weekly in HR-/HER2+ early breast cancer: ADAPT-HR-/HER2+ biomarker and survival results.

First Author: Nadia Harbeck, Breast Center, Dept. Obstetrics & Gynecology, University of Munich (LMU) and CCCLMU and West German Study Group, Munich, Germany

Background: Optimal use of de-escalated, particularly chemotherapy(CT)-free, neoadjuvant regimens in HER2+ early breast cancer (EBC) is currently unclear as there are limited survival data so far. In ADAPT-HR-/HER2+, we previously showed an excellent pCR rate of 90% after 12-week neoadjuvant paclitaxel (Pac) +pertuzumab (P) +trastuzumab (T) and a substantial and clinically meaningful pCR rate of 34% after P+T alone in HR-/HER2+ EBC. Here, we present first survival data. **Methods:** The prospective multicenter WSG-ADAPT-HR-/HER2+ phase II-trial is part of the ADAPT-umbrella protocol. Patients with cT1-cT4c, cN0-3 HR-/HER2+ EBC (n = 134) were randomized to 4 cycles of P+T +/- pac d1,8,15 q3w. All tumors were HR-negative (ER and PR < 1%) and HER2-positive (central lab, i.e., 2+ FISH positive or 3+ by immunohistochemistry. Primary endpoint was pCR (ypT0/is/ypN0); omission of further CT was allowed in pts with pCR. Trial objective was to compare pCR in P+T+pac arm vs. early responders in P+T arm (defined as low cellularity and/or Ki67 decrease >30% after 3 weeks). The trial was stopped early due to the observed pCR superiority in the P+T+pac arm. Secondary endpoints included safety, 5-y (distant)-DFS, OS and translational research. Cox-regression analysis was applied. PAM50 subtype was assessed using the BC360 panel. **Results:** 134 patients were randomized to P+T (n = 92) or P+T+pac (n = 42). 60% of tumors were cT2-4, 42% clinically node-positive. After a median follow-up of 5 years, no significant differences between study arms were observed regarding DFS, dDFS, and OS; only 13 iDFS events (7 dDFS) were observed in the whole ITT population. pCR (vs. non-pCR) after the 12-week study treatment (irrespective of study arm) was strongly associated with improved iDFS (5y DFS 98.5% vs. 82%, HR = 0.14, 95% CI 0.03-0.64). Of the 69 patients with pCR, 39 (56.5%) received no further CT (P+T arm: n = 9, 29% vs. (P+T+pac arm n = 30, 79%); only 1 distant relapse (1.4%) was observed in these patients. In the CT-free P+T arm, no pCR was observed in patients with low HER2 expression (IHC 1+/2+ and FISH positive) and/or basal-like subtype by PAM50 (n = 17, 19%). In the total study population, low HER2 expression and/or no early response was strongly associated with worse dDFS (p = .029) and iDFS (p = .068). No new safety signals were observed. **Conclusions:** For the first time, we have shown both excellent pCR and survival in patients treated by de-escalated neoadjuvant CT+P+T irrespective of further CT use in a prospective multicenter study. Investigation of CT-free regimens may need to be focussed on selected patients only (e.g. with high HER2 expression/non-basal-like tumors). In ADAPT HR-/HER2+, early pCR after only 12 weeks of neoadjuvant P+T+pac was strongly associated with improved outcome and may thus serve as a predictive clinical marker for further treatment (de)-escalation. Clinical trial information: NCT01779206. Research Sponsor: Roche, AOK.

504 **Oral Abstract Session**

Prognostic impact of recurrence score, endocrine response and clinical-pathological factors in high-risk luminal breast cancer: Results from the WSG-ADAPT HR+/HER2- chemotherapy trial. *First Author: Oleg Gluz, West German Study Group and Ev. Hospital Bethesda, Breast Center Niederrhein, Moenchengladbach, Germany and University Hospital Cologne, Cologne, Germany*

Background: In HR+/HER2- N0-1 early BC, postmenopausal patients (pts) with RS™ > 25 and a substantial proportion of premenopausal pts seem to benefit from addition of adjuvant chemotherapy (CT) to endocrine therapy (ET). However, the magnitude of absolute benefit from this treatment intensification seems to depend on clinical-pathological and biological prognostic factors. For the first time, we present outcome from the CT part of the prospective phase III WSG-ADAPT HR+/HER- trial combining both static (RS in baseline core biopsy (CB) and dynamic (Ki67 response) biomarkers to optimize adjuvant therapy in luminal EBC. **Methods:** Pts with clinically high-risk HR+/HER2- EBC (cT2-4 OR clinically N+ OR G3 OR Ki67>15%) were initially treated by 3 (+/-1) weeks of standard ET (postmenopausal: mostly AI; premenopausal: TAM) before surgery or sequential CB. Pts with cN2-3 or G3/Ki67>40% were randomized directly to the CT trial. pN0-1 pts with RS0-11 OR RS12-25/ET-response (central $Ki67_{postendocrine}$<10%) received ET alone; the remaining high-risk cohort was randomized to the CT trial: (neo)adjuvant dose-dense CT (4xPaclitaxelà4xEC q2w vs. 8xNab-Paclitaxel q1wà4xEC q2w) followed by ET. Primary endpoint is efficacy comparison of CT schedules for survival; secondary endpoints reported here involve impacts of key prognostic factors on survival. Kaplan-Meier and Cox proportional hazard models were used to estimate survival curves and hazard ratios. For this analysis, subgroups free of selection bias by RS/ET-response were defined. **Results:** 5625 pts were screened and 4621 (ITT) entered the trial. After 4.9y median follow-up, higher baseline and post-endocrine Ki-67 levels were associated with poorer iDFS (both $p < 0.001$). In the CT cohort (n = 2331), higher RS, nodal status, and tumor size were generally associated with poorer iDFS. However, iDFS differed between N1 and N0 status only among younger pts (<50 years). In pts with >4 positive LN (n = 390), lower RS was associated with improved iDFS (RS0-11 vs RS > 25: $p_{log-rank}$= 0.016, 5y-iDFS 90% vs. 64%). In pts with RS > 25 (n = 965), low $Ki67_{postendocrine}$, N0 status, and c/pT1 status were associated with improved iDFS. In particular, ET-responders had higher 5y-iDFS (84%) than ET-non-responders (77%; $p_{log-rank}$= 0.040). Younger patients (<50 years old) with N0-1 RS 12-25/ ET-non-responders treated by CT had non-significantly poorer 5-year iDFS (89%) compared to those with ET-response treated by ET only (92%) ($p_{log-rank}$= 0.249). **Conclusion**: First results from the prospective high risk cohort from a large prospective phase III ADAPT trial provide evidence for good prognosis in some pts with >4 positive LN and e.g. low RS. Moreover combination of lower post-endocrine Ki-67 and limited tumor burden may be a promising criterion for CT de-escalation strategies even in patients with high RS. Clinical trial information: NCT01779206. Research Sponsor: Genomic Health (Exact Science), Celgene, Amgen, AOK.

Neoadjuvant talazoparib in patients with germline *BRCA1/2* (g*BRCA1/2*) mutation-positive, early HER2-negative breast cancer (BC): Results of a phase 2 study. *First Author: Jennifer Keating Litton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Talazoparib (TALA) is a poly(ADP-ribose) polymerase inhibitor approved as monotherapy for treating adult patients (pts) with g*BRCA1/2*-mutated HER2-negative locally advanced or metastatic BC. **Methods:** This phase 2, non-randomized, single-arm, open-label study (NCT03499353) evaluated the efficacy and safety of TALA in the neoadjuvant setting for pts with early g*BRCA1/2*-mutated HER2− BC. Primary endpoint was evaluation of pathologic complete response (pCR) as assessed by Independent Central Review (ICR) after completing 24 weeks of neoadjuvant TALA monotherapy 1 mg QD (0.75 mg for moderate renal impairment) followed by surgery. Secondary endpoints included pCR by investigator (INV) and residual cancer burden (RCB) by ICR (RCB: 0 [pCR], I [minimal], II [moderate], III [extensive]). The evaluable population included pts who received at least 80% of the TALA dose prescribed at treatment start and underwent breast surgery and pCR assessment, plus those who progressed before pCR could be assessed. The intent-to-treat (ITT) population included all pts who received at least 1 dose of TALA. **Results:** Of 61 pts treated with TALA (ITT and safety populations), 48 comprised the evaluable population. All pts had triple-negative BC. 60 pts had adenocarcinoma and 1 had squamous cell histology, with the following staging: I=20, II=27, III=14. Mean age was 44.6 years, mean duration of 4.5 wks since disease onset, mean duration of treatment of 23.3 wks, and mean overall relative dose intensity of 84.5% (ITT population). pCR (assessed by ICR and INV) and RCB (by ICR) for the evaluable and ITT populations are shown in the table below. Ten (16.4%) patients discontinued treatment due to progressive disease. One pt had a disruption of treatment as a result of COVID-19 restrictions, 2 pts for other reasons: to undergo surgery early and consent withdrawal; 9 patients received <80% dose. Treatment-emergent adverse events (AEs) were reported in 98.4% of pts (27.9% grade [G] 1, 23.0% G2, 45.9% G3, 1.6% G4); the most common were fatigue (78.7%; G1 54.1%; G2 21.3%; G3 3.3%), nausea (68.9%; G1 54.1%; G2 13.1%; G3 1.6%), and alopecia (57.4%; G1 54.1%; G2 3.3%). Three (4.9%) pts discontinued treatment due to AEs (G3 anemia [n=2] and G3 vertigo [n=1]) and continued on study. **Conclusions:** TALA monotherapy in the neoadjuvant setting was active and showed pCR rates comparable to those observed with combination anthracycline and taxane-based chemotherapy regimens and was generally well tolerated. Clinical trial information: NCT03499353. Research Sponsor: Pfizer.

Durvalumab improves long-term outcome in TNBC: results from the phase II randomized GeparNUEVO study investigating neodjuvant durvalumab in addition to an anthracycline/taxane based neoadjuvant chemotherapy in early triple-negative breast cancer (TNBC). *First Author: Sibylle Loibl, German Breast Group (GBG), Neu-Isenburg, Germany*

Background: The GeparNuevo trial investigated the addition of durvalumab, an anti-PD-L1 checkpoint inhibitor (CPI), to standard neoadjuvant chemotherapy (NACT) in patients with early TNBC. Durvalumab increased the pathological complete response (pCR) rate particularly in patients treated with durvalumab alone before start of chemotherapy (Loibl et al. Ann Oncol 2019). **Methods:** GeparNuevo randomized patients with cT1b-cT4a-d tumors and centrally confirmed TNBC to durvalumab (D) 1.5 g i.v. or placebo every 4 weeks. D/placebo monotherapy (0.75 g i.v.) was given for the first 2 weeks (window phase), followed by D/placebo plus nab-paclitaxel 125 mg/m^2 weekly for 12 weeks, followed by D/placebo plus epirubicin/cyclophosphamide (EC) q2 weeks for 4 cycles. Randomization was stratified by stromal tumor infiltrating lymphocytes (sTILs) (low (≤10%), intermediate (11-59%), high (≥60%)). The primary objective was pCR (ypT0 ypN0). Secondary time-to-event endpoints included invasive disease-free survival (iDFS), distant disease-free survival (DDFS) and overall survival (OS). **Results:** A total of 174 patients were enrolled between June 2016 and September 2017. The pCR rate with durvalumab was 53.4% versus placebo 44.2% (OR 1.45, 95% CI 0.80–2.63, unadjusted Wald p = 0.224). Durvalumab effect was seen only in the window cohort (pCR 61.0% versus 41.4%, OR 2.22, 95% CI 1.06–4.64, p = 0.035; interaction p = 0.048). After a median follow-up of 42.2 months, 34 events occurred in 174 patients. 3-year iDFS in pCR vs non pCR was 92.0% vs 71.9% (log-rank p = 0.002). 3-year iDFS was 84.9% with durvalumab vs 76.9% with placebo (HR 0.54, 95%CI 0.27-1.09, stratified log-rank p = 0.0559); 3-year DDFS 91.4% vs 79.5% (HR 0.37, 95%CI 0.15-0.87, p = 0.0148); 3-year OS 95.1% vs 83.1% (HR 0.26, 95%CI 0.09-0.79, p = 0.0076). No difference was seen in iDFS, DDFS and OS between the window and no window cohort. **Conclusions:** Durvalumab added to neoadjuvant chemotherapy in TNBC significantly improved long-term outcome despite a small pCR increase and no continuation after surgery. It needs to be questioned whether adjuvant therapy with CPI is needed at all. Clinical trial information: NCT02685059. Research Sponsor: GBG Forschungs GmbH, Pharmaceutical/Biotech Company.

507 **Poster Discussion Session**

Usefulness of assessment of circulating tumor DNA(ctDNA) of cerebrospinal fluid(CSF) samples for early detection of brain metastasis (BrM) in patients with triple-negative breast cancer (TNBC). *First Author: Lucrezia Raimondi, U.O.C. Territorial Oncology of Aprilia, Sapienza University of Rome, Aprilia, Italy*

Background: Despite improvements in treatments, patients diagnosed with TNBC still have poor prognosis for a higher tendency of developing BrM. Identifying patients at high risk of BrM, enabling to predict who will take advantage from appropriate additional treatment, remains a critical problem. ctDNA represents a valuable tool associated with the outcome and the aggressiveness of breast cancer but no prognostic and predictive biomarker has been identified to predict the development of BrM in TNBC. We studied the usefulness of assessment of CSF-ctDNA for early identification of the risk of BrM in TNBC. **Methods:** Between January 2016 and December 2020, 323 newly diagnosed non-metastatic TNBC patients who underwent neoadjuvant therapy+surgery(NACT) with complete response(CR)were prospectively enrolled. After surgery, samples of CSF measuring ctDNA were obtained from all patients: CSF-ctDNA was extracted with the QIAamp Circulating Nucleic Acid Kit (Qiagen, Valencia, CA, USA) and ctDNA levels were measured. Survival curves were estimated using the Kaplan-Meier method and compared with the Log-rank test. Multivariate Cox regression was used to identify the risk of mortality at three years. **Results:** After NACT, CSF-ctDNA was detectable in 126/323 (39%) patients, 101/126 (80%) were diagnosed at III stage. 124 of 126 (98.4%) ctDNA+ patients subsequently developed BrM. In contrast, only 2 (2/197, 1%) ctDNA- patients subsequently developed BrM and the 195 other patients remain in a CR ($p < 0.001$, Fisher's exact test). CSF-ctDNA did associate with PFS and OS: undetectable ctDNA was associated with superior PFS (HR 0.3; p = 0.002) and OS (HR 0.2; $p < 0.01$), indicating survival is largely determined by the onset of BrM. With a median follow-up of 3 years, median PFS of ctDNA+ vs ctDNA- patients was 13 months vs not reach, p = 0.004 (by Log-rank test). Median OS for ctDNA+ vs ctDNA- patients was 16 months after NACT vs not reach, p = 0.0016 (by Log-rank test). At multivariate analysis detectable CSF-ctDNA emerged as the best predictor of the develop of BrM and 24-month mortality (HR:3.62; $p < 0.0001$). Age, stage, Ki67% and response to chemotherapy were not significantly associated with the prognosis. **Conclusions**: After NACT, detectable CSF-ctDNA significantly associates with PFS and OS, identifying early at-risk patients to develop BrM in TNBC. Research Sponsor: None.

Evaluation of intra-tumoral (IT) SD-101 and pembrolizumab (Pb) in combination with paclitaxel (P) followed by AC in high-risk HER2-negative (HER2-) stage II/III breast cancer: Results from the I-SPY 2 trial. *First Author: Amy Jo Chien, University of California, San Francisco, San Francisco, CA*

Background: I-SPY 2 is a multicenter, phase 2 trial using response-adaptive randomization within molecular subtypes defined by receptor status and MammaPrint (MP) risk to evaluate novel agents as neoadjuvant therapy for women with high-risk breast cancer. SD-101 is an investigational Toll-like receptor 9 (TLR9) agonist CpG-C class oligodeoxynucleotide that stimulates the production of IFN-α and interleukin (IL)-12, functional maturation of plasmacytoid dendritic cells, and production of cytotoxic antibodies. IT SD-101 was combined with systemic anti-PD-1 antibody Pb to investigate the antitumor and immunologic activity of this novel immunotherapeutic strategy. **Methods:** Women with tumors $\geq$ 2.5cm were eligible for screening. Only pts (pts) with HER2- disease were eligible for this treatment. Treatment included weekly P x 12 in combination with IT SD-101 2 mg/ml (1 ml for T2 tumors, 2 ml for >T3 tumors) weekly x 4, then q3 weeks x 2, and IV Pb q3 weeks x 4, followed by doxorubicin/cyclophosphamide (AC) q2-3 weeks x 4 (SD-101+Pembro 4). Pts in the control arm received weekly P x 12 followed by AC q2-3 weeks x 4. The I-SPY 2 methods have been previously published. This investigational arm was eligible for graduation (>85% chance of success in a 300-person phase 3 neoadjuvant trial) in 3 of 10 pre-defined signatures: HER2-, hormone receptor (HR)+/HER2- and HR-/HER2-. **Results:** 75 pts were randomized and evaluable in SD-101+Pembro 4 treatment arm. The control arm included 329 historical controls enrolled since April 2010. The study arm was stopped due to maximal patient accrual. Pt characteristics were balanced; 56% HR+, 44% HR-. The probability that SD-101+Pembro4 was superior to control exceeded 97% for all eligible tumor signatures, but did not reach the threshold for graduation in any of the signatures. However, it is notable that the rate of pCR/Residual Cancer Burden 1 (RCB1) in the HR+/HER2- signature was 51%. Preliminary safety events for SD-101+Pembro 4 include increased rates of fever, neutropenia, febrile neutropenia, transaminitis, and immune-related events, including adrenal insufficiency. **Conclusions:** The SD-101+Pembro 4 regimen was active but did not meet the pre-specified threshold for graduation in I-SPY 2. pCR/RCB 1 analysis suggests improved response in the HR+/HER-negative signature compared to control. The clinical significance of these findings needs to be weighed against the potential risk of immune-related toxicities. Clinical trial information: NCT01042379. Research Sponsor: Quantum Leap Healthcare Collaborative.

Lisinopril or carvedilol in prevention of trastuzumab-induced cardiotoxicity in patients with HER2-positive early stage breast cancer: Longitudinal changes of left ventricular ejection fraction below normal levels (LVEF <50%). *First Author: Pamela N. Munster, University of California San Francisco, San Francisco, CA*

Background: Treatment of HER2-positive breast cancer patients with trastuzumab is highly effective. However, a trastuzumab-associated decline in the left ventricular ejection fraction (LVEF) and clinical heart failure often prompt interruption and discontinuation of treatment. We therefore evaluated the preventive impact of an ACE inhibitor or beta blockers on the left ventricular ejection fraction (LVEF) during treatment of trastuzumab and chemotherapy. **Methods:** In a prospective randomized study, women with early stage HER2 positive breast cancer undergoing (neo)adjuvant chemotherapy with trastuzumab were randomized to receive either once daily lisinopril (10mg), carvedilol (10mg) or placebo during treatment with trastuzumab and further stratified by anthracycline use (AC+T versus nonAC+T). In a follow up to the initially presented primary endpoint of overall cardiotoxicity, we measured the protective effects of lisinopril or carvedilol to prevent a trastuzumab induced LVEF decrease to less than 50% over the course of therapy as well as the impact on LVEF decrease by >10% within normal LVEF levels. **Results:** A total of 468 women (mean age was 51±10.7 years) with HER2 overexpressing early-stage breast cancer from 127 community-based oncology practices were enrolled, a prespecified minimum target of 189 (40%) patients were treated with AC+T and 279 (60%) with nonAC+T. Baseline cardiac risk factors of this study population included obesity and an elevated blood pressure. Patients in the anthracycline group were younger and without hypertension. A small, not clinically relevant decrease in LVEF was observed during trastuzumab therapy in all patients which was not significantly altered by any of the cardiac interventions. The rate of LVEF decline to <50% was much more frequent in patients treated with an anthracycline than those with a non-anthracycline containing regimen (21% vs 4.1%). Treatment with lisinopril averted the decline in LVEF in the AC+T group compared to placebo (10.8% vs 30.5%, p=0.045). A smaller but not significant effect was seen by carvedilol. The incidence of cardiotoxicity manifesting as LVEF decrease by $\geq$10% within the normal range was similar in both AC+T and the nonAC+T arms, and not affected by either lisinopril or carvedilol. **Conclusions:** In patients treated with trastuzumab without anthracyclines, the impact of trastuzumab on LVEF is small and infrequent. In contrast, patients treated with anthracyclines prior to trastuzumab, demonstrated a decrease in LVEF to below normal levels in a larger than previously reported number of women in this community based setting. The trastuzumab-anthracycline induced decline in LVEF could be prevented with concurrent treatment with lisinopril, which was tolerable even in patients without hypertension. Clinical trial information: NCT01009918. Research Sponsor: U.S. National Institutes of Health.

510 **Poster Discussion Session**

Cardiac safety of dual anti-HER2 blockade with pertuzumab plus trastuzumab (P+T) in the APHINITY trial. *First Author: Evandro de Azambuja, Institut Jules Bordet and Université Libre de Bruxelles (U.L.B), Brussels, Belgium*

Background: Trastuzumab (T) increases the incidence of cardiac events (CEs) in patients (pts) with early breast cancer (BC). Dual blockade with P+T improves BC outcomes and is the standard of care for high-risk HER2-positive BC pts following the phase 3 APHINITY trial that evaluated the addition of P or placebo (Pla) to T and chemotherapy (CT). We analyzed the cardiac safety of P+T in APHINITY. **Methods:** APHINITY eligibility required a left ventricular ejection fraction (LVEF) $\geq$55% at study entry. LVEF assessment was performed every 3 months (mos) during treatment, every 6 mos up to month 36, and yearly thereafter. Primary CE was defined as heart failure (HF) class III/IV and a significant decrease in LVEF of at least 10 percentage points from baseline and to <50%, or cardiac death. Secondary CE was defined as a confirmed significant decrease in LVEF or CEs confirmed by the cardiac advisory board. **Results:** The safety analysis population consists of 4,769 pts. With 74 mos median follow-up (FU), CEs were observed in 159 pts (3.3%): 83 (3.5%) in the P+T and 76 (3.2%) in Pla+T arms, respectively. Most CEs occurred during anti-HER2 therapy: 123/159 (77.4%) and were asymptomatic or mildly symptomatic LVEF decrease (133/159; 83.6%) (Table 1). There were 2 cardiac deaths in each arm (0.1%). More CEs occurred in pts receiving an anthracycline-based CT compared to those receiving non-anthracycline CT (139 vs. 20 CEs, respectively). Acute recovery from a CE based on subsequent LVEF values was observed in 127/155 pts (81.9%). **Conclusions:** Dual blockade with P+T does not increase the risk of CE compared to Pla+T alone. The use of anthracycline-based CT increases the risk of a CE; hence non-anthracycline CT may be considered particularly in pts with other cardiovascular risk factors. Clinical trial information: NCT01358877. Research Sponsor: Roche/Genentech.

Discovery and validation of a genomic signature to identify women with early-stage invasive breast cancer who may safely omit adjuvant radiotherapy after breast-conserving surgery. *First Author: Martin Sjöström, University of California, San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Adjuvant radiotherapy (RT) is currently the standard of care for women with early-stage invasive breast cancer (BC) treated with breast conserving surgery (BCS). However, some women may have very low risk of recurrence and could safely be spared RT. This study aimed to identify these women using a molecularly-based approach. **Methods:** We performed an analysis of the SweBCG91-RT cohort, a trial randomizing women with node-negative stage I-II invasive BC +/- RT following breast conserving surgery, with sparse use of adjuvant systemic therapy. Only patients with ER+, HER2- tumors, and not treated with adjuvant systemic therapy, were included in this analysis. Transcriptome-wide profiling of tumors was performed using the Affymetrix Human Exon 1.0 ST microarray. The SweBCG91-RT cohort was divided into a training cohort of 243 patients and a validation cohort of 354 patients. Biological gene sets and individual genes related to locoregional recurrence in patients not receiving RT of the training set were identified, and a 16-gene signature was trained using elastic net regression. The signature, named Profile for the Omission of Local Adjuvant Radiation (POLAR), was locked prior to validation. **Results:** In the validation cohort, POLAR was prognostic for locoregional recurrence (LRR) in patients not treated with RT (multivariable Cox model adjusting for age, grade, tumor size, and luminal A vs luminal B: HR = 1.7 [1.2,2.3], p < 0.001). Patients categorized as POLAR low-risk had a 10-year locoregional recurrence rate of 7% in the absence of RT. Notably, there was no significant benefit from RT for these POLAR low-risk patients (HR = 1.1 [0.38,3.3], p = 0.83), whereas patients categorized as POLAR high-risk had a significant decreased risk of locoregional recurrence when treated with RT (recurrence rate without RT at 10-years 19%, HR = 0.43 [0.24,0.78], p = 0.0053). **Conclusions:** These data suggest that the novel POLAR genomic signature based on LRR biology can not only identify patients who have a low risk of LRR without adjuvant RT after BCS but who also would not benefit from RT, thus being prime candidates for RT omission. A novel biosignature identifies DCIS patients with a poor biologic subtype with an unacceptably high rate of local recurrence after breast conserving surgery and radiotherapy. *First Author: Frank Vicini, NRG Oncology, and 21st Century Oncology, Pontiac, MI*

Background: There is an unmet need to identify women diagnosed with DCIS who have a low recurrence risk and could omit radiotherapy (RT) after breast conserving surgery (BCS), or an elevated recurrence risk after treatment with BCS plus RT. DCISionRT and its response subtype (Rst) biosignature were evaluated in a contemporary cohort treated with BCS with or without RT to identify these risk groups. **Methods:** Pathology, clinical data, and FFPE tissue samples were evaluable for 485 women diagnosed with DCIS at centers in Sweden (1996-2004), the USA (1999-2008), and Australia (2006-2011). Patients were treated with BCS (negative margins) with or without whole breast RT. Ipsilateral breast tumor recurrence (IBTR) included DCIS or invasive breast cancer (IBC) that was local, regional, or metastatic. The patients were classified into Low and Elevated risk groups to assess IBTR and IBC rates. Patients in the Elevated risk group were categorized by two subtypes: a good response subtype (good Rst) or a poor response subtype (poor Rst) after BCS plus RT. Biosignatures were calculated using biomarkers (p16/INK4A, Ki-67, COX-2, PgR, HER2, FOXA1, SIAH2) assayed using IHC on FFPE tissue. Hazard ratios and 10-year risks were calculated using Cox proportional hazards (CPH) and Kaplan-Meier analyses. **Results:** In the DCISionRT Elevated risk group, RT was associated with significantly reduced recurrence rates, but only for those patients with a good Rst (Table, IBTR HR=0.18, p<0.001, IBC HR=0.15, p=0.003, n=241). For Elevated risk group patients with a poor Rst, no benefit to RT was noted (Table). Additionally, irrespective of RT, patients with a poor Rst had 10-year IBTR/IBC rates of 25%/16%, which were much higher than good Rst rates of 6.6%/4.5% (IBE HR=3.6, p=0.02, IBC HR=4.4, p=0.04, n=190). For patients in the Low risk group, there was no significant difference in 10-year IBTR/IBC rates with and without RT (Table, IBTR p=0.4, IBC p=0.9, n=177). The distribution of clinicopathologic risk factors (age <50 years, grade 3, size >2.5 cm) did not identify poor vs. good response subtypes, and multivariable analysis (n=485) indicated these traditional clinicopathologic factors and endocrine therapy were not significantly associated with IBTR (p≥0.22) or IBC (p≥0.34). **Conclusions:** Biosignatures identified a Low risk patient group with low 10-year recurrence rates with or without RT who may be candidates for omitting adjuvant RT. Biosignatures also identified an Elevated risk group receiving BCS plus RT with a poor response subtype that had unacceptably high recurrence rates, warranting potential intensified or alternate therapy. Long-term results of simplified lymphatic microsurgical preventing healing approach (SLYMPHA) for the prevention of breast cancer-related clinical lymphedema after axillary lymph node dissection. *First Author: Tolga Ozmen, University of Miami, Miller School of Medicine, Division of Surgical Oncology, Miami, FL*

Background: Lymphedema (LE) is a serious complication of axillary lymph node dissection (ALND) with an incidence rate of 16%. SLYMPHA is a safe and relatively simple method, which decreases incidence of LE dramatically. Our initial study showed an 88% decrease in clinical LE rate after a median follow up of 15 months. The aim of this study was to confirm these results after a longer follow up period. **Methods:** All patients, undergoing ALND between January 2014 and November 2020 were included in the study. During follow-up visits, tape-measuring limb circumference method was used to detect clinical LE. The incidence of clinical LE was compared between patients with and without SLYMPHA. Univariate and multivariate analysis were used to assess the role of other factors in the appearance of clinical LE. **Results:** 580 patients were included in the study. 35% of cohort underwent SLYMPHA. Mean follow-up time was 44 ±31.9 months. Patients, who underwent SLYMPHA, had a significantly lower LE rate (10% vs 26%; p=0.002; OR 0.4 [0.31-0.77]). Diabetes and removing ^{3}22 lymph nodes also correlated with increased LE however this effect disappeared on multivariate analysis. **Conclusions:** SLYMPHA is a safe and relatively simple method, which continued its efficacy after 4-years follow up. It should be considered as an adjunct procedure to ALND for all patients during initial surgery. Research Sponsor: None.

Outcome of breast cancer patients treated with chemotherapy during pregnancy compared with non-pregnant controls. *First Author: Frederic Amant, University Hospitals Leuven, Leuven, Belgium*

Background: Overall a diagnosis of breast cancer during pregnancy (BCP) appears not to impact maternal prognosis if standard treatment is offered. However, caution is warranted as gestational changes in pharmacokinetics with respect to the distribution, metabolism and excretion of drugs may lead to reduced chemotherapy concentration in pregnant patients. This cohort study was designed to focus on the maternal prognosis of BCP patients that receive chemotherapy during pregnancy. **Methods:** The outcome of BCP patients treated with chemotherapy during pregnancy was compared to non-pregnant breast cancer patients treated with chemotherapy, diagnosed after 2000, excluding postpartum diagnosis and with an age limit of 45 years. The data was registered by two multicentric registries (the International Network of Cancer, Infertility and Pregnancy and the German Breast Cancer Group) that collect both retro-and prospectively breast cancer data. Cox proportional hazards regression was used to compare disease-free (DFS) and overall survival (OS) between both groups, adjusting for age, stage, grade, hormone receptor status, human epidermal growth factor 2 status and histology, weighted by propensity scoring in order to account for the differences in baseline characteristics between pregnant patients and controls. **Results:** In total, 662 pregnant and 2081 non-pregnant patients, were eligible for analysis. Median age at diagnosis was 34 (range 22-47) years for pregnant and 38 (range 19-45) years for non-pregnant patients. Pregnant patients were more likely to have stage II breast cancer (60.1% vs 56.1%, p = 0.035), grade 3 tumors (74.0% vs 62.2%, p < 0.001), hormone receptor-negative tumors (48.4% vs 34.0%, p < 0.001) or triple-negative breast cancer (38.9% vs 26.9%, p < 0.001). Median follow-up was 66 months. DFS and OS were comparable for pregnant and non-pregnant patients (DFS: HR 1.02, 95%CI 0.82-1.27, p = 0.83; OS: HR 1.08, 95% CI 0.81-1.45, p = 0.59). A subgroup analysis of 339 women that received more than 60% of chemotherapy during pregnancy (cut-off at median) revealed a comparable survival compared to non-pregnant women (DFS: HR 0.81, 95%CI 0.62-1.06, p = 0.13; OS: HR 0.85 95% CI 0.58-1.23, p = 0.39). **Conclusions:** Pregnancy-induced alternations in chemotherapy concentration do not seem to affect maternal prognosis in breast cancer patients. These results support initiation of chemotherapy for BCP where indicated for oncological reasons. Research Sponsor: European Research Council, Research foundation Flanders, Kom op tegen kanker.

516 **Poster Discussion Session**

Final analysis of the PROMISE-GIM6 phase III trial assessing GnRH agonist use during chemotherapy as a strategy to preserve ovarian function in premenopausal patients with early breast cancer. *First Author: Matteo Lambertini, U.O. Clinica di Oncologia Medica, IRCCS Ospedale Policlinico San Martino, Department of Internal Medicine and Medical Specialties (DiMI), University of Genova, Genoa, Italy*

Background: Current guidelines recommend GnRH agonist (GnRHa) use during chemotherapy (CT) as a strategy to reduce the risk of premature ovarian insufficiency (POI) in premenopausal patients with early breast cancer (EBC). However, no long-term safety data are available raising some concerns on concurrent use of GnRHa during CT in patients with hormone receptor-positive disease. In addition, there is no evidence on the protective role of this strategy in patients with germline *BRCA* mutations (*mBRCA*). Here, we report the final analysis of the PROMISE-GIM6 phase III randomized study, the largest trial addressing the role of GnRHa use during CT in premenopausal EBC patients (Del Mastro et al, JAMA 2011 & Lambertini et al, JAMA 2015). **Methods:** From October 2003 to January 2008, 281 premenopausal patients aged 18 to 45 years with stage I-III EBC candidates for (neo)-adjuvant CT were randomized to receive CT alone or combined with the GnRHa triptorelin. Primary endpoint was incidence of CT-induced POI (defined as amenorrhea and post-menopausal FSH/estradiol levels 1 year following CT). This final analysis reports on post-treatment pregnancies, disease-free survival (DFS) and overall survival (OS). An exploratory descriptive analysis in *mBRCA* patients is also reported. (ClinicalTrial.gov: NCT00311636) **Results:** Of the 281 randomized patients (CT+GnRHa arm = 148; CT alone arm = 133), 80% had hormone receptor-positive disease. At the time of this final analysis, 38 (13.5%) patients were lost to follow-up. Median follow-up was 12.4 years (IQR: 11.3-13.2 years). In the CT+GnRHa and CT alone arms, respectively, 9 (10-year cumulative incidence of pregnancy 6.5%, 95% CI 3.5%-12.3%) and 4 (10-year cumulative incidence of pregnancy 3.2%, 95% CI 1.2%-8.3%) patients had a post-treatment pregnancy (HR 2.14, 95% CI 0.66-6.92). No differences in 10-year DFS (72.4% in CT+GnRHa arm vs. 71.2% in CT alone arm: HR 1.16, 95% CI 0.76-1.77) nor in 10-year OS (82.0% in CT+GnRHa arm vs. 85.9% in CT alone arm: HR 1.17, 95% CI 0.67-2.03) were observed. There was no interaction between treatment effect and hormone receptor status. In patients with hormone receptor-positive disease, HR was 1.02 (95% CI 0.63-1.63) for DFS and 1.12 (95% CI 0.59-2.11) for OS. Out of 43 patients tested for *BRCA*, overall incidence of POI, irrespective of treatment arm, was 20% in *mBRCA* patients (n = 10) and 12% in patients without *mBRCA* (n = 33). In *mBRCA* patients, incidence of POI was 0% and 33% in the CT+GnRHa and CT alone arms, respectively. One post-treatment pregnancy was described in a patient with *mBRCA1* in the CT alone arm. **Conclusions:** The final analysis of the PROMISE-GIM6 trial at a median follow-up of 12.4 years provides reassuring evidence on the safety of GnRHa use during CT as a strategy to preserve ovarian function in premenopausal patients with hormone receptor-positive EBC. Clinical trial information: NCT00311636. Research Sponsor: AIRC - Italian Association for Cancer Research.

Abemaciclib combined with adjuvant endocrine therapy in patients with high risk early breast cancer who received neoadjuvant chemotherapy (NAC). *First Author: Miguel Martin, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: monarchE, a phase 3, open-label, randomized study evaluating abemaciclib combined with adjuvant endocrine therapy (ET) compared to ET alone in patients with HR+, HER2-, high risk early breast cancer (EBC), resulted in a statistically significant improvement in invasive disease-free survival (IDFS) (HR = 0.713; 95% CI: 0.583, 0.871). NAC is used in patients with HR+, HER2- EBC at higher risk of recurrence despite often limited response, suggesting a need for enhanced adjuvant ET. **Methods:** Patients with ≥4 positive notes (LNS), or 1-3 LNS and either Grade 3 disease, tumor size ≥5 cm, or central Ki-67 ≥20% were eligible. Prior chemotherapy (NAC, adjuvant, none) was one of the stratifications factors. Prior therapy and tumor characteristics prior to study entry were collected. Here, we present the results of the prespecified subgroup of patients who received NAC. **Results:** Out of 5,637 randomized patients, 2056 (36.5%) received NAC. For 84.8%, the chosen regimen included anthracycline + cyclophosphamide + taxane, for 4.4%, it included anthracycline + taxane. A total of 1044 (50.8%) patients who received NAC had a radiologic tumor size between 2-5 cm and 599 (29.1%) had tumors ≥5 cm at diagnosis. 6.2%, 49.4% and 36.7% of patients had tumors with histologic Grade 1, 2, 3 respectively. 55.2% of patients had LNS ≥4+ and 44.4% had 1-3+ LNS. Central Ki-67 prior to NAC was ≥20% in 64.8% of patients with available Ki-67 results (664 (32.3%) patients had missing Ki-67 results). Evaluation of clinical and pathological measures of response will be presented. A multivariate cox regression analysis of IDFS in the intent-to-treat (ITT) population, identified prior chemotherapy as prognostic, suggesting patients who received NAC were at risk of a worse outcome. Primary outcome efficacy data for patients who received NAC are shown in the table below. Abemaciclib + ET demonstrated treatment benefit in terms of IDFS vs ET alone (HR: 0.614 95% CI: 0.473, 0.797) with 2-year IDFS rates of 87.2% vs 80.6%, respectively. The addition of abemaciclib to ET resulted in an improvement in distant relapse-free survival (DRFS) (HR: 0.609, 95% CI: 0.459, 0.809), with 2-year DRFS rates of 89.5% and 82.8%, respectively. Safety profile was similar to the overall safety population. **Conclusions:** Patients with HR+, HER2- EBC who received NAC were noted to be at a higher risk of recurrence. In this subgroup, abemaciclib combined with ET demonstrated a clinically meaningful treatment benefit in IDFS and DRFS, which was numerically greater than in the ITT population. Safety data were consistent with abemaciclib safety profile. Clinical trial information: NCT03155997. Research Sponsor: Eli Lilly and Company.

518 **Poster Discussion Session**

Palbociclib combined with endocrine treatment in breast cancer patients with high relapse risk after neoadjuvant chemotherapy: Subgroup analyses of premenopausal patients in PENELOPE-B. *First Author: Frederik Marmé, Medical Faculty Mannheim, Heidelberg University, University Hospital Mannheim, Mannheim, Germany*

Background: PENELOPE-B assessed efficacy of the CDK4/6 inhibitor 1-year palbociclib versus placebo added to endocrine therapy (ET) as post-neoadjuvant treatment in a high-risk breast cancer population. Palbociclib did not improve invasive disease-free survival (iDFS) compared to placebo (3-year iDFS 81.3% vs 77.7%) (Loibl et al. J Clin Oncol 2021). Here we report results from the subpopulation of premenopausal women. **Methods:** Patients with hormone receptor positive, HER2-negative breast cancer without pathological complete response after taxane-containing neoadjuvant chemotherapy and at high risk of relapse (CPS-EG score ≥3 or 2 and ypN+) were randomized (1:1) to receive 13 cycles of palbociclib 125mg daily or placebo on days 1-21 in a 28d cycle in addition to standard endocrine treatment including tamoxifen (TAM) +/- gonadotropin-releasing hormone analogue (GnRH) and aromatase inhibitor (AI) +/- GnRH. Randomization was stratified by nodal status at surgery, age (< 50 vs ≥50 years), Ki-67, region, and CPS-EG score. **Results:** 616/1250 patients were premenopausal at the time of enrollment, 185 of these patients (30.0%) were younger than 40 years of age. 95.2% had ypN+ after surgery; 42.8% had ypT2 and 46.8% a CPS-EG score of 3. 23.1% of the premenopausal women had a Ki67 of > 15% in residual disease. 66.1% started with TAM alone; 19.3% with TAM and ovarian function suppression (OFS); and 13.6% received an AI+OFS. There was no difference in iDFS between palbociclib and placebo in the premenopausal women HR 0.948 (0.693-1.30). The 3-year iDFS was 80.6% and 78.3%, respectively. Palbociclib vs placebo in subgroups by endocrine treatment: TAM alone HR 1.05 (0.715-1.53) p = 0.817; TAM+GnRH HR 0.52 (0.267-1.02) p = 0.057 and AI+GnRH HR 1.58 (0.548-4.56) p = 0.397; $p_{interaction}$0.124. Hematologic toxicity was significantly more common with palbociclib. Non-hematological toxicity any grade palbociclib vs placebo were: fatigue 67.4% vs 51.3%; hot flushes 52.2% vs 54.8%; bone pain 15.6% vs 16.6%; and vaginal dryness 11.0% vs 11.5%. When receiving palbociclib fewer patients in the AI+GnRH group vs the TAM +/- GnRH cohort experienced anemia (54.1% vs 80.5%) and thrombocytopenia (37.8% vs 65.1%). Fatigue (75.7% vs 66.3%) and nausea (40.5% vs 24.9%) were more common with AI+GnRH than TAM +/-GnRH when palbociclib was added. Thromboembolic events were low with overall 9 events (4 vs 5; AI+GnRH 2.4% vs 1.3% TAM+/-GnRH). **Conclusions:** The addition of palbociclib to endocrine therapy did not improve iDFS in premenopausal women. These are the first safety results from a phase III study for the combination tamoxifen +/-GnRH and palbociclib. The addition of palbociclib to tamoxifen +/-GnRH in premenopausal women did not increase side effects compared to AI+GnRH and seems to be an alternative to AI+GnRH. Clinical trial information: NCT01864746. Research Sponsor: Pfizer.

519 **Poster Discussion Session**

Subgroup of post-neoadjuvant luminal-B tumors assessed by HTG in PENELOPE-B investigating palbociclib in high risk HER2-/HR+ breast cancer with residual disease. *First Author: Carsten Denkert, Institute of Pathology, Philipps-University Marburg and University Hospital Marburg, Marburg, Germany*

Background: About one third of patients with hormone-receptor-positive (HR+), HER2-primary breast cancer with residual invasive disease after neoadjuvant chemotherapy will relapse despite adjuvant endocrine therapy. Therapeutic inhibition of cyclin-dependent kinase 4 and 6 (CDK 4/6) by palbociclib combined with endocrine therapy demonstrated highly relevant efficacy in metastatic breast cancer. The phase III PENELOPE-B (NCT01864746) study did not show a significant benefit from palbociclib in women with centrally confirmed HR+, HER2- primary breast cancer without a pathological complete response after taxane-containing neoadjuvant chemotherapy and at high-risk of relapse (CPS-EG score ≥3 or 2 and ypN+) for the primary endpoint (Loibl et al. JCO 2021). **Methods:** After completion of neoadjuvant chemotherapy and locoregional therapy, PENELOPE-B patients were randomized (1:1) to receive 13 cycles (1 year) of palbociclib 125mg daily or placebo on days 1-21 in a 28d cycle in addition to standard endocrine therapy. Analysis of the primary endpoint of invasive disease-free survival (iDFS) was planned after 290 events. Secondary objective included iDFS in luminal-B group by treatment. Gene expression in post-neoadjuvant surgical residual tumor tissue samples was profiled using the HTG EdgeSeq Oncology Biomarker Panel targeting 2559 genes (HTG Molecular Diagnostics Inc.). Based on 91 genes of this panel the AIMS subtype (Paquet & Hallett, JNCI 2014) was calculated. **Results:** Gene expressions were measured in tumors from 906 of 1250 (72%) PENELOPE-B patients; 663 had LumA subtype, 64 LumB, 135 NormL, 16 BasalL, and 28 HER2E. Compared to LumA the LumB patients were older, had higher post-neoadjuvant Ki-67, higher risk status (CPS-EG), and higher grade; no significant correlation was found for the region of participating sites, cT, ypT, and ypN. Patients with LumB tumors had an estimated 3-year iDFS of 71.9% with palbociclib vs 44.8% with placebo HR = 0.50 (0.24-1.05); outcome was similar in patients with LumA tumors (3-year iDFS 83.9% vs 79.5%, HR = 0.93 (0.68-1.28), interaction p = 0.132); this was confirmed in multivariable analyses. Ki-67 by IHC and proliferation biomarkers from the HTG panel also showed no significant interaction with treatment. **Conclusions:** PENELOPE-B did not show a benefit from the addition of 1 year palbociclib to endocrine therapy compared to placebo in the total enrolled high-risk primary breast cancer population. However, the small group of luminal-B tumors (n = 64) derived benefit from palbociclib, although without a statistically significant interaction. Further investigation is required in a larger cohort to validate a palbociclib benefit that might be confined to this group. Research Sponsor: Pfizer.

Inflammatory cytokines and distant recurrence in HER2-negative early breast cancer in the ECOG-ACRIN 5103 trial. *First Author: Joseph A. Sparano, Montefiore Medical Center/Albert Einstein College of Medicine/ Albert Einstein Cancer Center, Bronx, NY*

Background: Systemic inflammation may contribute to cancer progression (PMC2803035), including recurrence of early breast cancer (PMC4828958). We hypothesized that inflammatory cytokines and/or chemokines may be associated with distant recurrence (DR). **Methods:** We performed a case:control study in women with stage II-III Her2-negative breast cancer, all of whom had surgery and adjuvant chemotherapy (doxorubicin/cyclophosphamide, then weekly paclitaxel) with/without bevacizumab, plus endocrine therapy if ER-positive (PMC6118403). Propensity score matching was used to identify approximately 250 case:control pairs (with/without DR). Serum samples obtained before adjuvant chemotherapy were analyzed using the MSD V-Plex Human Cytokine 36-Plex Kit for detection of human cytokines and chemokines involved in the Th1/Th2 pathway, chemotaxis, the Th17 pathway, angiogenesis, and immune system regulation. Conditional logistic regression analysis, with models fit via maximum likelihood, were used to estimate hazard ratios (HRs) and test for associations. Due to skewed nature of cytokines, HRs are reported on log base 2 scale. If adjusted for multiple testing including 36 markers, a p value of < 0.0014 would be required for statistical significance. **Results:** A total 249 matched pairs (498 patients) were identified. Covariates used for propensity score matching included age, menopausal status (post 54% vs. pre/peri 46%), ER/PR status (one/both pos 64% vs. both neg 36%) tumor size (< = 2cm 17%, > 2-5cm 67%, > 5cm 16%) nodal status (neg 15%,1-3+ 32%, 4+ 53%), and grade (low 3%, int. 31%, high 66%). The only biomarker associated with a significantly increased DR risk when adjusted for multiple testing was the proinflammatory cytokine IL-6 (HR 1.37, 95% confidence intervals [CI] 1.15, 1.65, p = 0.0006). Others associated with a 2-sided p value < 0.05 included the chemokine MDC(macrophage-derived chemokine/CCL22) (1.90, 95% CI 1.17, 3.1, p = 0.0098), the T helper cell inflammatory cytokine IL-17A (HR 1.36, 95% CI 1.10, 1.67, p = 0.0052), and the cytokine VEGF-A (HR 1.13 for, 95% CI 1.01, 1.27, p = 0.037). There was no statistical interaction between VEGF-A and bevacizumab benefit. The median and mean value for IL-6 was 0.95 and 7.5 pg/ml (range 0.04-2761.24 pg/ml). **Conclusions:** This analysis provides level 1B evidence indicating that higher levels of the cytokine IL-6 at diagnosis are associated with a significantly higher DR risk in high-risk stage II-III breast cancer despite optimal adjuvant systemic therapy. This provides a foundation for confirmatory validation of IL-6 as a prognostic biomarker, and potentially as a predictive biomarker for testing therapeutic interventions targeting the IL-6/JAK/STAT3 pathway. Supported by NCI U10CA180820,180794,180821; UG1CA189859,232760,233290, 233196; Komen Foundation; Breast Cancer Research Foundation. Clinical trial information: NCT00433511. Predict the benefit of metronomic capecitabine maintenance in early-stage triple-negative breast cancer: Results from the SYSUCC-001 study. *First Author: Zhongyu Yuan, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Recent clinical trials and meta-analysis have suggested the benefit of adding capecitabine to standard chemotherapy in early-stage triple negative breast cancer (TNBC). We aimed to develop an individualized prediction model to quantify the clinical benefit of metronomic capecitabine maintenance in TNBC. **Methods:** Patients from the SYSUCC-001 trial, randomized to standard treatment with or without metronomic capecitabine maintenance, were pooled. Candidate covariates included age, tumor size, lymph node, histological grade, Ki-67 percentage, lymphovascular invasion, chemotherapy regimen and capecitabine medication. The primary endpoint was disease-free survival (DFS). The nonlinear effect of continuous covariate was modelled by restricted cubic spline. We developed a survival prediction model using the Cox proportional hazards model. **Results:** A total of 434 patients were recruited (306 in development cohort and 128 in validation cohort). The estimated 5-year DFS in the development cohort and validation cohort were 77.8% (95% CI, 72.9-82.7%) and 78.2% (95% CI, 70.9-85.5%), respectively. Age and lymph node had significant nonlinear effects on DFS. Four covariates significantly associated with DFS in the final prediction model were age, lymph node, lymphovascular invasion and capecitabine medication. The model demonstrated suitable calibration and fair discrimination ability with a C-index of 0.722 (95% CI, 0.662-0.781) and 0.764 (95% CI, 0.668-0.859) in the development cohort and validation cohort, respectively. We design an easy-to-use online calculator based on the model, capable of predicting capecitabine maintenance benefit. **Conclusions:** The evidence-based prediction model could identify those patients who most warrant metronomic capecitabine maintenance and thus help treatment decision making in daily clinical practice. Clinical trial information: NCT01112826. Research Sponsor: None.

Efficacy and safety analysis of Chinese patients in monarchE: Abemaciclib combined with adjuvant endocrine therapy for high risk HR+, HER2- early breast cancer. *First Author: Zhimin Shao, Department of Breast Surgery, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: In monarchE, abemaciclib (oral CDK4&6 inhibitor) plus endocrine therapy (ET) as adjuvant treatment for HR+, HER2- high risk early breast cancer (EBC), demonstrated a statistically significant improvement in invasive disease-free survival (IDFS) compared to ET alone. Here we present the efficacy and safety analysis of Chinese patients from monarchE. **Methods:** The overall study design was reported previously. Eligible patients were randomized to receive abemaciclib (150 mg BID for 2 years) combined with standard adjuvant ET or ET alone. The primary endpoint was IDFS per STEEP criteria. Secondary endpoints included distant relapse-free survival (DRFS), overall survival, and safety. Exploratory subgroup analyses were conducted among Chinese patients enrolled from Mainland China, Hong Kong, and Taiwan in the intent-to-treat (ITT) population. **Results:** A total of 501 Chinese patients were randomized to receive abemaciclib plus ET (259 patients) or ET alone (242 patients). At the time of data cutoff (July 8, 2020), 356 (71.1%) patients were still in the 2-year treatment period. A total of 26 IDFS events were observed (11 and 15 events in abemaciclib plus ET and ET arm, respectively). Comparing to ET alone, abemaciclib combined with ET reduced the risk of developing invasive disease or death by 34.3% (HR: 0.657, 95% CI: 0.301, 1.435) for Chinese patients, together with a clinically meaningful improvement in the 2-year IDFS rate (95.6% vs 92.1%). The addition of abemaciclib to ET also resulted in an improvement in DRFS (HR: 0.601, 95% CI: 0.245, 1.477) for Chinese patients, with the 2-year DRFS rate at 96.7% (ET alone: 93.4%). In the abemaciclib arm, the most frequent treatment-emergent adverse events (TEAEs) and grade ≥3 TEAEs: diarrhea (90.3% and 5.0%), leukopenia (76.8% and 21.2%), and neutropenia (76.4% and 23.9%), respectively. **Conclusions:** Abemaciclib combined with adjuvant ET demonstrated clinically meaningful IDFS and DRFS benefits among Chinese patients with HR+, HER2-, high risk EBC, which was consistent with the ITT population as reported previously. The safety profile of abemaciclib in Chinese EBC patients was consistent with global population and also with that observed in Chinese metastatic breast cancer patients. Clinical trial information: NCT03155997. Research Sponsor: Eli Lilly and Company.

Association of statin use with clinical outcomes in patients with triple-negative breast cancer. *First Author: Malgorzata Nowakowska, Baylor College of Medicine, Houston, TX*

Background: Statins have been shown to target pathways related to breast cancer carcinogenesis, specifically in more aggressive breast cancer subtypes such as triple negative breast cancer (TNBC). Given the limited toxicity profile, low cost, and ease of use of statins, an association between statin therapy and improved breast cancer outcomes, particularly in aggressive breast cancers with more limited treatment options, could have important public health implications. Here we examine the association of statin therapy with breast cancer outcomes in women with stage I-III breast cancer, specifically TNBC. **Methods**: We utilized Surveillance, Epidemiology, and End Results (SEER)-Medicare and Texas Cancer Registry (TCR)-Medicare data. We included women age 66 years or older with histologically confirmed stage I-III breast cancer diagnosed from 2008-2015. We used multivariable Cox proportional hazards regression models to examine the association of statin use with overall survival (OS) and breast cancer specific survival (BCSS) adjusting for age, race, education, state buy-in, residence area, stage, subtype, endocrine therapy, radiation, chemotherapy, surgery, baseline statin use, comorbidity, and baseline hypertension. For BCSS, we accounted for the competing risk of death using the Fine and Grey method. We required all individuals to survive until 12 months post-diagnosis, which we defined as the start of the follow-up period, to account for immortal time bias. **Results**: We identified 45,063 patients with stage I-III breast cancer meeting inclusion criteria, out of which 22,518 (50.0%) received a statin within one year following diagnosis (statin-users). The 5-year cumulative estimates of breast cancer specific deaths were 5.9% and 6.9% for statin-users and non-users ($P < .001$), respectively. In the overall cohort, adjusted models showed a statistically significant association between statin use and improved BCSS (subdistribution hazard ratio [SHR], 0.82; 95% CI, 0.70 to 0.97; $P = .021$), but no association with OS (hazard ratio [HR], 0.96; 95% CI, 0.90 to 1.03; $P = .23$). The association was strongest in patients with TNBC for BCSS (SHR, 0.60; 95% CI, 0.42 to 0.86; $P = .006$) and OS (HR, 0.76; 95% CI, 0.61 to 0.95; $P = .018$). Stratification by stage showed that the effect of statin therapy in TNBC was limited to patients with localized disease. Our results were consistent using propensity score matched models and when limiting our analysis to statin therapy initiated following breast cancer diagnosis. **Conclusions:** Among women with non-metastatic breast cancer, we found that statin use was associated with an OS and BCSS benefit among women with TNBC. Our data suggest that statins may have a role as an adjuvant therapy in select patients with breast cancer and supports further investigation, particularly among patients with TNBC, for whom effective treatment options are more limited. The prognostic performance of PREDICT+ in patients (pts) with HER2-positive (HER2+) early-stage breast cancer (EBC). *First Author: Elisa Agostinetto, Institut Jules Bordet and Université Libre de Bruxelles (U.L.B), Brussels, Belgium*

Background: PREDICT+ is a widely used, free, online tool based on traditional clinico-pathological features, including HER2, developed to predict individual mortality of EBC pts and to aid clinical decision making for adjuvant therapy. However, its prognostic role in HER2+ EBC pts treated with chemotherapy (CT) and anti-HER2 therapies remains unclear. We aimed to investigate the prognostic performance of PREDICT+ in HER2+ EBC pts enrolled in the ALTTO trial. **Methods:** ALTTO is a phase III study evaluating adjuvant lapatinib (L) +/- trastuzumab (T) vs. T alone in pts with HER2+ EBC. Pts enrolled in the ALTTO trial and receiving T-based therapy started concurrently with CT were eligible for this analysis. We calculated PREDICT+ estimates using variables extracted from ALTTO database, blinded to pts outcomes. The prognostic performance of PREDICT+ was evaluated by assessing its calibration and discriminatory accuracy. For calibration, median predicted 5-year (5-yr) overall survival (OS) was compared to observed 5-yr OS. For discriminatory accuracy, the area under the receiver-operator characteristic (AUC under the ROC) curve and corresponding 95% confidence intervals (CI) for predicted 5-yr OS were calculated. Subgroup analyses were performed according to type of anti-HER2 therapy, type of CT, age, hormone receptor (HR) status, nodal status and tumor size. **Results:** This analysis included 2,794 pts. After a median follow-up of 6.0 years (IQR, 5.8-6.7), 182 deaths were observed. Overall, PREDICT+ underestimated 5-yr OS by 6.7% (95% CI, 5.8-7.6): observed 5-year OS was 94.7% vs. predicted 88.0%. The underestimation was consistent across all subgroups (Table). For discriminatory accuracy, AUC under the ROC curve was 73.7% (95%CI 69.7-77.8) in the overall population, ranging between 61.7% and 77.7% across the analysed subgroups. **Conclusions:** In HER2+ EBC pts enrolled in the ALTTO trial, the PREDICT+ score highly underestimated OS. The low performance of this prognostic tool was consistent across all pts subgroups. PREDICT+ should be used with caution to give prognostic estimation in HER2+ EBC pts treated in the modern era with effective chemotherapy and anti-HER2 targeted therapies. Research Sponsor: Grant (number 2018-09) from Les Amis de l'Institut Bordet, submitted by P. Aftimos (title: The prognostic performance of PREDICT + in breast cancer patients with early-stage HER2-positive disease in the ALTTO trial).

Retrospective cohort study of estrogen receptor low positive early breast cancer using real world data. *First Author: Shahla Bari, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Estrogen receptor (ER) positive breast cancer (BC) is a heterogeneous disease, with ongoing debate on the optimal cut off point for clinically relevant ER expression. Tumors harboring ≤10% ER expression are associated with poor outcomes. We used a real-world database to assess prognostic and predictive value of an alternative ER expression cut points. **Methods**: This retrospective cohort study used the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database. During the study period, the de-identified data originated from approximately 280 US cancer clinics (~800 sites of care). We evaluated the association between ER expression (assessed locally by immunohistochemistry according to ASCO/CAP guidelines) with tumor characteristics, and treatment patterns of patients with early-stage BC (stage I-III) using descriptive statistics. Recurrence free survival and overall survival was defined as time in months from date of surgery until the data of documented cancer recurrence or death respectively. We used Kaplan Myer survival curves to calculate recurrence free (RFS) and overall survival (OS) of patients with ER low, ER intermediate and ER high tumors. To define an alternative ER expression cut point, the data set was divided into 2/3 training and 1/3 test data. A cut point analysis was performed on the training data set to find the optimum cut point of ER+ staining based on correlation with recurrence free survival as the outcome. **Results**: Among 4,697 ER positive early-stage BC patients, 83 (1.8%) had ER low (ER expression :1-10%) and 36 (0.8%) had ER intermediate BC (11-20%). Median follow up time was 63 months (range 24-84). ER low tumors were associated with higher tumor grade, larger size, and higher axillary tumor burden compared to ER high positive tumors ($>$ 20% ER expression). African American patients had a higher prevalence of both triple negative and ER low positive BCs compared to ER high tumors- 21%, 22%, and 8% respectively. No significant differences in patient- or tumor-associated characteristics were observed between Low ER and intermediate-ER positive BC patients. Both ER low and intermediate positive tumor patients had survival outcomes similar to patients with TNBC and worse than ER high positive tumors ($p < 0.001$). No significant correlations between endocrine therapy and RFS or OS were observed among patients with either ER low or intermediate BCs (HR 1.47 and 2.57, $p > 0.05$; respectively). Sensitivity analysis showed that tumors with ≤ 20% ER expression were associated with worse RFS in both univariate and multivariate analyses ($p < 0.05$). **Conclusions:** These findings suggest that patients with ER expression rates ≤ 20% have poor outcomes and derive minimal benefit from endocrine therapies. Research Sponsor: None.

Trastuzumab deruxtecan (T-DXd) in patients with HER2+ metastatic breast cancer with brain metastases: A subgroup analysis of the DESTINY-Breast01 trial. *First Author: Guy Heinrich Maria Jerusalem, Centre Hospitalier Universitaire du Sart Tilman Liège and Liège University, Liège, Belgium*

Background: Patients (pts) with HER2+ metastatic breast cancer (mBC) are at high risk of developing brain metastases (BMs), and treatment options are limited once BMs occur. T-DXd is an antibody-drug conjugate composed of an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a topoisomerase I inhibitor payload. On the basis of findings of the phase 2 DESTINY-Breast01 trial (NCT03248492), T-DXd was approved for the treatment of adult pts with HER2+ unresectable or mBC who have received ≥2 prior anti-HER2–based regimens (US and Europe) or had prior chemotherapy and are refractory to or intolerant of standard treatments (Japan). Here we describe a subgroup analysis from DESTINY-Breast01 in pts with a history of BMs. **Methods:** DESTINY-Breast01 is an ongoing, 2-part, multicenter, open-label, phase 2 trial of T-DXd in adult pts with HER2+ unresectable or mBC previously treated with trastuzumab emtansine. Pts with baseline BMs that were treated, asymptomatic, and did not require therapy to control symptoms were eligible for enrollment. All treatment to control symptoms had to be completed ≥60 days before randomization. An MRI of the brain every 6 wks was only required for pts with BMs at baseline. Brain lesions were considered non-target lesions, and thus collection of diameter measurements was not required. This analysis includes pts with a history of BMs at baseline who received T-DXd at the approved dose of 5.4 mg/kg every 3 wks. **Results:** Twenty-four pts with a history of BMs were included (data cutoff, August 1, 2019). In these pts, the objective response rate (ORR), median progression-free survival (mPFS), and median duration of response (mDoR) per independent central review with T-DXd 5.4 mg/kg were 58.3% (95% CI, 36.6%-77.9%), 18.1 mo (95% CI, 6.7-18.1 mo), and 16.9 mo (95% CI, 5.7-16.9 mo), respectively, and were comparable to those in the total pt population (N = 184) treated at 5.4 mg/kg in the DESTINY-Breast01 study (ORR, 60.9%; mPFS, 16.4 mo; mDoR, 14.8 mo; median follow-up, 11.1 mo). The pattern of disease progression was similar in pts with and without BMs with 8 of 24 pts having progressed (33%; 2 in the brain) in the BMs subgroup and 40 of 160 pts (25%; 2 in the brain) in the non-BMs subgroup, suggesting durable systemic disease control. Baseline diameters of BMs were available for 14 of 24 pts (radiotherapy prior to study enrollment was reported in 12 of 14). Among the pts with information available on baseline BM diameter, the central nervous system response rate per investigators was 50% (7 of 14 pts). **Conclusions:** T-DXd showed strong clinical activity in both the overall population of pts with HER2+ mBC and the subgroup of pts with BMs. The demonstrable response of BMs to treatment and durable clinical activity of T-DXd in pts with a history of BMs at baseline are promising and warrant further investigation. Clinical trial information: NCT03248492. Research Sponsor: Daiichi Sankyo, Inc. and AstraZeneca.

527 **Poster Session**

Bone safety profile of steroidal aromatase inhibitor in comparison to non-steroidal aromatase inhibitors in postmenopausal women with breast cancer: A network meta-analysis. *First Author: Shanshan Chen, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Steroidal and non-steroidal aromatase inhibitors (AIs) provide better therapeutic response in comparison to other endocrine therapies in the adjuvant treatment of breast cancer (BC). They interfere with bone turnover which may lead to increased incidence of bone related safety events. There are no head-on studies comparing the incidence of bone safety events and hence we performed this network meta-analysis (NMA) to compare the incidence of bone safety events among patients treated with steroidal and non-steroidal AIs. **Methods:** Literature searches were performed in PubMed and Embase with key words to identify randomized controlled trials in BC patients treated with AIs in adjuvant settings compared against tamoxifen or other AIs, reporting any bone-related safety events. The study was designed as per PRISMA guidelines; publication bias was evaluated by comparison-adjusted funnel plots. Bayesian NMA was done by R software (ver 3.2), GemtC package. Odds ratio (OR) and the surface under the cumulative ranking curve (SUCRA) values were used to interpret the results. **Results:** 15 studies reporting 6 different bone-related endpoints were included. Treatment with steroidal AI, exemestane led to lower incidence of bone pain (OR Vs anastrozole and letrozole: 0.59, p=0.63; 0.54, p=0.75), fracture episodes (OR Vs anastrozole and letrozole: 0.84, p=0.41; 0.85, p=0.73), joint stiffness (OR Vs anastrozole: 0.55, p=0.73) and osteoporosis (OR Vs anastrozole and letrozole: 0.86, p=0.41; 0.74, p=0.29) (Table) in comparison to letrozole and anastrozole. Reduction in bone mineral density was also lesser in exemestane than anastrozole (mean reduction in hip: 1.08; lumbar spine: 1.34). SUCRA values suggested exemestane to be the drug with maximum likelihood for reducing the incidence of bone-related adverse events. **Conclusions:** This NMA suggested that bone-related safety events might be lower in early BC patients treated with exemestane in comparison to non-steroidal AIs, anastrozole and letrozole. Although there was no statistical significance, further head-on studies are required to substantiate our results. Research Sponsor: Pfizer ONC-2 Medical Affair.

The impact of COVID-19 on breast cancer stage at diagnosis. *First Author: Maxwell Lloyd, Beth Israel Deaconess Medical Center, Boston, MA*

Background: During the SARS-CoV-2 pandemic, routine screening mammography (SM) was stopped and diagnostic mammography (DM) was limited for several months across the United States in order to reduce patient exposure and redeploy medical personnel. We hypothesized that this delay would result in patients presenting with later-stage disease following the initial shutdown. **Methods:** Patients diagnosed with invasive breast cancers from 2016-2020 were identified using the Beth Israel Deaconess Medical Center Cancer Registry. Baseline patient characteristics, demographics, and clinical information were gathered and cross-referenced with our electronic medical record. Late-stage disease was defined as initial anatomic stage III-IV disease in the AJCC 8th edition staging system. The control cohort consisted of patients diagnosed from 2016-2019; patients diagnosed in 2020 were the test cohort. Chi-squared analysis was used to compare monthly distributions in stage at diagnosis between the control and test cohorts. Multivariate analysis was performed using a logistic regression model. **Results:** There were 1597 patients diagnosed with invasive breast cancer between 2016-2019 and 333 in 2020. Median age at diagnosis was 60 years; 99% were female, and 69.1% were white. Mammography was limited from 3/16/20-6/8/20, with 90% reduction in volume during this time. The number of screening studies performed in March, April, May, and June of 2020 were 987, 1, 4, and 721 compared to 2042, 2141, 2241, and 2142 in 2019. The volume of new diagnoses per month decreased substantially during the shutdown (see table). The proportion of patients diagnosed with late-stage disease was 6.6% in the control cohort compared to 12.6% in the 2020 test cohort ($p < 0.001$); 92.9% of late-stage diagnoses in 2020 occurred from June to December following the shutdown period. On multivariate analysis, year of diagnosis (2020 vs 2016-2019; OR = 4.25 95% CI 0.035-0.095, $p < 0.001$), lower income (<200% of the federal poverty level; OR = 2.73 95% CI 0.016-0.099, p = 0.006) and increased Charlson Comorbidity Index (OR = 12.01 95% CI 0.037-0.052, $p < 0.001$) were associated with later stage at diagnosis. **Conclusions:** Patients were more likely to be diagnosed with late-stage breast cancer following the global shutdown due to the SARS-CoV-2 pandemic. Patients with lower income and medical comorbidities were disproportionately affected. These data raise significant concerns regarding the impact of SARS-CoV-2 on cancer diagnoses and long-term outcomes, especially in vulnerable patient populations. Research Sponsor: None.

Efficacy of epirubicin plus cyclophosphamide followed by taxanes versus carboplatin plus taxanes as adjuvant chemotherapy in triple-negative breast cancer: 8.1 years median follow-up on a randomized clinical trial. *First Author: Fangchao Zheng, National Cancer Centre/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Four cycles of adjuvant taxanes (paclitaxel or docetaxel) after four cycles of adjuvant doxorubicin plus cyclophosphamide (ECT) are considered a standard adjuvant treatment and improves survival outcomes of triple negative breast cancer (TNBC). The purpose of this analysis was to further assess whether adjuvant carboplatin plus taxanes (TP) was non-inferior to or superior to standard ECT chemotherapy in prolonging the survival time. **Methods:** This randomized, open-label, multicenter clinical trial conducted at three hospital in China from June, 2009 and October, 2015. Eligible early triple-negative breast cancer (TNBC) patients were randomized (1:1) to receive ECT (four cycles of epirubicin 90 mg/m2 + cyclophosphamide 600 mg/m2 followed by four cycles of docetaxel 75 mg/m2 or paclitaxel 175 mg/m2 every 3 weeks, ECT arm, n = 154) or receive TP (six cycles of docetaxel 75 mg/m2 or paclitaxel 175 mg/m2 + carboplatin AUC 5 every 3 weeks; TP arm, n = 154), which was then followed by surgery. **Results:** Three hundred and eight patients were recruited in this trial and final date of follow-up was January 20, 2021. Baseline characteristics were balanced between ECT arm and TP arm. Median follow-up was 97.6 months. Median disease free survival (DFS) was not reached; 8-year DFS rate was 78.35% with ECT arm and 81.73% with TP arm (hazard ratio [HR] = 0.84; 95% confidence interval [CI] = 0.50 - 1.40; P = 0.496). Median overall survival (OS) was also not reached; 8-year OS rate was 87.15% with ECT arm and 89.14% with TP arm (HR = 0.87; 95% CI = 0.44 - 1.70; P = 0.676). For TNBC patients with DFS $>$ 4 year, TP arm had a longer DFS than ECT (P = 0.01), and had a tendency with better OS (P = 0.4). In this subgroup analysis of SPARC $>$ 50%, TP arm had a longer DFS than ECT (P $<$ 0.05), and also had a tendency with better OS (P = 0.06). In subgroup analysis of PD-1 (-) and intravascular invasion (+), TP arm had a better DFS (P = 0.02) and OS (P = 0.03) than ECT arm. DFS or OS had no significant differences in ECT and TP arm with BRCA mutation or BRCA wild (all P values $>$ 0.05). **Conclusions:** TP chemotherapy showed significant non-inferiority for PFS and OS versus ECT in the first-line adjuvant treatment of early TNBC. For some particular subgroup of TNBC, TP may be a more effective chemotherapy than ECT. TP may be considered an effective alternative to early TNBC. Clinical trial information: NCT01150513. Research Sponsor: None.

Use of a novel convolutional neural network-based mammographic evaluation to assess response to adjuvant endocrine therapy in women with early-stage breast cancer. *First Author: Julia Elizabeth McGuinness, Columbia University Irving Medical Center, New York, NY*

Background: The standard of care for early-stage hormone receptor (HR)-positive breast cancer (BC) is 5-10 years of adjuvant endocrine therapy (ET), which leads to a 50-60% relative risk reduction in BC recurrence. However, 10-40% of patients may relapse up to 20 years (y) after diagnosis, and there is a need for biomarkers of response to ET. We developed a novel, fully-automated convolutional neural network (CNN)-based mammographic evaluation that accurately predicts BC risk, which is being evaluated as a pharmacodynamic response biomarker to adjuvant ET. **Methods:** We conducted a retrospective cohort study among women with HR-positive stage I-III unilateral BC diagnosed at Columbia University Irving Medical Center from 2007-2017, who received adjuvant ET and had at least 2 mammograms of the contralateral breast (baseline and annual follow-up). Demographics, clinical characteristics, BC treatments, and relapse status were extracted from the electronic health record and New York-Presbyterian Hospital Tumor Registry. We performed CNN analysis of mammograms at baseline (start of ET) and annual follow-up. Our primary endpoint was change in CNN risk score, expressed as a continuous variable (range, 0-1). We used two-sample *t*-tests to assess for differences in mean CNN scores between patients who relapsed or remained in remission. We evaluated if CNN score at baseline and change from baseline were associated with relapse using logistic regression, with adjustment for known prognostic factors. **Results:** Among 870 evaluable women, mean age at diagnosis was 59.5y (standard deviation [SD], 12.4); 60.3% had stage I tumors, 72.6% underwent lumpectomy, and 45.8% received chemotherapy. With a median follow-up of 4.9y, there were 68 (7.9%) breast cancer relapses (36 distant, 26 local, 6 new primary). Median number of evaluable mammograms per patient was 5 (range, 2-13). Mean baseline CNN risk scores were significantly higher among women who relapsed compared to those in remission (0.258 vs 0.237, p = 0.022), which remained significant after adjustment for known prognostic factors. There was a significant difference in mean absolute change in CNN risk score from baseline to 1y follow-up between those who relapsed vs. remained in remission (0.001 vs. -0.022, p = 0.027), but this was no longer significant in multivariable analysis. **Conclusions:** We demonstrated that higher baseline CNN risk score was an independent predictor of BC relapse. A greater decrease in mean CNN risk scores at 1-year follow-up after initiating adjuvant ET was seen among BC patients who remained in remission compared to those who relapsed. Therefore, baseline CNN risk scores may identify patients at high-risk for breast cancer recurrence to target for more intensive adjuvant treatment. Early changes in CNN risk scores may be used to predict response to long-term ET in the adjuvant setting. Research Sponsor: Herbert Irving Comprehensive Cancer Center Velocity Pilot Award.

Breast Cancer Index and prediction of benefit from extended endocrine therapy based on treatment compliance: An IDEAL study. *First Author: Gerrit-Jan Liefers, Leiden University Medical Center, Leiden, Netherlands*

Background: The IDEAL trial randomized hormone receptor-positive (HR+) breast cancer patients to 5 vs 2.5y of extended letrozole after completion of 5y of adjuvant endocrine therapy. In the parent trial, approximately 60% of patients overall were compliant with endocrine treatment (59% vs 74% compliance in 5y and 2.5y arms, respectively), with patient experiences as the most significant factors leading to treatment discontinuation. Breast Cancer Index is a gene expression-based signature that predicts which HR+ patients are likely to benefit from extended endocrine therapy (EET) vs those unlikely to benefit [BCI (H/I)-High and -Low, respectively]. The current study examined EET compliance and outcome by BCI (H/I) status in patients treated in the IDEAL trial. **Methods:** Patients with available primary tumor specimens were eligible for this blinded study. Primary endpoint was recurrence-free interval (RFI), including locoregional and distant recurrences. Kaplan-Meier and Cox proportional hazards regression analysis were used to analyze the benefit of EET. Non-compliance was defined as completion of $\leq$60% of treatment duration ($\leq$3y for 5y arm; $\leq$1.5y for 2.5y arm) for any reason other than disease events. Overtreatment was defined as % compliant BCI (H/I)-Low patients in the 5y arm; undertreatment was % noncompliant BCI (H/I)-High patients in the 5y arm. **Results:** 908 HR+ patients (73% pN+, 59y, 45% pT1, 48% pT2) were included. 78% (n = 708) of patients were compliant, of which 48% (n = 338) were BCI (H/I)-High and 52% (n = 370) were BCI (H/I)-Low. In non-compliant patients (22%, n = 200), 45% (n = 91) were BCI (H/I)-High and 55% (n = 109) were BCI (H/I)-Low. BCI (H/I)-Low patients irrespective of compliance status did not derive significant benefit from EET (P = 0.922, compliant subset; 0.894 non-compliant subset). Compliant BCI (H/I)-High patients showed significant benefit from EET (HR 0.35, 95% CI 0.16-0.79; absolute benefit 11.7%; P = 0.008) whereas non-compliant BCI (H/I)-High patients did not (HR 0.75, 95% CI 0.17-3.35; absolute benefit 2.1%, P = 0.704). In this study, 38% of patients in the 5y EET arm were BCI (H/I)-Low and compliant and thus were overtreated, while 13% of patients in the 5y EET arm were BCI (H/I)-High and non-compliant and thus were undertreated. **Conclusions:** Patients that were BCI (H/I)-Low did not derive significant benefit from 5 vs 2.5y of EET even when compliant, and thus may be considered for treatment de-escalation. Importantly, BCI (H/I)-High patients with endocrine responsive disease showed significant improvements in outcome when compliant and should be guided to continue treatment. BCI may serve as an important genomic tool to increase EET compliance and identify patients that may be candidates for increased side effect management and support to potentially improve outcomes. A validated model to predict low recurrence risk distinguished by 21-gene recurrence score in hormone receptor-positive invasive breast cancer patients. *First Author: Yasue Tsuchida, Department of Breast Surgical Oncology, St. Luke's International Hospital, Tokyo, Japan*

Background: In the prospective TAILORx and RxPONDER trials, the 21-gene Recurrence Score (RS) showed endocrine therapy alone was non-inferior to chemo-endocrine therapy in the analysis of invasive disease-free survival in postmenopausal hormone-receptor (HR)-positive breast cancer patients with RS $<$ = 25. They also indicated chemotherapy was associated with benefit for women 50 years or younger with RS 11 to 25. However, in Japan, the test is not conventionally available because of non-coverage by national insurance. We aimed to develop and validate a model to predict RS using clinicopathological factors that identify patients who would have low risk shown by testing the 21-gene RS and can avoid chemotherapy. **Methods:** Four hundred patients, including 187 N0/1 postmenopausal, and 213 N0 premenopausal women who underwent surgery and had the RS from St. Luke's International Hospital, Tokyo, Japan, were included in derivation cohort. Derivation cohort was divided into 2 groups by RS 25; patients with RS of 0 to 25 (n = 321) and with RS over 26 (n = 79). Multivariate logistic regression analysis was performed using candidate factors for all patients and pre- or postmenopausal patients. The prediction model was validated using an external cohort of 70 patients from Showa University School of Medicine, Tokyo, Japan. **Results:** Nuclear grade (NG) (adjusted OR, 5.28, 95% CI, 2.47–11.30), high Progesterone receptor (PgR) expression (Allred score 7-8) (adjusted OR, 10.62, 95% CI, 5.34–21.13) and low Ki67 level ($<$ = 20%) (adjusted OR, 5.29, 95% CI, 2.33-12.01) were significant independent predictors of RS of 0 to 25. With these factors could predict RS of 0 to 25 (AUC of 0.848, 95% CI, 0.803-0.893) with the highest probability of low-RS for 100%. The prediction model of the validation cohort had same discriminatory ability having an AUC of 0.812 (95% CI, 0.701-0.923). In postmenopausal patients, NG (adjusted OR, 4.81, 95% CI, 1.72–13.42), high PgR expression (adjusted OR, 10.62, 95% CI, 4.52–37.72), and low Ki67 level (adjusted OR, 4.94, 95%CI, 1.87-13.04) were significantly associated with RS of 0 to 25 in multivariate analysis. A regression model with these 4 factors could predict RS of 0 to 25 (AUC of 0.842, 95%CI, 0.782-0.902). In premenopausal patients, NG (adjusted OR, 8.76, 95% CI, 1.14–67.40), high PgR expression (adjusted OR, 3.22, 95% CI, 1.61–6.43), and low Ki67 level (adjusted OR, 2.87, 95% CI, 1.20–6.87) were significantly associated with RS of 0 to 10 in multivariate analysis. These factors could predict RS of 0 to 10 (AUC of 0.811, 95% CI, 0.731-0.891). However, the highest probability of low-RS provided this model for premenopausal women was 46.8%. **Conclusions:** Our validated model could provide useful information to distinguish low-RS especially for postmenopausal patients with high reproducibility. However, for premenopausal women, the 21-gene RS is warranted. Research Sponsor: None.

Clinical trial testing superiority of combination plinabulin (Plin) and pegfilgrastim (Peg) versus peg alone in breast cancer treated with high-risk febrile neutropenia risk chemotherapy (chemo): Final results of the phase 3 protective-2 in chemo-induced neutropenia (CIN) prevention. *First Author: Douglas W. Blayney, Stanford University, Stanford, CA*

Background: Peg is standard of care (SoC) for the prevention of CIN. Peg's mechanism of action leaves patients vulnerable to FN in week 1 of the chemo cycle(C), as the absolute neutrophil count (ANC) does not normalize until week 2. Plin is a first-in-class, non-G-CSF small molecule agent, which received breakthrough designation from FDA in CIN. It prevents CIN by protecting progenitor cells in bone marrow from chemo assault and has normal ANC in week 1 (Blayney JAMA Onc 2020). Phase 2 testing showed the combination of Plin and Peg achieved CIN protection throughout the entire cycle vs Peg alone (Blayney: St Gallen 2019, ASCO 2019). **Methods:** Plin is given on Day (D)1 after Chemo, has a favorable safety profile, and also has anticancer activity. A separate phase 3 study evaluating Plin as an anticancer agent (DUBLIN-3; NCT02504489) in NSCLC pts is underway, with anti-cancer results in OS expected in 2021. In PROTECTIVE-2 (Study 106; NCT0329457), we added Plin (on D1) to Peg (on D2), testing superiority of the combination for CIN prevention vs Peg alone. Study 106, is a global multicenter randomized (1:1) double-blind study to evaluate Plin 40 mg + Peg 6mg (Arm 1) versus Peg 6mg + Placebo (Plac) (Arm 2) in preventing Severe Neutropenia (N), (defined as ANC $<$0.5 cells $\times$ 10E9/L) in early-stage BC (node positive or node negative with a high risk of recurrence) pts. 221 pts with ECOG status 0 or 1 received Docetaxel (75 mg/m2), Doxorubicin (50 mg/m2), and Cyclophosphamide (500 mg/m2) (TAC) on D1 for four 21 D cycles and study treatment. Central laboratory ANC was assessed at Covance in Cycle 1 (C1) on D 1, 2, 3, 6, 7, 8, 9, 10, 11, 12, 13, and 15. Primary objective was to compare the percentage (%) of pts with a Duration of Severe Neutropenia (DSN) of 0 days [that is % of pts with no Grade (Gr) 4 neutropenia (N)] in C1 in each arm. Key secondary endpoints were DSN and ANC Nadir in C1. We also evaluated safety (AE frequency and Grade). **Conclusions:** Adding Plin to Peg offers superior CIN protection compared to Peg alone and also has a superior safety profile by lowering over 20% of grade 4 AE. The effect size of the CIN protection in the combination is also correlated to clinical meaningful FN reduction compared to peg alone. Clinical trial information: NCT03531099. Research Sponsor: BeyondSpring Pharmaceuticals,Inc.

Cost-effectiveness of the Oncotype DX Breast Recurrence Score test in postmenopausal women with node-positive early breast cancer based on the RxPONDER trial. *First Author: Vladislav Berdunov, PHMR Ltd, London, United Kingdom*

Background: The Oncotype DX test is a predictive and prognostic multigene assay used to guide adjuvant chemotherapy in HR+/HER2- early breast cancer. The ability of the Oncotype DX test to predict the benefit of chemotherapy in node-positive early breast cancer was demonstrated in SWOG-8814. This evidence, in combination with findings from a bespoke analysis of the TransATAC study, informed an economic evaluation of the Oncotype DX test by the National Institute for Health and Care Excellence in the UK. This study examined the impact of new evidence from the RxPONDER trial on the cost-effectiveness of the Oncotype DX test in postmenopausal women with node-positive early breast cancer. **Methods:** The cost-effectiveness of the Oncotype DX test compared to clinical risk tools only in postmenopausal HR+/HER2- early breast cancer was estimated using a model in Microsoft Excel. The pre-RxPONDER analysis using the old cut points (RS 0-17, RS 18-30, RS 31-100) was informed by TransATAC and SWOG-8814. The model was updated with 5-year probability of distant recurrence as first site estimates based on new RS cut points (RS 0-25, RS 26-100) from RxPONDER. The impact on incremental lifetime costs and quality-adjusted life-years (QALYs) gained was examined based on the list price for the Oncotype DX test in the UK. **Results:** The impact of adding data from RxPONDER into the cost-effectiveness analysis is summarized in the table below. **Conclusions:** The RxPONDER trial demonstrated that the addition of chemotherapy to endocrine therapy had no benefit for distant recurrence in postmenopausal women with RS 0-25, regardless of clinical features, which suggests that most patients with 1-3 positive nodes can be safely spared adjuvant chemotherapy. In the model this was reflected in reduced cost of chemotherapy and higher QALYs from avoiding short and long-term adverse effects of chemotherapy. Targeted chemotherapy of a minority (17%) of patients with RS 26-100 reduced the cost of distant recurrence and improved survival based on the model results. RxPONDER provides direct evidence to inform the probability of distant recurrence with endocrine and chemo-endocrine therapy, whilst previous models have had to synthesize multiple sources of DRFI and chemotherapy treatment effect. Future studies should examine the impact of the RxPONDER findings on chemotherapy treatment decision-making in routine clinical practice. Research Sponsor: Exact Sciences.

Summary of cost-effectiveness results (in 2020 pound sterling).

Category	Pre-RxPONDER model	Model with RxPONDER
Incremental cost	-£451	-£1,525
Multigene assay	£2,580	£2,580
Chemotherapy (incl. AEs)	-£3,153	-£3,958
Local and distant recurrence	£143	-£53
Follow-up	-£2	£4
Terminal care	-£38	-£91
Incremental QALYs	0.01	0.19

Outcome and immune landscape of HER2-positive invasive lobular carcinoma in the North Central Cancer Treatment Group (NCCTG) N9831 (Alliance) trial. *First Author: Saranya Chumsri, Mayo Clinic, Jacksonville, FL*

Background: Invasive lobular carcinoma (ILC) is a rarer form of breast cancer, accounting for 10% of the disease cases. HER2 overexpression in ILC is infrequent and limited data exist regarding clinical characteristics and outcome of HER2-positive (HER2+) ILC patients (pts) treated with adjuvant trastuzumab. **Methods:** Patient characteristics were compared between ILC and invasive ductal carcinoma (IDC) using Wilcoxon rank sum test for continuous variables and Chi-square test for categorical variables. Kaplan-Meier (KM) method was used to estimate the freedom from mortality and recurrence. Cox regression model was used to evaluate the association between ILC and outcomes adjusted for other characteristics. NanoString technology was used to quantify mRNA to develop immune-related gene signatures. **Results:** From a total of 3,304 pts, 122 (3.7%) pts had ILC. Pts with ILC were significantly older (median age 54 vs. 49 years), had larger tumors, lower grade, more ER and PR positive tumors, and more lymph node involvement (25.4% had N3 disease compared to 12.7% in IDC). Overall, with KM analysis, pts with ILC had significantly worse overall survival (OS, p = 0.005) and recurrence-free survival (RFS, p = 0.046) compared to IDC. The 15-year freedom from recurrence was merely 57.67% in ILC compared to 72.68% in IDC. A significant number of hormone receptor-positive (HR+) ILC pts developed late recurrence with cumulative event rates increasing from 23% at 5 years to 42% at 15 years. Nevertheless, in multivariate Cox regression analysis adjusting for other clinical characteristics, including age, tumor size, grade, ER/PR, and lymph node status, lobular histology was not significantly associated with worse outcome for OS (HR = 1.19, 95%CI 0.67-2.1, p = 0.55) and RFS (HR = 1.5, 95%CI 0.9-2.5, p = 0.12), as compared with IDC. However, ILC pts appeared to have similar degree of benefit from trastuzumab, with RFS HR = 0.58 compared to HR = 0.67 in the entire population. For immune landscape, there was no significant difference in gene signatures related to CD45, CD8, B cells, or cytotoxic cells. However, ILC had more enrichment in mast cell gene signature and fewer macrophage, NK CD56dim, and regulatory T cell signatures compared to IDC ($p < 0.05$). **Conclusions:** HER2+ ILC has distinct clinical characteristics and immune landscape compared to IDC. ILC pts appeared to have worse outcome compared to IDC likely because ILC pts often presented with more locally advanced disease. However, similar benefit of trastuzumab was observed in ILC pts. Due to high risk of late relapse in HR+ HER2+ ILC, extended adjuvant endocrine therapy should be considered in this group of high-risk pts. Clinical trial information: NCT00005970. Dose escalation for mitigating diarrhea: Ranked tolerability assessment of anti-diarrheal regimens in patients receiving neratinib for early-stage breast cancer. *First Author: Gavin M. Marx, University of Sydney, Sydney, Australia*

Background: The primary tolerability concern with neratinib (NERLYNX®; N), an irreversible pan-HER tyrosine kinase inhibitor, is diarrhea. Data from the multi-cohort, open-label, phase 2 CONTROL trial [Barcenas et al. Ann Oncol 2020] demonstrated significant improvement in grade 3 diarrhea and diarrhea-related discontinuations vs the ExteNET trial, which did not mandate anti-diarrheal prophylaxis. We report a systematic analysis of tolerability in CONTROL and ExteNET. **Methods:** Patients (pts) ≥18y with stage I–IIIc HER2+ breast cancer received N (240 mg/d po for 1y) after trastuzumab-based adjuvant therapy and were enrolled sequentially into cohorts assessing different modalities to mitigate diarrhea. Cohorts with complete data were included: loperamide (L); L+budesonide (BL); L+colestipol (CL); CL as needed (CL-PRN); and N dose escalation (DE; 120 mg/d on d1–7, 160 mg/d on d8–14, and 240 mg/d thereafter). Integrated ranking (IR) analysis was performed on 13 endpoints in 4 domains (exposure, diarrhea, adverse events [AEs], quality of life [QoL]) identified with input from clinicians; cohorts were ranked from 1 (best) to 5 (worst). Index scores (IS) based on individual pt data from CONTROL were calculated as supportive analysis to confirm selection of the regimen with best overall tolerability, which was then compared with ExteNET. **Results:** Of the 5 CONTROL cohorts evaluated, DE ranked best for most endpoints. Average ranks per IR method: L 3.4; BL 3.2; CL 3.0; CL-PRN 3.3; DE 2.0. The IS analysis supported DE as the cohort with best overall tolerability. Comparison of CONTROL DE vs ExteNET showed improvement in tolerability in all domains (table). **Conclusions:** These analyses suggest superiority of weekly DE vs other anti-diarrheal strategies. A lower rate of grade 3 diarrhea was observed with CONTROL DE vs ExteNET (13.3 vs 39.9%, respectively), as well as a comparable or improved AE profile. The data also reveal greater compliance with N (fewer early discontinuations, longer treatment duration, higher cumulative dose) and reduced impact on QoL with DE, suggesting improved tolerability. Clinical trial information: NCT02400476. Research Sponsor: Puma Biotechnology Inc.

Clinical validation of EndoPredict in premenopausal women with estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2-) primary breast cancer. *First Author: Anastasia Constantinidou, The Institute of Cancer Research and The Royal Marsden Hospital, London, United Kingdom*

Background: The EndoPredict 12-gene prognostic assay is validated to predict distant recurrence-free survival (DRFS) and response to chemotherapy in post-menopausal women with ER+, HER2- breast cancer. This study evaluated the performance of EndoPredict in pre-menopausal women. **Methods:** Stored tumor samples from women with ER+, HER2- primary breast cancer who were pre-menopausal at the time of diagnosis and were systemically treated with endocrine therapy alone were obtained from two sites (University of Nottingham and University of Cyprus). These samples were tested with EndoPredict to produce a 12-gene molecular score (EP). Pathologic tumor size and nodal status were algorithmically combined with the EP score to produce the clinicomolecular EPclin score. Cases with tumors > pT3, which were treated with chemotherapy, or for whom the EPclin score was missing or invalid were excluded. Associations of EP and EPclin with 10-year DRFS were evaluated in terms of hazard ratios (HRs) from Cox proportional hazards models stratified by cohort. 10-year DRFS was estimated for EPclin high-risk and low-risk women by Kaplan-Meier analysis. **Results:** Out of 411 eligible cases, 385 had a valid EPclin score and were included in the analysis. Mean age at breast cancer diagnosis was 46.5 years (standard deviation 4.7). Most women (N = 239, 62.6%) had grade II tumors and 16.1% (N = 62) had node-positive disease. Over the observation period (median 9.7 years, interquartile range 6.6-13.9 years), 35 women had a distant recurrence within 10 years. Both the molecular EP score and the molecular-clinicopathologic EPclin score were associated with increased risk of distant recurrence [HR 1.3, 95% confidence interval (CI) 1.2-1.5; $p < 0.001$ and HR 3.6, 95% CI 2.3-5.7; $p < 0.001$, respectively]. Of these patients, 249 (64.7%) were categorized as low risk by EPclin score while the remaining 136 (35.3%) were categorized as high risk. Compared to EPclin low-risk women, EPclin high-risk patients were more likely to experience distant recurrence (HR 4.6, 95% CI 1.4-15.2; p = 0.004). At 10 years post-diagnosis, EPclin low-risk women who received endocrine therapy alone had a DRFS of 97% (95% CI 93-99%). Conversely, EPclin high-risk women had a DRFS of only 76% (95% CI 67-82%). **Conclusions:** The EPclin score is highly associated with DRFS in pre-menopausal women who received adjuvant endocrine therapy alone. Based on these data, pre-menopausal women with EPclin low-risk breast cancer may safely forgo adjuvant chemotherapy in addition to endocrine therapy. Research Sponsor: Myriad Genetics, Inc.

De-escalation of five years adjuvant endocrine therapy duration in patients with ER-low positive (immunohistochemical 1% to 10%) early-stage breast cancer: A propensity-matched analysis from the prospectively maintained database. *First Author: Keda Yu, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: There are limited data on endocrine therapy benefits for patients with estrogen receptor (ER)-low positive breast cancer (staining 1% to 10% of tumor nuclei by immunohistology). We aimed to compare the effect of short-term 2-3 years versus standard 5 years of adjuvant endocrine therapy on survival outcomes in patients with ER-low positive early breast cancer. **Methods:** We used data from the prospectively maintained Breast Surgery Database of Fudan University Shanghai Cancer Center for this propensity-matched analysis. Women with ER-low positive, operable, and unilateral early-stage invasive ductal breast cancer were enrolled in this study. Patients with advanced disease, having received neoadjuvant chemotherapy or ovarian function suppression, or with unknown duration or longer than 5 years of adjuvant endocrine therapy were excluded. Enrolled patients were divided into three groups: received no endocrine therapy; received 2-3 years of endocrine therapy; and received approximately 5 years of endocrine therapy. The primary endpoint was disease-free survival (DFS). Multivariate Cox regression analysis and propensity score matching were performed to minimize bias. Hazard ratios (HR) with 95% CIs were calculated. **Results:** From 2012 to 2017, 634 patients with ER-low positive breast cancer in the database met the inclusion criteria. At a median follow-up of 60 months (interquartile range, 46-74), the 5-year DFS of the whole cohort was 84.9%, with 77.6% for patients who received no endocrine therapy (N = 89), 83.7% for patients who received 2-3 years endocrine treatment (N = 185), and 87.5% for patients who received 5 years endocrine therapy (N = 360). When compared with those receiving no endocrine therapy, patients receiving 5 years treatment was associated with a significantly improved DFS (HR, 0.55; 95% CI 0.32-0.95; P = 0.03); however, there was no significant difference in DFS between patients receiving 2-3 years and 5 years endocrine therapy (HR, 0.79; 95% CI, 0.48-1.28; P = 0.33). In the multivariate Cox regression analysis of the propensity score-matched samples of 360 patients, the DFS was not significantly better for patients who received 5 years of endocrine therapy than 2-3 years treatment (HR, 0.74; 95% CI 0.41-1.34; P = 0.32). An exploratory analysis of re-biopsy of the recurrence lesions indicated more than half of relapsed disease displayed ER-negative, and less than 5% lesions were proved to be ER ≥10% positive. **Conclusions:** Our data did not support the necessity of 5 years duration of endocrine therapy for patients with ER-low positive breast cancer. Short-term 2-3 years duration might be an alternative option. Further translational research on identifying endocrine-sensitive cases within ER-low positive patients is needed. Research Sponsor: Chinese NSFC.

Comprehensive genomic profiling (CGP) of 275 male breast cancer (BC) tissue (TBx) and liquid (LBx) biopsies: Comparative analysis to a female cohort (FBC) and therapeutic considerations. *First Author: Arun Kadamkulam Syriac, Dana Farber Cancer Institute/St. Elizabeth Hospital, Boston, MA*

Background: Male BC accounts for < 1% of all BC and is often diagnosed at later stage, which can result in higher mortality. Due to the rarity of this diagnosis, limited data exist on genomic alterations and prevalence of cancer susceptibility genes (CSG). We aimed to comprehensively describe the genomics of male BC and compare these to a FBC cohort across subtypes to provide insight on tumor biology and opportunities for targeted therapies. **Methods:** 275 male BC TBx or LBx were sequenced by Foundation Medicine (FM) using hybrid capture-based CGP. Both TBx and LBx were evaluated for all classes of genomic alterations (GA). Histological subtype, receptor status, and biopsy site were extracted from pathology reports. Paired samples with both TBx and LBx were available in 7 cases. The male BC TBx cohort with known receptor status (n = 253) was compared to a FBC cohort (n = 2855). Mutational prevalence in 5 breast CSG *(ATM/BRCA1/BRCA2/CHEK2/PALB2)* were compared along with their associated genomic LOH (gLOH) values. **Results**: Among male BCs, subtype distribution was: ER+/HER2- n = 210 (83%), ER+/HER2+ n = 22 (9%), TNBC n = 20 (8%). ER+/HER2+ male BC cases had higher rates of *ERBB2* SV *(*22.7% v. 0.62%, $p < 0.0001$), *PIK3CA* (68.2% vs. 34%, p = 0.01), *MDM2* amplifications (36% v. 4%, $p < 0.0001$) and *GATA3* (36.6% v. 6.2%, p = 0.0002) than ER+/HER2+ FBC. In the ER+/HER2- cohort, male BC had more alterations in *BRCA2* (13.8% v. 5.3%, $p < 0.0001$) and *GATA3* (26% vs. 15%, p = 0.0004) and less alterations in *TP53* and *ESR1* ($p < 0.0001$ both). 28.6% of male BC v. 16.6% of FBC (p = 0.004) had one or more variants in one of 5 CSG of potential germline origin with a higher % of *BRCA* mutations in male BC vs. FBC (17.5% v. 9.9%, p = 0.0006). In the paired male BC Bx's we saw genomic heterogeneity in a case showing 5 unique *ESR1* alts and a *PIK3CA* SV unique to LBx done at the same time as TBx. We saw evidence of resistance with a shared *BRCA1* alteration and several reversion mutations unique to LBx taken 471 days later, and a longitudinal pair with unique *ESR1,PIK3CA* and *MTOR* mutations in a LBx 547 days apart. **Conclusions**: Although male and female BC share some common alterations, our study revealed potentially important findings that may explain biological differences and provide treatment opportunities. Despite HR+/HER2+ male BC being rare, it was notable for increased co-mutations with *ERBB2* SV, *PIK3CA* SV, and *GATA3* SV, which can be associated with a worse prognosis but perhaps allow more novel combinations. *ESR1* mutations appear more common in ER+/HER2- FBC reflective of treatment with aromatase inhibitors versus tamoxifen for male BC. *TP53* mutations were more common in all subtypes of FBC. *BRCA2* mutations and other potential germline CSG variants were more common in male BC, suggesting an opportunity for PARP inhibitors. LBx identified additional biomarkers and resistance mutations not seen in TBx. Research Sponsor: None.

Association between treatment duration and overall survival in early-stage HER2+ breast cancer patients receiving extended adjuvant therapy with neratinib in the ExteNET trial. *First Author: Beverly Moy, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Completion of planned treatment has been shown to improve clinical outcomes. In the ExteNET trial (NCT00878709), where diarrhea prophylaxis was not mandated, 17% of patients (pts) discontinued neratinib early due to diarrhea. This compares with 3.3% of pts from the CONTROL trial (NCT02400476) who used a neratinib dose-escalation strategy. Prior analyses have shown improved invasive disease-free survival (iDFS) in pts who completed planned duration of neratinib therapy in ExteNET (Table). Here we assess outcomes, including overall survival (OS), for pts who completed planned therapy in 3 groups from ExteNET: intent-to-treat (ITT) population; pts with hormone receptor-positive (HR+) disease who initiated neratinib within 1y after prior trastuzumab (HR+/≤1y, the population neratinib is approved for in the EU); and HR+/≤1y with residual disease post-neoadjuvant therapy (no pathologic complete response [pCR]). **Methods:** Pts with early-stage HER2+ breast cancer received oral neratinib 240 mg/d or placebo after trastuzumab-based (neo)adjuvant therapy. Pts who completed neratinib therapy (defined as ≥11m or cessation of neratinib if recurrence occurred prior to 11m) were compared with placebo (all randomized pts). iDFS and OS were analyzed using Kaplan-Meier methods; hazard ratios (HR) with 95% confidence intervals (CI) were estimated using Cox proportional-hazards models. Data cutoff: July 2019. **Results:** There were 2840 pts in the ITT population. The table shows iDFS and OS in the overall population and in pts who completed planned duration of neratinib therapy. Completion of planned neratinib was associated with improvements in iDFS and OS in all groups evaluated. **Conclusions:** These descriptive findings suggest that pts who receive the recommended duration of treatment of 1y with neratinib may have improved outcomes. Clinical trial information: NCT00878709. Research Sponsor: Puma Biotechnology Inc.

PD-L1 expression and TOP3A mutation as prognostic factors for adjuvant chemotherapy in triple negative breast cancer. *First Author: Xue Wang, National Cancer Center/National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Triple negative breast cancer (TNBC) is a highly aggressive subtype of breast cancer that is markedly heterogeneous and lacks specific targets. The aim of this study is to explore potential predictors and therapeutic targets based on clinical and genetic characteristics. **Methods:** 138 patients with triple-negative breast cancer after surgical treatment were 1:1 randomly assigned to the paclitaxel combined with carboplatin (TCb) group or the epirubicin combined with cyclophosphamide sequential paclitaxel (EC-T) adjuvant chemotherapy group. PD-L1 was retrospectively analyzed by surgically resected specimens, and 733 cancer-related genes were detected by NGS. Pathway enrichment analysis was performed using DAVID for functional enrichment genetic alterations. Cox regression models and Kaplan-Meier were used to evaluate disease-free survival (DFS). **Results:** In this study, there was no significant difference in DFS between the TCb and EC-T groups. 31 (22.5%) of 138 TNBC patients were positive for PD-L1 expression, including 15 (10.9%) patients positive for PD-L1 in tumor cells (TCs) and 29 (21.0%) patients positive for PD-L1 in tumor-infiltrating immune cells (TICs). Patients with positive PD-L1 expression, either in TCs or TICs, achieved better DFS [HR=0.13 (95% CI: 0.02-0.93), p=0.016], the difference was also shown in the EC-T group [HR=0 (95% CI: 0- inf), p=0.037], but not in the TCb group [HR=0 (95% CI: 0.04-2.1), p=0.189]. In addition, we identified 7 patients with mutations in DNA topoisomerase IIIα(TOP3A), a homologous recombination (HR)-related gene, and patients with mutations in this gene had worse DFS than those without mutations [HR=4]. However, there was no statistically significant association between BRCA mutation and response to either therapeutic regimens. **Conclusions:** In this TNBC patient population, immunohistochemistry (IHC) and NGS analyses identified potential prognostic markers. PD-L1 positive and TOP3A mutation were significantly associated with early triple-negative breast cancer prognosis. Research Sponsor: Capital Health Development Research Project (2018-2-4023).

Final five-year median follow-up safety data from a prospective, randomized, placebo-controlled, single-blinded, multicenter, phase IIb study evaluating the use of HER2/neu peptide GP2 + GM-CSF vs. GM-CSF alone after adjuvant trastuzumab in HER2-positive women with operable breast cancer. *First Author: Snehal Patel, Greenwich LifeSciences, Stafford, TX*

Background: The final analysis of the GP2 prospective, randomized, placebo-controlled, single-blinded, multicenter Phase IIb trial investigating GP2+GM-CSF administered in the adjuvant setting to node-positive and high-risk node-negative breast cancer patients with tumors expressing any degree of HER2 (immuno-histochemistry [IHC] 1-3+) (*NCT00524277*) is now complete with 5 year follow-up. The trial enrolled HLA-A02 patients randomized to receive GP2+GM-CSF versus GM-CSF alone. It was previously reported that completion of the GP2+GM-CSF Primary Immunization Series (PIS) reduced recurrence rates to 0% over a 5 year follow-up period in HER2 3+ patients, who received a standard course of trastuzumab after surgery. **Methods**: Each enrolled and consented patient was randomly scheduled to receive a total of 6 GP2+GM-CSF (500 mcg GP2: 125 mcg GM-CSF) or GM-CSF only intradermal injections every 3-4 weeks as part of the PIS for the first 6 months and 4 GP2+GM-CSF or GM-CSF only booster intradermal injections every 6 months thereafter. Boosters were introduced during the trial, thus some patients did not receive all 4 boosters. Injection sight reactions were measured. **Results:** Safety data was analyzed to assess local and systemic toxicity of each treatment arm. Most subjects completed the planned PIS, 81 (91.0%) GP2+GM-CSF and 86 (94.5%) GM-CSF only. In addition, 77 GP2+GM-CSF and 80 GM-CSF only subjects received all 4 booster injections. The most common local toxicities were erythema, induration and pruritis and they occurred with similar frequency in the two treatment arms. Local reactions were reported by almost all subjects over the course of vaccinations. Occurring in a smaller percentage of subjects, the most common systemic toxicities were fatigue, headache, and myalgia/arthralgia, again with similar incidence by treatment group. The majority of all events reported were of Grade 1 mild severity (GP2+GM-CSF 92.5%, GM-CSF only 90.6%). Only 5 events in 4 subjects were considered Grade 3: induration and maculopapular rash/pruritis, in two GP2+GM-CSF subjects and chest pain and hypersensitivity reaction in two GM-CSF only subjects. The incidence of local reactions minimally increased with subsequent vaccinations however, the types of events remain unchanged. No serious adverse events were reported over the full 5 year treatment and follow-up periods. **Conclusions:** The study confirms the finding from the Phase I trial evaluating GP2+GM-CSF that the vaccine is safe and well-tolerated. The majority of patients experienced only mild local and systemic toxicities. Importantly, toxicities in the GP2+GM-CSF group were comparable to those seen in the GM-CSF only group, suggesting the toxicities are attributable to GM-CSF. Clinical trial information: NCT00524277. Survival following locoregional recurrence in breast cancer by clinical subtype. *First Author: Kirsten Allen, BC Cancer-Kelowna, Kelowna, BC, Canada*

Background: We sought to explore the impact of locoregional recurrence (LRR) on survival in breast cancer (BC) patients in British Columbia treated in the modern era. **Methods:** A retrospective cohort study design identified patients diagnosed with stage I-III BC from 04/2005-12/2013 treated with surgery and who had a subsequent LRR. Exclusions were death or distant metastasis within 120 days of LRR, bilateral previous/synchronous BC, and other invasive cancers. After LRR, overall survival (OS) and factors associated with OS, including clinical subtype and adjuvant therapy (AdTx), were examined. We defined clinical subtypes as: Luminal (Lum) A-estrogen receptor (ER) and progesterone receptor (PR) positive, HER2 negative, and grade 1 or 2; Lum B-as Lum A but grade 3, or as Lum A but only one of ER or PR positive; triple negative (TNBC)-ER and PR and HER2 negative; and HER2 positive (with any ER, PR). In the absence of earlier LRR, we defined adequate AdTx as: (a) TNBC: >=50% of planned chemotherapy (Chx), (b) HER2 positive: >=50% of planned Chx and >=8 cycles of anti-HER2 therapy, (c) Lum A, B: >=4 years of endocrine therapy and (d) after partial mastectomy or positive final margins: >=50% of radiation therapy dosage. **Results:** The final cohort had 492 patients with a median follow-up of 7.2 years from LRR and 11.8 years from diagnosis. LRR was local in 69.3% (n=341) and regional +/- local in 30.7% (n=151). Compared with local only, regional recurrences were associated with higher T and N stage, grade, and Lum status (p<=0.01). Biomarkers were re-evaluated at LRR in 82% and changed from initial diagnosis in 32% of those tested: ER expression 3.8% gain, 6.1% loss; PR expression 9.1% gain, 15.1% loss; HER2 overexpression 3.7% gain and 4.8% loss. Over half of patients (n=255, 52%) did not receive adequate AdTx, either by choice or recommendation. A similar proportion with local vs. regional recurrence had inadequate AdTx. Time to death from 1st LRR did not vary significantly between local vs. regional recurrences (median 2.7 years). OS after LRR was lowest in TNBC (median 3.1 years, 24.2% 10-year OS) and longest in Lum A (median not reached, 64.7% 10-year OS) (Table). **Conclusions:** Our data provide rates of OS after LRR in the era of modern adjuvant therapy. OS after LRR varied by clinical subtype, with TNBC faring the worst, and Lum A the best. Over half had not received adequate AdTx. Despite similar treatment options, OS after LRR was significantly longer for Lum A than B subtypes, underscoring the need for therapy tailored to biology. OS was low in all other subtypes, emphasizing the importance of avoiding LRR. Research Sponsor: Centre Priorities Advisory Group (CPAG) through BC Cancer Foundation.

Overall survival (OS) by clinical subtype (from date of first locoregional recurrence).

n	10 year OS Estimate (%) & 95% CI	Median OS (years), &95% CI	p-value
Luminal A 174	64.7 (55.5, 72.5)	Not reached	<0.001
Luminal B 145	26.8 (17.1, 37.5)	4.8 +/- 0.5	<0.001
HER2+ 85	43.7 (31.2, 55.5)	7.3 +/- 0.4	<0.001
Triple Negative 75	24.2 (13.9, 36.0)	3.1 +/- 0.7	<0.001

Potential non-drug cost differences associated with the use of the fixed-dose combination of pertuzumab and trastuzumab for subcutaneous injection (PH FDC SC) in the treatment of HER2-positive early breast cancer patients in Western Europe and the United States. *First Author: Federico Manevy, F. Hoffmann-La Roche Ltd., Basel, Switzerland*

Background: In patients with HER2-positive early breast cancer (BC), pertuzumab (P) added to trastuzumab (T) and chemotherapy has been recognized as a standard-of-care, improving the risk of recurrence. P and T treatments can be given intravenously (PT IV) or, more recently, subcutaneously – via PH FDC SC. Both methods are comparable in terms of efficacy and safety profiles. However, PH FDC SC allows for a faster infusion than that of PT IV, and this can be associated with lower costs. The aim of this study is to estimate the incremental difference in non-drug costs between PH FDC SC and PT IV for a typical patient receiving treatment for HER2-positive early BC in Western Europe and the United States. **Methods:** A model-based cost-minimization analysis was performed to quantify mean non-drug cost differences per patient over a full course of therapy (18 cycles). Western Europe: costs in the analysis are based on an archetypal country, and explicitly include estimates for costs for patient chair time, active healthcare professional (HCP) time, usage of non-drug consumables, port-a-cath placement surgeries and patients' productivity losses. Costs are calculated by multiplying the resource use by its corresponding unit price. Costing data were obtained from literature sources on T SC time and cost savings for Western European countries, and assumptions on PH FDC SC and PT IV times and costs. United States: non-drug costs for the two strategies were estimated using average net reimbursement amounts for relevant procedure codes for intravenous and SC therapy administration among commercial payers in the MarketScan databases. **Results:** PH FDC SC is estimated to reduce non-drug costs by 73% – 80% in Western Europe, and 75% in the United States. Total monetary non-drug savings per patient over 18 cycles of treatment are estimated in the range of €2,474 – €8,975 in Western Europe, and at $10,138 in the United States. In Western Europe, where the analysis allows for a disaggregation by cost category, cost savings related to savings in patient chair time (excluding patients' productivity losses) are estimated to account for up to 62% of overall non-drug cost savings. Patients' productivity losses are estimated to explain up to 11% of non-drug cost differences. **Conclusions:** The use of PH FDC SC for the treatment of HER2-positive BC can potentially result in substantial non-drug cost savings. These savings could easily derive in overall net cost savings to the healthcare system, contributing to the long-term sustainability of the healthcare spending, while still providing a safe and effective therapy. Research Sponsor: F. Hoffmann-La Roche Ltd.

	Western Europe	United States
Non-drug cost savings per patient – full course of therapy (18 cycles)	€2,474 (73%) – €8,975 (80%)	$10,138 (75%)

Impact of endocrine therapy on overall survival in ER negative/PR positive locoregional breast cancer: An analysis of the National Cancer Database. *First Author: Vidya Kollu, Gundersen Health System, Lacrosse, WI*

Background: Breast cancer expressing PR, but not ER (ER-/PR+) are uncommon, comprising 2–8% of breast cancers, with less known about their characteristics and responsiveness to therapy. The role of adjuvant endocrine therapy (ET) in ER-/PR+ locoregional breast cancer is unclear as these patients have been largely excluded from prospective clinical trials. Despite a lack of data patients are often treated with adjuvant ET due to perceived possible benefit. We used the National Cancer Data Base (NCDB) to assess role of adjuvant ET in ER-/PR + breast cancer. **Methods:** Using the NCDB, we included adults ≥ 18 and ≤ 70 years old in order to minimize the non-cancer related deaths. We selected only female patients with stage I, II, and III. Patients have received definitive surgery (lumpectomy with radiation or mastectomy) with negative margins. Systemic therapy (ST) was defined as receipt of chemotherapy and/or immunotherapy. We excluded those who had unknown ST status, unknown ET status, unknown HER 2 status, who did not receive definitive surgery and those whose survival time was missing. Patients were stratified into four groups based on HER2 status and receipt of ET. Both Multivariable Cox proportional hazards regression modeling was utilized to determine predictors of overall survival (OS). A propensity score matched cohort was developed based on relevant demographic and clinical factors. The primary endpoint assessed was OS. All analyses were performed using SAS 9.4. **Results:** We identified 5344 patients (74% were Caucasian, 20% were African American and 6% were others) with ER-/PR+(74% were HER2 - and 26% were HER2 +) locoregional breast cancer (51% were Stage I, 38 % were stage II and 11% were stage III). Grade 1 cancer was seen in 2%, grade 2 in 18%, and majority being grade 3 in 80%. Of which 3093 (58%) patients received ET and 4462 (83%) received ST. Majority of patients were in age group 50-70 comprising of 69% patients, 8 % in age 18—39, 23% in age 40-49 with Charlson-Deyo Score of 0 in 83%, 1 in13%, 2-3 in 4%. In a propensity matched cohort (N=3980), ET was not significantly associated with OS among HER2 negative (HER2-) patients (HR=1.05, 95% CI 0.86-1.28, p=0.63). In HER2+ patient ET was associated with significantly improved OS (HR=0.65, 95% CI 0.42-0.99, p=.047). **Conclusions:** Receiving ET was not associated with improved OS in locoregional ER-/PR+/HER2- breast cancer based on our study using a propensity matched cohort in the NCDB. However, was frequently administered. Interestingly, improved OS was seen in locoregional ER-/PR+/HER2+ breast cancer with adjuvant ET. Research Sponsor: None.

Chemotherapy induced profound neutropenia (PN) in patients (pt) with breast cancer (BC) after chemotherapy and plinabulin (Plin) plus pegfilgrastim (Peg) combination versus (vs) peg alone: Final phase 3 results from protective-2 (BPI-2358-106). *First Author: Yuankai Shi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: PN [absolute neutrophil count (ANC) of <0.1 cells x 10E9/L)] is the most severe form of chemotherapy (Chemo)-induced neutropenia (CIN), and is associated with severe adverse clinical outcome. According to literature, PN leads to 80% death in first week of infection[1], 48% FN and 50% Infection[2]. Peg is standard of care for the prevention of CIN. Peg has a slow onset of action with absolute neutrophil count (ANC) recovery occurring in week 2 of the cycle (C), leaving patients (pts) vulnerable in the first week of the Cycle (C), which >75% of negative clinical consequences occur. Plin, which received breakthrough designation from FDA, is a novel, non-G-CSF small molecule agent for the prevention of CIN and has CIN protection in week 1 (Blayney JAMA Onc 2020), which is the rationale for adding Plin to Peg to achieve superior protection against CIN throughout the entire cycle vs Peg alone (Blayney, St Gallen 2019; ASCO 2019). **Methods:** Plin is given on Day (D)1 after the last Chemo, has a favorable safety profile, and also has anticancer activity. A phase 3 study evaluating Plin as an anticancer agent (DUBLIN-3; NCT02504489) in NSCLC pts, is fully enrolled, with anti-cancer OS results expected in 2021. In PROTECTIVE-2 (Study 106; NCT0329457), we compare the CIN preventive effects of Plin (on D1) added to Peg (on D2) vs Peg alone. Here we report on PN results. Study 106 is a global multicenter randomized (1:1) double-blind study to evaluate Plin 40 mg + Peg 6mg (Arm 1) versus Peg 6mg + Plac (Arm 2) in early-stage BC (node positive or node negative with a high risk of recurrence) pts (n=221) with ECOG status 0 or 1, receiving docetaxel (75 mg/m2), doxorubicin (50 mg/m2), and cyclophosphamide (500 mg/m2) (TAC). Primary objective was to compare the prevention of severe (Gr 4) neutropenia between Plin+-Peg and Peg+Plac. As an exploratory objective in C1, we evaluated PN between the Plin/Peg and Peg/Plac. ANC (Covance Central Laboratory) was assessed in Cycle 1 (C1) on D 1, 2, 3, 6, 7, 8, 9, 10, 11, 12, 13, and 15. **Results:** Shown in the table below. **Conclusions:** In conclusion, Peg still cannot protect patients with the most severe form of neutropenia, PN, at 46.4% in this study. Adding Plin to Peg offers superior protection for the prevention of profound neutropenia by reducing > 50% of PN, and its clinical sequelae in FN and hospitalization as compared to Peg alone. References: 1. Bodey et al. Ann Intern Med 64(2): 328 (1966); 2. Bodey et al. Cancer 41(4): 1610 (1978). Clinical trial information: NCT03531099. Research Sponsor: BeyondSpring Pharmaceuticals,Inc.

	Pts with PN (%)	Mean duration of PN (days)	Pts with PN and Febrile Neutropenia (%)	Pts with PN and Hospitalizations (%)

547 **Poster Session**

Head-to-head comparison of single agent (SA) plinabulin (Plin) versus pegfilgrastim (Peg) for the prevention of chemotherapy-induced neutropenia (CIN) in the phase 3 trial PROTECTIVE-1. *First Author: Douglas W. Blayney, Stanford University, Stanford, CA*

Background: Peg is the current standard of care (SoC) for the prevention of CIN, with a low absolute neutrophil (N) count (ANC) week 1 after chemotherapy (chemo) with normalization in week 2. Breakthrough designation agent from FDA, Plin, a novel, non-G-CSF agent for the prevention of CIN, produces a normal ANC in week 1 of cycle (C) 1 by potentially protecting progenitor cells in bone marrow from chemo assault, and also has anticancer activity (Blayney, St Gallen 2019; ASCO 2019). Here we report data from a pre-specified interim analysis from PROTECTIVE-1 (Study 105; NCT03102606). **Methods:** Breast cancer (BC), lung (NSCLC) and prostate cancer (HRPC) pts with at least 1 risk factor as per NCCN, received docetaxel (Doc) 75 mg/m2 with either Peg 6mg (n=53) or Plin 40 mg (n=52) over 4 cycles, and had ANC blood draws on Day (D) 1, 2,6,7,8,9,10,15 in C1 (Covance Central Laboratory). Plin was given on D1, as a 30 min IV infusion, 30 min after Doc, and Peg, 24 hrs after Doc. Primary objective was to demonstrate non-inferiority (NI) of SA Plin vs SA Peg for duration of severe neutropenia (DSN) in C1. NI of Plin vs Peg would be declared if the upper limit of 95% confidence interval for the mean DSN difference between Plin and Peg would be <0.65 day. Other endpoints included C1 platelet count, C1 bone pain scores (validated questionnaire), C1-4 clinical sequelae of CIN through [febrile neutropenia (FN), infection, antibiotic and hospitalization rate, and Doc discontinuation (Discont) and delays], and safety (AEs, hematology and chemistry, vital signs) **Results:** Predefined DSN NI criterion between SA Plin and SA Peg was met. C1 Grade 4 toxicity was not different between Plin and Peg (p=NS). Clinical sequelae of CIN were comparable or slightly better for Plin vs Peg (see Table). Plin caused less bone pain (p=0.01) and less thrombocytopenia (p<0.0001 on D15) vs Peg. AE frequency and overall safety was comparable for SA Plin and SA Peg. **Conclusions:** SA Plin has efficacy for Doc CIN prevention non-inferior compared to SoC Peg, and accordingly has comparable (or numerically better) profile for clinical sequelae of CIN. Plin has an advantage for bone pain, platelet counts, convenience of use (same day vs next day dosing) over SoC Peg and has anticancer activity. Clinical trial information: NCT03102606. Research Sponsor: BeyondSpring Pharmaceuticals,Inc.

	FN	Infection	Antibiotics	Hospitalization	Doc Discont	Doc Delay
Plin (n=52)	0%	7.69%	15.4%	3.84%	13.5%	3.85%
Peg(n=53)	1.89%	15.1%	13.2%	1.89%	26.4%	5.66%

Long-term outcomes of patients with node-negative (N0), triple-negative breast cancer (TNBC) who did not receive adjuvant chemotherapy according to stromal TILs (sTILs). *First Author: Roberto Antonio Leon-Ferre, Mayo Clinic, Rochester, MN*

Background: sTILs are a well-established prognostic and predictive biomarker in patients with operable TNBC receiving pre or postoperative systemic therapy. We[1] and others[2,3] have also shown that sTILs are prognostic in patients who did not receive adjuvant chemotherapy. Here, we detail the outcomes of systemically untreated patients with N0 TNBC according to sTIL score. We focused on the N0 subset as a group of patients who may be candidates for future prospective therapy de-escalation trials. **Methods:** From a clinically annotated cohort of 605 patients with centrally confirmed TNBC (ER/PR < 1% and HER2 negative) with long-term outcomes data, we identified 182 patients treated with locoregional therapy only (breast surgery +/- radiation therapy and no chemotherapy). The clinicopathological characteristics of this cohort have previously been published[1]. In this analysis, we report the 5- and 10-year invasive disease-free survival (iDFS) and overall survival (OS) rates of patients with N0 TNBC according to sTIL levels. IDFS and OS were defined as per the STEEP classification and estimated using the Kaplan–Meier method. Comparisons of the survival distributions between groups were assessed by the log-rank test. sTILs were assessed as a continuous parameter according to the International TIL Working Group guidelines. For comparisons of outcomes between groups, tumors were classified as lymphocyte-predominant TNBC (defined as containing ≥50% sTILs) vs non-lymphocyte-predominant (< 50% sTILs). **Results:** Of 182 systemically untreated patients, 149 (82%) were N0 and most (78%) were post-menopausal. T stage distribution was T1: 68%, T2: 28%, T3/4: 4%. Among N0 patients, 31 (21%) had lymphocyte-predominant TNBC, and in this group the 5-year iDFS and OS were 89% (95% CI 76-100) and 96% (95% CI 89-100), while the 10-year iDFS and OS were 89% (95% CI 76-100) and 87% (95% CI 73-100), respectively. In contrast, outcomes for patients with non-lymphocyte predominant TNBC were significantly worse. For this group, 5-year iDFS and OS were 62% (95% CI 53-73) and 78% (95% CI 71-86) while the 10-year iDFS and OS were 45% (95% CI 36-58) and 66% (95% CI 68-76), respectively (log-rank p = 0.02 for iDFS and log-rank p = 0.03 for OS). **Conclusions:** sTIL quantification identifies a subset of patients with early-stage N0 TNBC with an exceedingly good prognosis, even in the absence of adjuvant chemotherapy. These data provide support for the evaluation of sTILs as part of prospective investigation of systemic therapy de-escalation strategies in N0 TNBC. Validation of the RSClin risk calculator using the National Cancer Database (NCDB). *First Author: Frederick Howard, Section of Hematology/Oncology, Department of Medicine, University of Chicago, Chicago, IL*

Background: Clinical practice guidelines recommend the use of genomic assays to aid decision making regarding the use of adjuvant chemotherapy (CT) for hormone receptor-positive, HER2-negative (HR+/HER2-) early breast cancer (EBC). Recently, the RSClin clinical tool, which integrates the 21-gene recurrence score (RS) and clinicopathologic features, was developed using data from the TAILORx trial. By integrating clinical and genomic risk, RSClin demonstrated greater precision in guiding adjuvant CT use in HR+/HER2- EBC than the 21-gene RS alone. As outcomes differed by race and ethnicity in TAILORx, further validation in real world datasets of diverse populations is needed. **Methods:** This study includes patients (pts) from the NCDB who were diagnosed with HR+/HER2- EBC from 2010-2017 and received adjuvant endocrine therapy (ET) with or without CT. RSClin provides a predicted absolute reduction in distant recurrence at 10 years with CT, while the NCDB database only provides overall survival (OS) metrics. While OS underestimates distant recurrence, we correlated RSClin predictions with survival differences between pts receiving ET versus those who received ET plus CT. Inverse probability of treatment weighting was used to correct for differences in age, comorbidity index, insurance, and race/ethnicity. OS benefit of CT was assessed in pts with low ($< 2\%$), intermediate (2-5%), and high ($>5\%$) absolute CT benefit (ACB) per RSClin using the log-rank test. **Results:** 150,268 pts with EBC were included. Average (avg) age was 59 yrs; 84% were white, 8% black, 4% Hispanic, and 4% Asian/Pacific Islander. Avg tumor size was 1.7 cm, avg RS 17, and 82% had lymph node (LN) negative disease. A significant OS benefit with CT was seen in the intermediate (HR 0.70) and high (HR 0.66) RSClin predicted ACB in the LN negative pts. When analyzed by racial / ethnic subgroup, all pts with a high RSClin ACB had improvement in survival with CT; in pts with an intermediate RSClin ACB, only white pts demonstrated significantly higher OS with CT (HR 0.72). **Conclusions:** Although developed to predict distant recurrence rates, the RSClin tool also correlates with OS in pts receiving ET with or without CT, which can aid in clinical decision making in pts with HR+/HER2- EBC. Predictive accuracy of RSClin differs by race/ethnicity. Accurate risk stratification in diverse populations is essential in ensuring equitable treatment and mitigating disparities in breast cancer outcomes in different racial/ethnic groups. 550 Poster Session

Molecular characterization of luminal breast tumors in African American women. *First Author: Yael Simons, University of Illinois at Chicago College of Medicine, Division of Medical Oncology, Chicago, IL*

Background: Racial disparities in breast cancer (BC) mortality are attributed to later stage diagnoses and a higher incidence of triple-negative BC among African American (AA) women. In previous work, we showed that AA women with ER+ BC are more likely to develop biologically aggressive disease and are more likely to die from early stage, ER+ BC than non-Hispanic White women (Hoskins et al, JAMA Oncol, 2021). The underlying molecular drivers of this disparity are unknown. Here we report the molecular characterization of a series of luminal BC from AA women. **Methods:** Consecutive breast tumor specimens received in the Pathology Department underwent next generation sequencing (NGS). Unstained FFPE tissue sections were macrodissected to isolate tumor cells, and nucleic acids were extracted using commercially available kits. DNA and RNA sequencing libraries were prepared with the Oncomine Comprehensive Assay v3 (OCAv3) (Thermo Fisher), which includes 161 driver genes and detects SNVs, CNVs, INDELs and gene fusions. Sequencing was performed on the Ion S5XL sequencer. Sequencing reads were mapped to the UCSC human genome build GRCh37/hg19 using Torrent Suite™ software (version 5.10; Thermo Fisher). Data analysis and variant calling was performed using the Ion Reporter analysis tool. **Results:** We identified 60 somatic driver gene alterations in luminal tumors from 35 AA patients (primary tumors, n = 26; metastatic tumors, n = 9). Recurrently altered genes identified in $> 5\%$ of tumors are listed in the Table. The most frequently altered gene was *PIK3CA* (42% of tumors). *ESR1* gene fusions were seen in 25% of tumors. Interestingly, an equal frequency of *ESR1* fusions were detected in primary (27%) and metastatic (22%) tumors, in contrast to activating mutations which are found in recurrent tumors following treatment with aromatase inhibitors. *ARID1A* alterations were identified in 17% of primary tumors. *ARID1A* encodes a subunit of the SWI/SNF chromatin remodeling complex. Alterations in *ARID1A* confer endocrine resistance, and are enriched in recurrent tumors in the literature. We also found a high number of CNVs in members of the *FGF* gene family (36% of tumors), which are also associated with resistance to endocrine therapy. An *in silico* analysis comparing our findings with publicly available datasets will be presented. **Conclusions:** This study of somatic driver gene alterations in a consecutive series of luminal breast tumors from AA patients found a higher than expected frequency of alterations in genes associated with endocrine resistance in untreated primary tumors, suggesting a partial explanation for racial disparities in survival. Research Sponsor: None.

Recurrent somatic alterations in driver genes.

Gene	Number of tumors with alteration (%)
ARID1A	6 (17%)
ATM	4 (11%)
CCND1	5 (14%)
ERBB2	7 (20%)
ESR1	2 (6%)
ESR1-AKAP12	3 (8%)
ESR1-ARMT1	2 (6%)
ESR1-CCDC170	4 (11%
FGF19	4 (11%)
FGF3	4 (11%)
FGFR1	5 (14%)
PIK3CA	15 (42%)
PTEN	4 (11%)

Population-based estimates of the age-specific cumulative risk of breast cancer for pathogenic variants in *CHEK2*: Findings from the Australian Breast Cancer Family Registry. *First Author: Tu Nguyen-Dumont, Monash University, Clayton, Australia*

Background: Case-control studies of breast cancer have consistently shown that pathogenic variants in *CHEK2* are associated with about a 3-fold increased risk of breast cancer. Information about the recurrent protein truncating variant *CHEK2*c.1100delC dominates this estimate. There have been no formal estimates of age-specific cumulative risk of breast cancer for all *CHEK2* pathogenic (including likely pathogenic) variants combined. **Methods:** We conducted a genetic screen of *CHEK2* in an Australian population-based case-control-family study of breast cancer. This study is focused on disease at an early age and participants were unselected for family history. The age-specific cumulative risk (penetrance) of breast cancer was estimated using segregation analysis. **Results:** The estimated hazard ratio for carriers of pathogenic *CHEK2* variants (combined) was 4.9 (95% CI 2.5-9.5; $p < 0.0001$) relative to non-carriers. The HR for carriers of the *CHEK2* c.1100delC variant was estimated to be 3.5 (95% CI 1.02-11.6) and the HR for carriers of all other *CHEK2* variants combined was estimated to be 5.7 (95% CI 2.5-12.9). The age-specific cumulative risk of breast cancer was estimated to be 18% (95% CI 11-30%) and 33% (95% CI 21-48%) to age 60 and 80 years, respectively. **Conclusions:** These findings provide important information for the clinical management of breast cancer risk for women carrying pathogenic variants in *CHEK2*. Research Sponsor: National Breast Cancer Foundation Australia, Monash University.

Use of a high-sensitivity anti-Mullerian hormone (AMH) assay to determine ovarian function after chemotherapy for early breast cancer. *First Author: Florian Clatot, INSERM U1245, IRON Group, Centre Henri Becquerel, University Hospital, University of Normandy, Rouen, France*

Background: It is now well established that AMH can indicate the extent of chemotherapy-induced damage on the ovarian reserve. Very low AMH levels in women after chemotherapy for early breast cancer (eBC) may indicate treatment-induced premature ovarian failure (POI), but the evidence to implement its routine clinical use remains limited. **Methods:** AMH was measured (Roche cobas autoanalyser) in 197 women aged 40-45 years at diagnosis treated with anthracycline/cyclophosphamide/taxane based chemotherapy for eBC, with no previous endocrine therapy and no subsequent aromatase inhibitor exposure or ovarian suppression. 76% were ER positive and received tamoxifen. The primary objective was to assess the relationships between AMH levels at 6 months after chemotherapy (AMH6) with subsequent ovarian function at 30 months. This included accuracy of prediction of loss of ovarian function at 30 months (E30) after chemotherapy by AMH levels at 6 months (AMH6) and the value of other endocrine/clinical factors pretreatment and at 6 months. Multivariate analysis was performed with data were split into 70% training and 30% testing sets with results reported for model performance on the test set. **Results:** AMH fell from a median of 0.62 (IQR 0.21-1.31) ng/ml pretreatment to become undetectable (< 0.01ng/ml) in 137 (70%) of women at 6 months. AMH showed very little recovery, being undetectable in 115 women at 18 months and 119 at 30 months. In those with detectable AMH at 30 months, it remained very low, median 0.07ng/ml, max 0.82ng/ml but nevertheless it reflected ovarian function. Thus median estradiol at 30 months (E30) was 50 pmol/l (IQR 34-68) in women with undetectable AMH at that time, vs 313 pmol/l (IQR 102-1052) in the 80 women with detectable AMH. AMH at 6 months was predictive of ovarian function at 30 months, as E30 was 56 pmol/l (IQR 40-104) in women with undetectable AMH6 vs 258pmol/l (IQR 69-780; $p < 0.0001$) in women with detectable AMH6, and the positive predictive value (PPV) of AMH being undetectable at 6 months and remaining so at 30 months was 77%. Random forest analysis identified BMI as a non-endocrine predictive factor of E30. Using a stringent cutoff of $\leq$50pmol/l (13.6 pg/ml) and adding 1:9 weighting to improve PPV gave a test validated PPV of 79.0% while maintaining AUC at 83.7% for prediction of E30. Other classifiers performed less well than random forests. **Conclusions:** Measurement of AMH at 6 months after chemotherapy has predictive value for later ovarian function, and combining this with other endocrine and baseline data improves discriminative ability. This approach indicates the potential role of multivariate analysis based on AMH measured shortly after chemotherapy to helping optimise subsequent endocrine therapy. A gp78/AMFR protein-driven gene signature that predicts breast cancer outcome. *First Author: Sandeep K Singhal, Department of Pathology, School of Medicine and Health Sciences, University of North Dakota, Grand Forks, ND*

Background: gp78, also known as the autocrine motility factor receptor (AMFR) or RNF45, is a polytopic RING-type E3 ubiquitin ligase resident to the endoplasmic reticulum (ER) that plays major role in the cellular response to stress by regulating ER homeostasis and signaling through its participation in the unfolded protein response (UPR) and ER associated degradation. We used machine learning (ML) and statistical modeling (SM) to assess gp78 as a protein biomarker that is an independent predictor of breast cancer (bc) survival exclusively in women of self-reported African descent as opposed to European ancestry. **Methods:** We examined a cohort of racially diverse 555 BC bc patients who underwent surgery for their primary BC in Greenville, NC using ML and SM approach. We leveraged the availability of RNA-seq gene expression data on a portion of our bc cohort (N=136 of 555) to construct gene expression signatures. **Results:** Using antibodies developed in the Weissman lab and established methods for quantitative IHC, we have found that gp78 expression is significantly increased in the tumors of bc patients compared to normal breast epithelia. In addition, we found that gp78 is expressed at significantly higher levels in bc of non-Hispanic black women (NHB) compared to non-Hispanic white women (NHW) (p=0.0038), and that bc subtypes known to be more aggressive and associated with higher grades like, Basal (p=1.6e-12), Luminal B (p=2.3e-4) and HER2(8.3e-4), display significantly higher levels of gp78 compare to Luminal A. Moreover, Kaplan-Meier survival curve analyses show that gp78 protein expression is more significantly associated with poor survival in NHB women (HR:1.65, p=0.073) compared to NHW women (HR:2.01, p=0.004). Finally, multivariate analysis reveals that gp78 protein expression, based on quantitative IHC, is an independent predictor of poor bc survival exclusively in women of African (NHB) ancestry (HR:1.99, p=0.017). We leveraged the availability of RNA-seq gene expression data on a portion of our bc cohort to construct gene expression signatures or gene modules. An analysis of pooled publicly available data from 845 patients that underwent neoadjuvant chemotherapy for bc (primarily taxane and anthracycline based), reveals that gp78 gene modules are highly predictive of patient response to therapy. gp78-derived gene modules show both high fold difference and significance in predicting response to therapy (AUC:0.72) which is very similar to other multi-gene panels that are currently in clinical use including Prosigna, MammaPrint, and Oncotype Dx. **Conclusions:** Our results show that gp78/AMFR is an independent predictor of bc survival and response to therapy, based on race, thus implicating a role for this protein, and potentially the UPR, as underlying biological differences in tumor properties linked to genetic ancestry. Neoadjuvant talazoparib (TALA) in patients (pts) with germline *BRCA1/2* (g*BRCA1/2*) mutation-positive, early HER2-negative breast cancer (BC): Exploration of tumor *BRCA* mutational status and zygosity and overall mutational landscape in a phase 2 study. *First Author: Melinda L. Telli, Stanford University School of Medicine, Stanford, CA*

Background: TALA is a poly(ADP-ribose) polymerase inhibitor approved as monotherapy for adult pts with g*BRCA1/2*-mutated HER2-negative locally advanced/metastatic BC. We report biomarker analyses from a phase 2, nonrandomized, single-arm, open-label study (NEOTALA; NCT03499353) evaluating the efficacy and safety of TALA in the neoadjuvant setting for pts with early g*BRCA1/2*-mutated HER2− BC. Efficacy and safety results are presented separately. **Methods:** The biomarker analysis population was all pts treated with TALA for whom biomarker results are available. To support molecular eligibility, blood was tested using BRCAnalysis CDx (Myriad Genetics). Baseline tumor tissue was retrospectively tested using FoundationOne CDx, with *BRCA1/2* zygosity assessed using somatic-germline-zygosity (SGZ; Sun et al. JCO PO, 2018). Germline mutational status of 14 non-*BRCA* DNA damage response (DDR) genes was retrospectively assessed in baseline saliva samples using Ambry CustomNext-Cancer. Mutations were defined as known/likely pathogenic/deleterious variants, including copy number alterations (CNAs). Association between mutational status of *MYC* or *RAD21* and primary endpoint pathological complete response (pCR) as per Independent Central Review was investigated with logistic regression. **Results:** Of 52 evaluable tumor samples from 61 treated pts, 39 (75%) and 13 (25%) pts exhibited *BRCA1* and *BRCA2* mutations, respectively; 1 (2%) pt exhibited mutations in both genes, and 1 (2%) pt had mutations in neither. *BRCA* loss of heterozygosity (LOH) was seen in 42/43 (98%) evaluable *BRCA*-mutant tumors. Of 45 pts evaluable centrally for both germline and tumor, 44/45 (98%) pts exhibited the same *BRCA* mutation in tumor as originally detected in germline, with the remaining pt exhibiting a g*BRCA1* mutation, but lacking a tumor *BRCA* mutation. None of 49 saliva-evaluable pts exhibited non-*BRCA* germline DDR mutations. *TP53* (51 [98%] pts) was the most frequently mutated gene in tumors. *MYC* and *RAD21* (each 14 [27%] pts) were the most frequent CNAs. No evidence of association between mutational status of *MYC* or *RAD21* and pCR was found (odds ratio=0.39, 95% CI 0.12-2.30). Based on a cutoff of ≥16%, genomic LOH was elevated in 24/27 (89%) tumors evaluable for both gLOH and pCR, precluding assessment of the potential association of gLOH high/low status with pCR. **Conclusions:** Tumor *BRCA* mutations were evident in nearly all pts in the biomarker analysis population, with *BRCA* LOH evident in all but 1 *BRCA*-mutated tumor. No pts had non-*BRCA* germline DDR gene mutations; tumor *TP53* mutations were near-universal. *MYC* and *RAD21* each exhibited CNAs in 27% of tumors, with no association with pCR. These results support the central role of *BRCA* mutations in tumor pathobiology in this indication. Clinical trial information: NCT03499353. Research Sponsor: Pfizer Inc.

ER and immune-related signatures define benefit to palbociclib, trastuzumab, pertuzumab +/- fulvestrant in ER+/HER2+ breast cancer patients in the NA-PHER2 trial. *First Author: Giampaolo Bianchini, IRCCS Ospedale San Raffaele, Milan, Italy*

Background: In the NA-PHER2 study we assessed the association between biological pathways with pathological complete response (pCR) and Ki67 down-regulation **Methods:** Patients with centrally confirmed ER+ (> 10%) HER2+ breast cancer (BC) were treated in two independent, non-randomized cohorts with neoadjuvant trastuzumab, pertuzumab, palbocilib with (Fulv, n = 30) or without (NoFulv, n = 28) fulvestrant (+/-LHRH analogues). We assessed RNA-seq on core-biopsies obtained pre-treatment [n = 53/58 (91.4%)], at day 14 [n = 49/58 (84.5%)], and on residual disease at surgery [n = 42/45 (93.3%)]. We investigated biomarker dynamics and association with pCR or Ki67 down-regulation (centrally evaluated) at day 14 and at surgery. In the overall population and in each cohort, we primarily assessed three pre-defined biomarkers (ER-metagene [from OncotypeDX], a CD8-metagene and ERBB2 expression), and secondarily we explored a pre-defined list of genesets. Continuous and categorical (median cut-point) variables were evaluated. **Results:** In the biomarker population, pCR rate was 22.5% (28.6% and 16.0% in Fulv and NoFulv cohorts). At baseline, continuous CD8-metagene (OR 1.85 [1.12-3.06], p = 0.016) and ER-metagene (OR 0.56 [0.34-0.90], p = 0.016) associated with higher and lower pCR rate, respectively. High ERBB2 (above median) was marginally associated with pCR (OR 3.83 [0.90-16.3], p = 0.068). Only ER- and CD8-metagenes retained significance in multivariate analysis and were similarly predictive in both cohorts. Combining categorical variables, the groups with high-CD8/low-ER and low-CD8/high-ER had 61.5% and 0% pCR rate respectively, whereas low-CD8/low-ER and high-CD8/high-ER had similar 15% pCR (p = 0.001). The association was significant in both cohorts (p = 0.019 Fulv; p = 0.028 NoFulv). Dynamic assessment of the same biomarkers at day 14 did not improve prediction. Higher ER-metagene at baseline, but not CD8 and ERBB2, was associated with robust down-regulation of Ki67 at day 14 (Ki67 < 2.7%, complete cell cycle arrest) only in Fulv cohort (p = 0.016). ER-metagene also associated with retained Ki67 down-regulation (Ki67 < 10%) at surgery (p = 0.002). Alternative ER- and immune-related signatures provided very similar results. The comprehensive landscape of complex molecular dynamics and exploratory association with outcome will be presented. **Conclusions:** In ER+/HER2+ BC, low expression of ER-related and high expression of immune-related genes identified patients with very high likelihood of achieving pCR with a chemo-free regimen. In the fulvestrant cohort, the group with high ER-metagene, despite a lower pCR rate, had higher Ki67 down-regulation at day 14, which has been associated with long-term benefit in luminal tumors. These findings provide a potential tool for tailored de-escalation strategies. Dysregulation of soluble immune checkpoint proteins in newly-diagnosed early breast cancer patients. *First Author: Bernardo Leon Rapoport, Department of Immunology, Faculty of Health Science, University of Pretoria, Pretoria, South Africa*

Background: Checkpoint proteins regulate the immune system. Breast cancer (BC) cells exploit the up-regulation or down-regulation of these proteins to evade anti-tumor immune responses. Soluble forms of immune checkpoint molecules (ICM) can be measured in human plasma, however their biological and clinical significance remains essentially unknown. The aim of the present analysis was to measure the pre-treatment ICM in newly- diagnosed BC patients (pts) and compare them to healthy controls. **Methods:** Soluble forms of ICM, as well as cytokines and chemokines, were measured using Multiplex bead array and ELISA technologies. Plasma samples from 98 BC pts and 45 healthy controls were analyzed for each protein. Data was prospectively obtained. Measured levels were compared between BC pts and healthy controls using a non-parametric test (Mann-Whitney). P-values below 0.05 were considered statistically significant. **Results:** Soluble stimulatory molecules GITR ($p < 0{,}000002$), GITRL ($p < 0{,}007$), CD27 ($p < 0{,}002$), CD28 ($p < 0{,}003$), CD40 ($p < 0{,}003$), CD80 ($p < 0{,}009$), ICOS ($p < 0{,}0006$), as well as inhibitory molecules PD-L1 ($p < 0.0000001$), CTLA-4 ($p < 0{,}005$), TIM-3 ($p < 0{,}00006$), HVEM ($p < 0{,}00002$) TLR-2 ($p < 0{,}05$), levels were significantly lower in early BC pts compared to healthy controls. When analyzed according to BC characteristics (TNBC vs. non-TNBC, tumor size, stage, nodal status and age) no significant difference was detected between the soluble levels of these ICM between the different subsets. Additionally, serum CXCL5 ($p < 0{,}000001$), CCL23 ($p < 0{,}04$), IL-16 ($p < 0{,}00005$), interferon-α ($p < 0{,}03$) and IL1-RA ($p < 0{,}03$) were significantly lower compared to healthy controls. Serum CX3CL1 or fractalkine ($p < 0{,}024465$) was significantly higher compared with healthy controls. Serum interferon-γ ($p < 0{,}2$), IL-6 ($p < 0.6$) and IL-2 ($p < 0.6$) levels were not significantly different between the BC pts and the healthy controls. **Conclusions:** We identified low levels of both the stimulatory and inhibitory immune checkpoint molecules, in newly-diagnosed, non-metastatic BC pts compared to healthy controls. These results indicate that early BC is associated with a down-regulation of both soluble stimulatory and inhibitory immune-checkpoint pathways. Newly-diagnosed early BC pts have a generalized immune-suppression independent of subtype (TNBC vs non-TNBC) and stage, which, to our knowledge, is the first study to describe soluble immune checkpoints in early BC pts. Genomic characteristics of breast cancer to predict response of neoadjuvant chemotherapy and long-term prognosis. *First Author: Ji-Yeon Kim, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: To precisely predict neoadjuvant chemotherapy (NAC) response and long-term prognosis, we developed prediction model with clinical and genomic characteristics of breast cancer (BC). **Methods:** We included early and locally advanced BC that would be scheduled to receive standard NAC (four cycles of anthracycline and cyclophosphamide and four cycles of docetaxel or docetaxel plus trastuzumab for HER2+ BC) followed by curative surgery. For each patient, tumor tissue and matched blood were prospectively collected three times: at diagnosis (T1), three weeks after the first cycle of chemotherapy (T2), and curative surgery (T3). Whole exome sequencing (WES) was performed to detect somatic mutation, mutational signature and tumor mutational burden (TMB) while RNASeq with PAM50 prediction was to classify intrinsic subtype. In terms of clinical variables, clinical stage and IHC subtype at diagnosis, residual cancer burden (RCB) class and distant recurrence free survival (DRFS) were used. Logistic regression was used for predicting RCB class with clinical and genomic variables at T1. Univariate and multivariate Cox regression were performed to identify prognostic factors for DRFS. **Results:** In total, 210 patients were enrolled and treated with NAC as scheduled. We successfully conducted WES in 231 BC tissues (T1:117, T2:101 and T3:13) from 117 patients. In NAC response, 13 patients were in RCB class 3, 39 in class 2, 14 in class 1 and 46 in class 0. Median follow up duration was 44months and distant recurrence was observed in 13 patients. *TP53* mutation (68%) was the most commonly detected genetic alteration. *ARID1A*, *CDH1*, *CSMD3*, *LRP1B*, *PIK3CA*, *RUNX1* and *TP53* were significantly mutated genes in driver gene analysis. Median TMB was 87 (range, 14-570) and signature 3 was most frequently observed. Among genetic characteristics, high TMB was significantly associated with better NAC response compared with low TMB (hazard ratio[HR] for RCB class III: 0.11, 95% confident interval[CI]: 0.01, 0.74, p = 0.05). In prediction model, combination of seven variables: intrinsic subtype, TMB, *LRRK1*, *OPLAH*, and *PIK3CA* hotspot mutation, *ERBB2* amplification, and clinical stage had 0.83 in area under curve (AUC) and 0.75 in accuracy. High clinical stage, *PTEN* and *PIK3CA* hotspot mutation negatively affected to DRFS while high TMB had protective effect (all ps < 0.05). Prediction model made with five variables: intrinsic subtype, TMB, *PTEN* mutation, *PIK3CA* hotspot mutation and clinical stage had 0.88 in c-index (95% CI: 0.81, 0.95). **Conclusions:** TMB, *PIK3CA* hotspot mutation and clinical stage showed predictive roles on NAC response and distant recurrence of BC in NAC setting. In prediction model, intrinsic subtype, TMB, *LRRK1*, *OPLAH*, and *PIK3CA* hotspot mutation, *ERBB2* amplification, and clinical stage affected to RCB class while intrinsic subtype, TMB, *PTEN*, *PIK3CA* hotspot mutation and clinical stage did to DRFS. Clinical trial information: NCT02591966. Research Sponsor: None.

MamaPred: A new and innovative approach to determine recurrence risk in HR+/HER2- early-stage breast cancer using HTG EdgeSeq technology. *First Author: Jose Antonio Lopez Guerrero, Department of Pathology, Medical School, Catholic University of Valencia, Valencia, Spain*

Background: Genomic platforms, such as Mammaprint (Agendia) (MP) and OncoType (Genomic Health) (OT), have been validated to determine the risk of relapse in therapeutic decision-making in early-stage hormone receptor positive (HR+), epidermal growth factor receptor 2 (HER2) negative breast cancer (BC). Discordances in risk allocation between these platforms affect up to 30% of patients. This study aims to develop the MamaPred test to improve the diagnostic performance of recurrence risk in HR+/HER2- early-stage BC. **Methods:** A total of 606 HR+/HER2- early-stage BC previously tested with OT [n = 287; Low Risk (LR) = 165, Intermediate Risk (IR) = 103 and High Risk (HR) = 19] and MP (n = 319; LR = 217 and HR = 102) were included. A retrospective independent series of 144 HR+/HER2- early-stage BC [median follow-up: 10.53 years (range: 3.1-23.1 yrs); age (median = 62.9 yrs (33-89 yrs); systemic relapse 10.5% (n = 15)] was used as validation set.The expression levels of 2560 cancer-related mRNAs were evaluated from one 5 μm thin-section of a FFPE block (15 mm2 tumor area) using the Oncology Biomarker Panel (OBP) and the HTG EdgeSeq System (HTG Molecular Diagnostics. Inc) and quantified by NGS on a NextSeq550 sequencer (Illumina). A predictive model was built from normalized and logarithmically transformed values (rescaled to [0, 1]) using as response a binary metavariable constructed by taking the values -1 (for LR of MP and OT together the OT IR) and 1 (for HR MP and OT). Differential expression, GSEA and visualization were performed with DESeq2, gage and pathview packages respectively in R v4.0.1. **Results:** MamaPred consists of a logistic regression classifier with an elastic net penalty (mix of L1 and L2 priors as regularizer) where the mixing parameter is optimized along with regularization strength by selecting the ones that minimize the area under the precision and recall curve over a validation split for each training fold. Metrics of MamaPred were: balanced accuracy, 80.5%; Kappa, 0.562; specificity, 80.7%; and NPV, 91.4%. GSE analysis on differentially expressed genes ($q < 0.1$) showed four KEGG pathways overrepresented in HR ($p < 0.05$): *adherens junction*, *tight junction*, *glutathione metabolism* and *focal adhesion*; and two underrepresented: *DNA replication* (p = 0.0765) and *pyrimidine metabolism* (p = 0.086).The prognostic prediction of MamaPred was validated on the independent retrospective series, distant disease-free survival for HR and LR being 88.63% (95% IC: 78.72%-99.78%) and 98.1% (95% IC: 95.6%-100%) respectively (p = 0.00603). Correlation between the probabilities assigned to any given sample and its replicas was extremely high ($r > 0.9$ $p <$ 1e-5). **Conclusions:** MamaPred identifies HR+/HER2- early-stage BC patients with high-risk of distant relapse improving the prognostic value of those studies that compare MP and OT, suggesting a more precise risk classification. Gene expression associated with lymphovascular invasion and genomic risk in early-stage breast cancer. *First Author: Nina D'Abreo, Perlmutter Cancer Center at NYU Langone Hospital-Long Island, NYU Long Island School of Medicine, Mineola, NY*

Background: Lymphovascular invasion (LVI), the passage of carcinoma cells through lymphatic and blood vessels, is an important early step in metastasis; however, LVI is excluded from most breast cancer (BC) clinical risk assessments. Previous studies assessed the prognostic value of LVI to estimate clinical outcomes. To gain understanding of the molecular basis of LVI, we evaluated differentially expressed genes (DEGs) between tumors with LVI *versus* those without LVI, stratified by the 70-gene signature (MammaPrint/MP) and 80-gene molecular subtyping signature (BluePrint/BP). **Methods:** The prospective, observational FLEX Study (NCT03053193) includes stage I-III BC patients who receive MP/BP testing and consent to full transcriptome and clinical data collection. Patients with LVI (n=581) and without LVI (n=600, randomly selected), enrolled from 2017 to present, were included. LVI was assessed by local pathology laboratories. Differential gene expression analysis of 44k Agilent microarray data was performed with R limma package. DEGs were compared within all samples, BP Luminal subtype, MP risk groups (Low Risk [LR]/Luminal A and High Risk [HR]/Luminal B), and by lymph node (LN) status. DEGs with FDR<0.05 were considered significant. **Results:** Of tumors with LVI (LVI+), 66% were MP HR; notably, 51% of tumors without LVI (LVI-) were MP HR. LVI was associated with larger T stage, LN involvement, high grade, negative ER status by IHC, and younger patient age (LVI+ vs. LVI-, $p<0.05$ for all comparisons). Patient ethnicity, obesity, and tumor type did not differ by LVI status; however, prevalence of type 2 diabetes trended higher in patients with LVI+ HR tumors (21%), compared with LVI- HR (15%, p=0.09) and LVI+ LR (11%, p=0.004). There were significant transcriptomic differences between LVI+ and LVI, *with most DEGs evident in the Luminal B subset.* DEGs in LVI+, LN-negative (LN-) tumors overlapped substantially with the overall Luminal group analysis. Functional enrichment analysis showed dysregulation of cell cycle, extracellular matrix (ECM) organization, cell adhesion, and cytokine receptor pathways. Gene sets related to insulin growth factor pathways were also enriched in LVI+ tumors. **Conclusions:** DEGs associated with LVI were primarily found in MP HR Luminal, LN-negative tumors; enrichment analysis suggested dysregulation of ECM organization and cell adhesion pathways, consistent with previous reports. DEGs were not associated with LVI presence in LN+ tumors, suggesting that LVI assessment may be less relevant in LN+ breast cancer. Future studies will assess clinical outcomes, as well as LVI-associated gene expression in BP Basal- and HER2-type tumors. However, the current analysis indicates few DEGs in LVI+ MP LR tumors; thus, the potential prognostic information gained from LVI-associated gene expression is likely already captured by the MP and BP signatures. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

Race, subjective social status and metabolic syndrome in women with breast cancer. *First Author: Giampaolo Greco, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Metabolic syndrome (MS) is associated with worse breast cancer prognosis. Black women have higher rates of advanced breast cancer, as well as MS, diabetes and obesity. As socioeconomic status is associated with MS, we asked whether the subjective perception of social status (SSS), might influence this association in black and white women with a new breast cancer (BC) diagnosis. **Methods:** We surveyed, obtained serum and conducted anthropometric measures of 1206 women with a new BC diagnosis. Triglycerides, systolic blood pressure (SBP), waist circumference (cm), HDL and glucose were used to calculate a severity index of MS (MS-Zscore: mean=0; sd=1). Women reported their SSS on the 10 rung McArthur US social status ladder, their household income, education attained, diet quality (5 point scale), and exercise measured with metabolic equivalents (METS). Data were analyzed with multivariable generalized linear models. Missing data were imputed with multiple imputation. **Results:** Average age was 58 yrs of 295 black and 911 white women. BC stage > II was in 11.6% of black and 2.4% of white women. On average black women had higher BMI (31.5 vs 26.6; p<0.001), waist circumference (103 vs 93; p<0.001) glucose (96 vs 92; p<0.001) and SBP (132 vs 126; p<0.001); lower triglycerides (92 vs 104; p<0.001) and HDL (59 vs 68; p<0.001). Black women were more likely than white women to live in poverty (23.7% vs 4.6%; p<.001); report poor diet (32.4% vs 10.4%; p<.001) and less exercise (29.7% v 23.6% in the 25th %ile), and less likely to graduate college (30.3% vs 70.4%). MSZ-score was positively associated with age (.02 per year; p<.001) and black race (0.35; <.001) and negatively with better diet (-.20 per point in 4 point scale); p<.001), exercise (-.11 per quartile increase in METS; p<.001) and SSS (-.04 per ladder rung; p=.004). SSS was lower in black women within the same levels of income and education). **Conclusions:** Race, age, diet, exercise and subjective social status all impact metabolic syndrome, a risk factor for breast cancer. Of concern, among breast cancer patients, black women are more likely to rate their SSS below white women, within each education or income level. Subjective social status among women with a new breast cancer diagnosis is associated with MS and may be important to address as a risk factor among breast cancer patients. Research Sponsor: U.S. National Institutes of Health.

Association of allograft rejection response score with biological cancer aggressiveness and with better survival in triple-negative breast cancer (TNBC). *First Author: Masanori Oshi, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Although the importance of immunity in the progression of breast cancer was widely reported, the clinical relevance of enhanced immune response is still unclear. We hypothesized that the enhanced immune response is associated with better breast cancer patient survival. **Methods:** We used 6,245 breast cancer patient sample data from publicly available data sets (METABRIC, GSE96058, TCGA cohorts). To elucidate the function of immunity in breast cancer, we calculated the immune function score using hallmark allograft rejection gene sets by Gene Set Variation Analysis algorithm. **Results:** The immune response score correlated most with cytolytic activity among hallmark immune-related gene sets in both cohorts (Spearman's rank correlation (r) = 0.892 and 0.860, respectively, both $p < 0.01$). The score reflected the amount of infiltrating immune cells, including several anti-cancer immune cells (CD8+ T cells, CD4+ memory T-cells, T helper Type 1 cells, M1 macrophages, plasmacytoid dendritic cells), T helper Type 2 cells, and B cells. The score also correlated with expression levels of immune checkpoint molecule genes (all $r > 0.500$). A high score was significantly associated with high intratumor heterogeneity, homologous recombination deficiency (HRD), and mutation rate in the TCGA cohort (all $p < 0.001$). A high score was significantly associated with advanced Nottingham histological grade, advanced stage, and lymph node metastasis. High score breast cancer enriched not only immune-related gene sets but also pro-cancer-related gene sets, such as epithelial-mesenchymal transition (EMT) and p53 pathway, in both ER-positive/HER2-negative breast cancer and TNBC. The score was highest in TNBC compared to other subtypes, and TNBC with high score was significantly associated with better survival. **Conclusions:** The counterbalance between malignant biology and the enhanced immune response is an important factor in clinical outcomes. Association of changes of pro-inflammatory markers with physical function in women with breast cancer receiving chemotherapy. *First Author: Nikesha Gilmore, University of Rochester Medical Center, Rochester, NY*

Background: Chemotherapy adversely affects the immune system and physical function. Inflammation is independently associated with functional decline. Compared to the individual cytokines [e.g., interleukin-6 (IL-6)], the pro-inflammatory index, IL-6/IL-10 ratio, is a better predictor of poor outcomes and mortality in many diseases. Other markers of inflammation such as soluble tumor necrosis factor (sTNFR) I, and sTNFRII have also been shown to be predictive of poor outcomes. We have previously reported a significant increase in sTNFRI/II with chemotherapy in patients with breast cancer. However, it is not yet understood if chemotherapy-related changes to inflammatory makers is associated with physical function after treatment. In this study, we assessed the relationship between changes of pro-inflammatory markers during chemotherapy with physical function after completing chemotherapy. **Methods:** This was a secondary analysis of a large nationwide cohort study in women with stage I-III breast cancer (NCT01382082). Serum levels of IL6, IL10, sTNFRI, and sTNFRII were measured $\leq$7 days before chemotherapy (T1) and $\leq$1 month after chemotherapy (T2), and the IL6/IL10 ratio was calculated. Absolute changes (T2-T1) of sTNFR-I and sTNFRII (reported in pg/mL) and the IL6/IL10 ratio were calculated. Physical function was measured by the Functional Assessment of Cancer Therapy: General – physical well being (FACT-PWB) at T1 and T2 and contains 7-items, each using a 5-point rating scale ranging from 0 (Not at all) to 4 (Very much), with a total score ranging from 0-28; higher scores represent higher physical function. ANOVA was used to compare means of FACT-PWD scores and mean changes of pro-inflammatory markers. Multivariate linear regressions were used to determine if increased pro-inflammatory markers were associated with lower FACT-PWD at T2, controlling for baseline FACT-PWD, age, race, education, and marital status. **Results:** We included 580 patients (mean age=53 years, range 22-81). Physical function significantly and clinically declined from T1-T2 (mean=22.2, SE=0.23 vs mean=19.4, SE=0.25; $p<0.001$). From T1-T2, there was a significant increase in IL6/IL10 (average change = 0.32, SE=0.09; p=0.004). A greater increase in pro-inflammatory markers from T1 to T2 was associated with lower FACT-PWD score at T2; sTNFRI (β=-3.92, SE=1.4), sTNFRII (β=-14.9, SE=7.1), and IL6/IL10 (β=-0.17, SE=0.06); all $p<0.05$. **Conclusions:** Serum pro-inflammatory markers increased from pre-chemotherapy to post-chemotherapy in patients with breast cancer. Greater increases in pro-inflammatory markers are associated with lower physical function within one month of the completion of chemotherapy. Pro-inflammatory markers; sTNFRI, sTNFRII, and IL6/IL10, may serve as useful biomarkers to help identify patients at risk of reduced physical function after chemotherapy. Molecular profiles of genomically high risk ER+ HER2- breast cancer tumors classified as functionally basal or luminal B by the 80-gene signature. *First Author: Joyce O'Shaughnessy, Texas Oncology-Baylor Sammons Cancer Center, US Oncology, Dallas, TX*

Background: The 80-gene signature (BluePrint/BP) classifies early-stage breast cancers based on functional molecular pathways as luminal, HER2, or Basal-type. In the NBRST study, 13% of immunochemistry (IHC) defined ER+ HER2- cancers reclassified as Basal-type by the BP assay (ER+ Basal), and these had worse prognosis but responded better to neoadjuvant chemotherapy than ER+ HER2- cancers classified as genomically luminal-type. The 70-gene risk of recurrence signature (MammaPrint/MP) further stratifies luminal-type cancers into low risk luminal A or high risk (HR) luminal B. HR cancers can be further stratified into High 1 (H1) or High 2 (H2), and the I-SPY2 trial has shown higher pCR rates in ER+ cancers classified as H2. Here, we investigated biological differences among ER+ Basal, ER- Basal, H1 luminal B, and H2 luminal B cancers by full transcriptome analysis. **Methods:** From the FLEX Study (NCT03053193), 1501 breast cancers with known IHC ER status were classified by MP and BP: 103 ER+ Basal, 210 ER- Basal and 1188 luminal B (H1 n=1034, H2 n=154). Clinical factors were assessed by either the Chi-square or Fisher's exact tests; ANOVA or *t* test were used to analyze age. Differentially expressed genes (DEGs) were detected using Limma and pathway analyses were performed with GSEA. DEGs with a fold change >2 and FDR < 0.05 were considered significant. **Results:** Basal-type cancers (ER+/ER-) were larger and higher grade than luminal B cancers. Clustering analysis showed similar transcriptional profiles between ER+ Basal and ER- Basal cancers, distinct from luminal B cancers. Few DEGs were detected between ER+ Basal and ER- Basal cancers, and significantly more DEGs were found between ER+ Basal and luminal B cancers. Only three upregulated genes were detected in ER+ Basal compared to ER- Basal cancers: *ESR1* and two immune-related genes (*FDCSP* and *LTF*). Enrichment analysis of DEGs indicated increased immune activation and cell proliferation in ER+ Basal and ER- Basal cancers, and decreased estrogen response between ER+ Basal and luminal B cancers. Enrichment analysis between luminal B H1 and H2 cancers showed H2 cancers had higher immune activation and cell proliferation and lower estrogen response. **Conclusions:** Reclassification by BP of IHC defined ER+ HER2- cancers identified a subgroup of ER+ cancers that are biologically closer to ER- Basal than luminal-type cancers. Significant differences in response to neoadjuvant chemotherapy that have been seen between ER+ Basal and luminal B breast cancers lend support to the clinical importance of these findings. These data explain the poor prognosis observed in patients with ER+ Basal cancers and suggest that optimized chemotherapy, such as that for triple negative cancer, might be of benefit. BP provides clinically actionable information beyond pathological subtyping, which may guide neoadjuvant treatment recommendations. Clinical trial information: NCT03053193. Characterization of the tumor immune microenvironment of triple-negative breast cancer (TNBC) patients who self-identify as African American (AA) or non-African American (NonAA). *First Author: Kim Blenman, Yale University, New Haven, CT*

Background: What tumor biological differences, if any, contribute to the higher incidence and worse prognosis of triple negative breast cancer (TNBC) in African American (AA) compared to NonAA patients are unknown. We hypothesized that differences in the tumor immune microenvironment may contribute to the outcome disparities. The purpose of this study was to characterize and compare the immune microenvironment of TNBC between patients self-identified as NonAA or AA. **Methods**: Formalin fixed paraffin embedded surgically resected cancer and paired normal tissues collected before any systemic therapy and the corresponding clinical data were collected for NonAA (n = 56) and AA (n = 54) stage I-III TNBC treated at Yale Cancer Center between 2000-2017. The two cohorts were matched for clinical stage, age of diagnosis, and year of diagnosis. We performed somatic and germline whole exome sequencing (WES), bulk RNA sequencing, and immunohistochemistry to assess PD-L1 expression (SP142). Stromal tumor infiltrating lymphocytes (sTILs) were assessed on H&E slides. Mutation load, mutation frequencies, and gene expression differences were compared at gene and pathway level. Immune cell composition was estimated through gene expression deconvolution analyses (TIDE). **Results**: Tumor mutational burden was similar between the two cohorts. At gene level, few genes had significantly different somatic mutation frequencies, or differential mRNA expression between AA and NonAA samples. Pathway level alterations showed inflammation, immunity (adaptive; innate), antigen presentation, and allograft rejection pathways were more affected by somatic mutations in AA samples. The affected genes differed from cancer to cancer and were not recurrent and therefore were missed at gene level analysis. Gene set enrichment and co-expression analysis also showed higher immune related pathway expression in AA samples. Unsupervised co-expression cluster analysis confirmed coordinated overexpression of genes involved in immunity, inflammation, and cytokine/chemokine signaling in AA patients. Two immunotherapy response predictive signatures, immune inflamed and the IFNG as well as sTILs score and PD-L1 positivity were also higher in AA samples. These findings raise the possibility that immune checkpoint inhibitors might be particularly effective in AA patients. In NonAA samples, the EMT transition, angiogenesis, adipogenesis, myogenesis, fatty acid metabolism, TGFβ signaling, UV-response, and hypoxia pathways were overexpressed. TIDE analysis suggested higher levels of TAM M2, overall TIDE score, and the Immune Exclusion score in NonAA samples. **Conclusions**: TNBC in AA patients more frequently harbor somatic mutations in genes involved with immune functions and overexpress immune and inflammatory genes compared to NonAA patients. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Whole transcriptome analysis comparing HR+ HER2- breast cancer tumors from patients < 50 years and >50 years. *First Author: Cathy Graham, Emory University School of Medicine, Atlanta, GA*

Background: Recent prospective clinical trials have demonstrated a differential chemotherapy effect based on age (≤ 50 vs. > 50 years) or menopausal status (pre- vs. post-) in a genomic low risk group. Whether this is a direct anti-tumor effect of chemotherapy or a secondary ovarian function suppression effect caused by chemotherapy is unclear. We aimed to compare the biological characteristics of breast cancer tumors from patients aged ≤ 50 years and from patients aged > 50 years using whole transcriptome analysis to provide insights into this differential chemotherapy response. **Methods:** The FLEX Registry (NCT03053193) enrolls stage I-III breast cancer patients who receive 70-gene signature (MammaPrint/MP) test with or without 80-gene signature (BluePrint/BP) test and consent to clinically annotated transcriptome data collection. 3868 patients with HR+HER2- tumors were evaluated, of whom 808 were aged ≤ 50 years and 3060 were aged > 50 years. Clinical risk was assessed based on the MINDACT algorithm. MP classified tumors as low risk (LR) or high risk (HR). HR was stratified to H1 or H2; H2 exhibits a greater chemotherapy response. BP and MP classified tumors as luminal A-, luminal B-, HER2-, or basal-type. Differences in MP, BP, and clinical features were assessed by chi-squared or *t* test. For gene expression analysis, older patients were randomly selected to obtain an equal sample size as younger patients. Differentially expressed genes (DEGs) were detected using limma and considered significant with FDR <0.05 and fold change ≥ 2. **Results:** Approximately 70% of patients aged ≤ 50 were pre or peri-menopausal, whereas 90% of patients aged > 50 were post-menopausal. A higher proportion of patients aged ≤ 50 had tumors of high clinical risk (54%) compared to patients aged > 50 (39%) (p < 0.001). Approximately 53% of patients aged ≤ 50 had a HR tumor, of whom 25% classified as H2, while patients aged > 50 had a lower frequency (44%) of HR tumors (p<0.001). Additionally, younger patients had more tumors that classified as BP Luminal B and Basal-type than older patients (p<0.001). Principal component analysis of the top 500 genes with the highest variance revealed no distinct clustering by age group. Accordingly, only 5 DEGs were detected in tumors from patients aged ≤ 50 compared to patients aged > 50, and even fewer DEGs were detected when adjusting for MP risk and BP subtype group. **Conclusions:** Whole transcriptome analysis identified no substantial differences in gene expression between tumors, including Low Risk Luminal-type tumors, from women aged ≤ 50 (mostly pre or peri-menopausal) and women aged > 50 (mostly post-menopausal). These data support the likely explanation that the observed age-dependent difference in chemotherapy benefit in women ≤ 50 or >50 years of age is not due to intrinsic biological differences in breast cancers due to age, but rather to differences in the effect of chemotherapy on the host. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

Adding carbon nanoparticles to dual-tracers for the sentinel node evaluation after neoadjuvant chemotherapy in patients with pretreatment node-positive breast cancers: The TT-SLNB trial. *First Author: Jie Chen, Department of Breast Surgery, West China Hospital, Sichuan University, Chengdu, China*

Background: This study measures the feasibility and accuracy of sentinel lymph node biopsy (SLNB) with triple-tracers (TT-SLNB) which combines carbon nanoparticles (CNS) with dual tracers of radioisotope and blue dye, hoping to achieve an optimized method of SLNB after neoadjuvant chemotherapy (NAC) in ycN0 breast cancer patients with pretreatment positive axillary lymph nodes. **Methods:** Clinically node-negative invasive breast cancer patients with pre-NAC positive axillary lymph nodes who received surgeries from November 2020 to January 2021 were included. CNS was injected at the peritumoral site the day before surgery. Standard dual-tracer (SD)-SLNs were defined as blue-colored and/or hot nodes, and TT-SLNs were defined as lymph nodes detected by any of hot, blue-stained, black-stained, and/or palpated SLNs. All patients received subsequent axillary lymph node dissection. Detection rate (DR), false-negative rate (FNR), negative predictive value (NPV) and accuracy of SLNB were calculated. **Results**: Seventy-six of 121 (62.8%) breast cancer patients converted to cN0 after NAC and received TT-SLNB. After NAC, 28.95% (22/76) achieved overall (breast and axilla) pCR. The DR was 94.74% (72/76), 88.16% (67/76) and 96.05% (73/76) for SLNB with single-tracer of CNS (CNS-SLNB), SD-SLNB, and TT-SLNB, respectively. The FNR was 22.86% (8/35) for CNS-SLNB and 10% (3/30) for SD-SLNB. The FNR of TT-SLNB was 5.71% (2/35), which was significantly lower than those of CNS-SLNB and SD-SLNB. The NPV and accuracy was 95.0% and 97.3% for TT-SLNB, respectively. Moreover, a significant relation was seen between the pretreatment clinical T classification and the DR of TT-SLNB (Fisher's exact test, $p = 0.010$). **Conclusions**: TT-SLNB revealed ideal performance in post-NAC ycN0 patients with pretreatment node-positive breast cancers. The application of TT-SLNB reached a better balance between more accurate axillary evaluation and less intervention. Clinical trial information: ChiCTR2000039814. Research Sponsor: This study is supported by the funding from the National Natural Science Foundation of China (32071284 and 81902686) and the Program of the Science and Technology Bureau of Sichuan (2019YFS0338).

Clinicopathologic features of breast cancers diagnosed in females treated with prior radiation therapy for Hodgkin lymphoma: Results from a population-based cohort. *First Author: Stephanie M Wong, McGill University, Jewish General Hospital Stroll Cancer Prevention Centre, Montréal, QC, Canada*

Background: Childhood and young adult survivors of Hodgkin Lymphoma are at an increased risk of developing breast cancer, although little data exist on the characteristics and biologic subtype of breast cancers that develop in this high-risk population. **Methods**: The Surveillance, Epidemiology, and End Results (SEER) database was used to identify all histologically confirmed breast cancers diagnosed between 1990-2016 in women treated with prior radiation therapy for Hodgkin Lymphoma ≤ 30 years of age. Clinicopathologic features of subsequent breast cancers (BC-HL) were examined and compared to breast cancers diagnosed in women with no prior malignancy (BC-NPM). The association between prior chemotherapy use and biologic subtype of BC-HL was evaluated. **Results**: We identified 321 breast cancers diagnosed in 257 women with a history of radiation therapy for Hodgkin Lymphoma. The median age at Hodgkin Lymphoma diagnosis was 22 years (range, 12-30 years), and nearly all BC-HL (97.9%) were diagnosed 8 or more years after radiation therapy. Overall, 56 (21.8%) BC-HL patients developed bilateral breast cancer, of which 28 (50%) were synchronous. When compared to women with BC-NPM, women with BC-HL were significantly younger at time of diagnosis (median age, 43 years vs. 60 years, p<0.001) and less likely to present with ductal carcinoma *in situ* (8.4% vs. 14.9%, p=0.001). Patients with invasive BC-HL were more likely to have high grade (43.8% vs. 32.9%, p<0.001), estrogen receptor (ER) negative breast cancer (27.7% vs. 18.2%, p<0.001), although pathologic tumor size, nodal status, and stage were not significantly different from those with BC-NPM. Compared to women with BC-NPM, the majority of operable BC-HL patients underwent surgical management with mastectomy (86.5% vs. 42.5%, p<0.001). In subset analysis of 102 women for which HER2 status was available, BC-HL were HER2+ in 18.7% of patients. Distribution of biologic subtype between BC-HL and BC-NPM are shown in the table below. In BC-HL patients, prior chemotherapy exposure was not associated with substantial differences in the proportion of ER+HER2- breast cancers (65.8% vs. 63.5%, p=0.82). **Conclusions:** Breast cancers in women treated with radiation therapy for Hodgkin Lymphoma are characterized by earlier onset and more aggressive biologic features, although the majority remain estrogen sensitive and early stage at presentation. Further studies are warranted to evaluate the use of preventive strategies in this high-risk patient population. Research Sponsor: None.

	BC-HL (n = 102)		BC-NPM (n = 327,335)	
Biologic Subtype	% BC-HL	95% CI	% BC-NPM	95% CI

Impact of patient, tumour and treatment factors on psychosocial outcomes in invasive breast cancer. *First Author: David W Lim, Women's College Hospital, Toronto, ON, Canada*

Background: In breast cancer, clinicians aim to improve survival while patients value quality of life. We aim to delineate the impact of patient, tumour and treatment factors on psychosocial outcomes after treatment. **Methods:** A prospective cohort of women with unilateral stage I-III breast cancer were recruited at University Health Network in Toronto, Canada between 2014-2017. Validated questionnaires (BREAST-Q, Impact of Event, Hospital Anxiety & Depression Scales) were completed pre-operatively, and 6 and 12 months after surgery. Change in psychosocial scores over time by surgical procedure was assessed using linear mixed models, controlling for age, pathologic stage, hormone (HR) and HER2 receptor, and treatments. Predictors of psychosocial outcomes at 12 months were assessed using multivariable linear regression models. *P* values < .05 were significant. **Results:** 413 women underwent unilateral lumpectomy (48%), unilateral mastectomy (36%) and bilateral mastectomy (16%). Pathologic stage were: 18 *yp*T0/Tis (4%), 201 stage I (49%), 136 stage II (33%) and 58 stage III (14%). Receptor profiles were as follows: 277 HR+/HER2- (68%), 59 HR+/HER2+ (14%), 31 HR-/HER2+ (8%) and 39 HR-/HER2- (10%). Over time, women having unilateral lumpectomy had the highest scores of breast satisfaction ($P < .01$), psychosocial ($P < .01$) and sexual ($P < .01$) well-being, with no difference between unilateral versus bilateral mastectomy groups. Age was inversely related with distress ($P < .01$), psychosocial ($P < .01$) and physical ($P = .001$) well-being. Radiotherapy was associated with worse breast satisfaction (-8.1, $P < .01$), psychosocial (-6.9, $P < .01$) and physical (-5.8, $P < .01$) well-being, while chemotherapy was associated with worse sexual well-being (-5.5, $P = .04$). Endocrine therapy was associated with worse distress (6.7, $P < .01$), physical (-5.2, $P < .01$) and sexual (-6.4, $P = .03$) well-being. Women with a pathologic complete response had less anxiety compared to stage I (-2.0, $P = .03$). Women with triple-negative disease had worse breast satisfaction (-8.0, $P = .03$), distress (8.0, $P = .01$), anxiety (2.4, $P < .01$) and psychosocial (-7.5, $P = .047$) well-being than HR+/HER2- disease. In our regression model at 12 months, surgical procedure was a significant predictor of breast satisfaction ($P < .01$), psychosocial ($P < .01$), physical ($P < .01$) and sexual ($P < .01$) well-being. HER2 positivity predicted worse satisfaction ($P = .045$), psychosocial ($P = .047$), physical ($P = .02$) and sexual ($P = .01$) well-being. Income level ($P = .01$) predicted breast satisfaction and physical well-being. Ethnicity ($P < .01$) and education level ($P = .04$) predicted distress scores. **Conclusions:** Psychosocial functioning after breast cancer is influenced by an interplay between patient, tumour and treatment factors. Delineating these influences identifies potentially modifiable factors with de-escalation therapy and enhancing psychosocial support. Research Sponsor: None.

Survival in male breast cancer (MaBC) over the past three decades. *First Author: Jose Pablo Leone, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Background: Breast cancer mortality in women has declined significantly over the past several years. In men, it is unclear whether survival has changed over time. The aim of this study was to evaluate changes in breast cancer-specific survival (BCSS) and overall survival (OS) in MaBC over the past three decades. **Methods:** We evaluated men diagnosed with breast cancer between 1988 and 2017, with known cause of death reported in the Surveillance, Epidemiology, and End Results registry. Patients were categorized into 3 groups by year of diagnosis: 1988-1997, 1998-2007 and 2008-2017. BCSS and OS were estimated by Kaplan-Meier and differences between groups were compared by log-rank test. Cox proportional hazards regression was used to evaluate the independent association of tumor and patient characteristics with BCSS and OS. **Results:** We included 8,412 men diagnosed between 1988-1997 (N = 1,033), 1998-2007 (N = 2,938) and 2008-2017 (N = 4,441). Median age for the overall population and within each decade of diagnosis was 68 years. Median follow-up was 23.6 years, 14.3 years and 4.5 years in periods 1988-1997, 1998-2007 and 2008-2017, respectively. Overall, BCSS at 5 years was 83.5%, 83.6% and 84.3% in periods 1988-1997, 1998-2007 and 2008-2017, respectively; p = 0.8. There was no significant difference in BCSS between the three periods of diagnosis within each stage of breast cancer (stage I, II, III and IV). Among all patients, OS at 5 years was 64.7%, 67.2% and 69.3% in periods 1988-1997, 1998-2007 and 2008-2017, respectively; p = 0.01. In multivariate Cox models, older age at diagnosis, black race, grade 3 disease, increasing stage, hormone receptor negative status and no surgery were all independently associated with worse BCSS and OS. In these adjusted Cox models, each additional year of diagnosis had no significant association with BCSS (hazard ratio, 1.0; 95% CI, 0.99 – 1.01; p = 0.78), and a significant improvement in OS (hazard ratio, 0.99; 95% CI, 0.98 – 0.99; p = 0.01). **Conclusions:** Over the past three decades, there has been no significant improvement in BCSS in MaBC. The changes in OS over time suggest increasing life expectancy. Efforts to improve BCSS in MaBC are warranted. Research Sponsor: None.

Role of 21- gene recurrence score in patients age ≥70 with T1N0 ER/PR+ HER2- breast cancer treated with breast-conserving surgery and endocrine therapy. *First Author: Neil Chandrabhan Chevli, The University of Texas Medical Branch, Department of Radiation Oncology, Galveston, TX*

Background: Based on the results of the CALGB 9343 trial, patients age ≥70 with T1N0 ER/PR+ HER2- breast cancer who are treated with breast conserving surgery (BCS) and endocrine therapy (ET) are candidates for omission of radiotherapy (RT). This trial predated the 21- gene RT-PCR recurrence score (RS) test, which is an assay now available for patients with hormone receptor positive, HER2 negative, node negative breast cancer to determine who will benefit from chemotherapy. Whether the RS can predict for patients most likely to benefit from radiation therapy (RT) following BCS has not been previously examined. The purpose of this study was to use a large database of patients age ≥70 with T1N0 ER/PR+ HER2- disease to determine if RS could predict who would benefit from RT following BCS. **Methods:** The National Cancer Database (NCDB) was queried (2004-2017) for female patients age ≥70 with pT1N0 ER+ PR+ HER2- breast cancer treated with BCS and ET and who had an available RS. Patients were stratified based on their RS (low risk [LR] = 1-10, intermediate risk [IR] = 11-25, high risk [HR] = 26-99). For survival analysis, propensity score matching (PSM) was conducted overall and for each group to create 1:1 matched cohorts of patients who received radiotherapy and patients who did not. Kaplan-Meier analysis with log-rank testing was used to evaluate overall survival (OS). Univariable (UVA) and multivariable (MVA) analysis were conducted using Cox proportional hazard models to determine which clinical and treatment factors were prognostic for OS. **Results:** A total of 13,614 patients met the selection criteria: 3,840 in the LR cohort, 8,383 in the IR cohort, and 1,391 in the HR cohort. A total of 79% received RT: 77% in the LR cohort, 79% in the IR cohort, and 85% in the HR cohort. Because PSM could not be efficiently performed in the HR cohort alone, the IR and HR cohort were merged (IRHR) for matching. After PSM, overall the 5-year OS was 90% for those who received RT and 88% for those who did not (p = 0.03). The 5-year OS in the LR cohort was 89% for those who received RT and 89% for those who did not (p = 0.517). In the IRHR cohort, the 5-year OS was 93% for those who received RT and 88% for those who did not (p = 0.004). On MVA in the overall cohort, RT (p = 0.037) was predictive of improved OS while increasing age ($p < 0.001$) and CDCC comorbidity score ($p < 0.001$) were predictive of worse OS. On MVA in the LR cohort, RT (p = 0.602) was not predictive of improved OS. However, on MVA in the IRHR cohort, RT (p = 0.004) was a positive prognostic factor for OS. **Conclusions:** This is the first study investigating the role of RS in this subset of patients eligible for omission of radiotherapy. There is an OS benefit with the use of RT in patients with IRHR RS, but not in patients with LR RS. Pending prospective evaluation, assessment of RS in this older subset of patients is recommended with consideration of RT when RS is ≥11. Research Sponsor: None.

Trends in breast cancer mortality according to molecular subtypes: A population-based study. *First Author: Yunan Han, Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO*

Background: Breast cancer is the second leading cause of cancer death in U.S. women. On the molecular level, breast cancer is a heterogeneous disease. Heterogeneous expressions of estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (HER2) are etiologically and clinically meaningful, as they map to distinct risk factors and different treatment strategies. Although breast cancer mortality has been declining since 1990, little is known about mortality trends according to molecular subtypes at the population level. **Methods:** We examined the incidence-based mortality rates and trends among women who were diagnosed with invasive breast cancer from 2010 through 2017 using the Surveillance, Epidemiology, and End Results (SEER) database. We defined incidence-based mortality using a moving 5-year calendar period starting in 2014. We further assessed mortality according to breast cancer molecular subtypes: luminal A (ER and/or PR positive, HER2 negative), luminal B (ER and/or PR positive, HER2 positive), HER2-enriched (HER2 over-expressed or amplified, ER and PR negative) and triple-negative (ER and PR negative, HER2 negative) tumors. We calculated annual percent changes (APC) in incidence-based mortality using joinpoint regression models. **Results:** Overall, incidence-based mortality for breast cancer significantly decreased by 1.5% annually from 2014 through 2017 (APC, -1.5%; 95% coefficient interval [CI], -2.3% to -0.7%; $p<0.001$). Incidence-based mortality decreased annually by 2.0% for luminal A breast cancer (APC, -2.0%; 95% CI, -3.7% to -0.3%; $p<0.001$), 2.1% for luminal B breast cancer (APC, -2.1%; 95% CI, -5.4% to 1.4%; p=0.1), 1.1% for triple-negative breast cancer (TNBC) (APC, -1.1%; 95% CI, -2.1% to -0.0%; $p<0.001$). However, incidence-based mortality for HER2-enriched breast cancer increased 2.3% annually during the study period (APC, 2.3%; 95% CI, -2.4% to 7.2%; p=0.2). **Conclusions:** Between 2014 and 2017, incidence-based mortality for luminal A, luminal B, and TNBC decreased among U.S. women, with a larger decrease observed for luminal tumors. However, incidence-based mortality for HER2-enriched breast cancer increased. The favorable incidence-based mortality trends for luminal tumors and TNBC are likely due to the continuing improvement in treatments and early detection. The increasing trend of incidence-based mortality for HER2-enriched breast cancer constitutes a priority for cancer control activities and further research. Research Sponsor: None.

Pyrotinib as neoadjuvant therapy for HER2+ breast cancer: A multicenter, randomized, controlled, phase II trial. *First Author: Xiaowen Ding, Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Institute of Cancer and Basic Medicine (ICBM), Chinese Academy of Sciences, Hangzhou, China*

Background: Pyrotinib is a new irreversible tyrosine kinase inhibitor (TKI) which significantly improved the progression-free survival (PFS) of patients with HER2+ metastatic breast cancer (MBC). In this study we aim to investigate the efficacy and safety of pyrotinib in neoadjuvant therapy. **Methods**: This is an open-label, multicenter, randomized controlled trial. Eligible patients (pts) aged 18–70 years with invasive carcinoma, $cT_{2\text{-}3}N_{0\text{-}3}M0$ stage, HER2-positive breast cancer were included. We randomized 34 pts into the treatment group and 33 into the controlled group from 2019-2021. Pts in the treatment group received 6 cycles of pyrotinib 400mg + trastuzumab 6mg/kg (LD 8mg/kg) + docetaxel 75mg/m^2 + carboplatin (AUC = 6mg/ml·min) (TCbH+Py) treatment while the controlled group received 6 cycles of trastuzumab 6mg/kg (LD 8mg/kg) + docetaxel 75mg/m^2 + carboplatin (AUC = 6mg/ml·min) (TCbH). Total pathologic complete response (tpCR) was defined as no invasive or in situ disease in the breast or axilla (ypT0/Tis, ypN0) and was assigned to be the primary outcome (NCT03756064). **Results**: 51 cases had completed 6 cycles of neoadjuvant therapy and successfully underwent operation (21 in the treatment group and 30 in the controlled group). In the treatment group, 6 cases have not complete neoadjuvant therapy, 6 cases quitted because of poor compliance and 1 patient has not receive operation yet. For controlled group, 3 patients have not complete neoadjuvant therapy. The tpCR rate in the treatment group is 71.4% (15/21) versus 36.7% (11/30) in the controlled group. A significant difference was determined between the two groups ($p < 0.05$). All pts achieved an objective response in the treatment group while in the controlled group for about 83.3% (25/30). 4 cases showed stable disease (SD) and 1 case was evaluated as progressive disease (PD) in the controlled group. The most common AE in the treatment group is diarrhoea with grade 3 occurred in 6 cases (28.6%), most of this event limited in the first treatment cycle. In the controlled group 3 pts (10%) occurred grade 3 diarrhoea. **Conclusions**: In this study TCbH+Py neoadjuvant therapy significantly improved the tpCR rate of HER2+ breast cancer pts for about twice higher than TCbH with a manageable safety. Clinical trial information: NCT03756064. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Racial differences and trends in pathologic complete response following neoadjuvant chemotherapy for breast cancer. *First Author: Sung Jun Ma, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Given improvements in systemic therapy, pathologic complete response (pCR) rates following neoadjuvant chemotherapy were over 60% in breast cancer patients in recent clinical trials, especially in human epidermal growth factor receptor 2 (HER2)-positive and triple negative cases. While racial minority groups were associated with worse survival outcomes despite receiving standard of care in prospective studies, they were under-represented in clinical trials. To address this knowledge gap, we performed an observational cohort study to evaluate pCR and survival outcomes stratified by racial and ethnic groups. **Methods:** The National Cancer Database (NCDB) was queried for female patients with stage I-III breast cancer diagnosed between 2010 and 2017 treated with neoadjuvant chemotherapy followed by surgery. Cochran-Armitage test was used to analyze the trend of pCR over time. Logistic multivariable analysis (MVA) was used to identify variables associated with pCR defined as ypT0/isN0. Cox MVA was used to analyze the overall survival (OS) benefit. **Results:** A total of 105,804 patients (n = 72,631 for non-Hispanic white [NHW], n = 7,632 for Hispanic white [HW], n = 19,505 for black, n = 4,393 for Asian or Pacific Islander [API], n = 1,643 for other race) were included for analysis. Median follow up was 49.2 months (interquartile range 32.7-71.3). Overall pCR rate increased from 15.1% in 2010 to 27.2% in 2017, largely driven by API women (15.7% to 31.6%) and hormone receptor (HR)-HER2+ tumors (28.6% to 53.1%; all trend $p < 0.001$). On logistic MVA, when compared to NHW women, HW women were more likely to have pCR for HR-HER2+ (adjusted odds ratio [aOR] 1.18, p = 0.02) and HR+HER2+ tumors (aOR 1.29, p = 0.005), while black women were more likely to have pCR for HR+HER2- tumors (aOR 1.13, p = 0.01) and less likely for HR-HER2+ (aOR 0.80, $p < 0.001$) and triple negative tumors (aOR 0.82, $p < 0.001$). API women were more likely to have pCR for HR-HER2+ tumors compared to NHW women (aOR 1.17, p = 0.04). On Cox MVA, when compared to NHW women, HW (ypT+N0: adjusted hazards ratio [aHR] 0.75, $p < 0.001$; ypN+: aHR 0.79, $p < 0.001$) and API women (ypT0/isN0: aHR 0.52, p = 0.005; ypT+N0: aHR 0.63, $p < 0.001$; ypN+: aHR 0.86, p = 0.03) were associated with improved OS, while black women were associated with worse OS for ypN+ only (aHR 1.18, $p < 0.001$). **Conclusions:** To our knowledge, this is the largest study using a nationwide oncology database suggesting the improving trend of pCR rate over time for all racial cohorts. In our study, when compared to NHW, HW and API women were more likely to have pCR for select HER2+ tumors, while black women were less likely to have pCR for HR-HER2+ and triple negative tumors but not for HR+HER2- tumors. HW and API women were associated with improved survival in the setting of any residual disease compared to NHW women, while black women were associated with worse survival only for residual nodal disease. Research Sponsor: None.

Evaluation of risk-stratification using gene expression assays in patients with breast cancer receiving neoadjuvant chemotherapy. *First Author: Sung Jun Ma, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Among patients with hormone receptor-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer, several prospective studies investigated various gene expression assays, such as 21-gene recurrence score (21 RS) and 70-gene signature (70 GS), to identify a subgroup of patients with pathologic complete response (pCR) from neoadjuvant chemotherapy. However, in the absence of large prospective trials to validate such findings, the National Comprehensive Cancer Network guideline does not recommend the routine adoption of such assays in the setting of neoadjuvant therapies. To address this knowledge gap, we performed an observational cohort study to compare pCR and survival outcomes based on these assays. **Methods:** The National Cancer Database (NCDB) was queried for female patients diagnosed between 2010 and 2017 with stage I-III breast cancer who underwent neoadjuvant chemotherapy and either 70 GS or 21 RS. Logistic multivariable analysis (MVA) was performed to identify variables associated with pCR. Cox MVA was performed to evaluate overall survival (OS). Subgroup analyses were performed among patients with favorable hormone receptor status (hormone receptor-positive, HER2-negative) and with RS $\geq$26 instead of RS $\geq$31. **Results:** A total of 3,009 patients met our inclusion criteria, with 2,075 (n = 1,287 for RS $<$ 31, n = 788 for RS $\geq$31) and 934 (n = 175 for low risk, n = 759 for high risk) patients who underwent 21 RS and 70 GS, respectively. The median follow up was 48.0 months (interquartile range 32.2-66.7). On logistic MVA for all patients, those with a high risk from 70 GS or with RS $\geq$31 were more likely to have pCR. When compared to RS $\geq$31, a high risk from 70 GS was not associated with pCR. However, among those with favorable hormone receptor status, similar findings were noted, except that those with a high risk group from 70 GS were less likely to have pCR compared to those with RS $\geq$31. On Cox MVA for all patients, pCR was associated with improved OS. While RS $\geq$31 was associated with worse mortality, a high risk from 70 GS was not. No interaction was observed between pCR and risk groups for OS in both groups (interaction p = 0.23 for 70 GS, p = 0.66 for 21 RS). When analyses were repeated using a high risk group from 21 RS defined as RS $\geq$26, similar findings were noted, except that having favorable hormone receptor status and RS $\geq$26 was not associated with pCR when compared to the high risk from 70 GS. **Conclusions:** To our knowledge, this is the largest study using a nationwide oncology database suggesting that high recurrence risk groups in both assays were associated with pCR and that pCR was associated with improved survival. For those with favorable hormone receptor status, RS $\geq$31 may be a more selective prognostic marker. Further studies would be warranted to investigate the role of gene expression assays in the setting of neoadjuvant chemotherapy. Research Sponsor: None.

Evaluation of pharmacodynamic (PD) and biologic activity in a preoperative window-of-opportunity (WOO) study of giredestrant (GDC-9545) in postmenopausal patients (pts) with estrogen receptor-positive, HER2-negative (ER+/HER2–) operable breast cancer (BC). *First Author: Heather M. Moore, Genentech, Inc., South San Francisco, CA*

Background: Modulation of ER activity and/or estrogen synthesis is the mainstay therapeutic strategy in ER+ BC treatment. Giredestrant is a highly potent, nonsteroidal oral selective ER degrader (SERD) that achieves robust ER occupancy and is effective regardless of *ESR1* mutation status. The first short-term preoperative WOO study (NCT03916744) of giredestrant in ER+/HER2– operable BC was designed for dose selection, while providing an early readout of PD as measured by traditional immunohistochemistry (IHC) and transcriptional profiling by assessing treatment effects in paired tumor tissue pre/posttreatment. We present an interim analysis. **Methods:** Pts were assigned to 14 days' preoperative treatment with 10, 30, or 100 mg PO giredestrant QD. Pts had newly diagnosed, stage I–III operable, ER+/HER2– untreated BC $\geq$1.5 cm in diameter (by ultrasound). Modulation of ER signaling and cell proliferation were assessed using paired formalin-fixed paraffin-embedded tumor specimens collected before and after ~14 days of study treatment. ER, progesterone receptor (PR), and Ki67 protein levels were analyzed by IHC. Change from baseline in tumor cell proliferation by Ki67 was the primary endpoint. Gene expression analysis was performed using the Illumina TruSeq RNA Access method. **Results:** From Jul 26, 2019 to Oct 15, 2020, 46/75 biomarker-evaluable pts were enrolled across three dose cohorts (10 mg: n = 15; 30 mg: n = 18; 100 mg: n = 13). Pt demographics and tumor characteristics were similar across cohorts. Baseline PAM50 analysis classified tumors as Luminal A (77%) or B (23%). Giredestrant treatment resulted in robust and indistinguishable PD and biologic activity at all doses. Geometric mean posttreatment proportional reduction of Ki67 was 79% (95% CI: 69–89; 10 mg: 80%; 30 mg: 76%; 100 mg: 80%), and 51% of tumors exhibited complete cell cycle arrest, defined as Ki67 $\leq$2.7%. Mean posttreatment proportional reductions of ER and PR H-scores were 71% (95% CI: 67–75) and 60% (95% CI: 51–70), respectively. An analysis of a predefined, experimentally derived set of 38 ER target genes (the 'ER activity signature'), was completed for 42 paired tumor specimens. Forty-one of 42 pts (98%) showed a posttreatment reduction in ER activity with a mean proportional decrease of 79% (95% CI: 70–88). A wide range of baseline ER activity was observed with no correlation to baseline ER or PR H-score, or Ki67. There were no discontinuations due to adverse events (AEs). A single grade 3 serious AE was reported in each cohort (all assessed as unrelated to giredestrant). No grade 4 or 5 AEs were reported. **Conclusions:** Giredestrant was well tolerated in the preoperative setting in ER+/HER2– operable BC, and PDs were consistent with the 30 mg dose achieving maximal ER inhibition. Clinical trial information: NCT03916744. Research Sponsor: Genentech, Inc.

A phase 2 trial of talimogene laherparepvec (TVEC) in combination with neoadjuvant chemotherapy for the treatment of nonmetastatic triple-negative breast cancer. *First Author: Hatem Hussein Soliman, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: TVEC is a modified oncolytic herpes simplex 1 (HSV1) virus currently FDA approved for the treatment of unresectable cutaneous and nodal melanoma. TVEC is designed to preferentially lyse tumor cells over normal tissue to release tumor associated antigens, produces GM-CSF to activate dendritic cells, and stimulates T cells to infiltrate the tumor (TILs). TILs in breast cancer are associated with better response to neoadjuvant chemotherapy (NAC), so we hypothesized that intratumoral TVEC may enhance response to NAC. We report results of a phase 2 trial combining NAC with TVEC in stage 2-3 TNBC. **Methods:** Stage II-III TNBC pts (N = 37) were to be enrolled into a single arm, optimal Simon 2 stage phase 2 trial with TVEC (10^6 PFU 1st dose then 10^8 PFU x 4 doses) weeks 1,4,6,8,10 + weekly paclitaxel (80mg/m2) IV x 12, followed by dose dense AC (doxorubicin/cyclophosphamide 60/600 mg/m2) IV q2weeks x 4 alone given preoperatively. Primary endpoint was residual cancer burden 0 rate (RCB0). Trial meets primary endpoint with $\geq$15 RCB0 responses out of 37 evaluable pts, assuming p1 = 45% vs. p0 = 30% with one sided type I error rate at 0.10 and power at 70%. **Results:** Forty pts were enrolled at Moffitt (5/2018 – 4/2020) and evaluable for safety with 3 pts non-evaluable for efficacy due to incomplete treatment. Study demographics: median age 49 (27-66), 67.5% White, 10% Black, 15% Hispanic, clinical stage II 83% and III 17%, node + 42%. The RCB0 rate = 16/37 (43%, 95% CI 27-61%) and additional 9 pts with RCB-1 (RCB0/1 rate 68%, 95% CI 50-82%). Toxicities did not differ significantly from expected NAC toxicities except for increased brief G1-2 fevers, chills, injection site pains. Four pts had G2-3 thromboembolic events (10%) slightly greater than expected 6% rate on NAC. **Conclusions:** Addition of TVEC to NAC increased RCB0 rates with manageable toxicities and warrants additional investigation in TNBC. Immune correlates and updated survival data will be presented at the meeting. Clinical trial information: NCT02779855. Research Sponsor: Amgen.

Pathological complete response rate and survival in patients with *BRCA*-associated triple-negative breast cancer after 12 weeks of de-escalated neoadjuvant chemotherapy: Translational results of the WSG-ADAPT TN randomized phase II trial (NCT01815242). *First Author: Lisa Katharina Katharina Richters, Center for Familial Breast and Ovarian Cancer and Center for Integrated Oncology (CIO), Medical Faculty, University Hospital Cologne, Cologne, Germany*

Background: The phase II trial WSG-ADAPT TN randomized triple-negative breast cancer (TNBC) patients to receive 12 weeks of neoadjuvant nab-paclitaxel (nab-pac) combined with carboplatin (carbo) vs gemcitabine (gem) and showed a substantial improvement of pathological complete response (pCR: ypT0/is, ypN0) with carbo (45.9% vs 28.7%). pCR had a strong favorable impact on iDFS after 3-year follow-up. Distribution of tumor mutations in BC-associated genes and impact of *BRCA* mutation status on pCR and outcome are analyzed here. **Methods:** NGS-based mutational analysis of *BRCA1/2* and 18 further (potentially) BC-associated genes was performed on DNA derived from pretreatment FFPE samples (gem: n = 158, carbo: n = 108) using a customized gene panel. Variants with a variant fraction of ≥5% were included and classified according to IARC and ENIGMA guidelines. **Results:** In 42 of the 266 analyzed samples, at least one deleterious *BRCA1/2*-variant was found (15.8%; *BRCA1* n = 37, *BRCA2* n = 3, *BRCA1+BRCA2* n = 2) one of which displayed an additional *STK11*-mutation. In the *BRCA1/2*-negative cohort, a mutation in one of 14 further analyzed (potential) BC-risk genes was found in 19 samples (7.1%; *BARD1* n = 3, *CHEK2* n = 2, *CDH1* n = 2, *FANCM* n = 3, *PALB2* n = 5, *RAD50* n = 1, *RAD51C* n = 1, *RAD51D* n = 1, *XRCC2* n = 1; no deleterious mutations were found in *ATM*, *BRIP1, MRE11A, NBN*). At least one deleterious variant in *TP53*, *PIK3CA*, *PTEN* or *MAP3K1* was seen in 89.1% (n = 237; *TP53* n = 233, *PIK3CA* n = 22 *PTEN* n = 15, *MAP3K1* n = 1). In 22 samples (8.3%) no deleterious mutation was identified in the analyzed genes. Overall, patients with tumor *BRCA* mutation (carbo n = 14, gem n = 28) had 45.2% vs 34.4% pCR (OR = 1.58, 95%-CI: 0.81-3.07, p = .18) without a mutation. pCR in the small group with mutation receiving carbo (n = 14) was 64.3% vs. 34.5% in all others (OR = 3.41, 95%-CI: 1.11-10.50; p = .03); direct comparison to *BRCA*-positive patients receiving gem (n = 28, 35.7%, OR = 3.2, 95%-CI: 0.85-12.36, p = 0.079) did not reach statistical significance. The results suggest that the strong favorable impact of pCR on iDFS is preserved even among *BRCA*-positive patients (n = 42, p = .07), as well as in the *BRCA*-negative subgroup (p < .001). No evidence for a predictive impact of *BRCA* mutation on efficacy of 4xEC additional chemotherapy was seen overall or within pCR subgroups. **Conclusions:** Twelve weeks of neoadjuvant nab-pac/carbo is a highly effective anthracycline-free regimen that leads to an excellent pCR-rate of 64% in tumor *BRCA1/2*-mutated cases. *BRCA1/2* mutation status could support this de-escalation strategy in early TNBC, but further prospective validation of survival impacts in larger cohorts and with longer follow up is needed. More detailed survival analyses will be presented at the meeting. Clinical trial information: NCT01815242. Research Sponsor: Celgene, Teva.

Evaluation of sensitivity to endocrine therapy index (SET2,3) for response to neoadjuvant endocrine therapy (NET) and subsequent prognosis. *First Author: William Fraser Symmans, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients (pts) in Cohort A of the American College of Surgeons Oncology Group Z1031 (Alliance) trial of NET for cStage II-III breast cancer were randomized to anastrozole [ANA], letrozole [LET] or exemestane [EXE] for 16-18 weeks (wks). In Cohort B, pts chose between ANA and LET and switched to chemotherapy or surgery if a tumor biopsy after 2-4 wks of NET had Ki67 >10%. Treatments after surgery were not defined by the trial protocol. SET2,3 measures nonproliferation gene expression related to estrogen and progesterone receptors adjusting for a baseline prognostic index that combines clinical tumor and nodal stage and a 4-gene molecular subtype (RNA4) defined by *ESR1*, *PGR*, *ERBB2* and *AURKA*. High SET2,3 in a pre-treatment biopsy using cStage information is defined as SET2,3 >1.77. **Methods:** 379 pts had gene expression data from a research tumor biopsy prior to NET (Agilent 44K microarrays). A bioinformatician blinded to pt treatment and clinical outcomes determined SET2,3. The trial statistician then examined the association between SET2,3 and pharmacodynamic response at 2-4 wks (N=141, Cohort B): Ki67 ≤10% and complete cell cycle arrest (CCCA Ki67 ≤2.7%); pathologic outcomes in pts who completed NET: ypStage 0/1 (N=329, Cohorts A&B), PEPI-0 rate (N=155, Cohort B); and event-free survival (EFS) post-registration (N=244, Cohorts A&B). We used Fisher's exact tests to assess whether responses, and Cox modeling to evaluate whether EFS, differed with respect to SET2,3 status. **Results:** High SET2,3 in 48% of pts (183/379) was associated with older age (median: 66 vs 63 years; p=0.012); cStage II (95% vs 75%; p <0.001); and pre-NET Ki67 ≤10% (37% vs 20%; p< 0.001) in pts with low SET2,3. In Cohort B, pts with high SET2,3 had a higher rate of pharmacodynamic response in their tumor at wk 2-4 than pts with low SET2,3 (Table). In the subset of Cohort B pts with wk 2-4 Ki67 ≤10%, pre-treatment SET2,3 trended numerically higher in pts who achieved PEPI-0 score (p=0.049) but the proportion achieving PEPI-0 did not differ by SET2,3 high/low status (Table). EFS was significantly longer for pts with high SET2,3 than pts with low SET2,3 (HR[H/L]: 0.52; 95% CI: 0.34-0.80; p=0.003). **Conclusions:** An exploratory analysis of Z1031 data demonstrated that the rate of pharmacodynamic suppression of proliferation by NET at 2-4 wks was greater and EFS was longer for pts with breast cancer expressing high SET2,3 disease than pts with low SET2,3. Effect of moderate physical exercise on the immune system modulation in patients with breast cancer during preoperative chemotherapy: The NEORUNNER study. *First Author: Ornella Garrone, Breast Unit AO S. Croce e Carle Teaching, Cuneo, Italy*

Background: The link between physical activity (PA) and the immune system (IS) is known. However, it is not yet fully understood the immune mechanisms activated by PA. We investigated the immune effect of moderate PA (MPA), nordic or fit walking, during neoadjuvant chemotherapy (NACT) in patients (pts) with breast cancer. **Methods:** Pts received sequential epirubicin and cyclophosphamide for 4 cycles followed by paclitaxel for 12 weeks. Blood samples from pts underwent MPA (TR) were collected before starting chemotherapy (CT) at baseline (T0), at day 1 of week 6 of paclitaxel (before starting MPA) (T1), before surgery (S) (T2) and after S (T3). Samples were also collected in a group of pts who declined MPA (UN) at the same time points and in 15 healthy volunteers (HV). MPA consisted of 3 workouts per week, 1 hour each, in the 9 weeks before S. At each time point the level of 17 cytokines (IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12, IL-13, IL-15, CCL-2, CCL-4, CXCL-10, CCL-22, IFN-γ, TGF-β, TNF-α, VEGF) was measured. The difference among the median value of cytokines was analyzed using non parametric Mann Whitney *U* test. Principal component analysis (PCA) was computed to compare the best discriminating cytokine, identified by ROC analysis, of pts at T1, T2, T3 and in HV. Each patient was distributed in the PCA. Pts having similar cytokine values were plotted in the near position. Normalized values of 8 cytokines (IL-2, IL-4, IL-5, IL-6, IL-13, IL-15, CCL-2, VEGF) were used in PCA. **Results:** Data from 27 pts are available: 10 TR and 17 UN. A significant increase of IFN-γ, IL-5, IL-8, CCL-2 and CXCL-10 between T0 and T1 (P = 0.004, P = 0.013, P = 0.032, P = 0.046, P = 0.046, respectively) was found in the whole population. CXCL-10 significantly increased also between T1 and T2 in UN pts (P = 0.033). TR pts showed a significant lower level of IL-6, IL-13, CCL-2 at T2 (P = 0.012, P = 0.038, P = 0.023) and higher IL-15 level at T3 (P = 0.047) compared to UN pts. Moreover, a significant decrease of IL-5 was observed between T2 and T3 (P = 0.031). PCA showed that TR and UN pts were mixed at T1. HV were clustered all together and distinct from pts. At T2 TR pts moved toward HV and mixed with them while UN remained separated. TR pts tended to separate from HV at T3, while UN pts still remained distinct. **Conclusions:** NACT upregulated median values of IFN-γ, IL-5, IL-8, CCL-2 and CXCL-10; CXCL-10 value continues to increase during CT only in UN pts supporting the inflammatory effect of CT. On the contrary, during MPA the level of IL-6, IL-13, CCL-2 decreases in TR compared to UN pts. All together these data suggest that MPA damps the inflammatory response to NACT. Our results show that the majority of TR pts reach an immune profile similar to that of HV in PCA. However, at T3 the effect of MPA is dampened, suggesting a potential negative effect of S. Independent validation of simbiosys tumorscope to predict response to neoadjuvant chemotherapy (NACT) in early breast cancer (EBC). *First Author: Gong He, University of Chicago Medical Center, Chicago, IL*

Background: Despite substantial advances in the understanding of breast cancer biology, the decision to use NACT for EBC is based on tumor size, lymph node status, and subtype. Even with aggressive therapy, the majority of women will not achieve a pathologic complete response (pCR). Investigational treatment regimens, including immunotherapy, can increase pCR rates, but are associated with irreversible immune-related toxicities. Being able to accurately predict pCR could identify candidates for intensification or de-escalation of NACT, allowing for personalized medicine. SimBioSys TumorScope (TS) is a biophysical model that utilizes baseline MRI, receptor status, and planned treatment regimen to simulate response to NACT over time. TS has demonstrated accurate prediction of pCR in prior studies. Here, we describe an independent external validation of TS. **Methods:** We conducted a retrospective study of University of Chicago patients (pts) who received NACT for EBC from Jan 2010 - March 2020. Pts must have had a pretreatment breast MRI. Tumors were analyzed using TS by investigators who were blinded to response data. TS predicted pCR was predefined as a residual tumor volume < 0.01 cm^3 or a 99.9% or greater reduction in tumor volume. Performance metrics of TS were calculated. **Results:** 144 tumors from 141 pts were analyzed. Average age was 52 yrs; 65% had stage II and 19% had stage III disease. Sensitivity and specificity of TS for predicting pCR were 90.4% and 92.4%, respectively. Of the 7 patients who were predicted to achieve a pCR but did not, 5 had a tumor cellularity < 5%. With a median follow-up of 4.7 yrs, the 4-yr distant disease free survival (DDFS) was 100% for patients predicted to achieve pCR, versus 81.5% for those predicted to have residual disease. Results were generally robust for all subgroups analyzed (Table). **Conclusions:** TS accurately predicts pCR and DDFS from baseline MRI and clinicopathologic data. Given the high sensitivity and specificity of this assay across breast cancer subtypes, TS can be used to aid in escalation/de-escalation strategies for EBC. Research Sponsor: None.

Phase II prospective open label study of neoadjuvant pertuzumab, trastuzumab, and nab-paclitaxel in patients with HER-2 positive advanced breast cancer. *First Author: Sayeh Moazami Lavasani, City of Hope National Medical Center, Duarte, CA*

Background: HER2 overexpression occurs in 20-25% of breast cancers (BC) and is associated with poor prognosis. The addition of trastuzumab (trast) to chemotherapy significantly improves disease-free (DFS) and overall survival (OS) in the adjuvant setting. Pertuzumab (pert) inhibits ligand-activated signaling and in combination with trast has synergistic inhibition of BC cells overexpressing HER2. In the neoadjuvant therapy (NT) setting, the combination of trast, pert, and docetaxel can improve the pCR rate. PCR may predict for improved DFS and OS. De-escalation with weekly paclitaxel combined with trast and pert appeared to be safe and efficacious but requires steroid premedication, whereas nab-paclitaxel (nab) does not require steroid premedication. To decrease treatment-associated toxicity in patients with HER2+ BC, we utilized a non-anthracycline regimen with pert, trast, and nab as NT. The objectives of this study were to evaluate the safety and efficacy of pert added to trast and nab in HER2+ locally advanced BC (LABC) to determine the pCR, as well as DFS and OS. **Methods:** A total of 45 patients with biopsy-confirmed HER2+ LABC or inflammatory BC were enrolled from 2013-2017, and were treated with 6 cycles of neoadjuvant pert (840 mg loading dose, then 420 mg IV day 1 every 21 days), weekly trast (4 mg/kg loading dose, then 2 mg/kg), and weekly nab (100 mg/m^2 IV). Patient characteristics, including age, race, menopausal status, grade, stage, and prior surgery and radiation were recorded. Median treatment cycles determined, and events (AE) were identified for each arm. PCR rate, DFS and OS were calculated. **Results:** Median age was 56 (31-78) years. 1/45 (2%) was stage I, 30/45 (67%) were stage II, 14/45 (31%) were stage III. pCR rate was 29/45 (64.4%). The initial primary tumor size was similar in pCR and non-pCR patients (mean 4.1 cm vs. 3.2 cm, respectively). Median follow-up was 36.1 months (95% CI [27.1, 41.8]). Median treatment cycles completed was 6 (1-6). A total of 4/45 (9%) patients had >1 cycle delayed, and 32/45 (71%) patients had >1 cycle modified. For the patients achieving pCR, the DFS (95% CI) at 3 years was 85.9% (66.7%, 94.4%) and for those without pCR, it was 87.5% (58.6%, 96.7%). OS was not reached (95% CI [NR, NR]). Grade 3 AEs (> 2 patients) included 7/45 (16%) of patients with hypertension; 4/45 (9%) with anemia; and 2/45 (4%) with diarrhea, ALT, fatigue, or rash. **Conclusions:** This anthracycline-free regimen which included nab achieved great pCR rate of 64.4% in HER2+ BC patients with fewer treatment-related toxicities. The pCR rate is comparable with docetaxel, carboplatin, trast, and pert (TCHP) therapy in NT setting, but without the treatment-associated toxicities. This suggests we may be able to safely avoid anthracyclines and carboplatin for NT in HER2+ BC patients. The improved pCR did not translate into DFS benefit. Clinical trial information: NCT01730833. Computational features of tumor-infiltrating lymphocyte architecture of residual disease after chemotherapy on H&E images as prognostic of overall and disease-free survival for triple-negative breast cancer. *First Author: Germán Corredor, Case Western Reserve University, Cleveland, OH*

Background: Approximately 30% of all breast cancers are characterized as triple-negative (TNBC). TNBC typically occurs in younger women and is associated with a poorer prognosis relative to other breast cancer subtypes. High levels of tumor-infiltrating lymphocytes (TILs) in residual disease after Neoadjuvant chemotherapy (NACT) have previously been shown to be associated with better prognosis in TNBC. In this work, we sought to evaluate the prognostic value of computationally derived measures of TIL spatial architecture in residual TNBC after NACT. **Methods:** H&E-stained samples from 92 patients (pts) with TNBC (41 died, 45 had disease recurrence) and residual disease after NACT were retrospectively collected from 2 sites: Instituto Nacional de Enfermedades Neoplásicas (S1) and University Hospitals (S2). 45 pts (16 deaths, 23 recurrences) from S1 formed the training set and 47 pts (25 deaths, 22 recurrences) from S2 formed the independent validation cohort. Samples were digitized at 20x. Computerized algorithms automatically identified 2 types of nuclei (TILs and non-TILs) and built clusters for each nuclei type based on cell proximity. The spatial arrangement of these clusters was then quantified using network graph metrics. The top 5 features, determined by least absolute shrinkage and selection operator, were used to train a Cox regression model that assigned a risk of death and recurrence to each patient on the training set. The percentile 33 risk score was used as a threshold for stratifying pts on the validation set as either low or high risk. For comparison, we also employed a model based on TIL density alone. Survival analysis was used to evaluate the performance of both approaches on disease-free survival (DFS) and overall survival (OS). **Results:** Pts in S2 (n=47) identified as "high risk" by the model based on spatial architecture of residual TILs had a significantly shorter survival time. The median OS for pts at high risk was 25 months vs. 55 months for low-risk pts. The median DFS for pts at high risk was 32 months vs 51 months for low-risk pts. Univariable analysis showed this model was prognostic for both OS (Hazard Ratio (HR) = 2.57, 95% Confidence Interval (CI): 1.07-6.16, p=0.03) and DFS (HR=2.38, CI: 1.01-5.62, p=0.04). In contrast, the model based on TIL density was not prognostic for OS (HR=1.24, CI: 0.33-4.63, p=0.73) nor DFS (HR=1.19, CI: 0.32-4.34, p=0.78). **Conclusions:** A computerized image analysis model based on measurements of spatial arrangement of residual TILs and surrounding cells was found to be prognostic in TNBC pts who received NACT. This method appears to be more prognostic than TIL density alone. Additional multisite validation and multivariable analysis is needed to further establish the independent prognostic utility of TIL based image biomarkers in the post-NACT TNBC. Impact of dendritic cell vaccines added to neoadjuvant CT on pathological complete responses in early breast cancer patients according to PD-L1 expression. *First Author: Ignacio Ortego, Clínica U. Navarra, Pamplona, Spain*

Background: Breast cancer (BC) in early stages exhibit a naïve and competent immune system that translates into a more prominent TIL infiltration and higher PD-L1 expression as compared to the advanced BC scenario were immunoescape and exhaustion are more prevalent. Expression of PD-L1 has been related to a better pCR when immune checkpoint inhibitors (IPI) have been added to neaodjuvant chemotherapy (NACT) in triple negative BC (TNBC). Our prior results shown dendritic cells vaccines (DCV) increased pCR in both TNBC and luminal B subtypes, with an absolute gain of 20% (p = 0.03) and a safe tolerance. **Methods**: Eighty-three HER2 negative BC patients with untreated stage II-III were included: 39 patients from the NCT01431196 trial that combine NACT with autologous DCV and 44 patients from a historic control group treated with the same NACT alone. NACT consists of dose dense Epirubicin plus Cyclophosphamide for 4 cycles sequenced to Docetaxel for 4 cycles. PD-L1 expression was measured in the membrane of tumoral cells with monoclonal rabbit anti PD-L1 28.8 pharmaDX (DAKO, Agilent Technologies) in FFPE samples at diagnosis. Primary endpoint was pathologic complete response (pCR) stratified by PD-L1 expression (positive or negative), while secondary endpoints were event-free survival (EFS) and overall survival (OS), also stratified by PD-L1 expression. **Results**: Both cohorts were well balanced in most of the features. Thirty-three percent of the tumors in the experimental group were PD-L1 positive, whereas 50% of them in the CG expressed PD-L1 (p = 0.06). Pathological CR was observed in 50% of the PD-L1 positive population, in contrast to a 2.8% in the PD-L1 negative in the NACT cohort ($p < 0.01$) as compared to the patients assigned to the DCV group (33.4% in PD-L1 positive vs 23.1% in PD-L1 negative population; p = 0.16). Among PD-L1 positive population, more pCR were seen in the CG than in the DCV group (50% vs 33.4%; p = 0.06). Within the PD-L1 negative population, more pCR were observed in the DCV group than in the CG (23.1% vs 2.8%; $p < 0.05$). With a median follow-up of 7 years, no significant differences were observed between the different subgroups neither in EFS (HR = 1.7; 0.42-6.8; p = 0.19) nor in OS (HR = 2.5; 0.56-11, p = 0.43). At 7 years, 20% and 14.4% of the patients relapsed according to the PD-L1 positive versus negative status respectively, and 10.78% versus 13.33% were dead. **Conclusions**: The benefit of DCV seems to be outstanding in the PD-L1 negative tumors that have a basal immune appropriate milieu. PD-L1 expression implies a more suppressed niche in which DCV are not able to stimulate antigen presentation and cell cytotoxic activity. PD-L1 positive population reach higher responses with both NACT±DCV than PD-L1 negative group, although the benefit seem to be higher in the NACT alone cohort. Further studies combining DVC+IPI together with NACT are needed. Clinical trial information: NCT01431196. Research Sponsor: 1. Principal investigator of the project: Estudio prospectivo fase II de la vacunación con células dendríticas autólogas en pacientes con cáncer de mama triple negativo en estadios II-III". Impact of different sequencing strategies of talazoparib and carboplatin combination upon efficacy and toxicity in BRCA-wild type and BRCA-mutant triple-negative breast cancer models. *First Author: Michele Beniey, Universite de Montreal, Montreal, QC, Canada*

Background: PARP inhibitors (PARPi) such as talazoparib and olaparib, have demonstrated an improvement in progression-free survival (PFS) amongst metastatic HER2-negative breast cancer patients with germline mutations in BRCA1/2 (BRCA-MUT). Clinical trials have evaluated PARPi in combination with carboplatin, but with mixed results. Earlier trials studied the combination of carboplatin and a low-dose PARPi of low potency, veliparib. The concomitant combination of carboplatin and talazoparib, a higher-potency PARPi, was also evaluated in solid tumors, using a heavily pretreated population. Here, we perform a comparative evaluation of different sequencing strategies of talazoparib and carboplatin to determine efficacy and toxicity in BRCA-MUT and BRCA wild-type (WT) TNBC models. **Methods:** We used three orthotopic xenograft models in NSG (NOD scid gamma) mice, with 7-14 mice in each treatment group: MDAMB231 (BRCA-WT), HCC1806 (BRCA-WT), and MX1 (BRCA-MUT). We treated mice with carboplatin (C) (35 mg/kg intraperitoneally) in combination with talazoparib (T) (0.33 mg/kg oral gavage) using 2 dosing strategies: a) concomitant administration of C + T; and b) T first, followed by C three days later, each compared to vehicle control. We evaluated primary tumor inhibition and hematologic toxicity. Kruskal-Wallis test and Dunn's multiple comparison test was used to assess statistical significance. **Results:** Using the MDAMB231 xenograft, we found the T-first approach led to a 66.7% ($P < 0.0001$), and the concomitant approach resulted in a 51.4% decrease in primary tumor volume, (P = 0.08), in comparison to control. In HCC1806, the T-first approach resulted in a 62.0% decrease in tumor volume ($P < 0.0001$), whereas the concomitant combination showed a 54.4% decrease (P = 0.002). In MX1, the T-first and concomitant approaches resulted in 72.7% ($P < 0.0001$) and 81.4% ($P < 0.0001$) decrease in tumor volume, respectively. With regards to neutrophil counts, T-first approach decreased neutrophils by 66.2% and 43.0% in MDAMB231 and HCC1806 xenografts respectively, similar to the trend with concomitant T + C: 61.4% and 38.0%. In the MX1 cohort, the T-first approach resulted in a 66.2% decrease in neutrophils (P = 0.001), and the concomitant approach led to a 77.5% decrease in neutrophils (P = 0.006). **Conclusions:** Our results demonstrate that the talazoparib-first approach is effective in two BRCA-WT models with no statistically significant neutropenia. While the concomitant combination approach demonstrated greater tumor inhibition in the BRCA-MUT model, this was also associated with significant neutropenia. This is suggestive that sequencing of talazoparib and carboplatin may have differential effect in BRCA-WT and BRCA-MUT tumors and may play an important role in improving efficacy in BRCA-WT tumors. Treatment Efficacy Score (TES), a continuous residual cancer burden-based metric to compare neoadjuvant chemotherapy efficacy between trial arms in the I-SPY 2 trial. *First Author: Michal Marczyk, Silesian University of Technology, Gliwice, Poland*

Background: Residual cancer burden (RCB) is a continuous score that captures the amount of residual cancer after neoadjuvant chemotherapy and predicts disease recurrence and survival across all breast cancer subtypes. RCB score 0 corresponds to pathological complete response (pCR; ypT0, ypN0). We hypothesize that comparison of the distributions of RCB scores between randomized treatment arms of a trial could predict treatment effect on recurrence free survival better than comparison of pCR rates only. **Methods:** The cancer Treatment Efficacy Score (TES) compares efficacies of two treatments using non-continuous RCB results. We examined (i) area between cumulative distribution (ABC) functions; (ii) density ratio of RCB scores; and (iii) density difference of RCB scores from two treatments, to select the most efficient metric to compute TES. A random permutation procedure was used to estimate the p-value from each test. These methods were applied to data from the durvalumab/olaparib arm and corresponding controls of the I-SPY2 trial, separately by molecular subtype. In subsampling and simulation experiments we assessed robustness of results including power and false positive rate control under variable sample sizes to select the most robust TES metric. The other 11 experimental arms of I-SPY2 were used to assess the performance of the final metric. We calculated correlation between TES and (i) pCR rate difference, and 3- and 5-year (ii) event-free (EFS) and (iii) distant recurrence free survivals (DRFS). **Results:** RCB scores are multimodal and do not follow normal distribution.In simulated data ABC provided more stable results than the other methods, had good power, performed well with small sample sizes, resulted in low false positive rate, required the least computational time, and therfore was selected as the TES metric for validation in 11 arms of I-SPY2. We found a high correlation between difference in pCR rate and TES value across all molecular subtypes in each of the 11 trial arms ($r = 0.92$, $p = 1.7e-8$). There was also significant linear relationship between TES and survival estimates in EFS ($r = 0.58$, $p = 9.3e-3$ for 3-years survival; $r = 0.62$, $p = 4.8e-3$ for 5-years survival) and DRFS ($r = 0.56$, $p = 1.2e-2$ for 3-years survival; $r = 0.54$, $p = 1.8e-2$ for 5-years survival). Statistically significant TES score correlated significantly with higher benefit in 3-years survival ($p = 9.7e-4$ for EFS; $p = 5.7e-3$ for DRFS) and 5-years survival ($p = 9.7e-4$ for EFS; $p = 3.0e-3$ for DRFS). In most instances, this correlation with survival was higher than seen with pCR difference. **Conclusions:** TES is a novel more optimal metric to identify the more effective cytotoxic neoadjuvant regimen from the entire distribution of pathologic response that significantly correlates with event and recurrence free survival and may serve as a better surrogate than pCR rate difference. Does timing of chemotherapy impact breast satisfaction after breast conservation therapy and mastectomy with immediate reconstruction? *First Author: Kate R. Pawloski, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Receipt of chemotherapy is associated with decreased postoperative breast satisfaction, but whether timing as neoadjuvant (NAC) versus adjuvant (AC) affects this outcome after breast conservation therapy (BCT) and mastectomy with immediate reconstruction (M-IR) is unclear. **Methods:** We retrospectively identified patients treated with chemotherapy and breast surgery (BCT and M-IR), from 1/2017-12/2019, who completed ≥ 1 BREAST-Q survey through 12/2020. Mean (standard deviation [SD]) Q-scores for satisfaction with breasts (SATBR) were compared between NAC versus AC groups in BCT and M-IR cohorts, respectively. Higher Q-scores on a 0-100 scale indicate superior satisfaction. A minimum 4-point difference was considered clinically important. Chemotherapy timing and significant covariates on univariate analyses were entered in multivariable linear regressions of 1- and 2-year SABTR. **Results:** 640 patients had BCT and 602 had M-IR; 210 (33%) BCT patients and 294 (49%) M-IR patients had NAC. Compared with M-IR, SATBR was higher after BCT in both NAC and AC groups, at all postoperative timepoints (Table). Following BCT, SABTR was highest in both NAC and AC groups at 6 months and returned to baseline in the NAC group by year 3. In the M-IR cohort, 331 (55%) patients had radiation and 120 (20%) had complications requiring re-operation or hospitalization. Compared with baseline, mean (SD) Q-scores were substantially lower at 6 months but improved to near baseline at 3 years in both NAC and AC groups. On multivariable analysis, radiation was associated with decreased SABTR at 1 year (Beta, -11; 95% CI, -17, -5.0; $p<0.001$) and 2 years (Beta, -12; 95% CI, -19, -5.5; $p<0.001$), as were complications at 1 year (Beta, -6.1; 95% CI, -12, -0.34; $p=0.038$) but not 2 years (Beta, -5.5; 95% CI, -12, 0.92; $p=0.09$). After multivariable adjustment, NAC was not significantly associated with 1- or 2-year SABTR after M-IR or BCT. **Conclusions:** SABTR was higher in BCT compared with M-IR cohorts, independent of chemotherapy timing. Following BCT, SABTR was lower in the NAC group at years 2-3 but remained at baseline or higher at all timepoints. In the M-IR cohort, both groups endorsed lower than baseline SABTR in years 0-2 but returned to near baseline at 3 years. Radiation and complications were independent predictors of decreased SABTR, but our findings suggest that patients who experience complications after M-IR can expect return to baseline breast satisfaction by 2 years. Research Sponsor: U.S. National Institutes of Health.

Mean (SD) of SABTR Q-scores among BCT and M-IR cohorts.

The impact of gut microbial composition on response to neoadjuvant chemotherapy (NACT) in early-stage triple negative breast cancer (TNBC). *First Author: Nour Abuhadra, MD Anderson Hematology/Oncology Fellowship, Houston, TX*

Background: The impact of gut microbiome on tumor biology, progression and response to immunotherapy has been shown across cancer types. However, there is little known about the impact of gut microbial composition on response to chemotherapy. We have previously shown that the gut microbiome remains unaltered during NACT in a cohort of 32 patients. Here we investigate the association between gut microbiome and response to NACT in a larger cohort of early-stage TNBC. **Methods:** Longitudinal fecal samples were collected from 85 patients with newly-diagnosed, early-stage TNBC patients enrolled in the ARTEMIS trial (NCT02276443). Patients all received standard NACT with adriamycin/cyclophosphamide (AC); volumetric change was assessed using ultrasound and patients with < 70% volumetric reduction (VR) after 4 cycles of AC were recommended to receive targeted therapy in addition to standard NACT to improve response rates. We performed 16S sequencing on bacterial genomic DNA extracted from 85 pre-AC fecal samples using the 2x250 bp paired-end read protocol. Quality-filtered sequences were clustered into Operational Taxonomic Units and classified using Mothur method with the Silva database version 138. For differential taxa-based univariate analysis, abundant microbiome taxa at species, genus, family, class, and order levels were analyzed using DESeq2 after logit transformation. Alpha-diversity indices within group categories were calculated using phyloseq. Microbial alpha diversity (within-sample diversity) was measured by Simpson's reciprocal index. β-diversity was measured using weighted UniFrac distances between the groups. The association between microbiota abundance and pathologic complete response (pCR) or residual disease (RD) was assessed using DESeq2 analysis. **Results:** Pre-AC fecal samples from 85 patients were available for analysis. Amongst them, there were 46 patients with pCR and 39 patients with RD. There was no significant difference in alpha diversity ($p = 0.8$) or beta-diversity ($p = 0.7$) between the pCR and RD groups. However, relative to patients with RD, the gut microbiome in patients with pCR was enriched for the Bifidobacterium longum species ($p = 0.03$). The gut microbiome in patients with RD was enriched for Lachnospiraceae ($p = 0.03$) at the genus level and the Bacteroides thetaiotaomicron species ($p = 0.02$). **Conclusions:** We have demonstrated significant differences in the gut microbial composition in patients with pCR as compared to patients with RD. Further investigation in larger studies is needed to support therapeutic exploration of gut microbiome modulation in TNBC patients receiving chemotherapy such as probiotic supplementation or fecal microbiota transplant. Multi-gene prognostic assays and age-related differences in prediction of pathologic complete response to neoadjuvant chemotherapy and survival in breast cancer. *First Author: Kent Hanson, University of Illinois at Chicago, Chicago, IL*

Background: Multi-gene testing of primary breast tumors in early-stage breast cancer is used to classify the risk of developing distant metastases and predict the benefit of adjuvant chemotherapy. The association between the tumor genomic prognostic score (GPS) and response to neoadjuvant chemotherapy (NACT) and survival is not well characterized. Our objective was to describe the association between GPS and rates of pathologic complete response (PCR) and subsequent overall survival among women with or without PCR. **Methods:** We utilized the National Cancer Database to perform a hospital-based, retrospective cohort study of breast cancer patients ages 18 years and older. We included women diagnosed with first primary stages I-III hormone receptor positive (HR+), HER2 negative (HER2-) breast cancer who received NACT and surgery between 2010 and 2017. Women were categorized as having low (0-10 or 200), intermediate (11-25 or 300), or high-risk (25-199 or 400) GPS based on OncotypeDX or MammaPrint scores. Multivariable modified Poisson regression models with robust error variance were used to estimate the crude and adjusted relative risk and 95% confidence intervals (CI) for PCR associated with GPS groups. Multivariable Cox proportional hazards models were used to estimate adjusted hazard ratios (HR) and 95% CI for associations between the GPS and overall survival (OS) in women who did and did not have PCR. **Results:** A cohort of 3,446 women (mean [SD] age, 56.7 [12.0] years; median [interquartile range] follow-up of 47 [31-68] months) who received genomic testing and neoadjuvant chemotherapy were included in our analysis, of which 935 (27%) were low risk, 1,357 (39%) intermediate risk, and 1,154 (34%) high risk GPS. The relative risk of PCR for all women with high GPS was 1.81 (95% CI, 1.47-2.22; $p < 0.001$) in crude models and 1.49 (95% CI, 1.16-1.92; $p = 0.002$) after full adjustment compared to low GPS. Across all models, having a high GPS was significantly associated with achieving PCR in younger women (< 65 years). In women ages ≥65 years, the association between GPS and PCR was not predictive nor statistically significantly. Among women with no response or partial response to NACT, high GPS was associated with a significantly increased risk of overall mortality (HR 2.41; 95% CI, 1.61-3.60; $p < 0.001$) compared to low GPS. Conversely, in women who did achieve PCR, GPS was not predictive of overall mortality across all age groups. **Conclusions:** In women with HR+/HER2- breast cancer, high risk GPS was predictive of PCR following NACT, primarily in younger women (< 65 years). Our findings also indicated GPS was associated with lower OS in high-risk patients who do not achieve PCR and unpredictive of OS in those without PCR. The utility of tumor genomic testing in the neoadjuvant setting needs further investigation. Research Sponsor: None.

Neoadjuvant atezolizumab (atezo) and nab-paclitaxel (nab-p) in patients (pts) with triple-negative breast cancer (TNBC) with suboptimal clinical response to doxorubicin and cyclophosphamide (AC). *First Author: Clinton Yam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Neoadjuvant anti-PD-(L)1 therapy confers an improvement in pathological complete response (pCR) rate in unselected TNBC. However, given the potential for long-term morbidity from immune related adverse events (irAE), it is important to optimize the risk-benefit ratio for the use of these novel agents in the curative neoadjuvant setting. Suboptimal clinical response to neoadjuvant therapy (NAT) by sonography is associated with low rates of pCR rate (2-5%, GeparTrio and Aberdeen trials). Here, we report the results of a single arm phase II study of atezo and nab-p as the second phase of NAT in pts with TNBC with suboptimal clinical response to AC (NCT02530489). **Methods:** Pts with stage I-III TNBC showing suboptimal response to 4 cycles of doxorubicin and cyclophosphamide (AC), defined as disease progression or a <80% reduction in tumor volume by sonography, were eligible. Pts received atezo (1200mg IV, Q3 weeks x 4), and nab-p (100mg/m2 IV, Q1 week, x 12) as the second phase of NAT before undergoing surgery followed by adjuvant atezo (1200mg IV, Q3 weeks, x 4 cycles). This single arm, two-stage Gehan-type study was designed to detect an improvement in pCR from 5% to 20% in order to deem the regimen worthy of further study in a large, randomized, phase II/III trial; success was defined as pCR in 8 out of 37 pts enrolled. In a subset of pts, sufficient baseline tumor tissue was available for stromal TIL assessment (n=29). **Results:** 34 pts were enrolled from 2/2016-12/2020. Among the 33 pts who have completed NAT, the pCR rate was 30% (10/33, 95% CI: 16-49%) and the pCR/RCB-I rate was 42% (14/33, 95% CI: 25-61%). Clinicopathological characteristics are described in the table below. Treatment-related adverse events (all grades) occurring in ≥ 20% of pts include fatigue (73%), anemia (55%), peripheral sensory neuropathy (55%), neutropenia (48%), rash (42%), ALT elevation (39%), AST elevation (33%), nausea (30%), anorexia (24%), diarrhea (21%), myalgia (21%). Discontinuation of atezo due to irAEs occurred in 4 pts (12%, nephritis [n=2]; adrenal insufficiency [n=1]; hepatitis [n=1]); 2 of these pts had pCR. **Conclusions:** This study met its primary endpoint, demonstrating a promising signal of activity in this high risk pt population (pCR=30% vs 5% in historical controls). The 12% discontinuation rate due to irAEs confirms that further evaluation of a strategy administering immunotherapy only to pts with high risk disease not responding to AC warrants further investigation. Exploratory genomic and immunological correlative studies are ongoing. Clinical trial information: NCT02530489. Research Sponsor: Genentech, Conquer Cancer Foundation of the American Society of Clinical Oncology, MD Anderson Breast Cancer Moon Shots Program.

Automated, IHC/FISH-free, H&E histopathology image-based HER2 amplification, tumor infiltrating lymphocyte (TIL) and tumor heterogeneity profiling in breast cancer. *First Author: Satabhisa Mukhopadhyay, 4D Path Inc., Newton, MA*

Background: Digital pathology has fostered the development of automated diagnostic solutions. However, current technologies in breast cancer remain unable to determine HER2 amplification status, which is established by immunohistochemistry (IHC) and/or fluorescent in situ hybridization (FISH). These ancillary tests carry a significant cost, prolong diagnostic time and fail to capture HER2 tumor heterogeneity and tumor infiltrating lymphocyte (TIL) burden, both of which determine the effectiveness anti-HER2 targeted therapy. **Methods:** This study describes the real-life clinical context development and validation of a patented novel, universal, automated, white-box, scanning platform agnostic solution that determines HER2 amplification status, prognostically significant TIL levels and tumor heterogeneity index (HI) from hematoxylin and eosin (H&E) stained malignant breast biopsy whole slide images (WSIs) alone. Unlike conventional artificial intelligence-based approaches, the underlying proprietary algorithm's prediction criteria are explainable and are based on deterministic, hard-coded observational relationships of scale constructed from image morphological features mapped to observables representing underlying tumor-related perturbations in biological pathways/mitotic checkpoints.This includes G1/S deregulation signatures reflecting oncogenic HER2-neu. **Results:** Blinded validation of HER2 status prediction (n = 197 WSIs; 118 independent cases/patients) showed excellent diagnostic performance (κ = 0.85) relative to existing standard-of-care methodologies. This was independent of WSI file format, background histology, tumor subtype/grade or hormone receptor status. The device also displayed good accuracy (92%) in determining TIL profiles, and its combined HER2-TIL and HER2-HI prediction scales both exhibited a significant association with progression-free survival (CoxPH hazard ratio: 1.856; 95% CI: 1.002-3.438; p = 0.049 and CoxPH hazard ratio: 3.45; 95% CI: 0.95-12.55; p = 0.060). **Conclusions:** This technology opens up the future possibility of bypassing existing ancillary HER2 profiling investigations, thus potentially reducing laboratory workloads/healthcare costs while accelerating diagnostic turnaround times for patient benefit. In the interim, if used as an adjunct tool, this device could provide an objective HER2 testing reference scale while the robustness of its prediction of patient response to anti-HER2 targeted therapy is fully explored. Investigating survivin as a novel target in black women with breast cancer. *First Author: Andrea Walens, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Black women with breast cancer have higher mortality than White women. Differences in tumor biology contribute to racial disparities in breast cancer outcomes. BIRC5 gene encodes survivin, an inhibitor of apoptosis protein, and an independent marker of poor prognosis in breast cancer. Cancer patients have anti-survivin antibodies and circulating survivin-specific T cells, suggesting that survivin may be targetable. Several ongoing antibody-mediated, vaccine strategies that target survivin are being developed. Nevertheless, most survivin studies were conducted in cohorts of White women. To date, the prevalence and/or role of survivin expression in breast tumors from Black women has not been studied. **Methods:** Associations between BIRC5 expression, clinicopathological and molecular features were measured in the population-based Carolina Breast Cancer Study (CBCS) and The Cancer Genome Atlas (TCGA) breast cancer cohort. Gene expression was measured by Nanostring RNA counting and split into BIRC5 high (4^{th} quartile) and low categories based on log2 gene expression values. Relative frequency differences (RFD) for the association between BIRC5 high and clinicopathologic features were estimated. RNA based p53 mutant status and homologous recombination deficiency (HRD) status were included in RFD analysis. Receiver operating characteristic (ROC) curves were used to illustrate the potential of BIRC5 expression to distinguish patients who achieved pathological complete response (pCR) after receiving neoadjuvant chemotherapy in CBCS (133 Black, 49 non-Black). **Results:** BIRC5 gene expression was significantly increased in tumors from 966 Black patients compared to 1,497 non-Black ($p < 0.00001$), adjusting for stage and subtype. BIRC5 high tumors were significantly more expressed in higher stage and basal-like breast cancer subtypes. BIRC5 high tumors were also significantly enriched for expression of genes involved in p53 loss and HRD. Furthermore, in an analysis of 182 CBCS patients, BIRC5 gene expression alone predicted pCR with similar overall AUC to ROR-PT multigene signatures (AUC 0.62 vs 0.64). **Conclusions:** Our study shows that survivin expression is particularly high in breast tumors from Black women. This was associated with more aggressive clinicopathological features in addition to p53 mutant and HRD status. Black women with breast cancer represent an area of unmet clinical need and could potentially benefit from anti-survivin targetable treatment strategies. Further studies are needed to help close this gap which constitutes the largest disparity among cancer-specific diseases. Research Sponsor: U.S. National Institutes of Health.

A011801 (CompassHER2 RD): Postneoadjuvant T-DM1 + tucatinib/placebo in patients with residual HER2-positive invasive breast cancer. *First Author: Ciara Catherine Maria O'Sullivan, NCI/NIH, Bethesda, MD*

Background: Patients (pts) with HER2+ early breast cancer (EBC) and invasive residual disease (RD) after neoadjuvant therapy (NAT) have a higher risk of relapse than pts with a pathologic complete response (pCR). Post neoadjuvant T-DM1 has improved invasive disease-free survival (iDFS), but pts with estrogen receptor (ER)-negative or nodal RD have suboptimal outcomes and recurrences in the central nervous system are a problem. More effective treatment strategies are needed. The CompassHER2 trials, EA1181 and A011801, leverage pCR to tailor post neoadjuvant therapy in HER2+ EBC. EA1181 is a NAT de-escalation trial of a taxane, trastuzumab and pertuzumab (THP) in clinical stage II-III HER2+ EBC; pts with a pCR complete HP +/- adjuvant radiation (RT) +/- endocrine therapy (ET). A011801 is an escalation trial for pts with high risk HER2+ RD after NAT, examining addition of the HER2 selective tyrosine kinase inhibitor (TKI) tucatinib to adjuvant T-DM1. **Methods:** Eligibility and Intervention: Pts. with high-risk HER2+ RD (e.g. ER- ,node-positive, or both) *after* a predefined course of neoadjuvant HER2-directed treatment are randomized 1:1 to adjuvant T-DM1+ placebo (pb), vs. T-DM1 and tucatinib with adjuvant RT +/- ET. Eligibility criteria include completion of ≥ 6 cycles of NAT, including ≥ 9 weeks of T and H +/- P. All chemotherapy (CT) must be completed preoperatively unless participating in EA1181 (~15-30% enrollees); these pts must receive postoperative CT to complete ≥ 6 cycles prior to enrollment on A011801. Pts who received prior HER2-targeted TKIs or antibody-drug conjugates are ineligible. Objectives: The primary objective is to determine if iDFS is higher with addition of T-DM1 to tucatinib in pts with HER2+ EBC with RD after NAT; secondary endpoints include overall survival, breast cancer free survival, distant recurrence-free survival, brain metastases-free survival and disease-free survival. Correlative objectives include the association of i) tumor infiltrating lymphocyte (TILs) levels in the primary tumor and RD with iDFS, ii) TILs with tucatinib benefit, iii) iDFS and circulating tumor cells (CTC) at serial timepoints and iv) the magnitude of benefit of tucatinib (iDFS) in pts with/without detectable pretreatment CTCs. Quality of life and pharmacokinetic endpoints will also be evaluated. Statistics: A011801 is a prospective, double-blind, randomized, phase III superiority trial; stratified by i) receipt of postoperative CT (Y/N), ii) hormone receptor-status (+/-),and iii) pathologic lymph node status (+/-). The study targets an absolute difference of 5% in iDFS (control vs. experimental arm 82% & 87%, HR = 0.7), with a two-sided alpha of 0.05 and power of 80%. The sample size is 981; target accrual = 1031 pts; activation and completion dates are 01/6/21 and ~ 01/2028. Support: U10CA180821, U10CA180882; Seagen Inc; ClinicalTrials.gov Identifier: NCT04457596 Clinical trial information: NCT04457596. TPS596 **Poster Session**

eMonarcHER: A phase 3 study of abemaciclib plus standard adjuvant endocrine therapy in patients with HR+, HER2+, node-positive, high-risk early breast cancer. *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Hormone receptor positive (HR+), human epidermal growth factor receptor 2-positive (HER2+) breast cancer (BC) with high-risk characteristics has a high risk of disease recurrence. Novel therapeutic options for this population are urgently needed. Abemaciclib is an oral, selective, and potent CDK4 & 6 inhibitor administered on a continuous schedule which is approved for HR+, HER2- advanced BC (ABC) as monotherapy and in combination with endocrine therapy (ET). Abemaciclib combined with ET demonstrated a statistically significant improvement in invasive disease-free survival (IDFS) in participants (pt) with HR+, HER2-, node-positive, high risk early breast cancer (EBC) and also clinical activity in HR+, HER2+ ABC. The eMonarcHER trial investigates whether abemaciclib plus ET will improve IDFS in pts with HR+, HER2+, node-positive, high risk EBC. **Methods:** eMonarcHER is a phase 3 global, randomized, double-blinded, placebo (PB)-controlled trial in participants with HR+, HER2+, node-positive, high risk EBC who have completed adjuvant HER2-targeted therapy (tx). Eligible participants are randomized 1:1 to receive either abemaciclib 150 mg twice daily or PB, plus standard ET. Study intervention period will be ≤26 cycles (approximately 2 years) followed by ≤8 years of ET as medically indicated. Participants must have undergone definitive surgery of the primary breast tumor and have high-risk disease. High-risk disease is defined as (i) detection of residual axillary nodal disease at the time of definitive surgery in participants with prior neoadjuvant (neoadj) tx; or (ii) in patients not receiving neoadj tx, must have either ≥4 pathologically positive axillary lymph nodes (pALNs), or 1-3 pathological pALNs and either: histologic Grade 2-3 and/or primary invasive tumor size ≥5 cm. Participants must have received either adjuvant pertuzumab plus trastuzumab with chemotherapy or adjuvant T-DM1. Stratification factors include treatment with neoadj tx, menopausal status, and region. The study is powered at approximately 80% to detect the superiority of abemaciclib plus ET over PB plus ET in terms of IDFS (as defined by the STEEP system) at a 1-sided α = .025 using a log-rank test. Assuming a hazard ratio of 0.73, this requires approximately 324 events at final IDFS analysis. Key secondary objectives include overall survival, distant relapse free survival, safety, pharmacokinetics, and patient-reported outcomes. The study is planned to start in March 2021. Approximately 525 centers in 23 countries plan to enroll ~2450 participants. Clinical trial information: NCT04752332. Research Sponsor: Eli Lilly and Company.

ALEXANDRA/IMpassion030: A phase 3 study of standard adjuvant chemotherapy with or without atezolizumab in patients with early-stage triple-negative breast cancer. *First Author: Shigehira Saji, Fukushima Medical University School of Medicine, Fukushima, Japan*

Background: Early stage triple negative breast cancer (TNBC) is associated with a high risk of distant relapse. Because TNBC does not currently have specific targeted agents approved for use in the early setting, it is treated primarily with chemotherapy. TNBC may be more immunogenic than other subtypes of breast cancer. Atezolizumab (an anti–PD-L1 antibody), in combination with nab-paclitaxel has been approved in >70 countries for the treatment of PD-L1-positive unresectable locally advanced or metastatic TNBC based on the results of the randomized phase 3 IMpassion130 trial. The phase 3 IMpassion031 study, evaluating atezolizumab in combination with chemotherapy (nab-paclitaxel followed by doxorubicin and cyclophosphamide) in comparison to placebo plus chemotherapy as neoadjuvant treatment demonstrated a statistically significant and clinically meaningful improvement in pCR in both PD-L1 positive and PD-L1 negative tumors. ALEXANDRA/IMpassion030 is a global, prospective, randomized, open-label, phase 3 trial currently investigating the efficacy, safety and pharmacokinetic profile of adjuvant atezolizumab plus standard anthracycline/taxane adjuvant chemotherapy versus chemotherapy alone in early stage TNBC. **Methods:** ALEXANDRA/IMpassion030 will randomize 2300 patients with operable stage II-III TNBC, confirmed by central pathology review. Patients are stratified by type of surgery, nodal status, and centrally assessed PD-L1 status. Adjuvant chemotherapy consist of weekly paclitaxel 80 mg/m^2 for 12 weeks followed by dose dense anthracycline (epirubicin 90 mg/m^2 or doxorubicin 60 mg/m^2) and cyclophosphamide 600 mg/m^2 for 4 doses every 2 weeks or the same chemotherapy regimen (T-EC/AC) given concomitantly with atezolizumab 840 mg every 2 weeks followed by maintenance atezolizumab 1200 mg every 3 weeks until completion of 1 year of atezolizumab. The primary endpoint is invasive disease-free survival (iDFS) and secondary endpoints include, iDFS in the PD-L1 selected tumour status (IC1/2/3) and node-positive subpopulations, overall survival, safety, patient functioning and health related quality of life (HRQoL). Tumor tissue and blood samples will be collected for biomarker research. The first site was activated on May 4 2018, and approximately 373 sites in 30 countries are currently participating in this trial. This trial is sponsored by F. Hoffmann-La Roche Ltd and conducted in partnership with the Breast International Group, Frontier Science and Technology Research Foundation, Institute Jules Bordet and Alliance Foundation Trials. Clinical trial information: NCT03498716. Research Sponsor: F. Hoffmann-La Roche Ltd.

ADAPTlate: A randomized, controlled, open-label, phase III trial on adjuvant dynamic marker—Adjusted personalized therapy comparing abemaciclib combined with standard adjuvant endocrine therapy versus standard adjuvant endocrine therapy in (clinical or genomic) high-risk, HR+/HER2- early breast cancer. *First Author: Oleg Gluz, West German Study Group and Ev. Hospital Bethesda, Breast Center Niederrhein, Moenchengladbach, Germany and University Hospital Cologne, Cologne, Germany*

Background: The WSG ADAPT trial program addresses the individualization of (neo)adj. decision-making in EBC. The ADAPT umbrella trial established early predictive molecular surrogate markers for response after a 3-wk endocrine treatment (ET) to omit chemotherapy (CT) in a cohort of early high-risk HR+/HER2- pts. ADAPTlate seeks to improve adj. therapy for pts. at high risk for late disease recurrence, who completed definite locoregional therapy (with / without (neo-)adj. CT) and are under adj. ET. This high-risk population does not derive optimal benefit from standard ET, develops secondary ET resistance, and late recurrences. **Methods:** Prospective, multi-center, interventional, two-arm, open, randomized, controlled adj. phase III trial (NCT04565054) to investigate additional benefit from 2 years of the CDK4/6-inhibitor abemaciclib combined with ET compared to ET alone in pts. with high-risk HR+/HER2- EBC. Abemaciclib demonstrated to improve outcome in metastatic BC and even in EBC when given as part of primary therapy. Primary objective is to demonstrate superiority of iDFS of abemaciclib + ET vs. standard ET. Secondary objectives include OS, dDFS, occurrence of CNS metastases, QoL, and translational research. Recruitment started in 9/2020 to screen 1250 pts. and to randomize 903 pts. in a ratio 3:2 . Until date of submission, 33 pts. were screened and 22 randomized. Pre-/postmenopausal pts. with histologically confirmed invasive HR+/HER2- EBC, 2-6 y after primary diagnosis, with either known high clinical risk (c/pN 2-3 OR high CTS score in pN 0-1 OR non-pCR after neoadj. CT in cN 1 or G3 tumors OR G3 and Ki-67 ≥ 40% in pN 0-1) or known high genomic risk (RS >25 in c/pN 0, RS >18 in c/pN 1 OR high risk Prosigna, EPclin or Mammaprint in pN 0-1) or intermediate clinical, but unknown genomic risk (luminal B-like (G3 or Ki-67 ≥20%) in c/pN 0-1 AND either RS >25 in c/pN 0 or RS >18 in c/p N1 in screening) will be eligible. Treatment duration is 2 years for the abemaciclib + ET (premenopausal: AI + GnRH) arm, followed by at least 3-6 years ET alone. Pts. in control arm will receive 5-8-years ET at investigator's choice. ePROs are collected using CANKADO. Translational analyses: Exploratory tissue biomarker research to assess alterations in molecular markers. Liquid biopsies (CTC/ctDNA/ctRNA) will be assessed for mutations and gene expression relevant for HR+/HER2- EBC using an appropriate technology at time of testing. Conclusions: ADAPTlate seeks to evaluate whether Abemaciclib + ET is superior to ET alone in pts. with clinical or genomic high-risk EBC even 2-6 years after initial diagnosis. Translational research aims at assessing potential mechanisms of resistance to endocrine and/or CDK4/6 targeted therapy. Clinical trial information: NCT04565054. Research Sponsor: Lilly; Exact Sciences.

Optima: Optimal personalised treatment of early breast cancer using multiparameter analysis, an international randomized trial of tumor gene expression test-directed chemotherapy treatment in a largely node-positive population. *First Author: Rob C. Stein, National Institute for Health Research University College London Hospitals Biomedical Research Centre, London, United Kingdom*

Background: Multi-parameter tumor gene expression assays (MPAs) are validated tools to assist adjuvant chemotherapy decisions for post-menopausal women with luminal-type node-negative breast cancer. Currently there is less certainty for women with 1-3 involved axillary lymph nodes and no information on MPA use for patients with higher level nodal involvement. Three RCTs with available data report chemotherapy benefit for premenopausal women; with limited use of ovarian function suppression (OFS) for non-chemotherapy treated participants, chemotherapy-induced menopause may explain these results. **Methods:** OPTIMA is an international academic, partially-blinded RCT of test-directed chemotherapy treatment with an adaptive design. Women and men aged 40 or older with resected luminal-type breast cancer may participate if they fulfil one of the following stage criteria: pN1-2; pN1mi with pT ≥20mm; pN0 with pT ≥30mm. Consenting patients are randomized between standard treatment with chemotherapy followed by endocrine therapy or to undergo Prosigna testing; those with high-Prosigna Score (> 60) tumors receive standard treatment whilst those with low-score tumors are treated with endocrine therapy alone. Patients are informed only of their treatment; test details, and randomization for chemotherapy-treated patients are masked. Clinical choice of chemotherapy is declared at randomization from a menu of standard regimens. Endocrine therapy must be for at least 5 years. Women postmenopausal at trial entry should receive an AI; men, tamoxifen; and premenopausal women, either an AI or tamoxifen, and OFS for 3 or more years; OFS initiation may be deferred because of post-chemotherapy amenorrhea. OPTIMA aims to randomize 2250 patients in each arm to demonstrate non-inferiority of test directed treatment, defined as not more than 3% below the estimated 85% 5-year IDFS for the control arm with a one sided 5% significance level. Power is 81% assuming recruitment over 96-months from January 2017 and 12 months minimum follow-up. OPTIMA also has at least 80% power to demonstrate 3.5% non-inferiority of IDFS for patients with low Prosigna Score tumors (estimated 65% of participants). Cox proportional hazards models will be used to explore important prognostic factors including menopausal status. Additional secondary endpoints include DRFI. A cost-effectiveness analysis of protocol specified MPA driven treatment against standard clinical practice will be conducted. At 31/01/2021, 2004 patients had been randomized. The DMC reviewed the trial in December 2020 with knowledge of related trial results and suggested that the trial continues as planned. OPTIMA is registered as ISRCTN42400492 and funded by the UK NIHR Health Technology Assessment Programme, award number 10/34/501. Clinical trial information: ISRCTN42400492. Research Sponsor: UK National Institute for Health Research (Health Technology Assessment programme), Local academic funding to support country-specific recruitment; support in kind from Veracyte Inc towards cost of Prosigna testing.

TPS600 **Poster Session**

Axillary management in T1-3N1M0 breast cancer patients with needle biopsy proven nodal metastases at presentation after neoadjuvant chemotherapy (ATNEC). *First Author: Amit Goyal, Royal Derby Hospital, Derby, United Kingdom*

Background: Neoadjuvant chemotherapy (NACT) results in eradication of cancer in the axillary nodes in 40% to 70% of patients. This raises questions about the benefit of further axillary treatment in those patients with no evidence of residual nodal disease (ypN0) after NACT. **Methods:** *Design:* ATNEC is a phase 3, randomised (1:1), multi-centre trial, with embedded economic evaluation, comparing standard axillary treatment (axillary lymph node dissection [ALND] or axillary radiotherapy [ART]) with no further axillary treatment in T1-3N1M0 breast cancer patients with needle biopsy proven axillary nodal metastases, who after NACT have no residual nodal disease (ypN0) on dual tracer sentinel node biopsy (SNB) and removal of at least 3 nodes (sentinel nodes and marked involved node). *Stratification:* Institution, type of surgery (breast conserving surgery vs mastectomy), receptor status (triple negative vs HER2 positive vs ER positive and/or PR positive and HER2 negative). *Inclusion criteria* are**:** Age ≥ 18, Male or female, T1-3N1M0 breast cancer at diagnosis (pre-NACT), FNA or core biopsy confirmed axillary nodal metastases at presentation, ER and HER2 status evaluated on primary tumour, received standard NACT as per local guidelines, ultrasound of the axilla at completion of NACT, dual tracer SNB after NACT and at least 3 nodes removed (sentinel nodes and marked node), no evidence of nodal metastases post NACT (ypN0). *Exclusion criteria* are: bilateral invasive breast cancer, SNB prior to NACT, marked node not removed *except* where at least one node removed shows evidence of down-staging with complete pathological response e.g. fibrosis/scarring and at least 3 nodes removed, previous ipsilateral axillary surgery, previous cancer within last 5 years or concomitant malignancy *except* basal or squamous cell carcinoma of the skin, in situ carcinoma of the cervix, in situ or stage 1 melanoma, contra- or ipsilateral in situ breast cancer. *Aims:* To assess whether, omitting further axillary treatment (ALND and ART) for patients with early stage breast cancer and axillary nodal metastases on needle biopsy - who after NACT have no residual nodal disease on SNB (ypN0) - is non-inferior to axillary treatment in terms of disease free survival, and reduces the risk of lymphoedema at 5 years. *Statistical methods:* All analyses will be carried out on an intention-to-treat basis to preserve randomisation, avoid bias from exclusions and preserve statistical power. *Radiotherapy quality assurance:* Study has in-built radiotherapy QA programme that will be co-ordinated by National Radiotherapy Trials QA (RTTQA) group. *Target accrual:* 1900. *Trial status:* Recruiting. *Number of sites:* 100. Clinical trial information: NCT04109079. Research Sponsor: UK National Institute for Health Research - Health Technology Assessment Programme (NIHR128311).

TPS601 **Poster Session**

A single-arm confirmatory study to evaluate the efficacy of nonsurgical therapy for HER2-positive early breast cancer with clinical complete response after primary systemic therapy (JCOG1806: AMATERAS-BC study). *First Author: Tomomi Fujisawa, Department of Breast Oncology, Gunma Prefectural Cancer Center, Gunma, Japan*

Background: The surgical treatment is a standard therapy for early breast cancer (EBC) after primary systemic therapy (PST). In more than half of HER2 positive (HER2(+)) breast cancer, pathological complete response (pCR) is achieved by PST with HER2 inhibitors and chemotherapy. In addition, hormone receptor (HR) negative HER2(+) (HR(-)HER2(+)) subtype has higher concordance between pCR and clinical complete response (cCR) before surgery than other subtypes, especially in EBC. However, non-surgical therapy is not an option for EBC with cCR after PST because of few evidence. We planned single arm confirmatory study to evaluate the efficacy and safety of the non-surgical therapy for HR(-)HER2(+) EBC with cCR after PST. **Methods:** The key eligibility criteria are as follows: 1) Histologically confirmed as invasive ductal carcinoma of breast, HR(-)HER2(+). 2) cT1-2, N0, M0 (UICC 8th). 3) No ipsilateral BC. 4) Women aged 20-74 years. 5) ECOG performance status 0 or 1. 6) Written informed consent. HER2 inhibitors (trastuzumab and pertuzumab) and cytotoxic drugs as PST are administered for all patients (pts). After completion of PST, cCR is diagnosed by breast imaging and physical examination. cCR is defined as 1) Not palpable breast mass by physical examination, 2) No enhanced breast mass by enhanced MRI, 3) No breast mass by sonography. After diagnosis of cCR, conventional radiotherapy for whole breast and boost radiation for tumor bed are mandatory, followed by pertuzumab and trastuzumab every 3 weeks during 9 months. In non-cCR cases, surgical resection is performed and adjuvant therapy are not specified. The primary endpoint is a distant metastasis-free survival (DMFS) at 3 year, the secondary endpoints are DFS, OS, RFS, proportion of local recurrence, and cosmetics outcome. Given that the threshold and expected of DMFS at 3-year is 93% and 98% with a significance level 2.5% (one sided) and 80% power, 170 cCR cases are required. Assuming half of HER2 pts reach to cCR, 350 pts are required as sample size started PST. Enrollment launched January, 2020 and 57 pts are enrolled as of January 12, 2021. Recent reports found that HR positive HER2(+) subtype has higher concordance between pCR and cCR by adding needle biopsy in the diagnosis, so we are planning to include HR positive subtype in this trial. This clinical trial has been registered at Japan Registry of Clinical Trials as jRCTs031190129 and conducted by the Japan Clinical Oncology Group (JCOG) Breast Cancer Study Group under public fund (National Cancer Center Research and Development Fund). Clinical trial information: jRCTs031190129. Research Sponsor: National Cancer Center Research and Development Fund.

TPS602 **Poster Session**

Phase III postneoadjuvant study evaluating sacituzumab govitecan, an antibody drug conjugate in primary HER2-negative breast cancer patients with high relapse risk after standard neoadjuvant treatment: SASCIA. *First Author: Frederik Marmé, Medical Faculty Mannheim, Heidelberg University, University Hospital Mannheim, Mannheim, Germany*

Background: Women with triple-negative breast cancer (TNBC) having residual disease after neoadjuvant chemotherapy (NACT) as well as HR-positive/HER2-negative breast cancer (BC) with a CPS (clinical and post treatment pathological stage) +EG (estrogen receptor status and grade) score ≥ 3 or score 2 and nodal involvement after NACT (ypN+) are at high risk of recurrence. Sacituzumab govitecan is approved for the treatment of patients with metastatic TNBC who received at least two prior therapies for metastatic disease and has shown activity in heavily pretreated patients with metastatic HR-positive/HER2-negative BC. Therefore, sacituzumab govitecan may represent a new option against the resistant residual disease after standard NACT. **Methods:** SASCIA is a phase III, prospective, international, multicenter, randomized, open label, parallel group study in patients with HER2-negative BC with residual disease after NACT (NCT04595565). Eligible patients must have received taxane-based NACT for 16 weeks, including at least 6 weeks of a taxane. Patients should be at high risk of recurrence after treatment, defined as having centrally confirmed HER2-negative BC (IHC score 0-1 or FISH negative according to ASCO/CAP guideline) assessed preferably on tissue from postneoadjuvant residual invasive disease of the breast and either HR-negative (<1% positive stained cells), with any residual invasive disease > ypT1mi after NACT or HR-positive (≥1% positive stained cells), with a CPS+EG score ≥ 3 or CPS+EG score 2 and ypN+ using local ER and grade assessed on core biopsies taken before NACT. Radiotherapy should be delivered before the start of study treatment. Patients are randomized 1:1 to receive either sacituzumab govitecan 10 mg/kg body weight (days 1, 8 q3w for eight cycles) or treatment of physician's choice (capecitabine 2000 mg/m^2 day 1-14 q21 or platinum-based chemotherapy i.e. carboplatin AUC 5 q3w or AUC 1.5 weekly for eight 3 weekly cycles or observation). Randomization is stratified by HR status (HR-positive vs negative) and nodal involvement after NACT (ypN+ vs ypN0). In patients with HR-positive BC, endocrine-based therapy will be administered according to local guidelines. The primary endpoint is invasive disease-free survival (iDFS). Secondary endpoints include comparison of overall survival (OS, key secondary endpoint), distant disease-free survival, locoregional recurrences-free interval, safety, compliance, iDFS and OS according to stratified and - predefined subgroups, patient reported outcome, and quality of life between treatment arms. As of February 2 2021, 7/1200 patients have been randomized in Germany. International study groups will join soon. Clinical trial information: NCT04595565. Research Sponsor: Gilead Sciences, Inc.

TPS603 **Poster Session**

TRIO-US B-12 TALENT: Phase II neoadjuvant trial evaluating trastuzumab deruxtecan with or without anastrozole for HER2-low, HR+ early stage breast cancer. *First Author: Sara A. Hurvitz, University of California Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Although patients with hormone receptor-positive (HR+)/HER2-negative breast cancer (BC) frequently respond clinically to neoadjuvant treatment, fewer than 10% achieve a pathologic complete response (pCR) with standard chemotherapy or endocrine therapy, even in combination with targeted agents such as CDK4/6 inhibitors. Thus, finding more effective therapies for this disease remains an area of unmet need. *HER2* amplification is a known driver of endocrine resistance and HER2 protein may be expressed at a low level (IHC 1+ or 2+) in up to 60% of HR+ BC. Trastuzumab deruxtecan (DS-8201a, T-DXd) is a novel HER2-targeting antibody drug conjugate (ADC) that is FDA approved for HER2-positive metastatic BC and has demonstrated promising clinical efficacy in HER2-low BC with an objective response rate of ~37%. The aim of TALENT (TRIO-US B-12) is to evaluate the clinical activity and toxicity of neoadjuvant T-DXd either alone or in combination with endocrine therapy in patients with HR+/HER2-low early BC. **Methods:** TRIO-US B-12 TALENT (NCT04553770) is an ongoing randomized, multicenter, open-label, two-stage, phase II neoadjuvant trial for participants with early stage, HR+, HER2-low expressing (1+ or 2+ by IHC) BC. Eligible participants include men and women with previously untreated, operable invasive BC greater than 2.0 cm (cT2) in size. Pts with recurrent or metastatic BC, or inflammatory BC are excluded. Pts are randomized 1:1 to receive six cycles of T-DXd (5.4 mg/kg IV q21 days) either alone or in combination with anastrozole (1 mg PO QD). Men and pre/peri menopausal women randomized to the anastrozole arm also receive standard of care GnRH agonist. Stratification factors include HER2 expression (1+ or 2+) and menopausal status. Tumor tissue is taken at baseline, cycle 1 day 17-21, and at surgery. Blood samples are taken at four time points for biomarker analysis. The primary endpoint is pCR rate (breast and lymph node) at definitive surgery. In stage I, 58 participants will be randomized (29/arm). If >2 participants in an arm achieve pCR, that arm will expand (stage II) to enroll an additional 15 participants (total of 44/arm). A pCR rate of >10% (5/44) would be considered favorable, warranting further evaluation of the treatment in a larger trial. Other endpoints include safety, changes in Ki67 expression, Residual Cancer Burden index, biomarker analysis (including serial cfDNA analysis), and health-related quality of life. As of January 2021, four participants have enrolled. **Conclusions:** To our knowledge this is the only ongoing study evaluating T-DXd with or without endocrine therapy for HR+, HER2-low breast cancer in the neoadjuvant setting. The study will shed light on clinical activity and biomarkers, which may guide larger confirmatory studies for patients with HR+, HER2-low early breast cancer. Clinical trial information: NCT04553770. Research Sponsor: Daiichi Sankyo.

TPS604 **Poster Session**

A prospective, randomized, multicenter, double-blinded, placebo-controlled phase III trial of the HER2/neu peptide GP2 + GM-CSF versus bacteriostatic saline/WFI placebo as adjuvant therapy after any trastuzumab-based therapy in HER2-positive women with operable breast cancer. *First Author: Snehal Patel, Greenwich LifeSciences, Stafford, TX*

Background: GP2 is a biologic nine amino acid peptide of the HER2/*neu* protein delivered in combination with an FDA-approved immunoadjuvant Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF, sargramostim, leukine) that stimulates an immune response targeting HER2/neu expressing cancers. In a prospective, randomized, single-blinded, placebo-controlled, multicenter Phase IIb clinical trial completed in 2018, no recurrences were observed in the HER2/neu positive adjuvant setting after median 5 years of follow-up, if the HLA 2+ patient received the 6 primary intradermal injections over the first 6 months ($p = 0.0338$) in a pre-specified subgroup analysis. Furthermore, the GP2 immunotherapy elicited a potent immune response measured by local skin tests and immunological assays. Of the 138 patients that have been treated with GP2 to date over 4 clinical trials, GP2 treatment was well tolerated and no serious adverse events were observed related to the GP2 immunotherapy. This Phase III trial aims to reproduce the Phase IIb study and will explore the use of GP2 + GM-CSF as adjuvant therapy to prevent the recurrence of breast cancer in HER2/neu positive and HLA 2+ patients, post-surgery and following the first year treatment with any trastuzumab-based therapy. **Methods:** This phase III trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy or an approved biosimilar, treatment with GP2 + GM-CSF or placebo (bacteriostatic saline/WFI) will be administered intradermally for the 6 primary immunization series over the first 6 months and 5 subsequent boosters over the next 2.5 years for a total of 11 injections over 3 years of treatment. The participant duration of the trial will be 3 years treatment plus 2 years follow-up for a total of 5 years following enrollment. An interim analysis is planned and patients will be stratified based on prior and current treatments, among other factors. Eligibility Criteria: The majority of breast cancer patients will be HER2/*neu* positive and HLA 2+, disease-free, conventionally treated node-positive, post breast tumor removal surgery and following the first year treatment with trastuzumab-based therapy. Trial Objectives: 1. To determine if GP2 therapy reduces recurrence in HER2/*neu* positive breast cancer patients. 2. To monitor the in vitro and in vivo immunologic responses to GP2 therapy and correlate these responses with the clinical outcomes. 3. To monitor for any unexpected adverse events and toxicities related to GP2 therapy. Accrual: The target enrollment is up to approximately 500 patients. Contact information: snehal.patel@greenwichlifesciences.com Funding: This trial is supported by Greenwich LifeSciences. Research Sponsor: Greenwich LifeSciences.

605 **Oral Abstract Session**

A randomized phase III post-operative trial of platinum-based chemotherapy (P) versus capecitabine (C) in patients (pts) with residual triple-negative breast cancer (TNBC) following neoadjuvant chemotherapy (NAC): ECOG-ACRIN EA1131 *First Author: Ingrid A. Mayer, Vanderbilt University, Nashville, TN*

Background: Pts with TNBC who have residual invasive disease (RD) after completion of NAC have a very high risk for recurrence, which is reduced by adjuvant capecitabine (C). Pre-clinical models support the use of platinum agents (P) in the TNBC basal subtype. EA1131 tested the hypothesis that invasive disease-free survival (iDFS) would not be inferior but improved in pts with basal subtype TNBC after NAC with the adjuvant use of a P instead of C (primary objective). **Methods:** Pts with clinical stage II/III TNBC post neoadjuvant taxane +/- anthracycline-based chemotherapy with at least 1 cm RD in the surgical specimen were randomized (1:1) to receive P (carboplatin or cisplatin once every 3 weeks for 4 cycles) or C (14/7d every 3 weeks for 6 cycles). TNBC subtype (basal vs. non-basal) was analyzed in the surgical specimen by PAM50. A non-inferiority design (non-inferiority margin of hazard ratio [HR] of 1.154) with superiority alternative (alternative HR of 0.754) was chosen, assuming a 4-year iDFS of 67% for the C arm. Non-inferiority was tested first. If non-inferiority was shown, a formal test for superiority of P compared to C would be conducted. **Results:** 401 participants were randomized to P or C between 2015 and 2020 (recruitment goal, 775), 310 (77%) had TNBC basal subtype disease (primary analysis population). Pts' median age was 52 years, 71% were White and 19% Black. At diagnosis, most tumors were high grade (78%), T2 (59%), 47% N0, and 40% N1. Residual tumors were 37% ypT1, 44% ypT2, and 47% ypN0. Overall incidence of any toxicity was similar (83% with P, 80% with C), but grade 3 and 4 toxicities (no grade 5) were more common with P (25% vs 15%). After median follow-up of 18 months, 113 iDFS events (58% of full information) had occurred. 3-year iDFS for P arm was 40% (95%CI, 29%-51%) and 44% (95%CI, 32%-55%) for C arm. The HR for arms P/C was 1.09 (95% Repeated Confidence Interval, 0.62-1.90) and the probability of eventually rejecting the null of inferiority (i.e., conditional power) was 6%. The Data Safety and Monitoring Committee recommended stopping the trial at the 5th interim analysis in March 2021 since it was unlikely that the trial would be able to show non-inferiority or superiority of the P arm. **Conclusions:** Participants with TNBC with RD after NAC had a lower than expected 3-year iDFS regardless of study treatment. Available data show that it is very unlikely that the study would be able to establish non-inferiority of P to C. In addition, severe toxicities were more common with P. In pts with TNBC, particularly basal subtype, with at least 1 cm RD after NAC and high-risk of recurrence, adjuvant P use does not improve outcomes. Correlative analyses of RD tissue (NGS), circulating markers (ctDNA and CTC pre/post treatment), and patient-reported outcomes (PRO) questionnaires will now occur. Clinical trial information: NCT02445391. Research Sponsor: U.S. National Institutes of Health.

1000 **Oral Abstract Session**

Overall survival (OS) with palbociclib (PAL) + fulvestrant (FUL) in women with hormone receptor–positive (HR+), human epidermal growth factor receptor 2–negative (HER2–) advanced breast cancer (ABC): Updated analyses from PALOMA-3. *First Author: Massimo Cristofanilli, Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Feinberg School of Medicine, Chicago, IL*

Background: In PALOMA-3, a randomized, double-blind, placebo-controlled, phase 3 study, PAL+FUL significantly prolonged progression-free survival (PFS) compared with placebo (PBO) + FUL (1-sided $P<0.0001$). The final protocol-specified OS analysis, which was conducted with a median follow-up of 44.8 months (mo), showed improved OS with PAL+FUL vs PBO+FUL (median OS, 34.9 vs 28.0 mo; hazard ratio, 0.814 [95% CI, 0.644–1.029]; 1-sided $P=0.0429$). Here, we report the results from an OS analysis with a longer median follow-up of 73.3 mo. **Methods:** A total of 521 patients (pts) with HR+/HER2– ABC who had progressed on prior endocrine therapy were randomized 2:1 to PAL (125 mg/d orally, 3/1 week schedule) + FUL (500 mg intramuscular injection) or PBO+FUL. Investigator-assessed PFS was the primary endpoint; OS was a key secondary endpoint. An ad hoc OS analysis was performed when 393 events (75% of the total population) were observed. Circulating tumor DNA (ctDNA) analysis was conducted among pts who consented for this study. **Results:** Improvement in OS continues to be observed with longer follow-up, with a hazard ratio of 0.806 (95% CI, 0.654–0.994; 1-sided nominal $P=0.0221$). The 5-year OS rate was 23.3% (95% CI, 18.7–28.2) with PAL+FUL and 16.8% (95% CI, 11.2–23.3) with PBO+FUL. Favorable OS with PAL+FUL vs PBO+FUL was observed in most subgroups except among pts who were endocrine resistant or had prior chemotherapy for ABC. No new safety signals were identified. Eighteen pts remain on study treatment, including 15 (4.3%) on PAL+FUL and 3 (1.7%) on PBO+FUL. A post-study cyclin-dependent kinase 4/6 inhibitor was received by 20 pts (7.5%) in the PAL+FUL arm and 32 pts (22.2%) in the PBO+FUL arm. ctDNA analyses of tumor mutation profiles (ie, *ESR1*, *PIK3CA*, *RB1*) at the end of treatment and their effect on OS will also be presented. **Conclusions:** The clinically meaningful improvement in OS with PAL+FUL was maintained with >6 years of median follow-up in pts with HR+/HER2– ABC who had progressed on prior endocrine treatment. Pfizer (NCT01942135) Clinical trial information: NCT01942135. Research Sponsor: Pfizer Inc.

1001 **Oral Abstract Session**

Updated overall survival (OS) results from the phase III MONALEESA-3 trial of postmenopausal patients (pts) with HR+/HER2- advanced breast cancer (ABC) treated with fulvestrant (FUL) ± ribociclib (RIB). *First Author: Dennis J. Slamon, David Geffen School of Medicine, University of California Los Angeles, Santa Monica, CA*

Background: The Phase III MONALEESA-3 trial (NCT02422615) previously demonstrated a statistically significant improvement in OS with RIB, a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i), plus FUL compared with placebo (PBO) plus FUL as first-line (1L) or second-line (2L) treatment in postmenopausal pts with HR+/HER2– ABC (median, not reached vs 40.0 mo; hazard ratio [HR], 0.72; 95% CI, 0.57-0.92, P = .00455). This analysis was final per the protocol; following the unblinding of the study, pts still on study treatment in the PBO arm were allowed to cross over to the RIB arm. We report an exploratory analysis of OS after an additional median 16.9 mo of follow-up, allowing for further characterization of long-term survival benefits of RIB. **Methods:** Postmenopausal pts with HR+/HER2– ABC were randomized 2:1 to receive RIB + FUL or PBO + FUL in 1L and 2L settings. Updated OS was evaluated by Cox proportional hazards model and summarized using Kaplan-Meier methods. Additional postprogression endpoints such as progression-free survival 2 (PFS2), time to chemotherapy (CT), and CT-free survival were also evaluated and summarized. **Results:** At the data cutoff (Oct 30, 2020), the median follow-up was 56.3 mo (min, 52.7 mo) and 68 (14.0%) and 21 (8.7%) patients were still on treatment in the RIB vs PBO arms, respectively. With this extended follow-up, RIB + FUL continued to demonstrate an OS benefit vs PBO + FUL (median, 53.7 vs 41.5 mo; HR, 0.73; 95% CI, 0.59-0.90). RIB + FUL had prolonged OS vs PBO + FUL in the 1L (median, not reached vs 51.8 mo; HR, 0.64; 95% CI, 0.46-0.88) and 2L subgroups (median, 39.7 vs 33.7 mo; HR, 0.78; 95% CI, 0.59-1.04). Subgroup analyses also showed a consistent OS benefit compared with the intent-to-treat (ITT) population for most subgroups. PFS2, time to CT, and CT-free survival for the ITT population favored RIB + FUL (Table). Among pts who discontinued study treatment, 81.9% and 86.4% received a next-line subsequent antineoplastic therapy, while 14.0% and 30.0% received a CDK4/6i as any subsequent line in the RIB vs PBO arms, respectively. No new safety signals were observed. **Conclusions:** The previously demonstrated robust and clinically meaningful OS benefit with RIB + FUL compared with PBO + FUL was maintained after almost 5 years of follow-up in postmenopausal pts with HR+/HER2– ABC. The OS benefit of RIB was observed in the 1L and 2L subgroups, which further supports the use of RIB in these populations. The results also demonstrated a significant delay in the use of subsequent CT with RIB vs PBO. Clinical trial information: NCT02422615. Research Sponsor: Novartis Pharmaceuticals Corporation.

1002 **Oral Abstract Session**

Dalpiciclib versus placebo plus fulvestrant in HR+/HER2- advanced breast cancer that relapsed or progressed on previous endocrine therapy (DAWNA-1): A multicenter, randomized, phase 3 study. *First Author: Binghe Xu, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Dalpiciclib (SHR6390), a novel CDK4/6 inhibitor, as monotherapy has demonstrated tolerability and preliminary antitumor activity in pretreated HR+/HER2– advanced breast cancer (ABC). Here we evaluated dalpiciclib with fulvestrant in ABC. **Methods:** In this randomized, double-blind, phase 3 trial, patients (pts) with HR+/HER2– locally advanced or metastatic breast cancer who had relapsed or progressed on previous endocrine therapy were enrolled. Eligible pts were randomized 2:1 to receive dalpiciclib (dalp; 150 mg po qd, d1-21, q4w) or placebo (PBO) with fulvestrant (fulv; 500 mg im, cycle 1 d1, d15, then d1 q4w). The primary endpoint was investigator (INV)-assessed PFS. As of Nov. 15, 2020, 162 (71.4% of total projected) events of disease progression or death had occurred and a preplanned interim analysis was done. The corresponding superiority boundary was 1-sided P = 0.0080 (Lan-DeMets [O'Brien-Fleming] boundary). **Results:** Overall, 361 pts were randomized to receive dalp-fulv (n = 241) or PBO-fulv (n = 120). With a median follow-up of 10.5 mo, dalp-fulv significantly improved INV-assessed PFS versus PBO-fulv (median, 15.7 [95% CI 11.1-NR] vs 7.2 [95% CI 5.6-9.2] mo; HR, 0.42 [95% CI 0.31-0.58]; P < 0.0001). PFS per IRC were consistent with INV assessment (Table). The benefit of dalpiciclib extended beyond initial study treatment based on time to first subsequent chemotherapy (TFSCT; HR, 0.47 [95% CI 0.32-0.69]; P < 0.0001). OS data were not mature with a total of 25 deaths documented. Median duration of exposure was 9.4 (IQR, 4.3-11.4) mo with dalpiciclib and 9.9 (4.7-11.9) mo with fulvestrant in the dalp-fulv group and was 6.1 (3.7-11.0) mo with fulvestrant in the PBO-fulv group. The most common (incidence ≥3%) grade 3 or 4 AEs with dalp-fulv were neutropenia (84.2%; vs 0% with PBO-fulv) and leukopenia (62.1%; vs 0%). Treatment discontinuation due to AE was reported for 2.5% of pts with dalp-fulv vs 3.3% with PBO-fulv. The incidence of SAE was 5.8% with dalp-fulv vs 6.7% with PBO-fulv. **Conclusions:** The study met its primary endpoint, demonstrating that dalpiciclib plus fulvestrant significantly improved PFS versus placebo plus fulvestrant, with a manageable safety profile. Our findings support dalpiciclib plus fulvestrant as a new treatment option in pts with HR+/HER2- ABC who relapsed or progressed on endocrine therapy. Clinical trial information: NCT03927456. Trastuzumab plus endocrine therapy or chemotherapy as first-line treatment for metastatic breast cancer with hormone receptor-positive and HER2-positive: The sysucc-002 randomized clinical trial. *First Author: Zhongyu Yuan, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: For metastatic breast cancer with hormone receptor-positive and HER2-positive, no evidence showed that which first-line regimens were preferred, either anti-HER2 therapy plus endocrine therapy or anti-HER2 therapy plus chemotherapy. This study aimed to determine whether trastuzumab plus endocrine therapy is as efficacious as trastuzumab plus chemotherapy and with decreased toxic effects. **Methods:** We conducted an open-label, non-inferiority, phase 3, randomized, controlled trial at nine hospitals in China. Patients with hormone receptor-positive and HER2-positive histologically confirmed advanced breast cancer were randomly assigned (1:1) to receive trastuzumab plus chemotherapy (CT group) or endocrine therapy (ET group). The primary endpoint was progression-free survival with a non-inferiority upper margin of 1.35 for the hazard ratio (HR). This trial is registered with ClinicalTrials.gov, number NCT01950182. **Results:** Between Sep 16, 2013, and Dec 28, 2019, 392 patients were enrolled and randomly assigned to receive trastuzumab plus endocrine therapy (n = 196) or trastuzumab plus chemotherapy (n = 196). In the intention-to-treat population, the median PFS was 14.8 months (95% CI 12.8-16.8) in the CT group and 19.2 months (95% CI 16.7-21.7) in the ET group (HR 0.88, 95% CI 0.71-1.09; $P_{\text{non-inferiority}} < 0.0001$). Significantly higher frequency of toxicities were observed in CT group compared with ET group, including: leucopenia (98 [50%] vs 13 [6.6%]), nausea (93 [47%] vs 24 [12%]), fatigue (47 [24%] vs 31 [16%]), vomiting (45 [23%] vs 12 [6%]), headache (65 [33%] vs 24 [12%]) and alopecia (125 [64%] vs 8 [4%]). No patients died from treatment-related causes. **Conclusions:** Trastuzumab plus endocrine therapy was non-inferior to and had decreased toxicities to trastuzumab plus chemotherapy in patients with metastatic breast cancer with hormone receptor-positive and HER2-positive. Trastuzumab plus endocrine therapy could provide more convenient treatment and allow better treatment tolerance. Clinical trial information: NCT01950182. Research Sponsor: None.

1004 **Oral Abstract Session**

Results from VERONICA: A randomized, phase II study of second-/third-line venetoclax (VEN) + fulvestrant (F) versus F alone in estrogen receptor (ER)-positive, HER2-negative, locally advanced, or metastatic breast cancer (LA/MBC). *First Author: Geoffrey J Lindeman, Peter MacCallum Cancer Centre/Walter and Eliza Hall Institute, Melbourne, Australia*

Background: For patients (pts) with ER-positive, HER2-negative MBC, CDK4/6 inhibitors + endocrine therapy (ET) is standard first-line treatment, with single-agent ET considered for second-line. Nevertheless, most pts progress. A novel therapeutic target is the antiapoptotic protein BCL2, which is overexpressed in ~85% of primary ER-positive breast cancers. VEN is a potent, selective BCL2 inhibitor that has shown promising clinical activity in pts with ER-positive and BCL2-positive MBC who have received prior ET. We report the prespecified primary and updated (for overall survival [OS]) analysis of VERONICA (NCT03584009), a phase II study of VEN + F vs F in ER-positive, HER2-negative LA/MBC. **Methods:** Pts were ≥18-year-old women with ER-positive, HER2-negative LA/MBC, who received ≤2 prior lines of ET and no prior chemotherapy in the LA/MBC setting and experienced disease recurrence/progression during/after CDK4/6 inhibitor therapy (received ≥8 weeks prior). Pts were randomized 1:1 to VEN (oral; 800 mg daily) + F (intramuscular; 500 mg day 1 and 15 of cycle 1; day 1 of subsequent 28-day cycles) or F, and were treated until disease progression, unacceptable toxicity, withdrawal of consent, death, or predefined study end. Pts were stratified by prior lines of therapy in the LA/MBC setting (1 vs 2) and BCL2 status (high vs low). Primary endpoint was clinical benefit rate (CBR; complete response, partial response, and stable disease ≥24 weeks). Secondary endpoints included progression-free survival (PFS) and OS; safety and exploratory subgroup analyses were also conducted. **Results:** At primary analysis (cutoff: Aug 5, 2020), 103 pts had been randomized (intention-to-treat [ITT] population). Median age was 58.0 and 59.5 years in the VEN + F and F arms, respectively. CBR was similar between arms (VEN + F: 11.8% [n = 6/51; 95% confidence interval (CI) 4.44–23.87]; F: 13.7% [7/51; 5.70–26.26]; risk difference: -1.96% [95% CI -16.86–12.94]). Median PFS was 2.69 months (95% CI 1.94–3.71) in the VEN + F vs 1.94 months (1.84–3.55) in the F arm (stratified hazard ratio: 0.94 [95% CI 0.61–1.45]). Results for CBR and PFS were similar in the BCL2-high and -low subgroups vs the ITT population. More grade 3–4 adverse events (AEs) were observed in the VEN + F vs F arm (n = 13/50 [26%] vs 6/51 [11.8%]). AEs observed with VEN + F were consistent with their individual safety profiles. At updated analysis (cutoff: Oct 22, 2020), OS data were not mature (35.0% event/pt ratio); median OS was 16.99 months in the VEN + F vs not reached in the F arm (stratified hazard ratio: 2.06 [1.04–4.09]). **Conclusions:** From the primary analysis, VERONICA did not show an improved CBR or PFS with VEN + F, vs F alone, in pts with endocrine- and CDK4/6 inhibitor-refractory LA/MBC. Biomarker analysis is ongoing. Clinical trial information: NCT03584009. Research Sponsor: F. Hoffmann-La Roche Ltd.

1005 **Oral Abstract Session**

Treatment-related side effects and views about dosage assessment to sustain quality of life: Results of an advocate-led survey of patients with metastatic breast cancer (MBC). *First Author: Anne L Loeser, Patient-Centered Dosing Initiative, Salt Lake City, UT*

Background: Metastatic breast cancer (MBC) is generally incurable and the majority of patients with MBC will remain on treatment indefinitely. Patients usually begin each new treatment at the Recommended Starting Dose (RSD) on the FDA-approved label based on results from clinical trials. However, patients' ability to tolerate the RSD in the real-world may differ from the clinical trial setting. While the importance of patient reported outcomes is recognized, understanding tolerability from the patient's perspective is lacking and patients' willingness to discuss individualized doses for MBC therapy has not been evaluated. **Methods:** Patient advocates from the Patient-Centered Dosing Initiative distributed a confidential online survey to patients with MBC via social media groups, organizational newsletters, and online support forums. The survey was developed by patients and medical oncologists to ascertain the prevalence and impact of patients' treatment-related side effects, quality of patient-physician communication, management of side effects, and interest in alternative approaches to the RSD when a new treatment is initiated or adverse side effects are experienced. **Results:** 1,221 patients with MBC completed the survey within 15 days. The median number of lines of MBC therapy was 2.5 (range 1 - ≥5) and 46% (n = 564) of patients received their MBC diagnosis within two years of taking the survey. 86% (n = 1,051) reported experiencing at least one significant treatment-related side effect, and of these, 20% (n = 213) visited the Emergency Room/hospital and 43% (n = 454) missed at least one treatment. 98% (n = 1,026) of patients with side effects discussed them with their doctors and 82% (n = 838) were helped by their physicians. The most common (non-exclusive) mitigation strategies were dosage reductions (66%, n = 556) and prescription medications (59%, n = 494). Of the 556 patients given a dosage reduction, 83% (n = 459) reported feeling better. Notably, 92% (n = 1,127) of patients expressed willingness to discuss alternative dosing options with their physicians based upon their personal characteristics and individual preferences. **Conclusions:** Given that 86% of patients with MBC experienced at least one significant treatment-related side effect and 83% improved after dosage reduction, innovative dosage-related strategies are warranted to sustain Quality of Life. Patient-physician discussions in which the patient's physical attributes and circumstances are periodically assessed may determine the right dose for the patient upon treatment initiation and afterwards, and the vast majority of patients would be receptive to such discussions. Research Sponsor: Anne Loeser.

1006 **Oral Abstract Session**

The tumor microenvironment (TME) and atezolizumab + *nab*-paclitaxel (A+nP) activity in metastatic triple-negative breast cancer (mTNBC): IMpassion130. *First Author: Leisha A. Emens, University of Pittsburgh Medical Center Hillman Cancer Center, Pittsburgh, PA*

Background: IMpassion130 was the first randomized phase 3 study to show clinical benefit of cancer immunotherapy (CIT) in untreated PD-L1+ mTNBC. Enhanced A + nP efficacy vs placebo (P) + nP was seen in pts with a richer immune TME but was confined to PD-L1 IC+ pts (PD-L1–expressing immune cells on ≥1% of tumor area; Emens JNCI 2021). While TNBC molecular subtyping and CD8 localization are prognostic in early TNBC, it is unknown whether these features are associated with CIT benefit in mTNBC. This exploratory analysis aimed to identify TME components associated with A + nP efficacy in IMpassion130. **Methods:** IHC was used to assess PD-L1 status (VENTANA SP142) and immune phenotypes (inflamed/excluded/desert per CD8 stromal/intratumoral localization; Mariathasan Nature 2018). RNA-seq was used for molecular subtyping (Burstein CCR 2015) and pathway analyses (MSigDB Hallmark). Cox regression was used to compare PFS/OS between A + nP vs P + nP, adjusted for prior taxanes, liver mets. **Results:** Sample classification and PD-L1 distribution are shown (Table). Improved PFS with A + nP vs P + nP was seen in PD-L1 IC+ inflamed and excluded tumors, but improved OS was limited to PD-L1 IC+ inflamed tumors. PD-L1 IC+ basal-like immune activated (BLIA) and immune suppressed (BLIS) subgroups derived PFS benefit, but OS benefit was limited to PD-L1 IC+ BLIA subgroups. In PD-L1 IC+ pts, pathway analysis identified proliferation/DNA damage repair (basal-like tumor features) and angiogenesis/ER response (higher in luminal androgen receptor [LAR]/ mesenchymal [MES] tumors) were associated with improved and reduced PFS, respectively. **Conclusions:** PD-L1 IC+ immune-inflamed tumors and PD-L1 IC+ BLIA tumors show highest CIT sensitivity, and LAR tumors may be resistant to CIT. These data warrant further study and validation. Clinical trial information: NCT02425891. Research Sponsor: F. Hoffman-La Roche Ltd.

1007 **Oral Abstract Session**

Combination of famitinib with camrelizumab plus nab-paclitaxel as first-line treatment for patients with immunomodulatory advanced triple-negative breast cancer (FUTURE-C-PLUS): A prospective, single-arm, phase 2 study. *First Author: Li Chen, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Camrelizumab (anti-PD-1 antibody) and nab-paclitaxel (nab-P) have demonstrated promising anti-tumour activity in patients with immunomodulatory (IM) subtype metastatic triple negative breast cancer (TNBC), with 52.6% of ORR observed in heavily pretreated patients in our previous umbrella trial (FUTURE). As antiangiogenic agents were known to enhance the response to immune checkpoint inhibitors, we assessed the efficacy and safety of novel triplet combination of famitinib (tyrosine kinase inhibitor targeting VEGFR-2, PDGFR and c-kit), camrelizumab and nab-paclitaxel in patients with IM subtype advanced TNBC. **Methods:** In this prospective, single-arm, phase 2 study, eligible patients were 18-70 years and had treatment-naive IM subtype unresectable locally advanced or metastatic TNBC. IM subtype was defined as CD8+ by immunohistochemistry. Eligible patients received camrelizumab (200 mg iv, d1, 15, q4w) with nab-P (100 mg/m^2 iv, d1, 8, 15, q4w) and famitinib (20 mg po qd, d1-28, q4w). Treatment was continued until disease progression, patient withdrawal, or unacceptable toxic effects. In the absence of intolerable toxicity, nab-P was to be administered for a minimum of 6 cycles. Primary endpoint was objective response rate according to RECIST v1.1. We explored the predictive biomarkers using targeted sequencing with a 484-gene panel. **Results:** From Oct 2019 to Oct 2020, 48 patients were enrolled. Confirmed objective responses were achieved in 39 (81.3%; 95% CI 70.2%-92.3%) of 48 patients in the intention-to-treat population and in 39 (84.8%; 95% CI 74.4%-95.2%) of 46 patients in the per-protocol population. Median time to response was 1.8 months (95% CI 1.8-2.0 months). With a median follow-up of 9.0 months, progression-free survival (PFS) and duration of response data were not mature. Thirty patients (62.5%) are still on the study treatment. The 9-month PFS rate was 60.2% (95% CI, 43.2% to 77.3%). Grade 3 or 4 adverse events were neutropenia (33.3%), anaemia (10.4%), febrile neutropenia (10.4%), thrombocytopenia (8.3%), hypertension (4.2%), hypothyroidism (4.2%), proteinuria (2.1%), septicemia (2.1%) and immune related myocarditis (2.1%). Adverse events that led to the discontinuation of any agent occurred in 6.3% of the patients. Two patients had treatment-related serious adverse events. No treatment-related deaths were reported. Biomarker analysis showed that somatic mutations of *GSK3A* may have the potential to predict immunotherapy response. **Conclusions:** Addition of famitinib to camrelizumab and nab-paclitaxel showed promising antitumour activity as first-line therapy with manageable toxicity profile for IM subtype advanced TNBC patients. Results from ongoing randomized controlled trial FUTURE-SUPER (NCT 04395989) are eagerly awaited. Clinical trial information: NCT04129996. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

1008 **Oral Abstract Session**

Randomized multicenter trial of 3 weekly cabazitaxel versus weekly paclitaxel chemotherapy in the first-line treatment of HER2 negative metastatic breast cancer (MBC). *First Author: Amit Bahl, University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom*

Background: Paclitaxel is commonly used as first line chemotherapy for HER2 negative MBC. However, with response rates of 21.5-53.7% and a significant risk of peripheral neuropathy there is a need for more effective and better tolerated chemotherapy (CCT). **Methods:** This open label randomised (1:1) phase 2 trial compared 6 cycles of cabazitaxel (25 mg/m^2) every 3 weeks, with weekly paclitaxel (80mg/m^2) over 18 weeks as first line CCT. HER2 negative and performance status ≤1 patients were eligible. Patients on cabazitaxel received GCSF prophylaxis. Primary endpoint was Progression Free Survival (PFS) with 127 events required to detect a hazard ratio (HR) of 0.65 with 85% power. Secondary endpoints included objective response rate (ORR; RECIST 1.1), time to response (TTR), overall survival (OS), safety and tolerability and quality of life (QoL). **Results:** 158 patients were recruited from 14 UK hospitals (79 in each arm). Median age (range) was 56(34-81) in the cabazitaxel arm and 61(34-79) in the paclitaxel arm. 61% of patients were performance status 0. Median time on treatment was 15 weeks for both arms, but more patients on paclitaxel had a treatment delay (61% vs 39%) or dose reduction (37% vs 24%). Comparing cabazitaxel to paclitaxel after 146 PFS events, median PFS was 6.7 vs 5.8 months (HR 0.84; 95%CI 0.60–1.18, P = 0.3). There was no difference in OS, median 19.3 vs 20.0 months (HR 0.94; 95%CI 0.63-1.40, P = 0.7), ORR (42% vs 37%) or TTR (HR 1.09; 95%CI 0.68–1.74, P = 0.7). Grade ≥3 adverse events occurred in 42% of patients on cabazitaxel and 48% on paclitaxel. Diarrhoea, febrile neutropenia and nausea were the most common grade ≥3 events in the cabazitaxel arm with rates of 11%, 11% and 10% respectively compared to 1%, 1% and 0% in the paclitaxel arm. In the paclitaxel arm the top grade ≥3 events were lung infection and peripheral neuropathy, 6% and 5% respectively compared to 2.5% and 0% in the cabazitaxel arm. Peripheral neuropathy of any grade was reported by 55% of patients treated with paclitaxel vs 17% on cabazitaxel. Alopecia occurred in 41% of patients on paclitaxel compared to 27% on cabazitaxel. Adverse events leading to discontinuation were more frequent with paclitaxel (22%) than cabazitaxel (14%). Over the course of treatment, mean EQ5D single index utility score (+0.05; 95%CI 0.004-0.09, P = 0.03) and visual analogue scale score (+7.7; 95%CI 3.1-12.3, P = 0.001) were higher in the cabazitaxel arm compared to paclitaxel suggestive of better QoL on Cabazitaxel. **Conclusions:** 3 weekly cabazitaxel as first line chemotherapy in HER2 negative MBC does not significantly improve PFS compared to weekly paclitaxel, though it has a lower risk of peripheral neuropathy with better patient reported overall health outcomes. Cabazitaxel is safe and well tolerated for MBC and requires fewer hospital visits, an important consideration in the COVID pandemic and beyond. Clinical trial information: NCT03048942. Research Sponsor: Sanofi, NIHR portfolio support.

1009 **Clinical Science Symposium**

Disparities within luminal breast cancer: Clinical and molecular features of African American and non-Hispanic white patients. *First Author: Kent Hoskins, University of Illinois at Chicago College of Medicine, Division of Medical Oncology, Chicago, IL*

Background: African American breast cancer patients (AA) are diagnosed younger, have more high-risk features, and poorer clinical outcomes than non-Hispanic White patients (NHW), despite similar treatments. Although comorbidities such as obesity and metabolic syndrome may contribute to differences, ancestry-specific factors and effects of structural violence that disproportionately afflict AA individuals may influence tumor biology and outcomes. We previously reported differentially expressed genes (DEGs) associated with tumor aggressiveness in Basal tumors from AA compared with NHW (Sharma et al., 2020). Here, we compare DEGs in luminal tumors between AA and NHW. **Methods:** The prospective, observational FLEX study (NCT03053193) includes stage I-III breast cancer patients who receive 70-gene signature (MammaPrint/MP)/80-gene signature (BluePrint/BP) testing and consent to full transcriptome and clinical data collection. AA (n=364) and NHW (n=400, random selection) with BP luminal tumors, enrolled from 2017 to present, were included. Race/ethnicity was self-reported. AA were younger than NHW (mean, 59 vs. 62 years, p=0.001); thus, an age-matched subset (n= 360 AA, NHW) was compared. Differential gene expression analysis was performed with R limma package. Comparisons were made between AA and age-matched or randomly selected NHW in: (1) all, (2) luminal A, (3) luminal B, and (4) luminal B, obese. DEGs with FDR<0.05 were significant. Different fold change (FC) thresholds were evaluated. **Results:** Compared with age-matched NHW, AA were similar in menopausal status, T stage, grade, and tumor type; obesity, T2DM status, and nodal stage were significantly different ($p<0.01$). Tumors from AA were more often MP high risk ($p<0.001$), regardless of age matching. Luminal B AA vs. age-matched NHW comparison resulted in more DEGs (n=1070) than other comparisons; however, most were FC<2. Notably, 5/6 DEGs (*PSPH*, *NOTCH2NL*, *POLR1A*, *MAP1LC3P* and *RPS26P10*) in basal tumors (Nunes et al. 2019) were also identified here. Of 9 DEGs (FC>1.7) in the luminal B age-matched comparison, 2 (*PSPH* and *LINC01139*) were also found in the luminal B, obese subset. Consistently upregulated DEGs in AA were associated with metabolism, translation, and cellular stress response pathways. **Conclusions:** We found significant transcriptomic differences between luminal tumors from AA and NHW, when controlling for age, obesity, and genomic classification. A subset of DEGs in luminal B tumors were consistent with those in Basal tumors, suggesting that similar race-associated factors drive DEGs regardless of tumor subtype. DEGs that may be unique to AA luminal tumors were also found. This study suggests that some biological differences in breast tumors may result from patient ancestry or shared adverse socioeconomic exposures and underscores the need for inclusion of diverse patient groups in clinical trials. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

Impact of African ancestry on the relationship between BMI and survival in early stage breast cancer: Retrospective analysis from E5103. *First Author: Tarah J. Ballinger, Indiana University, Indianapolis, IN*

Background: Both Black race and obesity are associated with worse survival in early stage breast cancer. Obesity disproportionately affects Black women; however, the degree this contributes to racial disparities in breast cancer remains unclear. Prior work evaluated heterogeneous populations or used self- reported race, rather than genetic ancestry. African ancestry is associated with higher BMI and worse survival in breast cancer; however, the intersection between genetic ancestry and obesity on survival outcomes remains unknown. **Methods:** We analyzed data from the adjuvant trial E5103. Patients with high risk, HER2 negative breast cancer received doxorubicin/cyclophosphamide x 4, followed by weekly paclitaxel x 12, with or without bevacizumab. Genetic ancestry was determined on the 2,854 patients with available germline DNA, BMI, and outcome data using principal components from a genome-wide array. The primary objective assessed impact of BMI on DFS and OS by ancestry. Multivariate Cox proportional hazard models evaluated correlation between continuous or binary BMI and survival in African (AA) and European (EA) Americans. **Results:** 13.4% of patients were genetically classified as AA and 86.6% as EA. Higher continuous BMI was significantly associated with worse DFS and OS only in AAs (DFS: HR = 1.25 95% CI 1.07-1.46, p = 0.004; OS: HR = 1.38 95% CI 1.10-1.73, p = 0.005); not in EAs (DFS HR = 0.97 95% CI 0.90-1.05, p = 0.50; OS HR = 1.03 95% CI 0.93-1.14, p = 0.52). By disease subtype, BMI was associated with worse outcomes only in AAs with ER+, and not TNBC. By categorical BMI, WHO class III obesity (^{3} 40) significantly associated with worse DFS and OS only in AAs (DFS HR = 1.98, p = 0.010; OS HR = 2.07, p = 0.064), not in EAs (DFS HR = 0.97, p = 0.86; OS HR = 1.28, p = 0.30). Proportion of African ancestry (proAA) was associated with higher BMI and worse outcomes in the total population; however, within AAs there was no significant interaction between proAA and BMI on DFS (HR = 0.36, p = 0.06) or OS (HR = 0.38, p = 0.24). In AAs, BMI remained associated with DFS (HR = 2.78, p = 0.019), suggesting higher BMI is associated with worse DFS regardless of proAA. Coefficients for the interaction term indicate that as proAA increases the impact of BMI on outcome is lessened. **Conclusions:** Higher BMI is significantly associated with worse breast cancer outcomes in women of African ancestry in E5103, but not in those of European ancestry. Categorically, this association was significant only for severe obesity, indicating the relationship may depend on the degree of obesity. As proAA increased in AAs, the impact of BMI on outcome was lessened, suggesting other host factors may contribute more to obesity's influence on outcome than genetics. Determination of the optimal populations for weight loss interventions will advance precision medicine efforts to impact racial disparities and outcomes in early stage breast cancer. Outcomes in patients (pts) aged ≥65 years in the phase 3 ASCENT study of sacituzumab govitecan (SG) in metastatic triple-negative breast cancer (mTNBC). *First Author: Kevin Kalinsky, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: Approximately 20% of pts diagnosed with TNBC are aged ≥65 y. Often, older pts are less fit for chemotherapy due to a greater rate of comorbidities, increased use of medications, and pre-existing frailty or functional loss. SG is an antibody-drug conjugate composed of an anti–Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolyzable linker. The landmark phase 3 ASCENT study (NCT02574455) showed improved outcomes with SG vs single-agent chemotherapy of physician's choice (TPC) in pts with relapsed/refractory mTNBC (median progression-free survival [PFS], 5.6 vs 1.7 mo; median overall survival [OS], 12.1 vs 6.7 mo). Here we assess the impact of age on the efficacy and safety of SG in ASCENT. **Methods**: Pts with mTNBC refractory/relapsing after ≥2 prior chemotherapies were randomized 1:1 to receive SG (10 mg/kg IV on days 1 and 8, every 21 days) or TPC (capecitabine, eribulin, vinorelbine, or gemcitabine) until disease progression/unacceptable toxicity. Primary endpoint was PFS per RECIST 1.1 by independent review in brain metastases-negative (BMNeg) pts. Safety outcomes were assessed in all treated pts. This prespecified subgroup analysis assessed the impact of age (pts ≥65 y) on PFS, OS, and safety. **Results:** Of 529 pts enrolled, 468 were BMNeg (median age, 54 y); of these, 44/235 pts (19%) who received SG and 46/233 pts (20%) who received TPC were aged ≥65 y. SG treatment improved median PFS vs TPC in pts ≥65 y (7.1 vs 2.4 mo; HR, 0.22; 95% CI, 0.12-0.40). SG vs TPC treatment also improved median OS in pts ≥65 y (15.3 vs 8.2 mo; HR, 0.37; 95% CI, 0.22-0.64). Treatment with SG vs TPC resulted in higher ORR (50% vs 0%) and clinical benefit rate (CBR, 61% vs 9%) in pts ≥65 y. Of the 7 pts ≥75 y who received SG, 2 had partial response, 4 had stable disease [SD], and 1 had SD > 6 mo as best response. In pts < 65 y, median PFS for SG vs TPC was 4.6 vs 1.7 mo (HR, 0.46; 95% CI, 0.35-0.59), and median OS was 11.2 vs 6.6 mo (HR, 0.50; 95% CI, 0.40-0.64), respectively; the ORR and CBR were 31% vs 6% and 41% vs 9%, respectively. Pts ≥65 y treated with SG vs TPC had similar rates of all grade and grade ≥3 treatment-emergent adverse events (TEAEs). TEAEs leading to dose reduction were similar in pts ≥65 y in the SG vs TPC arms (35% vs 33%) and were lower in pts < 65 y (19% vs 24%). Key treatment-related TEAEs leading to dose reduction in pts ≥65 y in the SG vs TPC arms were neutropenia (including febrile neutropenia; 14% vs 25%), fatigue (10% vs 4%), diarrhea (6% vs 0%), and nausea (4% vs 0%). TEAEs leading to treatment discontinuation with SG vs TPC were low in pts ≥65 y (2% vs 2%) and < 65 y (5% vs 6%). There were no treatment-related AEs leading to death in any SG-treated age group. **Conclusions:** Irrespective of age, pts who received SG had a significant survival benefit vs TPC, with a tolerable safety profile. Proactive AE monitoring and management will allow optimal therapeutic exposure to SG in older pts. Clinical trial information: NCT02574455. PALOMAGE, a French real-world cohort of elderly women beyond age 70 with advanced breast cancer receiving palbociclib: Baseline characteristics and safety evaluation. *First Author: Philippe Caillet, Hôpital Européen Georges Pompidou, Paris, France*

Background: Advanced breast cancer (ABC) is common in older patients, resulting from the high incidence of breast cancer beyond age 70. This population is often limited in clinical trials. Endocrine therapy (ET) combined with a CDK4/6 inhibitor is the standard of care in ABC overexpressing hormonal receptors (HR+). Data specific to older patients are scarce in the literature, deserving further research. **Methods:** PALOMAGE is an ongoing French prospective study evaluating palbociclib (PAL) + ET in real life setting in women aged ≥70 with HR+ HER2- ABC, split in 2 cohorts: ET sensitive patients with no prior systemic treatment for ABC (cohort A), and ET resistant patients and/or with prior systemic treatment for ABC (cohort B). Data collected include clinical characteristics, quality of life (EORTC QLQ-C30 and ELD14) and geriatric description [G8 and Geriatric-COre DatasEt (G-CODE)]. This analysis reports on baseline characteristics and safety data for the whole population. **Results:** From 10/2018 to 10/2020, 400 and 407 patients were included in cohort A and B, respectively. The median age was 79 years (69-98), 15.1% with an age > 85. ECOG performance status (PS) was ≥2 in 17.9% patients, 68.3% had a G8 score ≤14 suggesting frailty, 32.1% had bone only metastasis, and 44% had visceral disease. 35.8% of patients in cohort B had no prior treatment for ABC. Safety data were available for 787 patients. The median follow-up was 6.7 months (IC95% = 6.1-7.6). At start of treatment, full dose of PAL (125 mg) was used in 76% of the patients: 62.6%, 68.7% and 71.6% of patients aged ≥ 80, those with ECOG PS ≥2 and those with a G8 score ≤14, respectively. In the safety population, 70% had ≥1 adverse event (AE), including 43.1% grade 3/4 AE, and 22.9% ≥ 1 serious AE. Most frequent AE reported were neutropenia (43.2%), anemia (17.5%), asthenia (16.3%) and thrombocytopenia (13.6%). Grade 3/4 neutropenia was observed in 32.3% of patients, with febrile neutropenia in 1.1%. Grade 3/4 AE PAL-related were reported in 40.1%, 31.4% of patients aged < 80, ≥80, respectively. Regarding PAL, 23.4% of patients had a dose reduction and 41.8% had a temporary or permanent discontinuation due to AE. Safety data were similar in both cohorts. Geriatric data and impact on safety will be presented. **Conclusions:** PALOMAGE is a unique large real-world cohort focusing on older patients treated with PAL in France. These preliminary data do not suggest any new safety signal, matching data derived from PALOMA trials. The occurrence of less grade3/4 AE related to PAL in patients aged 80 and beyond might reflect the 30% decrease of PAL dose upfront. Effectiveness analyses are eagerly awaited. Clinical trial information: EUPAS23012. Research Sponsor: Pfizer.

Prospective longitudinal multi-omics study of palbociclib resistance in hormone receptor+/HER2- metastatic breast cancer. *First Author: Yeon Hee Park, Samsung Medical Center, Seoul, South Korea*

Background: The development of CDK4/6 inhibitors represents a significant advance in the treatment of metastatic breast cancer (MBC). To better understand the impact of treatment and drug resistance at the molecular level, we performed multi-omics profiling of matched pre-treatment, on-treatment, and post-progression tumor biopsies from patients treated with palbociclib combined with endocrine blockades (AIs and fulvestrant). The purpose of the study was to identify biomarkers of palbociclib resistance as well as to assess molecular changes during treatment, and those appearing at disease progression. **Methods:** Patients with Hormone Receptor positive (HR+)/HER2- MBC treated with palbociclib in combination with endocrine therapies were prospectively enrolled from July 2017 to June 2020. Of the 89 patients enrolled, we obtained tumor biopsies and matched blood samples, taken at pre-treatment, on-treatment (6 weeks or 12 weeks) and progressive disease (PD) from 71 patients (first line: 55, second line or later: 16 pts.) who had agreed to informed consent form. Tumor biopsies were profiled using whole-exome sequencing (WES) and whole-transcriptome sequencing (RNA-Seq). **Results:** Median follow-up duration was 20 (3-48) months and median age of the patients was 45 (range 30-71) years. The median progression free survival (PFS) of 71 patients was 15 (0.7-39.8) months. The Luminal B subtype is associated with shorter PFS compared to Luminal A (8.6 m vs 19.3 m, p=0.03, HR=1.96). The Luminal B subtype along with multiple cell cycle regulatory genes such as CCNE1 (8.3 m, p=0.015, HR=2.07), CCNE2 (8.5 m, p=8.5e-3, HR=2.2), CDK2 (8.45 m, p=0.05, HR=1.79) are associated with shorter PFS while estrogen response signatures (20.9 m, p=4.6e-3, HR=0.43) and PGR gene expression (20.2 m, p=6.2e-2, HR=0.56) are associated with more favorable prognosis. A Cox-regression multivariate model (p=5.17e-5, C-Index=0.72) was developed and revealed that PFS is independently associated with *BRCA1/2* (HR=1.44; CI=[0.49, 4.29]), *TP53* mutation statuses (HR=3.58; CI=[1.58, 8.13]), the HRD mutation signature (HR=1.40; CI=[1.09, 1.81]) and the proliferative index (HR=1.53; CI=[1.00, 2.34]), an expression signature of cell proliferation. Tumors classified as Luminal A at baseline frequently switched into Luminal B or Her2-enriched subtypes at PD, along with up-regulation of cell cycle markers and proliferation signatures. Further, tumor mutation burden (TMB) and HRD index, a DNA-based measure of genomic instability, significantly increased from baseline to PD in patients with *TP53* and *BRCA1/2* wild-type tumors. **Conclusions:** Our longitudinal multi-omics study identified prognostic biomarkers as well as post-treatment enrichment of HRD related genomic scars and frequent switching into molecular subtypes with aggressive and estrogen independence characteristics. Clinical trial information: NCT03401359. Research Sponsor: Oncology Research & Development, Pfizer.

CCNE1 mRNA and cyclin E1 protein expression as predictive biomarkers for efficacy of palbociclib plus fulvestrant versus capecitabine in the phase III PEARL study. *First Author: Javier Pascual, The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, London, United Kingdom*

Background: The randomized PEARL trial found no superiority of palbociclib plus endocrine therapy over capecitabine in patients (pts) with metastatic HR-positive, HER2-negative breast cancer resistant to prior aromatase inhibitors (Martin M, Ann Oncol 2020). Gene expression analysis showed high *CCNE1* mRNA (*CCNE1*) conferring relative resistance to palbociclib in the PALOMA-3 trial (Turner N, JCO 2019), but further validation is needed. Cyclin E1 protein (cyclin E1) expression in this context has not been studied in randomized trials. We explored *CCNE1* and cyclin E1 as predictive biomarkers in tumor samples from the PEARL study. **Methods:** Formalin-fixed paraffin-embeded tumor samples were retrieved from pts enrolled in PEARL cohort 2 (palbociclib (PAL) + fulvestrant (FUL) vs capecitabine (CAPE)). We measured *CCNE1* using the HTG EdgeSeq Oncology Biomarker Panel (HTG Molecular Diagnostics). Cyclin E1 immunohistochemistry (IHC) staining was performed using specific mouse monoclonal antibody HE12 (Abcam) and scored as percentage of invasive nuclei stained (0-100%). *CCNE1* and cyclin E1 correlations were explored using Pearson coefficients. Cox regression models were used for progression free-survival (PFS) analyses using expression levels split by median, to define high (> median values) vs. low expression. Site of disease and prior chemotherapy were used as confounders in multivariate models. **Results:** Analyses were conducted in 219 pts (47% receiving PAL + FUL and 53% CAPE) with available tumors, with the analysed patients representative of the overall study. Most samples were from the archival primary (72%), obtained > 5 years before this analysis° (74%). *CCNE1* and cyclin E1 were only moderately correlated (r = 0.5). Median *CCNE1* was higher in metastatic vs primary (7.37 vs 6.94, p < 0.01), and in luminal B and non-luminal subtypes compared to luminal A (p < 0.001). In patients with high *CCNE1* expression, median PFS on CAPE was 10.35 and PAL + FUL was 5.68 (HR = 1.63, 95% CI 1.02-2.59, p = 0.042). In patients with low *CCNE1* expression, median PFS on CAPE was 9.43 and PAL + FUL was 8.97 (adjusted HR = 0.93, 95% CI 0.59-1.48, p = 0.762, interaction p = 0.072). Median cyclin E1 protein was higher in luminal B and non-luminal subtypes compared to luminal A (p < 0.01). Cyclin E1 protein expression was not predictive of treatment effect (high cyclin E1 expression CAPE vs PAL + FUL HR = 1.17, low cyclin E1 expression CAPE vs PAL + FUL HR = 1.21, interaction p = 0.977). **Conclusions:** High tumor *CCNE1* mRNA expression identified patients with relative resistance to palbociclib plus fulvestrant, validating prior observations although without statistical significance for interaction. Assessment of Cyclin E1 protein expression did not show predictive value. Investigation treatments to enhance CDK4/6 inhibitor efficacy in tumors with high CCNE1 expression is warranted. Clinical trial information: NCT02028507. Research Sponsor: Pfizer and AstraZeneca.

1015 **Poster Discussion Session**

Characterizing demographics, clinical, and genomic characteristics for U.S. patients with HR+, HER2- metastatic breast cancer following progression on a CDK4 and 6 inhibitor. *First Author: Fabrice Andre, Gustave Roussy, Villejuif, France*

Background: Cyclin-dependent kinases 4 and 6 inhibitors (CDK4 & 6i) have advanced the therapeutic landscape for patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (MBC). However, there is an unmet need for treatment strategies following progression on CDK4 & 6i +/- endocrine therapy (ET). The objective of this analysis is to aid in the development of post-progression treatment by characterizing genomic profiles of tumor biopsies after progression on a CDK4 & 6i +/- ET. **Methods:** This is a retrospective study comparing two cohorts of US patients (pts) diagnosed with HR+, HER2- MBC since January 2011. One cohort underwent biopsy following progression on a CDK4 & 6i +/- ET (Cohortpost) while the second cohort underwent biopsy with no evidence of CDK4 & 6i treatment (Cohortpre). Tumor tissue was analyzed using the next generation sequencing Tempus xT assay that analyses 595 cancer-related genes. Of 595 molecularly profiled pts, 369 had sufficient medical record data to be eligible for this analysis. Patient characteristics at metastatic diagnosis and CDK4 & 6i initiation were described. For genomic profile comparison, Mann-Whitney *U*-test was used for continuous variables such as tumor mutation burden (TMB) with significance at P < 0.05; Chi-square or Fishers' exact test was used as appropriate for categorical variables including mutation frequency, with significance at false discovery rate (FDR) < 0.2. **Results:** Of 369 pts, 177 (48%) were in Cohortpre and 192 (52%) were in Cohortpost. Overall, the mean age at the time of MBC diagnosis was 59 and 55 years, respectively; 47% and 66% of patients had evidence of prior chemotherapy or ET; and 30% and 25% had de novo stage IV MBC. The most common biopsy site was liver, occurring in 38% of pts overall (Cohortpre, 23%; Cohortpost, 52.6%). The xT assay results indicated that pts in Cohortpost had significantly higher TMB compared to patients in Cohortpre (median 2.92 vs 1.67, P < 0.0001). A subset of patients with liver mets across both cohorts (n = 141) showed a similar, but nonsignificant trend (median 2.92 vs 2.08, P = 0.0565). Additionally, pts in Cohortpost had a higher *ESR1* alteration frequency compared to Cohortpre (mutations: 32.29% vs 9.60%, FDR < 0.0001; fusions: 7% vs 3%, P = 0.1420). No significant differences were noted in *TP53*, *CCNE1*, *CCND1*, *RB1*, *CDK4*, and *CDK6* between cohorts. **Conclusions:** These findings describe clinical characteristics and specific genomic alterations noted after progression on CDK4 & 6i +/- ET. Further analyses will evaluate timing of resistance, mutational and transcriptomic signatures. This may aid in understanding mechanisms of progression associated with CDK4 & 6i +/- ET, ultimately contributing to development of treatment options post progression. Research Sponsor: Eli Lilly and Company.

1016 **Poster Discussion Session**

Predictors of non-receipt of first-line CDK 4/6 inhibitors (CDK4/6i) among patients with metastatic breast cancer (MBC). *First Author: Kimberley T Lee, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: CDK4/6i improve survival outcomes for first-line treatment of patients with hormone receptor positive (HR+), human epidermal growth factor-2 negative (HER2-) MBC. Yet, not all eligible patients (pts) receive a first-line CDK4/6i. We sought to describe factors associated with not receiving a first-line CDK 4/6i among MBC pts treated at our institution. **Methods:** Retrospective cohort of pts with HR+, HER2- MBC diagnosed between May 1, 2015 and June 30, 2019 treated at Johns Hopkins clinic sites in Baltimore City (BCi), Baltimore County (BCo), and Washington DC (DC). Primary outcome was receipt of a first-line CDK 4/6i. Clinical and demographic factors were abstracted from the electronic medical record. Patient zip-code was used to define a low-income neighborhood (LIN) as an area where >10% of households have median income below the federal poverty level. Univariate and multivariable logistic regression models (determined using a stepwise model selection approach) were performed to identify factors associated with not receiving a first-line CDK 4/6i. **Results:** Of the 211 pts in the cohort, 203 (96.2%) were female, 133 (63%) were White, and 53 (25%) were Black. Median age was 58 yrs (range 25-90 yrs). 26% of pts had de novo MBC and 44% had visceral disease at diagnosis. About half, 104 (49%), were privately insured, 83 (49%) had Medicare, and 15 (7.1%) had managed care plans including Medicaid. 118 (56%), 43 (20%), and 50 (24%) pts were treated in BCi, BCo, and DC respectively. 60% (n=126) of pts received a first-line CDK 4/6i and there was a trend of increased utilization over time with 39% of pts receiving first-line CDK4/6i in 2015 and 67% in 2019. On univariate analysis, LIN, clinic site, and year of MBC diagnosis (2015-2017 vs 2018-2019) were associated with first-line CDK4/6i use. The multivariable model included age, race, clinic site, LIN, and year of MBC diagnosis. In this model, pts treated in BCi were 58% less likely to receive first-line CDK 4/6i compared to those treated in BCo (OR 0.42, 95% CI 0.18-0.95). Those diagnosed with MBC in 2017 or later were 2.6 times more likely to receive first-line CDK4/6i than those diagnosed prior (OR 2.63, 95% CI 1.45-4.83). Those who lived in a LIN were 39% less likely to receive first-line CDK4/6i vs those in a non-LIN, though this was no longer statistically significant (OR 0.61, 95% CI 0.32-1.13). **Conclusions:** We identified disparities in the use of CDK4/6i for first-line treatment of MBC. Lower use was observed among pts who received care at our urban Baltimore city site with a trend towards lower use among pts from lower-income neighborhoods. These findings highlight potential barriers with accessing oral cancer therapies - cost, patient distrust, and/or systemic bias. Further work is needed to delineate the multi-level factors contributing to these disparities and to develop resources to overcome these barriers and achieve equitable utilization of these drugs. Research Sponsor: Pfizer.

1017 **Poster Discussion Session**

Safety and activity of single-agent giredestrant (GDC-9545) from a phase Ia/b study in patients (pts) with estrogen receptor-positive (ER+), HER2-negative locally advanced/metastatic breast cancer (LA/mBC). *First Author: Komal L. Jhaveri, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Targeting ER activity and/or E synthesis is a mainstay of ER+ BC treatment, but many pts relapse during/after adjuvant endocrine therapy (ET) or develop resistance via *ESR1* mutations that drive E-independent transcription and proliferation. Most tumors remain ER signaling-dependent and pts may respond to second-/third-line ET after disease progression (PD) on prior therapies (Di Leo 2010; Baselga 2012). Giredestrant, a highly potent, nonsteroidal oral selective ER degrader, achieves robust ER occupancy, is active despite *ESR1* mutations, and was well tolerated ± palbociclib with encouraging antitumor activity in the nonrandomized, open-label, dose-escalation and -expansion, phase Ia/b GO39932 study (NCT03332797; Jhaveri 2019; Lim 2020). We present updated interim data from the dose-escalation and -expansion single-agent giredestrant cohorts. **Methods:** Pts had ≤2 prior therapies in the LA/mBC setting with disease recurrence/PD while being treated with adjuvant ET for ≥24 mo and/or ET in the LA/mBC setting, and derived a clinical benefit (CB) from therapy (tumor response/stable disease [SD] ≥6 mo). Pts received 10, 30, 90/100, or 250 mg PO giredestrant QD on D1–28 of each 28-day cycle. Pts were postmenopausal (medical menopause on LHRH agonists was allowed with ≥100 mg giredestrant). **Results:** Clinical cutoff: Jul 31, 2020; median prior therapy lines in the LA/mBC setting: 1; mean dose intensity: 98%. Safety/activity: see the table below. No adverse events (AEs) led to study drug withdrawal. No dose-limiting toxicities (DLTs) occurred; maximum tolerated dose was not reached. Most common AEs in 107 pts: fatigue (22; 21%), arthralgia (18; 17%), and nausea (17; 16%); largely grade 1/2. Related grade 3 AEs were infrequent (5; 5%); none were grade 4/5 per investigator assessment (grade 5 duodenal perforation occurred with 90/100 mg after stopping giredestrant due to PD). 8 (7%) had bradycardia (none with 10 mg or the 30 mg phase 3 dose; all grade 1 except one grade 2 at 250 mg; no treatment interruptions/dose reductions were required). Objective responses and CB were observed at all doses. **Conclusions:** Single-agent giredestrant was well tolerated at all doses, with no DLTs. AEs were generally low grade and in keeping with expected AEs for ETs. Clinical activity was observed at all doses. Updated data, including biomarker and correlative data, will be presented. Clinical trial information: NCT03332797. Research Sponsor: Genentech, Inc.

Phase I/II study of H3B-6545, a novel selective estrogen receptor covalent antagonist (SERCA), in estrogen receptor positive (ER+), human epidermal growth factor receptor 2 negative (HER2-) advanced breast cancer. *First Author: Erika P. Hamilton, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: H3B-6545, a selective, small molecule covalent antagonist of ERα demonstrated preclinical and preliminary clinical activity against ER+ breast cancer (Hamilton EP, SABCS, 2020). This study evaluated the activity and tolerability of H3B-6545 in patients (pts) with metastatic ER+, HER2-, breast cancer refractory to endocrine therapy. **Methods:** Patients received H3B-6545 once daily at the recommended phase II dose of 450 mg. The primary objective of the phase II is to estimate the objective response rate (ORR), progression-free survival (PFS), clinical benefit rate (CBR) and secondary objectives include safety. **Results:** 83 pts were treated with 450 mg in the phase II part of the trial. Additionally, 11 pts were treated with 450 mg in the phase I part of the trial and are included in this analysis. Median age was 62 years (range: 38 to 87 years), 81% had liver and/or lung metastases, and the median number of prior therapies for metastatic disease was 3 (range: 1 to 8). Prior CDK4/6 inhibitors, aromatase inhibitors, fulvestrant, and chemotherapy were received by 85%, 80%, 72%, and 50% of the pts, respectively. 58 pts (62%) had detectable *ESR1* mutations in liquid biopsies, including 10 (11%) and 19 pts (20%) who had clonal Y537S and clonal D538G mutation, respectively. As of January 29, 2021, grade (gr) 2 or higher adverse events (AE) reported in ≥10% were anemia (19%), fatigue (16%), nausea (17%), and diarrhea (12%). Laboratory gr 2 or higher abnormalities reported in ≥10% pts were creatinine clearance decrease (38%), hemoglobin decrease (37%), bilirubin increase (12%), ALT increase (14%), AST increase (13%), and creatinine increase (11%). AE of gr 1 sinus bradycardia (asymptomatic) was reported in 34% and gr 2 (symptomatic, no intervention needed) was reported in 5%. Gr 2 and 3 QTcF prolongation were reported in 2 and 3 pts, respectively. There were no treatment-related deaths. Efficacy estimates are presented in the table below. Responses were observed in heavily pretreated pts, pts with visceral metastases and in pts who received prior fulvestrant, CDK4/6 inhibitor, and/or chemotherapy in the metastatic setting. **Conclusions:** H3B-6545 has a manageable safety profile and demonstrated single-agent anti-tumor activity in heavily pretreated ER+, HER2-mBC patients. Clinical activity was observed in pts with *ESR1* mutations. Clinical trial information: NCT03250676. Research Sponsor: H3 Biomedicine / Eisai.

Efficacy estimates.

Efficacy endpoint	All pts (N = 94)	Pts with clonal Y537S (N = 10)	Pts with clonal D538G (N = 19)
ORR (n, %)	12 (17%)[1]	3 (30%)	0 (0%)

A phase Ib study of proxalutamide (GT0918) in women with androgen receptor-positive metastatic breast cancer. *First Author: Huiping Li, Beijing Cancer Hospital, Beijing, China*

Background: Androgen receptor (AR) is an emerging prognostic marker and therapeutic target in breast cancer. AR is expressed in 60% to 80% of breast cancers. Recent studies have shown the association between AR signaling and tumor carcinogenesis in breast cancer, suggesting AR pathway as a potential target for breast cancer treatment. However, no AR targeting therapies have been approved for treating breast cancer. GT0918 is a new chemical entity of AR antagonist with possible AR down-regulation. We had finished the phase I study and submitted the paper. Here we present a multicenter, open-label phase Ib trial assessing the safety and efficacy of GT0918 in women with AR positive metastatic breast cancer. The primary objective is to evaluate the efficacy of GT0918. The secondary objectives are to assess its safety and to explore the relevant biomarkers. **Methods:** This is an expansion study of a phase I dose-escalation trial. In this phase Ib study, only patients with AR positive metastatic breast cancer were enrolled. All eligibled patients would take GT0918 orally once a day, of a 28 -day cycle. After 2 cycles' safety and tolerability assessment, patients could choose to continue their treatment until they experience disease progression, intolerable toxicities, death, or withdrew consent. The primary efficacy endpoints were 8-week disease control rate (DCR) and 16-week DCR. The secondary efficacy endpoint was progression free survival (PFS). **Results:** In total, 45 patients were enrolled in the study at 200mg (n = 30) and 300mg (n = 15) doses. The most common (≥10%) treatment-related adverse events (AEs) were asthenia (42.2%), aspartate aminotransferase increased (26.7%), blood cholesterol increased(17.8%), alanine aminotransferase increased (17.8%), decreased appetite (17.8%), blood triglycerides increased (13.3%), blood lactate dehydrogenase increased (13.3%), anaemia (13.3%), blood alkaline phosphatase increased (11.1%), gamma-glutamyltransferase increased (11.1%), urinary tract infection (11.1%). Grade 3/4 AEs were reported in 9 patients (20%). No treatment-related deaths occurred. The 8-week and 16-week DCR were both 22.2% (n = 10) (95% CI 10.08%, 34.37%). The median PFS was 1.8 months (95% CI 1.8, 1.9) in all patients. 12 out of 45 (26.7%) were triple negative breast cancer cases. The median PFS was 1.9 months (95% CI 1.7, 9.1), 4 out of 12 patients (33.3%) > 6 months, 2 out of 12 patients (16.7%) > 9 months. **Conclusions:** GT0918 has been shown to be well tolerated and may provide potential clinical benefits to AR positive metastatic breast cancer patients. This study demonstrated triple negative in AR positive patients had more benefit. Clinical trial information: NCT04103853. Research Sponsor: the National Science and Technology Major Project of the Twelfth Five--Year Plan and the National Science and Technology Major Project of the Thirteenth Five-Year Plan.

1020 **Poster Discussion Session**

Efficacy of enobosarm, a selective androgen receptor (AR) targeting agent, correlates with the degree of AR positivity in advanced AR+/estrogen receptor (ER)+ breast cancer in an international phase 2 clinical study. *First Author: Carlo Palmieri, Clatterbridge Cancer Centre NHS Foundation Trust, Wirral, United Kingdom*

Background: The AR is expressed in up to 90% of ER+ breast cancer where it acts as a tumor suppressor. Historically, therapy with synthetic androgens had efficacy, but virilizing side effects and toxicity limited their use. Enobosarm is a selective AR activating agent that does not cause masculinization and has positive attributes such as promotion of bone and improvement of physical function. In a phase 2 study, correlation between the degree of AR staining and antitumor activity in AR+/ER+ patients with metastatic breast cancer (MBC) was examined. **Methods:** A phase 2, open label, parallel design randomized study was conducted in 136 patients to evaluate the efficacy and safety of enobosarm in heavily pretreated women with AR+/ER+ MBC. Patients were randomized to 9 mg (n=72) or 18 mg (n=64) of oral daily enobosarm. AR expression (%AR nuclei staining) in breast cancer samples was determined centrally by immunohistochemistry. The correlation between %AR staining and clinical outcomes was examined with a focus on the 9mg dose, selected for the phase 3 study and the optimal %AR staining established. **Results:** Tumor objective outcomes correlated with percent AR staining (Table). Further, using a 40% AR staining cutoff in patients with measurable disease, the clinical benefit rate (CBR) for ≥40% AR is 80% and <40% is 18% (p<0.0001). Best objective tumor response (BOR) in patients with ≥40% AR is 48% and <40% is 0% (p<0.0001). At ≥40% AR, median radiographic progression free survival (rPFS) is 5.47 and mean is 7.15 months vs <40% AR where the median rPFS is 2.72 and mean is 2.7 months. Similar %AR staining correlation was observed in the 18mg cohort. Enobosarm treatment was well tolerated with significant positive effects on quality of life measurements. **Conclusions:** Enobosarm is a novel oral selective AR activating agent in which a higher % AR staining correlates with a greater antitumor activity. By targeting and activating AR, enobosarm may represent a new hormone treatment approach for AR+/ER+ MBC. The phase 3, ARTEST trial will commence in early 2021 and randomize patients with AR+/ER+/HER2- heavily treated MBC that have progressed on a non-steroidal aromatase inhibitor, fulvestrant and CDK 4/6 inhibitor to receive enobosarm or standard endocrine therapy. Clinical trial information: NCT02463032. Research Sponsor: Veru Inc.

AR %	n	Median rPFS (months)	Average rPFS (months)	Objective Responses (CR+PR)	Objective Response Rate	Clinical Benefit Response Rate

1021 **Poster Discussion Session**

Prevalence of HER2 low in breast cancer subtypes using the VENTANA anti-HER2/neu (4B5) assay. *First Author: Marietta Scott, AstraZeneca R&D, Cambridge, United Kingdom*

Background: Breast cancer patients with HER2 low expression by immunohistochemistry (IHC), defined as IHC1+ or IHC2+ without gene amplification (ISH-) do not respond to conventional anti-HER2 therapies such as trastuzumab or pertuzumab. The HER2-targeted antibody-drug conjugate (ADC) trastuzumab deruxtecan (T-DXd) showed efficacy in late line HER2-overexpressing patients, with some responses in patients with low HER2 expression. Two of the market leading IHC IVDs are Dako Herceptest and Ventana 4B5. T-DXd is being investigated in HER2 low patients as determined by the VENTANA anti-HER2/neu (4B5) assay in the phase III DESTINY-Breast04 study. There is a paucity of information on prevalence of IHC1+/2+ in different breast cancer subtypes, which this study aims to address. **Methods:** HER2 status was calculated from 3750 consecutive primary or metastatic breast cancer patient samples successfully stained using the 4B5 assay and scored locally according to ASCO/CAP 2018 guidelines. Samples were obtained from 3 anatomic pathology labs that support networks of US community hospitals. 500 additional breast cancer samples, pre-selected to include a range of IHC staining (concordance cohort), were stained with both 4B5 and HercepTest (Dako/Agilent) and scored (IHC0, IHC1+, IHC2+, IHC3+) at a central laboratory. **Results:** Prevalence of HER2 categories in 3750 consecutive breast cancer samples is presented in the table below. >50% of estrogen-receptor positive (ER+ve) and progesterone receptor positive (PR+ve) subtypes are HER2 low. In the 500 sample concordance cohort, 28.0% were IHC1+/2+ using the 4B5 assay compared with 11.6% using HercepTest. HercepTest identified IHC1+/2+ staining in 21.6% [95%CI:15.1,29.4] of the patients classified as IHC1+/2+ by 4B5. 98.3% [95%CI: 96.2, 99.5] of samples IHC0 by 4B5 were also IHC0 by Herceptest. **Conclusions**: HER2 IHC1+/2+ (ISH-) by Ventana 4B5 represent a significant proportion of breast cancer patients and more than 50% of ER+ve and PR+ve subtypes. The 4B5 assay classed several patients as IHC1+/2+ that are IHC0 by Herceptest, but almost all patients IHC0 by 4B5 were also IHC0 by Herceptest. Research Sponsor: AstraZeneca.

Subtype (n)	Prevalence IHC0 % [95% CI]	Prevalence IHC1+/2+ (ISH-) [HER2 low] % [95% CI]	Prevalence IHC2+ (ISH+)/IHC3+ % [95% CI]
Total breast cancer (3727)	35.9 [34.4, 37.5]	51.1 [49.5, 52.8]	13.0 [11.9, 14.1]
ER+ve (3028)	34.1 [32.5, 35.9]	55.4 [53.6, 57.2]	10.4 [9.4, 11.6]
ER-ve (588)	43.9 [39.0, 48.0]	29.8 [26.1, 33.6]	26.4 [22.8, 30.1]
PR+ve (2671)	34.6 [32.8, 36.4]	55.9 [54.0, 57.8]	9.5 [8.4, 10.7]
PR-ve (945)	39.0 [35.9, 42.2]	38.0 [34.9, 41.2]	23.0 [20.3, 25.8]
ER or PR+ve (3086)	34.1 [32.4, 35.8]	55.2 [53.4, 57.0]	10.7 [9.6, 11.8]
ER/PR-ve (530)	45.3 [41.0, 49.6]	28.1 [24.3, 32.1]	26.6 [22.9, 30.6]
Triple negative (389)	61.7 [56.7, 66.6]	38.3 [33.4, 43.3]	Not applicable

1022 **Poster Discussion Session**

RC48-ADC, a HER2-targeting antibody-drug conjugate, in patients with HER2-positive and HER2-low expressing advanced or metastatic breast cancer: A pooled analysis of two studies. *First Author: Jiayu Wang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Currently, there are no standard ≥3 line regimens recommended for HER2-positive (IHC 3+, or IHC 2+/FISH+) advanced or metastatic breast cancer, and no recommended HER2-targeting treatment for HER2-low expressing (IHC 2+/FISH-, or IHC 1+) population. RC48-ADC is an innovative HER2-targeting antibody-drug conjugate with a cleavable linker and a potent microtubule inhibitor payload MMAE that has a bystanding effect in tumor cell killing. **Methods:** C001 CANCER (NCT02881138) was a dose-escalation phase I study (0.5, 1.0, 1.5, 2.0, and 2.5 mg/kg) with the 3+3 design among HER2-positive patients. C003 CANCER (NCT03052634) was a phase Ib study with 1.5, 2.0, and 2.5 mg/kg doses in the HER2-positive subgroup and 2.0 mg/kg dose in both IHC 2+/FISH-, and IHC 1+ HER2-low expressing subgroup. C003 CANCER is currently ongoing for IHC 1+ patients. Pooled analysis of the two studies was conducted for the efficacy and safety of RC48-ADC in HER2-positive or HER2-low expressing subgroups. **Results:** At the time of data cutoff (December 31, 2020), 118 female breast cancer patients were enrolled and treated with RC48-ADC. 70 patients (59.3%) were HER2-positive and 48 patients (40.7%) were HER2-low expressing. At baseline, 77 patients (65.3%) had liver metastases, 50 patients (42.4%) were ECOG PS 1, 47 patients (39.8%) had received ≥3 prior chemotherapy regimens. In the HER2-positive subgroup, ORRs for 1.5, 2.0, and 2.5 mg/kg doses were 22.2% (95% CI: 6.4%, 47.6%), 42.9% (95% CI: 21.8%, 66.0%), and 40.0% (95% CI: 21.1%, 61.3%). mPFSs for 1.5, 2.0, and 2.5 mg/kg cohorts were 4.0 months (95% CI: 2.6, 7.6), 5.7 months (95% CI: 5.3, 8.4) and 6.3 months (95% CI: 4.3, 8.8). In the HER2-low expressing subgroup, the ORR and mPFS were 39.6% (95% CI: 25.8%, 54.7%) and 5.7 months (95% CI: 4.1, 8.3). ORR and mPFS for IHC2+/FISH- patients were 42.9% (15/35) and 6.6 months (95% CI: 4.1, 8.5). For IHC1+ patients, even though the COVID-19 pandemic led to treatment postpone for some patients, ORR and mPFS reached 30.8% (4/13) and 5.5 months (95% CI: 2.7, 11.0). The common treatment-related adverse events (TRAEs) were AST increased (64.4%), ALT increased (59.3%), hypoesthesia (58.5%), white blood cell count decreased (48.3%), and neutrophil count decreased (47.5%); most were grade 1-2 in severity. Neutrophil count decreased (16.9%), GGT increased (12.7%), and fatigue (11.9%) were the grade 3 and above TRAEs occurring in ≥ 10% of the overall population. **Conclusions:** RC48-ADC showed consistent efficacy in HER2-positive and HER2-low expressing subgroups. The 2.0 mg/kg Q2W showed a more favorable benefit-risk ratio than other dose levels. No new safety signals were observed. Further studies are initiated to evaluate the efficacy and safety of RC48-ADC in various settings. Clinical trial information: NCT02881138; NCT03052634. Research Sponsor: Remegen.

1023 **Poster Discussion Session**

BEGONIA: Phase 1b/2 study of durvalumab (D) combinations in locally advanced/metastatic triple-negative breast cancer (TNBC)—Initial results from arm 1, d+paclitaxel (P), and arm 6, d+trastuzumab deruxtecan (T-DXd). *First Author: Peter Schmid, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

Background: Chemotherapy with immune checkpoint inhibitors can improve outcomes vs chemotherapy alone in patients (pts) with metastatic TNBC; however, many still have poor clinical outcomes. BEGONIA is an ongoing 2 part, multicenter, multiarm, open-label platform study evaluating safety and efficacy of D (anti–PD-L1)+P and D±P combined with novel therapies as first-line (1L) treatment for metastatic TNBC (NCT03742102). We report initial results from Part 1 of Arm 1, D+P, and Arm 6, D+T-DXd, an antibody-drug conjugate comprising an anti-HER2 antibody, tetrapeptide-based cleavable linker, and topoisomerase I inhibitor payload. **Methods:** Eligible pts had untreated unresectable locally advanced or metastatic TNBC. Pts with HER2-low–expressing tumors (IHC 2+/ISH–, IHC 1+/ISH–, or IHC 1+/ISH untested) per local testing were assigned to the D+T-DXd arm. Pts received D (1500 mg IV Q4W)+P (90 mg/m^2 IV Day 1, 8, 15 Q4W) in Arm 1 and D (1120 mg IV)+T-DXd (5.4 mg/kg IV) Q3W in Arm 6, until progression or unacceptable toxicity. Primary objectives are safety and tolerability. Secondary endpoints include objective response rate (ORR), duration of response (DoR), and progression-free survival (PFS). Tumors were assessed Q8W (D+P) or Q6W (D+T-DXd). The first 6 pts treated with D+T-DXd were evaluated for dose-limiting toxicities (DLTs), with additional pts enrolled if D+T-DXd was tolerated. Study arms are noncomparable due to differing eligibility criteria, treatments, and data maturity. **Results:** Arm 1 D+P (data cutoff Sep 2020): 23 pts received D+P (7 ongoing); 2 discontinued D+P due to AEs. Median follow-up time was 16.6 (range 8.5–19.8) mos. Any Grade 3/4 AEs and SAEs were experienced by 10 (44%) and 1 (4%) pts, respectively. D dose was delayed for 7 (30%) pts. Confirmed ORR was 13/23 (57%) with 54% of those remaining in response at 12 mos (median DoR not reached). Median PFS was 7.3 (95% CI 5.4–13.8) mos in the D+P arm. Arm 6 D+T-DXd (data cutoff Nov 2020): 11 pts received D+T-DXd to date (all ongoing). Median follow-up time was 2.3 (0–6) mos. Any Grade 3/4 AEs and SAEs were experienced by 4 (36%) and 1 (9%) pts, respectively. Pts who received D+T-DXd had no DLTs and 1 had a Grade 1 troponin increase. D dose was delayed and T-DXd dose reduced for 2 (18%) pts each. Confirmed ORR was 4/4 (100%; only 4 pts had the opportunity to complete 2 on-treatment disease assessments) with all 4 remaining in response at data cutoff (median DoR not reached). **Conclusions:** D+P demonstrated a tolerable safety profile and response rate as expected for a 1L TNBC IO/taxane combination. D+T-DXd showed promising early safety and efficacy in 1L HER2-low–expressing TNBC; pt evaluation and enrollment for D+T-DXd are ongoing. D+T-DXd data will be updated and the impact of PD-L1 expression in both arms will be examined. Clinical trial information: NCT03742102. Research Sponsor: AstraZeneca, Pharmaceutical/Biotech Company.

1024 **Poster Discussion Session**

Phase I study of A166 in patients with HER2-expressing locally advanced or metastatic solid tumors. *First Author: Xichun Hu, Department of Medical Oncology, Fudan University Cancer Hospital, Shanghai, China*

Background: A166 is an antibody-drug conjugate composed of a novel cytotoxic drug (Duo-5, anti-microtubule agent) site-specifically conjugated to an anti-HER2 antibody (transtuzumab) via a stable protease-cleavable valine citrulline linker. In a phase I trial in US patients (pts) with relapsed or refractory advanced solid tumor, A166 had an acceptable toxicity profile and best objective response rate (ORR) of 36% at efficacious dose levels (Yongheng Liu et al. ASCO 2020). Here we report a phase I study of A166 in Chinese pts with locally advanced or metastatic solid tumors (CTR20181301). **Methods:** KL166-I-01-CTP is a single arm, open-label, dose-escalation and dose-expansion phase I study evaluating A166 in pts with HER2-expressing locally advanced or metastatic solid tumors. Pts received A166 at doses of 0.1, 0.3, 0.6, 1.2, 2.4, 3.6, 4.8, 6.0 mg/kg IV Q3W. Dose cohorts were expanded at 4.8 and 6.0 mg/kg Q3W. The objectives were to determine the safety and tolerability, pharmacokinetics and antitumor activity of A166. **Results:** 57 pts (median age 53 [range 26-74], 50 female, 7 male) enrolled from Aug 1, 2018 to Nov 30, 2020. HER2 expression was available for all 57 pts: 51 HER2-positive (3+ or 2+/ISH+), 6 HER2-low (1+ or 2+/ISH-). 61.4% (35/57) had received ≥5 prior lines of therapy. No DLTs were observed in all dose groups. Any grade treatment-related AEs (TRAEs) were documented in 96.5% (55/57) of pts, with 31.6% (18/57) being grade 3 or higher. Common TRAEs were corneal epitheliopathy (73.7%), vision blurred (59.6%), peripheral sensory neuropathy (26.3%), dry eye (21.1%), anemia (19.3%), hyponatremia (19.3%). Most common grade ≥3 TRAEs were corneal epitheliopathy (17.5%), hypophosphatemia (5.3%), and dry eye (5.3%). Four pts had serious AEs, two of which were possibly related to the study drug, including thrombosis and fatigue. TRAEs led to 5.3% (3/57) dose reduction and 5.3% (3/57) treatment discontinuation. One death occurred during the treatment due to progressive disease. At the doses of 0.3-6.0 mg/kg, the exposure of ADC in serum were dose dependent and the mean half-life was found to be 1.17-11.04 days. Serum free toxins was about 0.1% and 0.2% of total A166 (ADC) on a molar basis with the Cycle 1 C_{max} and AUC, respectively. At efficacious dose, 36 HER2-positive breast cancer pts with measurable disease were assessed for efficacy, best ORR were 59.1% (13/22) and 71.4% (10/14) in 4.8 and 6.0 mg/kg cohort, respectively. Median progression-free survival (PFS) was not reached, and one patient in 4.8 mg/kg cohort has undergone the treatment for more than 19 months. **Conclusions:** A166 had a manageable safety profile and high stability in the circulation with much lower acute hematological and gastrointestinal toxicities in terms of incidence rate and grade. It demonstrated promising antitumor activity with clinically meaningful responses in heavily pretreated subjects with HER2-positive breast cancer. Clinical trial information: CTR20181301. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

1025 **Poster Session**

Serial circulating tumor DNA samples from patients with metastatic breast cancer and *BRCA1/2* mutations. *First Author: Katharine Collier, Division of Medical Oncology, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: Analysis of circulating tumor DNA (ctDNA) over time allows non-invasive evaluation of tumor genomic evolution. We characterize changes in tumor fraction (TFx), somatic copy number alterations (SCNAs), and somatic mutations (muts) over time in patients (pts) with *BRCA1/2* muts and metastatic breast cancer (mBC) who received a PARP inhibitor (PARPi) or platinum chemotherapy. Specifically, we seek to identify the frequency of *BRCA1/2* reversion muts. **Methods:** Pts with mBC and germline or somatic *BRCA1/2* muts were identified on a banking protocol of prospectively-collected serial samples of blood and plasma. Control pts without a *BRCA1/2* mut were matched 2:1 by age and hormone receptor (HR) status. Ultra-low-pass whole genome sequencing (ULPWGS) with 0.1x depth was performed on all plasma samples (n = 103) and the ichorCNA algorithm was used to determine TFx and SCNAs. Targeted panel sequencing (TPS) of 402 cancer-related genes was performed at 10,000x depth on plasma samples, and one blood sample per pt. The panel includes *BRCA1/2* and 38 other DNA damage repair (DDR) genes. Somatic muts were identified by joint calling with Mutect2 across plasma timepoints with paired pt normal blood. Germline variant calling from TPS on blood with HaplotypeCaller was used to confirm germline muts in *BRCA1/2*.**Results:** We identified 10 pts with mBC with a germline (n = 7) or somatic (n = 3) *BRCA1* (n = 2) or *BRCA2* (n = 8) mut and banked blood and plasma samples at 3-9 timepoints at a median of 8 weeks apart (range 1-43). The control cohort of 20 pts with mBC and wildtype *BRCA1/2* was well matched by age and HR status. All pts with *BRCA1/2* muts received a PARPi and/or platinum chemotherapy at some point during sample collection. Half of control pts received platinum chemotherapy. Germline *BRCA1/2* muts were confirmed in all 7 pts with known germline muts. Among the *BRCA1/2* mut cohort, median TFx was 0.04 (range 0-0.57) with 20% of samples having TFx > 0.10. A median of 1.5 (range 0-39) somatic muts per pt were found in DDR genes. Four pts (40%) had secondary non-reversion muts in *BRCA1/2*. A reversion mut of a germline *BRCA2* mut, restoring the open reading frame of *BRCA2*, was discovered at the last timepoint from 1 pt while receiving carboplatin. A germline *BRCA1/2* reversion mut in this cohort occurred in 2.3% of samples, 14.3% of pts. There was no significant difference in the percent of genome with a SCNA between the first and last time point, nor before and after PARPi/platinum. The somatic mut landscape and clonal evolution of TPS using PyClone will be presented. **Conclusions:** Evaluation of serial ctDNA samples for TFx, SCNAs, and somatic muts from banked plasma and blood from pts with mBC is feasible. The frequency of reversion muts in *BRCA1/2* was low, suggesting that either their incidence is low or ctDNA TPS is not sensitive enough to detect them. Secondary non-reversion muts in *BRCA1/2* and other somatic DDR muts were more common. SCNAs were stable over time. Favorable prognostic factors of oligometastatic breast cancer: A subset analysis of OLIGO-BC1. *First Author: Kun Wang, Department of Breast Cancer, Cancer Center, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: The Federation of Asian Clinical Oncology (FACO) conducted an international retrospective cohort study of oligometastatic breast cancer (BC) (OLIGO-BC1) (UMIN No.000030047). At ASCO2020, we demonstrated that locoregional and systemic therapy prolonged overall survival (OS) for patients with oligometastatic BC, especially for cases with some type of systemic therapy, younger age, ECOG performance status 0, stage I BC, non-triple negative subtype, fewer metastatic sites, local recurrence and longer disease-free interval from a multivariate analysis (#1025). Although BC is heterogeneous and a retrospective dataset has many kinds of bias, we attempted a subset analysis based on intrinsic subtype and several prognostic factors. **Methods:** Oligometastatic BC patients diagnosed from 2007 to 2012 were registered from CSCO, KSMO and JSCO. OS period was measured from the diagnosis of oligometastases to the latest follow-up. ER, PgR and HER2 status were determined by immunohistochemistry and/or in situ hybridization. A hazard ratio (HR) of OS was calculated by using a univariate analysis. **Results:** In 1200 eligible cases, one oligometastatic site was found in 578 cases, two in 289, three in 154, four in 102 and five in 77. Bone metastases were recorded in 301 cases, visceral metastases in 387, locoregional recurrence in 25, local recurrence in 83 and multiple metastatic sites in 404. Luminal subtype was recorded in 526 cases (44%), luminal-HER2 in 189 (16%), HER2 in 154 (13%), triple-negative in 166 (14%) and others in 165 (13%). In any subtype, locoregional and systemic therapy and ECOG performance status 0 were beneficial for OS. Stage I BC, one oligometastatic site and longer disease-free interval were also related to favorable prognosis in luminal and HER2 subtype. However, triple-negative subtype had no survival advantage with these 3 factors. On the other hand, pathological negative or micrometastatic lymph nodes at primary BC and one oligometastatic site of lymph node, lung, liver and bone were favorable prognostic factors. In addition, cases treated locally with surgical resection and conventional radiation therapy were expected to prolong OS. Discussions: Locoregional therapy for oligometastatic BC may be considered in luminal and HER2 subtype with some conditions. As reported in ASCO2020, triple-negative BC should be managed with systemic therapy. **Conclusions:** Oligometastatic BC is diagnosed by chance, but some cases seem to survive with multidisciplinary treatment. It is worthwhile to consider locoregional therapy in oligometastatic BC after evaluating favorable prognostic factors. Research Sponsor: The Federation of Asian Clinical Oncology.

Refining neutropenia risk assessment in patients treated with first-line endocrine therapy (ET) and cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) for metastatic breast cancer (MBC) through a cell-free DNA workflow (cfDNA). *First Author: Lorenza Palmero, Department of Medical Area, University of Udine; Department of Medical Oncology, IRCCS, CRO of Aviano, Udine, Italy*

Background: The combination of ET and CDK4/6i is the current standard of care for hormone receptor (HR)-positive/HER2-negative MBC (luminal MBC), with neutropenia being the main dose limiting toxicity. We previously observed the potential association between leucocyte count (WBC) and different fractions of cell free circulating DNA (cfDNA) (Bortot et al 2020). The present study aimed to evaluate the feasibility of a cfDNA-based workflow as a new tool to assess the risk of treatment induced neutropenia. **Methods:** The study analyzed a prospective cohort 83 luminal MBC patients (pts) treated with first line ET and CDK4/6i in the CRO-2018-56 multicenter study from 2018 to 2021. cfDNA was characterized through droplet digital PCR (ddPCR) based on different *ACTB* DNA fragments lengths: short (s), medium (m) and long (l). Blood samples were collected before treatment start (BL) and at the first clinical evaluation after 3 months (E1). Associations between clinical characteristics, neutropenia and cfDNA were explored through Kruskal Wallis, time to G3 neutropenia (NG3) (TTN) was analyzed through log-rank and Cox regression. **Results:** Neutropenia was G3 in 44 out of 83 pts (53%) and G4 in 2 pts (2%). Median TTN was 1.8 months, 60% of NG3 occurred within 3.7 months. Overall, 74 pts (89%) resolved toxicity within 7 days, 10 pts (12%) reduced CDK4/6i dose after NG3. BL neutrophils count (Neu) and WBC were significantly lower in pts that developed NG3 (P = 0.0013 and P = 0.0020 respectively). *De novo* metastatic pts had numerically higher Neu (median 4825 vs 3895), but only a numerically lower risk of NG3 was observed (HR 0.53 P = 0.064). Although bone involvement was not associated with risk of developing NG3, the total number of metastatic lesions was associated with higher NG3 (P = 0.0016). In particular, > 5 metastatic lesions were associated with higher NG3 risk (p = 0.013). E1 *ACTB*_m was significantly lower with respect to BL in pts that experienced NG3 (median 100% vs 16%, P = 0.0136 in NG3 no vs yes) with a consistent impact on the risk of NG3 (HR: 2.81, P = 0.025). No associations were observed for the other *ACTB* fragment length fractions. BL Neu and *ACTB*_m dichotomized at the median were then combined to describe 4 distinct TTN risk groups (P = 0.0006). Interestingly, pts with low BL Neu and low E1 *ACTB*_m had a median TTN of 0.9 months, while pts with high BL Neu and high E1 *ACTB*_m have not experienced NG3 after a median follow-up of 16.1 months. **Conclusions:** The present study proofed the concept of using cfDNA to provide clinically meaningful data not only about tumor biology, but also for a comprehensive patient assessment. Based on these results, a prospective study focused on a multiparametric neutropenia risk assessment will be started. Research Sponsor: Ricerca Finalizzata Italian Ministry of Health.

Identification of pathogenic *CDK12* alterations in cell-free DNA (cfDNA) from patients with breast cancer. *First Author: Mary Love Taylor, Duke University Medical Center, Durham, NC*

Background: Cyclin dependent kinase 12 (*CDK12*) has both tumor suppressive and proto-oncogenic potential in metastatic breast cancers (MBC). *CDK12* may be an important biomarker and target in MBC. However, a comprehensive genomic analysis of *CDK12* alterations from cfDNA in MBC has not been investigated and the genomic impact of *CDK12* alterations across the MBC spectrum is unknown. The purpose of this study was to identify the incidence of *CDK12* genomic alterations occurring in cfDNA from patients with MBC and elucidate which *CDK12* alterations may impact *CDK12* kinase activity. **Methods:** We queried 13,070 MBC samples from the Guardant Health database between April 2019 – November 2020 to identify the incidence of *CDK12* alterations detected in cfDNA. We classified each alteration type as: missense mutations, indels, or truncations. Amino acid changes occurring at conserved regions across multiple species were identified. Three-dimensional biochemical *in silico* analyses with ChimeraX were used to determine which *CDK12* alterations may impact *CDK12* kinase activity. To gain further biologic insights into *CDK12* altered MBC we made associations with *CDK12* alterations and co-occurring mutated genes. **Results:** Nonsynonymous *CDK12* alterations from the Guardant Health database were found in 317 samples from a cohort of 13,070 patients indicating an overall incidence of 2.43%. Alterations included: 239 (75.4%) missense mutations; 26 (8.2%) indels; and 52 (16.4%) truncations. We identified 62 alterations within the kinase domain with all occurring at highly conserved regions across species. The most frequent hotspot mutation identified was I76M/T, occurring in 11 unique breast cancers. Three-dimensional analyses indicate that *CDK12* alterations within the hinge, HRD, DFG, catalytic spine, and regulatory spine may impact *CDK12* kinase activity. The significantly co-occurring mutations from the Guardant Health breast cancer database in samples with *CDK12* alterations were *ARID1A, APC, RB1*, and *PTEN*. **Conclusions:** A modest incidence of *CDK12* genomic alterations occur in cfDNA from patients with breast cancer. Novel somatic alterations in *CDK12* were identified from Guardant Health that were not detected in the public domain. A portion of these occurred at highly conserved regions across species suggesting these specific *CDK12* mutations may impact *CDK12* kinase expression and be actionable therapeutic targets in breast cancers. Three dimensional analyses of the *CDK12* gene further illustrate which specific alterations may induce *CDK12* kinase expression or lead to inactivation. Co-occurring mutations reveal a unique genotype associated with *CDK12* alterations that may play a biologic role in *CDK12*-mediated breast cancer pathogenesis. Preclinical studies to determine the prognostic and therapeutic implication of *CDK12* alterations in MBC are warranted. Characterization of long-term responders following treatment with talazoparib (TALA) or physician's choice of chemotherapy (PCT) in the phase 3 embraca trial. *First Author: Johannes Ettl, Department of Obstetrics and Gynecology, Klinikum rechts der Isar, Technische Universität München, Munich, Germany*

Background: In the EMBRACA trial (NCT01945775), the poly(ADP-ribose) polymerase inhibitor (PARPi) TALA significantly improved progression-free survival (PFS) versus PCT in patients (pts) with germline *BRCA1/2*-mutated HER2-negative locally advanced/metastatic breast cancer (BC) (8.6 vs 5.6 months [mo]; hazard ratio [HR, 95% CI] 0.54 [0.41-0.71]; $P < 0.0001$). Predictive markers for response to PARPi, other than germline *BRCA1/2* mutational status, are largely unknown. A previous analysis investigated biomarkers associated with long and short responders in EMBRACA. Here, we report the clinical characteristics of long and short responders. **Methods:** Pts were randomized 2:1 to TALA or PCT. In this retrospective analysis, pts in the intent-to-treat (ITT) population were mapped into two groups based on response: LONG (pts in TALA arm with overall survival [OS] ≥30 mo and duration of treatment ≥24 mo; pts in PCT arm with OS ≥30 mo); SHORT (pts in either arm with a PFS event [progressive disease by Independent Radiological Facility or death] ≤12 wks). Data cutoff date was Sept 30, 2019. **Results:** Of 431 pts randomized, 412 pts were treated (286 received TALA; 126 received PCT). In the ITT population, 37 pts receiving TALA and 34 pts receiving PCT were identified as LONG responders; 40 pts receiving TALA and 32 pts receiving PCT were SHORT responders. The Table shows a summary of pt characteristics for LONG and SHORT responders. More pts with HR+ BC and no prior CT for ABC were associated with LONG response; more pts with TNBC and ≥2 prior CT regimens or platinum were associated with SHORT response (Table). Median treatment duration for LONG responders (n = 37, TALA; n = 31, PCT) was 33.5 (24.0-61.4) mo for TALA and 7.6 (1.1-36.3) mo for PCT; 51.4% receiving TALA and 91.2% receiving PCT had subsequent therapy. In SHORT responders, median treatment duration was 2.0 (0.1-5.5) mo (TALA) and 1.4 (0.2-5.6) mo (PCT); 67.5% and 68.8% received subsequent therapy following TALA or PCT, respectively. **Conclusions:** In this clinical characterization of responders from the EMBRACA study, a higher number of LONG responders had HR+ BC and received no prior CT for ABC. A greater proportion of SHORT responders had TNBC and received ≥2 prior CT regimens or platinum. Further investigation is warranted in a larger number of pts. Clinical trial information: NCT01945775. Research Sponsor: Pfizer.

Deep proteomic analysis of plasma exosomes in patients with advanced, hormone receptor-positive breast cancer treated with palbociclib and tamoxifen. *First Author: Xiuyuan Ma, University of Illinois at Chicago, Chicago, IL*

Background: Combining a CDK4/6 inhibitor (CDK4/6i) with endocrine therapy (ET) in advanced, hormone receptor (HR)-positive, HER2-negative breast cancer (BC) doubles median progression-free survival, but eventually drug resistance and disease progression occur. For most patients, the mechanism of resistance is unknown. Exosomes are membrane-bound extracellular vesicles that contain lipids, proteins, and nucleic acids, and are released from tumors as a form of intercellular communication. Exosomes can be recovered from plasma, and analysis of their cargo provides a dynamic read-out of biological pathways that are activated in cancer cells. Proteomic analysis of plasma exosomes may provide insight into mechanisms of resistance that emerge during treatment with CDK4/6i-ET. **Methods:** The Big Ten Cancer Research Consortium conducted a single arm, phase II trial of palbociclib plus tamoxifen as first line therapy for advanced, HR+/HER2- BC (NCT02668666). Whole blood was collected in Streck tubes from study participants (n = 49) at baseline, at disease progression, and at time points during study treatment. Plasma was separated and stored at -80C within 48 hours of collection. Exosomes were isolated from thawed plasma using commercially available kits and ultracentrifugation. Exosome extraction and purification was optimized for protein recovery. Purified exosomes were processed for proteomic analysis and labeled with TMT10 (tandem mass tag 10plex) and quantified with the QExactive HF mass spectrometer. Ultrasensitive mass spectrometry provided deep proteomic coverage of exosomal proteins and detected various post-translational modifications (PTM). Data were analyzed with a pipeline developed in our lab using an improved SEQUEST/ProLuCID database search engine and Percolator data filtering toolchain. Exosome protein expression was determined at baseline, at best response and at the time of progression. **Results:** With our ultrasensitive proteomic method, we detected more than 500 exosome proteins from as little as 100 ng of purified exosomes. A significant enrichment of exosome specific markers was observed when comparing patient samples with healthy donor samples. Enrichment of surface glycoproteins (e.g. CD44) was seen in BC patient samples, as in previous reports. Ultrasensitive proteomics also detected PTM including phosphorylation, methylation, oxidation, deamidation, and glycosylation. Differential proteomic and PTM profiles comparing samples collected from responding patients at baseline vs. at progression will be presented. **Conclusions:** Our innovative method provided an unparalleled portrait of the proteomic landscape of plasma exosomes during treatment with CDK4/6i-ET. This powerful approach may provide novel insights into mechanisms of resistance that emerge during treatment. This study was funded by Pfizer. Clinical trial information: NCT02668666. Research Sponsor: Pfizer, inc.

A retrospective study of characteristics and survival in patients with breast cancer brain metastases classified by subtype using NCI SEER registry. *First Author: Monika Devanaboyina, The University of Toledo College of Medicine and Life Sciences, Toledo, OH*

Background: Breast cancer brain metastasis (BCBM) de novo is associated with the worst prognosis among all types of metastases in breast cancer (BC). Analysis of factors associated with BCBM stratified by subtype of BC could lead to earlier identification of metastasis. **Methods:** 1,268 patients with BCBM at the time of BC diagnosis and known clinical subtype (580 HR+/HER2-, 225 HR+/HER2+, 176 HR-/HER2+, and 287 HR-/HER2-) who were ≥ 20 years of age from 2010 to 2017 were identified using the NCI's Surveillance, Epidemiology, and End Results (SEER) Program 18 registry. Baseline characteristics and survival were analyzed using Chi-Square and Kaplan-Meier methods. **Results:** Patients with HR-/HER2+ BC were the most likely to present with BCBM, compared to all BC patients (prevalence of 13.9% vs. 4.7%; $p<0.001$). Further analysis demonstrated that HER2+ patients had an odds ratio of presenting with BCBM of 2.52 (95% CI: 2.24-2.84) compared to HER2- patients. Interestingly, in patients ages 20-39 with HR-/HER2+ BC, higher rates of brain metastases are noted within the BCBM group compared to all HR-/HER2+ breast cancer cases (28% vs. 7.6%; $p<0.001$). The same trend is seen within the HR-/HER2+ African American population, with those in the BCBM group experiencing higher rates of brain metastases compared to all BC cases with the same subtype (14.3% vs. 5.9%; $p<0.001$). Upon exploring insurance demographics, uninsured patients with HR-/HER2+ BCBM had much higher rates of brain metastases compared to all HR-/HER2+ BC cases (14.8% vs 6.4%; p=0.001). When examining TNM status, significant associations were noted between brain metastases and increased tumor and nodal status. Patients with T4 or N3 status with HR-/HER2+ BCBM exhibited much higher rates of metastasis compared to all BC cases with the same subtype ($p<0.001$). Analysis of survival outcomes showed a median overall survival of 12 months for patients with HR-/HER2+ BCBM. The results displayed in the table below show that HR-/HER2- BCBM patients had the lowest 5-year percent survival, while HR+/HER2+ BCBM patients had the highest 5-year survival. **Conclusions:** This SEER database study provides insight into the demographics, clinical variables, and outcomes for BC clinical subtypes, specifically HR-/HER2+, from 2010 to 2017 in the United States. HR-/HER2+ breast cancer patients within the noted high-risk populations should be made aware of the increased rates of brain metastases compared to the general BC population, as earlier identification of brain metastases within the HR-/HER2+ cohort could improve patient survival. Research Sponsor: None.

Overcoming the breast tumor microenvironment by targeting MDSCs through CAR-T cell therapy. *First Author: Saisha Abhay Nalawade, Baylor College of Medicine, Houston, TX*

Background: Successful targeting of solid tumors such as breast cancer (BC) using CAR T cells (CARTs) has proven challenging, largely due to the immune suppressive tumor microenvironment (TME). Myeloid derived suppressor cells (MDSCs) inhibit CART's function and persistence within the breast TME. We generated CAR T cells targeting tumor-expressed mucin 1 (MUC1) (Bajgain P et al, 2018) for BC. To potentiate expansion and persistence of MUC1 CARTs and modulate the suppressive TME, we developed a novel chimeric co-stimulatory receptor, TR2.4-1BB, encoding a ScFv derived from a TNF-related apoptosis-inducing ligand receptor 2 (TR2) mAb followed by a 4-1BB endodomain. We hypothesize that engagement with TR2 expressed on TME-resident MDSCs, will lead to both MDSC apoptosis and CART co-stimulation, promoting T cell persistence and expansion at tumor site. **Methods:** Function of the novel TR2.4-1BB receptor, was assessed by exposing non-transduced (NT) and TR2.4-1BB transduced T cells to recombinant TR2 and nuclear translocation of NFκB was measured by ELISA. Functionality of in vitro generated MDSCs was determined by the suppression assay. In vitro CART/costimulatory receptor T cell function was measured by cytotoxicity assays using MUC1+ tumor targets in presence or absence of MDSCs. In vivo anti-tumor activity was assessed using MDSC enriched tumor-bearing mice using calipers to assess tumor volume and bioluminescence imaging to track T cells. **Results:** Nuclear translocation of NFκB was detected only in TR2.4-1BB T cells. MDSCs significantly attenuated T cell proliferation by 50±5% and IFNγ production by half compared with T cells cultured alone. Additionally, presence of MDSCs, diminished cytotoxic potential of MUC1 CARTs against MUC1+ BC cell lines by 25%. However, TR2.4-1BB expression on CAR.MUC1 T cells induced MDSC apoptosis thereby restoring the cytotoxic activity of CAR.MUC1 against MUC1+ BC lines in presence of TR2.4-1BB (67±8.5%). There was an approximate two-fold increase in tumor growth due enhanced angiogenesis and fibroblast accumulation in mice receiving tumors + MDSCs compared to tumors alone. Treatment of these MDSC-enriched tumors with MUC1.TR2.4-1BB CARTs led to superior tumor cell killing and significant reduction in tumor growth (24.54±8.55 mm^3) compared to CAR.MUC1 (469.79.9±81.46mm^3) or TR2.4-1BB (434.86±64.25 mm^3) T cells alone (Day 28 after T cell injection). The treatment also improved T cell proliferation and persistence at the tumor site. Thereby, leading to negligible metastasis demonstrating ability of CARTs to eliminate tumor and prevent dissemination. We observed similar results using HER2.TR2.4-1BB CARTs in a HER2+ BC model. **Conclusions:** Our findings demonstrate that CARTs co-expressing our novel TR2.4-1BB receptor have higher anti-tumor potential against BC tumors and infiltrating MDSCs, resulting in TME remodeling and improved T cell proliferation at the tumor site. Research Sponsor: CPRIT (Cancer Prevention and Research Institute of Texas).

1033 **Poster Session**

Uncovering the differential impact of *ESR1* and *PIK3CA* codon variants on the clinical phenotype of metastatic breast cancer (MBC) through circulating tumor DNA (ctDNA) next-generation sequencing (NGS). *First Author: Lorenzo Gerratana, Department of Medicine-Hematology and Oncology, Feinberg School of Medicine, Northwestern University; Department of Medicine (DAME), University of Udine, Chicago, IL*

Background: The exposure to endocrine therapy (ET) can induce the onset of *ESR1* gene alterations that have an impact on not only treatment resistance but also clinical phenotype. We previously demonstrated the potential of liquid biopsy in describing the metastatic behavior of MBC. The aim of this study was to explore the different clinical phenotype across the main *ESR1* and *PIK3CA* codon variants. **Methods**: The study retrospectively analyzed a cohort of 501 MBC patients (pts) characterized for ctDNA through NGS before treatment start at Northwestern University (Chicago, IL), Massachusetts General Hospital (Boston, MA), CRO National Cancer Institute (Aviano, IT) and ASUFC Hospital (Udine, IT) between 2014 and 2020. Associations between clinical characteristics and *ESR1* and *PIK3CA* codon variants were explored through logistic regression corrected for sites and *ESR1*/*PIK3CA* status. Survival was tested through Cox regression both for progression-free survival (PFS) and overall survival (OS). **Results**: Of the total 501 pts, 289 (58%) were diagnosed with hormone-receptor positive (HRpos) MBC, 114 (23%) with HER2-positive MBC, and 93 (19%) with triple-negative MBC. *ESR1* mutations were detected in 71 pts (14%) and *PIK3CA* in 154 pts (31%). The most represented *ESR1* gene mutations were found in codons 380 (9%), 536 (23%), 537 (34%), and 538 (34%), while alterations in codons 542 (19%), 545 (21%), and 1047 (60%) were the most common for *PIK3CA*. As expected, *ESR1* mutations were found only in HRpos pts previously exposed to ET ($P < 0.001$). No significant differences were observed for *PIK3CA*. After multivariable analysis, *ESR1*mutations were confirmed as highly associated with liver and bone metastases (OR 3.31, $P < 0.001$ and OR 5.09, $P < 0.001$). Moreover, an association with lung (OR 2.07, $P = 0.010$) was observed in this cohort. After multivariable analysis, codon 537 mutations were associated with bone involvement (OR 12.97, $P = 0.014$), codon 538 with liver (OR 4.73, $P = 0.010$), and codon 536 with soft tissue (OR 5.84, $P = 0.006$) and liver (OR 4.06, $P = 0.048$). *PIK3CA* mutations were associated with bone (OR 2.61, $P < 0.001$) and lung metastases (OR 1.62, $P = 0.044$). Specifically, codon 1047 mutations were the primary driver (OR 3.14, $P = 0.001$ and OR 1.97, $P = 0.019$). In HRpos MBC, baseline mutations in *ESR1* codon 537 and 538 had a negative impact on OS (HR 3.73, $P < 0.010$ and HR 2.99, $P < 0.021$), while 380 and 536 had a negative impact on PFS (HR 18.98, $P < 0.001$ and HR 2.60, $P = 0.015$). No impact was observed across *PIK3CA* gene variants. **Conclusions**: This study showed the different tumor biology across *ESR1* and *PIK3CA* gene variants. As novel selective estrogen receptor degraders (SERDS) and *PIK3CA* inhibitors are gaining momentum as new ET options in MBC, these results highlight the future pivotal role of ctDNA NGS in refining tumor biology characterization. Molecular characterization of the Ras-MAPK pathway in metastatic breast cancer. *First Author: Justin Wayne Wong Tiu-Iim, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: The Ras-MAPK pathway is a known driver of tumorigenesis and therapeutic target in a variety of cancers. Alterations in this pathway have been linked to decreased tumor immunogenicity. However, molecular alterations in the Ras-MAPK are rare in breast cancer (BC) and their clinical implications remain unclear. As mutational status does not accurately correlate with transcriptional activity, a MAPK pathway activity score (MPAS, Wagle et al., 2018, npj Precision Medicine) is indicative of MAPK activation and correlates with response to MEK (MEKi) or BRAF inhibition (BRAFi). Our goal was to determine the frequency of molecular alterations in the Ras-MAPK and correlate to MAPK pathway activation in MBC. **Methods:** A total of 6464 BC samples underwent comprehensive molecular profiling at Caris Life Sciences. Analyses included next generation sequencing of DNA (592 Gene Panel, NextSeq; whole exome sequencing, NovaSEQ), RNA (NovaSeq, whole transcriptome sequencing, WTS) and IHC. MPAS and immune cell fraction (ICF, Quantiseq) were assessed by mRNA analysis. Wilcoxon, Fisher's exact, or Dunnett's test was used. All results shown were statistically significant ($p < 0.05$). **Results:** The predominant alteration of RAS genes was mutation followed by amplification, no fusions were detected (Table). Only 0.17% of all tumors harbor KRAS G12c mutations. The highest MPAS scores were found in KRAS mutants (mut), HRAS mut (Q61, G1213), BRAF V600 (class 1) mut and NRAS Q61 mut (Table) and therefore used to define Genomic MAPK Activated Tumors (GMAT). GMAT compared to wild type (WT) had significantly higher PD-L1 expression, TMB and MSI/dMMR. GMAT had less B cells (3.4% vs 4.4%), more M1 Macrophages (4.4% vs 3.4%) and neutrophils (5.5% vs 2.7%) regardless of HR status but less NK cells (2.3% s 3.0%), MSDCs (0.9% vs 3.0%) only in HR- tumors with respect to WT. GMAT tumors showed more frequent mutation rate (mr) of PIK3CA (HR+: 57.3% vs 40%; HR-: 41.9% vs 17.9%). HR+ tumors had a higher mr of MSH3 (11.8% vs 0.6%) while HR- tumors had higher mr of PIK3R1 (9.6% vs 3.8%), RhoA (5.3% vs 0.5%), DNA repair genes (TERT, 18.2% vs 1.0%; ARID1A, 18.2% vs 5.9%; PRKDC, 3.9% vs 0) and lower TP53 mr (54.5% vs 85.8%) compared to WT. **Conclusions:** Our study demonstrates that RAS, BRAF and MEK1 mutations are associated with MAPK pathway activation indicative of benefit from MEKi or BRAFi. GMAT warrant further investigation for combinations targeting the RAS-MAPK pathway and immune checkpoint inhibitors. Research Sponsor: U.S. National Institutes of Health.

Cyclin-dependent kinase 4/6 (CDK4/6) inhibitor SHR6390 combined with pyrotinib and letrozole in patients with human epidermal growth factor receptor 2-positive (HER2+), hormone receptor positive (HR+) metastatic breast cancer (MBC): Phase Ib study results. *First Author: Jian Zhang, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: The combining of HER2 targeted therapy and endocrine therapy (ET) has been demonstrated to be a reasonable therapeutic approach and recommended for highly selected patients (pts) with HR+/HER2+ MBC. CDK4/6 inhibitors could sensitize HER2 targeted therapies in multiple patient-derived xenograft models and delay tumor recurrence in a transgenic model of HER2+ breast cancer. The aim of this phase Ib/II study was to investigate the safety and efficacy of adding a CDK 4/6 inhibitor to the combination. Primary phase Ib results were reported. **Methods:** Patients with HR+/HER2+ MBC who were eligible for first- or second-line treatment were enrolled, and orally received letrozole, pyrotinib, and a novel CDK4/6 inhibitor SHR6390. In the "3+3" dose-exploring phase, letrozole was given at a fixed dose of 2.5mg/d. Pyrotinib and SHR6390 were initially given at a dose of 400mg/d and 125 mg/d respectively (Level $_{I}$). If the initial dose level could be tolerated, subsequent pts were assigned to the higher level (Level $_{H}$) with pyrotinib 400 mg/d and SHR6390 150mg/d; otherwise, simultaneously to Level $_{L1}$ with pyrotinib 400 mg/d, and SHR6390 100 mg/d, or Level $_{L2}$ with pyrotinib 320mg/d, and SHR6390 125 mg/d. Primary endpoints of phase Ib included dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), recommended phase 2 dose (RP2D), safety and efficacy. **Results:** As of 4 Jan 2021, a total of 15 pts (Level $_{I}$ 5 pts, Level $_{L1}$ 6 pts, and Level $_{L2}$ 4 pts) were enrolled in phase Ib and received the study treatment. 6 of them had received systemic therapies in the advanced stage, and 10 of them had been previously treated with trastuzumab. The most frequent grade 3/4 adverse events included neutrophil count decreased (n = 6), white blood cell count decreased (n = 4), stomatitis (n = 4) and diarrhea (n = 3). 3 pts (2 in Level $_{I}$, and 1 in Level $_{L1}$) had experienced DLTs, all of which were grade 3 stomatitis. Of the 15 pts evaluable for response, 7 pts (46.7%) had achieved confirmed partial responses (1 in Level $_{I}$, 3 in Level $_{L1}$, and 3 in Level $_{L2}$) and 7 pts (46.7%) had stable disease. Based on DLTs and clinical efficacy, pyrotinib 320mg/d, SHR6390 125mg/d, and letrozole 2.5mg/d was declared as RP2D. **Conclusions:** Data from phase Ib showed the triplet combination of pyrotinib, letrozole, and SHR6390 had an acceptable safety profile and encouraging preliminary efficacy, potentially offering a chemotherapy sparing treatment option for patients with HR+/HER2+ MBC. Enrollment on phase II is ongoing. Clinical trial information: NCT03772353. Research Sponsor: None.

Concordance of HER2+ status by IHC/ISH and *ERBB2* status by NGS in a real-world clinicogenomic database and analysis of outcomes in patients (pts) with metastatic breast cancer (mBC).

First Author: Cheryl D. Cho-Phan, Flatiron Health, San Francisco, CA

Background: HER2 overexpression/amplification measured by IHC or ISH is a predictive biomarker for HER2-targeted therapies. Next-generation sequencing (NGS) can identify *ERBB2* amplification (amp) and mutations. We examined clinical characteristics, NGS testing patterns, and outcomes of pts treated with 1L HER2 therapy with HER2+ mBC based on *ERBB2* amp status using a real-world (RW) clinico-genomic database (CGDB). **Methods:** Pts with mBC (HER2+ by IHC and/or ISH) treated with 1L HER2 therapy who had undergone NGS and were treated within the Flatiron Health (FH) network were eligible. Clinical characteristics and HER2 testing results were obtained via technology-enabled abstraction of clinician notes and radiology/pathology reports and linked to genomic data from Foundation Medicine (FMI) in the nationwide (US-based), de-identified FH-FMI CGDB. Demographic, clinical and genomic characteristics were summarized and stratified by concordance between HER2+ (IHC 3+ or ISH amp+) and *ERBB2*amp+ status [copy number (CN) ≥ 5]. NGS testing patterns and 1L HER2 therapy were characterized and stratified by concordance status. Concordance was assessed based on contemporaneous timing of paired test specimen collection dates (FMI NGS ≤ 30 days of HER2+ status). RW overall survival (rwOS) stratified by HER2+/*ERBB2* amp concordance was estimated with Kaplan-Meier analysis and adjusted Cox proportional hazards models. **Results:** Among 268 eligible pts, HER2+/*ERBB2*amp+ concordance was 66% (176/268); concordance among contemporaneous paired specimens was 73% (106/145). Demographic and clinical features were overall well-balanced with most pts treated at community sites [94%, (252/268)]; the discordant (HER2+/*ERBB2*amp-) group (95/268) had more pts with hormone receptor positive disease (73% vs 62%). Concordance by assay type varied; IHC+ only, IHC+/ISH+, and ISH+ only agreement was 72% (95/132), 76% (26/34) and 52% (50/96), respectively. A higher proportion of discordance (35% vs 19%) was seen in pts treated at community vs. academic sites. Median rwOS was 32.9 months (IQR 25.9-38.9) among concordant (HER2+/*ERBB2*amp+) and 15.5 months (IQR 8.9-30.1) among discordant (HER2+/*ERBB2*amp-) pts, aHR = 0.71 [95% CI: 0.48-1.03; p = 0.073]. **Conclusions:** Among RW pts with HER2+ mBC receiving 1L HER2 therapy, discordance between *ERBB2*amp and IHC/ISH HER2 testing methods was observed. Pts with tumors HER2+ by IHC and/or ISH but negative for *ERBB2*amp had a trend towards worse rwOS following receipt of HER2 therapy compared to concordant cases. Contemporaneous timing of specimen collection was associated with greater concordance. Future analyses on the additive value of *ERBB2* CN as a predictive marker, and assessing factors that may affect discordance such as intratumor HER2 heterogeneity, tumor content, and biopsy site are warranted. Research Sponsor: None.

Pyrotinib plus capecitabine for HER2-positive metastatic breast cancer patients with brain metastases (PERMEATE): A multicenter, single-arm phase II study.

First Author: Min Yan, Breast Cancer Center, Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou, Henan, China

Background: HER2-positive metastatic breast cancer (BC) has a high risk of brain metastases (BM), leading to poor survival. Small molecule tyrosine kinase inhibitor (TKI) with enhanced penetrability to the blood brain barrier combined with capecitabine have demonstrated promising clinical outcomes in HER2-positive metastatic BC patients with untreated (such as lapatinib) or previously treated (such as neratinib) BM. The randomized phase III PHOEBE trial has proved better efficacy of pyrotinib, an irreversible pan-HER receptor TKI, versus lapatinib when in combination with capecitabine in HER2-positive local relapsed or metastatic BC. This study was conducted to investigate the efficacy and safety of pyrotinib plus capecitabine in HER2-positive metastatic BC patients with BM. **Methods:** In this multicenter phase II trial (NCT03691051), eligible patients received pyrotinib 400 mg orally once daily without breaks and capecitabine 1000 mg/m^2 orally twice daily for 14 days followed by 7 days off. Treatment was continued until disease progression or intolerable toxicity. Prior HER2 TKIs were not allowed. Cohort A included patients with radiotherapy-naive BM, and cohort B included those with progressive BM after whole brain radiotherapy or stereotactic conformal radiotherapy. The primary endpoint was confirmed central nervous system (CNS) objective response rate (ORR), as assessed according to the Response Evaluation Criteria In Solid Tumors version 1.1. **Results:** Between January 2018 and July 2020, a total of 78 female patients were included (Table). For cohort A (n = 59), the CNS ORR was 74.6% (95%CI: 61.6%-85.0%). For cohort B (n = 19), the CNS ORR was 42.1% (95%CI: 20.3%-66.5%). By the cutoff date on 25 January 2021, the median progression-free survival was 12.1 months (95%CI: 9.0-14.7) in cohort A and 5.6 months (95%CI: 3.4-10.7) in cohort B. The most common grade ≥3 adverse events were diarrhea (23.1% [18/78]), neutrophil count decreased (12.8% [10/78]), white blood cell count decreased (12.8% [10/78]), anemia (9.0% [7/78]), hand-foot syndrome (7.7% [6/78]), hypertriglyceridemia (6.4% [5/78]), and hypokalemia (5.1% [4/78]). **Conclusions:** Pyrotinib plus capecitabine resulted as an effective and safe treatment for HER2-positive BC patients with radiotherapy-naive BM, but the efficacy was modest in those with radiotherapy-treated BM. Clinical trial information: NCT03691051. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

	Cohort A (n = 59)	Cohort B (n = 19)

Safety and unique pharmacokinetic profile of ARX788, a site-specific ADC, in heavily pretreated patients with HER2-overexpresing solid tumors: Results from two phase 1 clinical trials.

First Author: Sara A. Hurvitz, David Geffen School of Medicine, University of California, Los Angeles/ Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: ARX788 is a site-specific, homogeneous, and highly stable ADC. The payload AS269 is conjugated to the synthetic amino acids para-acetylphenylalanine (pAF) in a humanized anti-HER2 mAb. ARX788 demonstrated promising activity in HER2-positive, HER2-low, and T-DM1 resistant tumors in preclinical studies. Here we present the phase 1 clinical data evaluating the safety, antitumor activity, and PK of ARX788 in advanced solid tumors. **Methods:** The standard 3+3 design (0.33 - 1.5 mg/kg; Q3W or Q4W) is used to determine the MTD and/or RP2D in two phase 1 studies in HER2-positive solid tumors in U.S. and Australia (ACE-Pan tumor-01) and in HER2-positive breast cancers in China (ACE-Breast-01). The efficacy endpoints include ORR and DCR. Intensive PK sampling in first 3 cycles is performed to characterize serum PK profiles of ARX788, total Ab, and pAF-AS269. **Results:** 69 and 34 heavily pretreated patients received ARX788 monotherapy in the ACE-Breast-01 (median 6 prior lines of therapy) and ACE-Pan tumor-01 trial (including breast, gastric/GEJ, NSCLC, ovarian, urothelial, biliary track, endometrial, and salivary gland cancer) respectively. Dose escalation for both studies have been completed with no DLT reported. MTD has not been reached. ARX788 was generally well tolerated with most AEs being grade 1 or 2. The most common grade >3 AEs include ocular AEs (5.7 %) and pneumonitis (4.3%) in the ACE-Breast-01 trial; pneumonitis (2.9%) and fatigue (2.9%) in the ACE-Pan tumor-01 trial. Low systemic toxicities in terms of the incidence rate and grade (as shown in table). No treatment-related death. In the 1.5 mg/kg cohort, ORR was 74% (14/19) and 67% (2/3) for ACE-Breast-01 and ACE-Pan tumor-01, respectively. DCR was 100%. Median DOR or median PFS has not been reached. PK profiles for total antibody and ARX788 were generally comparable across all dose levels. Mean T1/2 for ARX788 and total antibody had approximately 100 hours at the dose of 1.5 mg/kg. Serum pAF-AS269 concentrations peaked with a median time of 168 h. Serum exposure of pAF-AS269 was low with the Cmax and AUC at cycle 1 being approximately 0.1% and 0.18% of those for ARX788 on a molar basis, respectively. **Conclusions:** High stability of ARX788 and low serum exposure of pAF-AS269 may underlie the low systemic toxicity, which differentiates it from other ADCs. Clinical trial information: NCT032550070. Research Sponsor: Ambrx, Inc.

Low Systemic toxicity of ARX788.

Safety of trastuzumab emtansine (T-DM1) in patients (pts) with HER2-positive locally advanced or metastatic breast cancer (mBC): Final results from KAMILLA Cohorts 1 (global) and 2 (Asia).

First Author: Rachel Wuerstlein, University Hospital Munich, Department of Obstetrics and Gynecology, Breast Center and CCC Munich, LMU, Munich, Germany

Background: KAMILLA is an open-label, single-arm, phase 3b safety study of T-DM1 in pts with HER2-positive advanced BC (NCT01702571). The treated (safety) population of KAMILLA comprises 2 cohorts: a larger global Cohort 1 (n=2002) and a smaller Asia Cohort 2 (n=181 [China, n=154; Thailand, n=15; Indonesia, n=12]). Here we report results from Cohort 2 in the context of those previously reported for Cohort 1. **Methods:** Pts had HER2-positive, locally advanced or mBC with progression after chemotherapy and anti-HER2 therapy or ≤6 months (mo) of completing adjuvant therapy. T-DM1 3.6 mg/kg was given intravenously every 3 weeks until disease progression, consent withdrawal, or unacceptable toxicity. Primary endpoints were grade ≥3 (G≥3) adverse events of primary interest (AEPIs), specifically hepatic events, allergic reactions, thrombocytopenia (TCP), and hemorrhage events; all other G≥3 treatment-related AEs (TRAEs); and all-grade pneumonitis. **Results:** As of 31 July 2019,KAMILLA enrolled 2185 pts (Cohort 1, n=2003; Cohort 2, n=182), of which 2002 and 181 in each cohort, respectively, received ≥1 study dose and were included in the safety population. Baseline characteristics were generally similar between cohorts. Median (range) T-DM1 exposure was 5.6 mo (0–46) for Cohort 1 and 5.0 mo (0–31) for Cohort 2. The overall G≥3 AEPI rate was higher in Cohort 2 vs Cohort 1 (Table), mostly driven by a higher G≥3 TCP rate in Cohort 2. In Cohort 2, G≥3 TCP (the most frequently reported G≥3 AEPI) did not appear to be associated with G≥3 hemorrhagic events — the majority of G≥3 TCP events (128/138) fully resolved, with a duration of ≤15 days for 98/138 of these events. G≥3 TRAE rates were 18.4% in Cohort 1 and 48.6% in Cohort 2, the latter mainly due to TCP and platelet count decreased; any-grade pneumonitis rates were 1.0% and 2.2%, respectively. No other safety signals were identified. Median progression-free survival and overall survival were similar for both cohorts (Table). **Conclusions:** These data confirm prior observations in an Asian subgroup of the phase 3 EMILIA trial of T-DM1 in pts with previously treated mBC. Although the G≥3 TCP rate was higher in the Asia cohort, the majority of these events resolved fully. OS and PFS were similar in both cohorts. These data reinforce the favorable T-DM1 benefit-risk profile in mBC. Clinical trial information: NCT01702571. Research Sponsor: F. Hoffmann-La Roche/Genentech.

Comparison of therapy benefit from standard anti-HER2 directed approaches in metastatic breast cancer (MBC) between initially HER2-positive patients and patients initially HER2-negative with switch to HER2-positive. *First Author: Hans-Christian Kolberg, Marienhospital, Bottrop, Germany*

Background: Metaanalyses have demonstrated that 5% of initially HER2 negative breast cancer patients switch to HER2 positive during the course of the disease. Whether there is a difference in benefit from standard HER2 targeted therapies between patients initially HER2 positive and patients switching from negative to positive is unclear. We used data from the PRAEGNANT registry to compare the outcome of those patients. **Methods:** PRAEGNANT is a prospective advanced breast cancer registry (NCT02338167) focusing on molecular biomarkers. Patients in all therapy lines receiving any kind of treatment are eligible. This analysis compared progression-free survival (PFS) with standard HER2 targeted therapies between patients with tumors initially HER2 negative and switched to HER2 positive and patients with tumors that were initially HER2 positive adjusted for age and hormone receptor status. **Results:** At the time of this analysis 4061 patients with MBC were included in the PRAEGNANT registry, 49 of which met the requirements for this analysis. Median age was 56 (IQR 48-64) years and 87.8% of the patients were hormone receptor positive. At first diagnosis 15 patients were HER2 negative and 34 patients were HER2 positive. Within a median observation time of 9 months (95%CI: 3.8, 23.7) 35 PFS events occurred. Median observation time was 9 months (95% CI: 3.8, 23.7). Initially HER2 positive patients had a longer progression-free survival (HR = 0.49, 95% CI (0.24, 1.03), p = 0.07) as compared to initially HER2 negative patients switched to HER2 positive. The 1- and 2-year-PFS rates were also higher for patients initially HER2 positive: 1-year-PFS: 52% (95% CI: 36%, 73%) versus 26 % (95% CI: 12%, 52%); 2-year-PFS: 44% (95% CI: 29%, 67%) versus 19% (95% CI: 7%, 50%). **Conclusions:** Median PFS and 1- and 2-year PFS rate seem to be better in patients HER2 positive at initial diagnosis receiving standard HER2 directed therapies. Although our result has to be interpreted with caution because of the small cohort and the retrospective nature of our analysis, it justifies prospective research including the group of initially HER2 negative patients switched to HER2 positive as a distinct entity. Clinical trial information: NCT02338167. Research Sponsor: None.

Impact of extracranial disease status on survival after initial central nervous system (CNS) involvement and radiation therapy in HER2+ breast cancer brain metastases (BCBM). *First Author: Laura Noteware, Duke University School of Medicine, Durham, NC*

Background: BCBMs are very common in metastatic HER2+ breast cancer. CNS-directed local therapy is the gold standard for treatment, followed by systemic HER2-targeted therapies. In patients with HER2+ BCBM and stable extracranial disease (ECD), consensus guidelines recommend continuing current systemic therapy after local therapy. Our goal was to determine the implications of ECD status at time of HER2+ BCBM first CNS involvement on outcomes including intracranial progression-free survival (PFS1) and overall survival (OS). **Methods:** Retrospective analysis was performed on data extracted from 77 patients with HER2+ BCBM who received CNS radiation at Duke between 2006 and 2020 following initial documentation of CNS involvement. Demographics, dates of metastatic and intracranial diagnosis, ECD status at first CNS involvement, systemic therapy, and outcomes were collected. The primary endpoint was PFS1 defined as the time from first CNS radiation to the subsequent documentation of intracranial progression (RANO-BM). OS was defined as time from first CNS radiation and first metastatic disease to date of death or last known alive. ECD status was defined by RECIST1.1 from systemic staging scans within 30 days of first CNS involvement. **Results:** In this patient cohort of HER2+ BCBMs undergoing CNS radiation at first CNS involvement, >50% of patients had extracranial disease control: no ECD (25%) or stable/responding disease (31%). 52% of patients' tumors were ER+. Median age was 50 years (range 27 – 75). Most patients (58%) developed first CNS involvement during adjuvant or first/second line metastatic therapy. For first CNS radiation, 49% received SRS and 48% WBRT. All patients with no ECD presented with isolated CNS disease as first metastatic presentation. Median OS in this cohort from initial metastatic disease to death was markedly worse for patients with no ECD (25.3m, 95% CI: 16.8 to 35.3) compared to those with progressive or stable/responding ECD (48.8m, 95% CI: 28.1 to 65; and 52.9 months, 95% CI: 43.7 to 73.3, respectively; p=0.03). Median OS from first CNS involvement to death was not statistically different amongst groups. This analysis did not detect median PFS1 differences based on ECD after first CNS radiation: progressive ECD (6.3m), no ECD (8.7m), or stable/responding ECD (10.6m) (p=0.13), though clinically meaningful differences were observed. **Conclusions:** Patients with isolated HER2+ BCBM with no ECD at the time of their initial CNS involvement (25% of population) have substantially worse OS compared to patients who present with ECD and develop CNS metastases later in their disease course. This population with isolated CNS disease at metastatic presentation deserves investigation of novel treatment algorithms, including earlier introduction of brain penetrable HER2-targeted agents. Research Sponsor: None.

Phase I study of LZM005, a HER2 antibody, as monotherapy or in combination with trastuzumab and docetaxel in patients with HER2-positive metastatic breast cancer. *First Author: Cong Xue, Department of Medical Oncology, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: LZM005 is a novel anti-HER2 antibody that binds with elevated affinity to the domain II of HER2. This phase I study assessed the safety, tolerability, pharmacokinetics (PK) and activity of LZM005, as monotherapy or combined with trastuzumab and docetaxel in patients with HER2-positive metastatic breast cancer. **Methods:** The phase I trial included phase Ia and Ib. Phase Ia was the monotherapy dosage escalation design. LZM005 was administered intravenously with 5mg/kg, 10mg/kg, 15mg/kg and 20mg/kg. The endpoints were dose limited toxicity (DLT) and maximum-tolerated dose (MTD), safety, tolerability and PK analysis. In phase Ib, LZM005 was combined with trastuzumab and docetaxel with MTD. The endpoints included safety and tolerability, response, PK and biomarker analysis. **Results:** From Jan 2017 to Feb 2020, 35 patients received LZM005 (15 monotherapy, 20 combination). No DLT was observed from 5mg/kg to 20mg/kg. In phase Ib two arms were set: 420mg arm and 525mg arm. The pharmacokinetics of LZM005 were similar to pertuzumab (Table). Common adverse events included increased transaminases, diarrhea and anemia in monotherapy and combination therapy. The common AE in phase Ia trial included diarrhea (21.4%), anemia (14.3%), elevated transaminase (14.3%). The common AE in phase Ib trial included anemia (44.1%), diarrhea (41.2%), fatigue (26.5%), elevated transaminases (23.5%), nausea (20.6%), rash (17.6%) and asymptomatic urinary tract infection (11.7%). All adverse events were manageable. No treatment-related death occurred. The clinical benefit rate and objective response rate was respectively 42.90% (6/14) and 7.14% (1/14) with monotherapy, with combination cohort was 100% (8/8) and 62.5% (5/8) in trastuzumab-naive, 83.3% (11/12) and 41.7% (5/12) in trastuzumab-pretreated patients. The median progression free survival was 22.5 weeks. **Conclusions:** LZM005 was well tolerated and showed potent activity in patients with HER2-positive metastatic breast cancer. Further evaluation was warranted. Clinical trial information: CTR20191921. Research Sponsor: Livzon Mabpharm Inc, Other Foundation.

Updated results of tucatinib versus placebo added to trastuzumab and capecitabine for patients with pretreated HER2+ metastatic breast cancer with and without brain metastases (HER2CLIMB). *First Author: Giuseppe Curigliano, Istituto Europeo di Oncologia, Milan, IRCCS and University of Milano, Milan, Italy*

Background: Tucatinib (TUC) is an oral tyrosine kinase inhibitor (TKI) highly specific for HER2. TUC is approved for use in combination with trastuzumab (T) and capecitabine (C) in patients (pts) with and without brain metastases (BM) who have received 1 or more prior anti-HER2–based regimens in the metastatic setting. In the primary analysis from the pivotal HER2CLIMB trial, the addition of TUC to T and C in pts with HER2+ metastatic breast cancer showed a statistically significant and clinically meaningful prolongation of progression-free (PFS) (HR = 0.54 [95% CI: 0.42, 0.71]; P < 0.001) and overall survival (OS) (HR = 0.66 [95% CI: 0.50, 0.88]; P = 0.005) (Murthy, et al. NEJM 2020). TUC in combination with T and C was well tolerated with few discontinuations other than for disease progression. Based on these data, the protocol was amended for unblinding of sites to treatment assignment to allow for crossover from the placebo arm to receive TUC in combination with T and C. **Methods:** HER2CLIMB (NCT02614794) is a global, randomized, double-blind, placebo-controlled trial in pts with unresectable locally advanced or metastatic HER2+ breast cancer previously treated with T, pertuzumab, and T-emtansine (T-DM1), including pts with untreated, treated stable, or treated and progressing BM. Overall 612 pts were randomized 2:1 to receive TUC 300 mg BID or placebo, each in combination with T and C. Randomization was stratified by BM, ECOG performance status, and geographic region. Protocol prespecified analysis of OS, PFS (by investigator assessment) and safety in the total study population will be performed at approximately 2 years from the last patient randomized. **Results:** Updated Kaplan-Meier time-to-event analysis of OS and PFS with hazard ratios and 95% confidence intervals for TUC arm vs placebo arm will be presented overall, as well as for OS in the prespecified subgroups reported previously (Murthy, et al. NEJM 2020). Safety and tolerability assessments will include frequency of adverse events by severity, dose modifications and discontinuation of study medications. **Conclusions:** Conclusions will be presented in the presentation. Clinical trial information: NCT02614794. Research Sponsor: Seagen Inc.

Pharmacokinetic (PK) analyses in CSF and plasma from TBCRC049, an ongoing trial to assess the safety and efficacy of the combination of tucatinib, trastuzumab and capecitabine for the treatment of leptomeningeal metastasis (LM) in HER2 positive breast cancer. *First Author: Erica Michelle Stringer-Reasor, University of Alabama at Birmingham, Birmingham, AL*

Background: Tucatinib is a potent and highly selective HER2-targeted tyrosine kinase inhibitor approved for use in combination with trastuzumab and capecitabine for patients with metastatic HER2+ breast cancer (MBC) who have received ≥1 prior HER2-based regimen in the metastatic setting, including patients with brain metastases (BM). TBCRC049 (NCT03501979) is an investigator-initiated phase 2 single-arm study currently enrolling to evaluate the safety and efficacy of tucatinib, trastuzumab and capecitabine in HER2+ BC with newly diagnosed LM. Here, we report the pre-specified pharmacokinetic (PK) analysis for the first 15 patients to determine bioavailability of tucatinib and its predominant metabolite, ONT-993, in the CSF. **Methods**: Eligible patients included adults with HER2+ MBC, KPS > 50, and newly diagnosed, untreated LM (defined as positive CSF cytology and/or radiographic evidence of LM, plus clinical signs/symptoms). Patients with treated or concurrent/new BM were allowed. The primary endpoint is overall survival with an accrual goal of 30 pts. Parallel PK samples were collected in plasma and CSF via Ommaya reservoir on day 1 of cycles 1 and 2 at 0h (baseline), 2-3h, 5-7h and 24h (optional) following initiation of tucatinib 300 mg BID. Tucatinib and ONT-993 were quantified in plasma (n=15) and CSF (n=13) using validated liquid chromatography-mass spectrometry methods. **Results**: Tucatinib and ONT-993 plasma concentrations were consistent with previous studies and exhibited high interindividual variability. Tucatinib and ONT-993 were detectable in the CSF within 2 hours post tucatinib administration; concentrations ranged from 0.57 to 25 ng/mL for tucatinib (IC_{50} for tucatinib against HER2 is 3.3 ng/mL) and 0.28 to 4.7 ng/mL for ONT-993. Tucatinib concentrations in the CSF per timepoint were in a similar range to unbound plasma ($plasma_{ub}$) tucatinib. CSF to $plasma_{ub}$ ratios were generally consistent over time; the steady-state (cycle 2) median tucatinib CSF to $plasma_{ub}$ ratio was 0.83 (0.19 to 2.1). ONT-993 CSF to $plasma_{ub}$ ratios were similar to tucatinib CSF to $plasma_{ub}$ ratios. **Conclusions**: In patients with LM from HER2+MBC who were treated with tucatinib, trastuzumab, and capecitabine, tucatinib and ONT-993 were detectable in the CSF of all patients at median levels similar to $plasma_{ub}$ tucatinib. This is the first documented evidence of tucatinib distributing into the CSF in patients with HER2+MBC. Efficacy and safety of tucatinib, trastuzumab, and capecitabine in patients with HER2+ LM will be reported upon completion of TBCRC 049 accrual. Clinical trial information: NCT03501979. 68Ga-HER2 affibody PET/CT imaging as an option in patients whose HER2 status of any tumor in the body needs to be deciphered. *First Author: Haitao Miao, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Anti-HER2 targeted agents are standard of care for HER2 positive patients with either early or advanced breast cancer. Determination of tumor HER2 status helps diagnosing and treating breast cancer. In any tumor which required this biological information, we used a novel ^{68}Ga-NOTA-MAL-MZHER2 (^{68}Ga-HER2) affibody PET/CT to differentiate HER2 status of each lesion in the patient body. **Methods:** ^{68}Ga-HER2 affibody PET/CT was performed in breast cancer patients if HER2 status of any lesions in the patient body remained to be determined. **Results:** Twenty-four patients were enrolled. ^{68}Ga-HER2 affibody PET/CT was requested by physicians due to the following reasons: 6 with multiple primary cancers (including patients who harbored two primary breast malignancies but with different HER2 status, and patients who had at least another non-breast primary other than HER2-positve breast cancer), 13 with metastases inaccessible for biopsy or repeated biopsy, 6 with inconsistent HER2 status between the primary and metastatic lesions, and 4 with different HER2-status within metastases (ICH ranging from 0-3+). Assessment report showed that the ^{68}Ga-HER2 affibody tumor uptake was considered positive in 16 patients, negative in 7 patients, and equivocal in one patient. In 11 lesions which was pathological-confirmed HER2-positivity, 100% of the tumors were also positive with this PET/CT. The heterogeneity of ^{68}Ga-HER2 affibody uptake was obvious, with a maximal 8.5-fold difference within one patient and a maximal 11-fold difference among patients. **Conclusions:** ^{68}Ga-HER2 affibody PET/CT imaging is a valuable tool if HER2 status of any tumor needs to determined. We are now evaluating the ^{68}Ga-HER2 affibody PET/CT imaging as a non-invasive approach to classify the molecular subtype of metastatic breast cancer, and its potential application in the dynamic surveillance of anti-HER2 therapies. Research Sponsor: None.

Clinicopathological characteristics of exceptional responders who achieve durable remissions beyond five years (DR5) in HER2+(H+) metastatic breast cancer (MBC). *First Author: Darko Skrobo, St Vincent's University Hospital, Dublin, Ireland*

Background: The introduction of anti-H2 targeted therapies has resulted in substantially improved outcomes for patients (pts) with H+MBC, yet despite survival prolongation, most patients so-treated will still ultimately die from MBC. Some patients do however, achieved prolonged remissions. In this report we outline the long-term outcomes of patients with H+MBC who were treated in our institution, with at least five-year follow-up from the diagnosis of MBC. **Methods:** As part of our larger single-institution "Thousand Patient HER-2 Database", we conducted a retrospective review of all patients in whom a diagnosis of H+MBC was made prior to December 2015 (range 2000-2015 years). The DR5 category included only those who had never experienced relapse or progression following initial anti-H2 therapy for MBC, and who were alive at 5 years. Patients were designated as (1) DR5, defined as never relapse with an overall survival (OS) > 5 years; (2) nonDR, which included those who had no or shorter remission, but also included nine pts who did achieve a 5 year CR, but who subsequently relapsed. OS was calculated from the date of diagnosis of MBC. The frequency distribution was assessed by Fisher's Exact Test or Chi-Square Test, as appropriate. OS and PFS were calculated according to Kaplan Meier method, and evaluated by Log-rank test. Univariate and multivariate Cox proportional hazards regression analysis was used to evaluate the effect of clinicopathological features on OS and PFS. **Results:** A total of 245 patients diagnosed with advanced H+MBC were identified. The median survival was 38 months, (range 0.3 – 248 months). Among these, 85 patients (35%) experienced an OS > 5 years, with 34 designated as DR5. The median OS for DR5 was 117 months, whereas nonDR (n = 211) had median OS of 33 months. The median age was similar between groups (DR5 53 yrs vs nonDR 56 yrs). A higher incidence of visceral disease was present in nonDR compared to DR5 (69% vs 44%). Of all patients diagnosed with *de novo* H+MBC, 23% achieved DR5. Presence of visceral disease, number of metastases and site of metastases were statistically significant negative predictors of achieving DR5 ($P < 0.05$). Presence of ER positive disease was not associated with OS. **Conclusions:** A meaningful subset of patients (14%) with advanced H+MBC achieve prolonged remission beyond five years with H2 targeted therapy. Nearly one quarter of those with *de novo* H+MBC achieve DR5. As *de novo* H+MBC now constitutes a higher proportion of all H+MBC than it did in the pre-trastuzumab era, an increasing proportion of H+MBC may now be achieving DR5. Prospective identification of variables to predict DR5 could assist in the stratification of patients for whom additional therapy is needed. Research Sponsor: Cancer Clinical Research Trust.

Efficacy of CDK4/6i in the visceral crisis setting: Result from a real-world database. *First Author: Shaheenah S. Dawood, Mediclinic City Hospital, Dubai, United Arab Emirates*

Background: The combination of the CDK4/6 inhibitors(CDK4/6i) and endocrine therapy has improved overall survival(OS) in patients(pts) with either endocrine sensitive or resistant disease who are not in visceral crisis. The goal of this retrospective analysis of a real world database was to look at the efficacy of CDK4/6i among pts with hormone receptor positive (HR+ve)/HER2-ve metastatic breast cancer(MBC) who present with visceral crisis at diagnosis. **Methods:** For this analysis, we utilized a federated network of de-identified health data representing approximately 64 million patient lives available through the TriNetX Platform. We identified 5966 pts who had HR+ve/HER2-ve MBC diagnosed between 2015 and 2020. OS was computed using the Kaplan Meier product limit method. Propensity score matching was performed on all comparisons of survival. Visceral crisis was defined as either liver metastases with liver dysfunction, lymphangitis with dyspnea or the presence of pancytopenia. **Results:** 906(15%) pts received CDK4/6i. OS any time after treatment among pts who did and did not receive CDK4/6i was significantly different (p=0.0002) favoring the group receiving CDK4/6i, with median OS at 59.6 months and 46.2 months and 2-year OS at 71.6% and 61.4% respectively. Among pts who received CDK4/6i versus another treatment as first line therapy, OS was significantly different(HR 0.7, 95%CI 0.57 – 0.86, p<0.0001), and median OS was 59.6 months and 41.5 months respectively. 336 pts with HR+ve mbc presented with visceral crisis at the time of diagnosis of whom 61(18%) received CDK4/6i therapy as first line therapy. Median OS among pts who did and did not have visceral crisis at diagnosis and received treatment was 8.1 months and 210 months respectively. OS any time after initial treatment was significantly different among pts with visceral crisis who did and did not receive CDK4/6i (p=0.01), with 2-year OS at 26.1% and 8.1% and median OS at 11 months and 6 months respectively **Conclusions:** The use of CDK4/6i in the presence of visceral crisis at diagnosis was associated with a 5 month improvement in OS compared to chemotherapy. Future clinical trials should explore the use of CDK4/6i in the setting of visceral crisis. Research Sponsor: None.

Real-world cost-effectiveness of pertuzumab (P) with trastuzumab + chemo (T+Chemo) in patients (pts) with metastatic breast cancer (MBC): A population-based retrospective cohort study by the Canadian Real-world Evidence for Value in Cancer Drugs (CanREValue) collaboration. *First Author: Wei Fang Dai, University of Toronto, Toronto, ON, Canada*

Background: Addition of P to T+chemo for MBC pts has been shown to improve overall survival (OS) in a pivotal randomized trial (hazard ratio [HR] = 0.66, 95% CI: 0.52, 0.84) (Baselga et al., NEJM 2012). In Canada, the manufacturer submission to the health technology assessment agency estimated that P produced 0.64 life years gained (LYG) with an incremental cost-effectiveness ratio (ICER) of $187,376/LYG over 10 years (CADTH-pCODR, 2013). This retrospective cohort analysis aims to determine the comparative real-world population-based effectiveness and cost-effectiveness of P among MBC pts in Ontario, Canada. **Methods:** MBC pts were identified from the Ontario Cancer Registry and linked to the New Drug Funding Program database to identify receipt of treatment between 1/1/2008 and 3/31/2018. Cases received P-T-chemo after universal public funding of P (Nov 2013) and controls received T-chemo before. Demographic (age, socioeconomic, rurality) and clinical (comorbidities, prior adjuvant treatments, prior breast cancer surgery, prior radiation, stage at diagnosis, ER/PR status) characteristics were identified from linked admin databases balanced between cases and controls using propensity score matching. Kaplan-Meier methods and Cox regressions accounting for matched pairs were used to estimate median OS and HR. 5-year mean total costs from the public health system perspective were estimated from admin claims databases using established direct statistical methods and adjusted for censoring of both cost and effectiveness using inverse probability weighting. ICERs and 95% bootstrapped CIs were calculated, along with incremental net benefit (INB) at various willingness-to-pay values using net benefit regression. **Results:** We identified 1,823 MBC pts with 912 cases and 911 controls (mean age = 55 years), of which 579 pairs were matched. Cases had improved OS (HR = 0.66; 95% CI: 0.57, 0.78), with median 3.4 years, compared to controls median OS of 2.1. P provided an additional 0.63 (95% CI: 0.48 – 0.84) LYG at an incremental cost of $196,622 (95% CI: $180,774, $219,172), with a mean ICER = $312,147/LYG (95% CI: $260,752, $375,492). At threshold of $100,000/LYG, the INB was -$133,632 (95% CI: -$151,525, -$115,739) with < 1% probability of being cost-effective. Key drivers of incremental cost increase between groups included drug and cancer clinic costs. **Conclusions:** The addition of P to T-chemo for MBC increased survival but at significant costs. The ICER based on direct real-world data was higher than the initial economic model due to higher total costs for pts receiving P. This study demonstrated feasibility to derive ICER from person-level real-world data to inform cancer drug life-cycle health technology reassessment. A phase 1b study of chemoimmunotherapy with pegylated liposomal doxorubicin and pembrolizumab in estrogen receptor-positive, endocrine-resistant breast cancer. *First Author: Alberto A. Gabizon, The Oncology Institute, Shaare Zedek Medical Center, Jerusalem, Israel*

Background: This is a single center phase 1b study of a regimen of pembrolizumab (PBZ) and pegylated liposomal doxorubicin (PLD) in endocrine-resistant breast cancer. PLD was chosen as chemotherapy component because it is mildly myelosuppressive and non-immunosuppressive and contains doxorubicin, a strong immunogenic cell death inducer. **Methods:** Patients with estrogen receptor positive, HER2 negative, metastatic breast cancer, whose disease progressed on hormonal and biological therapy and up to 2 chemotherapy lines were eligible for enrollment. PLD, 30 mg/m^2, and PBZ, 200 mg flat dose, were infused on day 1 of every 3-week cycles. The main study objectives were safe dose clearance, characterization of dose-limiting toxicities (DLT), tumor response, and pharmacokinetic analysis of PLD and PBZ during the first 3 cycles of treatment in a 1st cohort of 6 patients and a 2nd confirmatory cohort of 6-9 patients. Patients with partial response (PR) or stable disease (SD) continued on the extended phase of the study consisting of 9 additional cycles during which further safety information was collected. All patients were followed-up for survival. **Results:** 12 patients were recruited (median age 61 y, range 45-91). 9 patients had received prior doxorubicin treatment. 82 treatments have been administered (median: 7, range 2-13). Overall, treatment was well tolerated. DLT including infusion reactions, grade ≥2 myelosuppression, hair loss and mucocutaneous toxicity were not observed in the first 3 cycles. Subsequently, skin toxicity (grade 2-3 palmar-plantar erythema) was observed forcing treatment delays of 1-2 weeks. Except for 2 cases of subclinical hypothyroidism, there were no other apparent PBZ-related side-effects. There was no evidence of cardiac toxicity. There were 2 early deaths (days 25 and 45) probably related to disease progression. Upon reevaluation on week 9, we observed: 2 patients with PD, 4 with SD, 2 with PR (15+ and 5+ mth), 1 with no measurable disease, and 1 early to evaluate. Three out of 5 patients responded well to post-study chemotherapy with durable improvement or stabilization (range, 5 to 11+ mth). Median follow-up is 14 mth. Median survival has not been reached with 4 deaths and a longest survivor of 19+ mth. Median progression-free survival is 6.0 mth. The clearance of PLD was slow with high Cmax, long T$^1/_2$ and small Vd. There was a significant increase in the AUC of PLD between the 1st and 3rd cycle (median: 2,649 vs 3,422 mg*h/l, p = 0.039). Analysis of PBZ plasma levels is ongoing. **Conclusions:** The combination of PLD and PBZ is well tolerated and feasible for extended treatment. Dose interval of PLD should be lengthened to 4 weeks after 2-3 cycles to prevent skin toxicity. The late appearance of skin toxicity is probably related to a delay in PLD clearance after 2 treatment cycles with PLD and PBZ. Clinical trial information: NCT03591276. Research Sponsor: Merck.

A first-in-human phase 1a/b trial of LY3484356, an oral selective estrogen receptor (ER) degrader (SERD) in ER+ advanced breast cancer (aBC) and endometrial endometrioid cancer (EEC): Results from the EMBER study. *First Author: Komal L. Jhaveri, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Novel degraders and antagonists of ER are under evaluation in aBC, to overcome both ER mediated resistance and the bioavailability and dosing limitations of fulvestrant, the only approved SERD. ER is also overexpressed in ~80% of EEC and endocrine therapy (ET) is utilized for these patients (pts). LY3484356, a novel, orally bioavailable SERD with pure antagonistic properties results in sustained inhibition of ER-dependent gene transcription and cell growth. Preclinically, LY3484356 shows favorable efficacy and pharmacokinetic (PK) properties, including antitumor activity in *ESR1* mutants. Here we present the initial clinical data from EMBER, an ongoing first-in-human phase 1a/b trial of this novel agent. **Methods:** Phase 1a evaluated LY3484356 dose escalation (i3+3 design) in women with ER+, HER2- aBC (≤3 prior therapies for aBC following protocol amendment; prior ET sensitivity) and ER+ EEC (prior platinum therapy). Premenopausal women received a concomitant GnRH agonist. Key endpoints included determination of the recommended phase 2 dose, safety and tolerability, PK, and objective response rate and clinical benefit rate per RECIST v1.1. **Results:** As of the data cut (November 9, 2020), 28 pts (n = 24 aBC, n = 4 EEC) were enrolled at doses ranging from 200-1200 mg QD. Median age was 59 years (range, 35-80). Median number of prior therapies for aBC was 2 (range, 1-8; 6 pts enrolled prior to protocol amendment had received ≥4 prior therapies), including prior fulvestrant (46%), a CDK4/6 inhibitor (83%), and chemotherapy (33%). No dose-limiting toxicities were observed. Treatment-emergent adverse events (TEAEs) were mostly grade 1-2, including nausea (32%), fatigue (25%), and diarrhea (18%). The only grade 3 treatment-related AE was diarrhea (n = 1). TEAEs of bradycardia and QTc prolongation were not observed despite intensive central ECG monitoring. Dose-proportional increases in LY3484356 exposures were observed across all evaluated doses and $t_{1/2}$ was 25-30 hours. At the starting dose level (200 mg QD), unbound LY3484356 exposures exceeded those achieved with fulvestrant. 16 of 28 pts were efficacy evaluable, with the remaining 12 pts ongoing prior to first scan. Among 16 evaluable pts, 11 (8 aBC, 3 EEC) had stable disease (10 pts ongoing), and 5 had progressive disease. RECIST responses were observed after the data cut and will be detailed at the meeting. Plasma ctDNA analysis indicated decreases in mutant allele frequencies, including mutant *ESR1* in 9/12 (75%) evaluable pts across all dose levels. **Conclusions:** LY3484356 QD dosing shows favorable safety and PK properties, along with preliminary efficacy in pts with heavily pretreated ER+ aBC and EEC. Updated data will be presented at the meeting. Clinical trial information: NCT04188548. Research Sponsor: Loxo Oncology at Lilly.

Correlation between work productivity loss (WPL) and European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire (QLQ-C30) domains from the MONALEESA-7 (ML-7) trial of premenopausal women with HR+/HER2- advanced breast cancer (ABC). *First Author: Debu Tripathy, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The international, randomized, double-blind, placebo-controlled, Phase III ML-7 trial (NCT02278120) assessed ribociclib + endocrine therapy (ET) vs ET alone in premenopausal women with HR+/HER2– ABC. To our knowledge, the relationship between WPL and domains of the EORTC QLQ-C30 and the tumor-specific module for breast cancer (QLQ-BR23) has not been explored in ABC. In this post hoc analysis (data cutoff, November 30, 2018) of all patients (pts) enrolled in ML-7, we assessed the correlation between the WPL component of the Work Productivity and Activity Impairment: General Health (WPAI:GH) questionnaire and domains of the EORTC QLQ-C30/BR23. **Methods**: We analyzed EORTC and WPAI:GH data from all pts enrolled in ML-7 who were employed at any point during the trial (N = 329 of 672 total pts). Domains of the EORTC QLQ-C30 and QLQ-BR23 that had the greatest correlation (pairwise Pearson correlation) with WPL were prioritized for analysis. Separate univariable mixed-model repeated-measures regression models were fitted for each domain, with WPL as the dependent variable and each EORTC domain as a single fixed-effect covariate. Linear and quadratic relationships were considered. Model selection was based on the Akaike information criterion (AIC). **Results**: Linear models were favored over quadratic models. WPL was negatively correlated with global health status (GHS) and the physical, role, social, and emotional functioning domains and was positively correlated with the fatigue and pain domains of the QLQ-C30 ($P < .001$; Table). The coefficients indicated the estimated mean change in WPL was associated with a 1-unit increase in each QLQ-C30 domain. For example, a 10-point increase in GHS was associated with an estimated mean decrease of 7.8% (95% CI, 7.1%-8.5%) in WPL. **Conclusions**: Greater WPL was associated with higher levels of fatigue and pain and with lower levels of overall quality of life and physical, role, social, and emotional functioning among pts with HR+/HER2− ABC in ML-7. Further investigation of the correlation with QLQ-BR23 and multivariable analysis could determine which EORTC domains and items independently drive these findings. Clinical trial information: NCT02278120. Research Sponsor: Novartis Pharmaceuticals Corporation.

Domain	AIC (Linear)	AIC (Quadratic)	Regression Coefficient (Linear Model) (95% CI)	*P* Value
Fatigue	19,475.96	19,486.02	0.61 (0.54 to 0.67)	< .001
Pain	19,469.70	19,470.45	0.53 (0.47 to 0.59)	< .001
Physical functioning	19,383.55	19,389.79	−0.98 (−1.07 to −0.88)	< .001
Global health status	19,291.10	19,303.40	−0.78 (−0.85 to −0.71)	< .001
Role functioning	19,359.71	19,373.50	−0.65 (−0.71 to −0.60)	< .001
Social functioning	19,443.55	19,457.02	−0.59 (−0.65 to −0.53)	< .001
Emotional functioning	19,557.42	19,570.86	−0.49 (−0.56 to −0.42)	< .001

The association of HER2 low expression with the efficacy of CDK4/6 inhibitor in hormone receptor positive HER2 negative metastatic breast cancer. *First Author: Kelvin K H Bao, Department of Clinical Oncology, Queen Elizabeth Hospital, Kowloon, Hong Kong*

Background: Markers for the efficacy of CDK4/6 inhibitor in estrogen receptor (ER) positive, HER2 negative advanced breast cancer are limited. The bidirectional crosstalks that exist between ER and HER2 pathways contribute to endocrine resistance. We investigated the association between low levels of HER2 expression and the clinical outcome of patients with ER+ HER2- metastatic breast cancer (MBC) treated with CDK4/6 inhibitors. **Methods:** We identified consecutive patients with ER+ HER2- MBC who received CDK4/6 inhibitor plus either letrozole or fulvestrant between Mar 2017 - Jun 2020 from an institutional cancer registry. HER2-low expression was defined as IHC score 1+, or 2+ with a negative ISH. Progression-free survival (PFS) was defined as the time from the initiation of CDK4/6 inhibitor to the date of radiological or clinical progression, or death. The relationship between HER2 expression levels and PFS was evaluated using log-rank test and multivariable Cox regression modelling. **Results:** 106 women with MBC were eligible for analysis. Median age at treatment was 58 (23.0-91.4). The majority received palbociclib (84%) while the rest received ribociclib. CDK4/6 inhibitor was used as first-line treatment in 50.9% of cases. Most tumors were of ductal histology (83%) and progesterone receptor (PgR) positive (84.9%), and 22.6% of the patients had bone-only disease. 77.3% of cases were considered HER2-low expressing. HER2-low expression was associated with a significantly shorter PFS compared with HER2 IHC 0 counterpart (median, 8.9 vs 18.8 months, p= 0.014). In multivariate analysis, HER-2 low expression remained significantly associated with an inferior PFS (HR 1.96, 95%CI 1.03-3.75, p= 0.041) after adjusting for the line of treatment, PgR status and disease extent (bone only vs extra-osseous disease). **Conclusions:** In patients with ER+ HER2- MBC treated with CDK4/6 inhibitors, HER2-low expression was associated with an inferior PFS, and may serve as a potential marker candidate for CDK4/6 inhibitor efficacy. As novel anti-HER2 antibody-drug conjugates demonstrated efficacy in HER2-low expressing MBC, coupled with the emerging evidence for the combination of CDK4/6 inhibitors with anti-HER2 agents, this HER2-low expression subgroup warrants prospective evaluations in future trials. Research Sponsor: None.

Resistance to CDK4/6 inhibitors (CDK4/6i): The clinical usefulness of liquid biopsy in metastatic breast cancer (mBC). *First Author: Lucrezia Raimondi, U.O.C. Territorial Oncology of Aprilia, Sapienza University of Rome, Aprilia, Italy*

Background: Palbociclib (P) in combination with fulvestrant (F) or letrozole (L), is used globally to treat metastatic breast cancer but despite therapeutic improvements most patients acquire resistance to CDK4/6i. *KRAS* tumor mutations (^{mut}KRAS) have been associated with worse PFS in several tumor types but have not been analysed extensively in breast cancer. To understand the molecular mechanisms of resistance to CDK4/6i and their clinical behavior, using liquid biopsy, we evaluated the opportunity to reveal the onset of resistance to CDK4/6i detecting ^{mut}KRAS ctDNA. **Methods**: We studied the KRAS mutation status of 211 patients with mBC treated with CDK4/6i plus L or F as first-line metastatic therapy. Using Bio-Rad QX200 droplet digital polymerase chain reaction (ddPCR) system we determined *KRAS* ctDNA levels in plasma. Using logistic and Cox regression, a predictive model for objective response (OR), progression-free survival (PFS) and overall survival (OS) was constructed. The PFS and the OS were estimated by the Kaplan–Meier method and compared with use of the log-rank test. **Results**: In 38% (81 patients, 24 in treatment with L and 57 in treatment with F) we observed ^{mut}KRAS ctDNA before starting CDK4/6i: the detection of ^{mut}KRAS significantly correlated with the onset of resistance to CDK4/6i within 6months from the evidence of *KRAS* mutation and worse PFS ($p<0.001$). OR was seen in 84 of 130 KRAS wild-type (WT) patients versus 0 of 81 in KRAS mutants. At 24-month follow up, median PFS was significantly better in KRAS WT versus mutants (3.1 [range: 1-6months,95%CI 0.9-3.6] versus NA months; $p<0.001$). Correlating the results of liquid biopsy both to tumoral burden and patients clinical features, we observed a higher ^{mut}KRAS circulating copies-number in those patients with two or more metastatic sites($p<0.001$). **Conclusions**: Despite the study's limitations, our data suggest ^{mut}KRAS ctDNA status leads to CDK4/6i resistance acquisition within 6 months from the detection and provide critical information for the prediction of therapeutic responses in mBC. Monitoring *KRAS* status with liquid biopsy, we could predict who will take advantage from CDK4/6i, decreasing wastes of resources ensuring the best patients' quality of life. Long-term (LT) disease control in patients (pts) with hormone receptor-positive (HR+), *PIK3CA*-altered advanced breast cancer (ABC) treated with alpelisib (ALP) + fulvestrant (FUL). *First Author: Dejan Juric, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: *PIK3CA* mutations, present in ~40% of HR+, HER2– ABC, are associated with therapeutic resistance and shorter survival. Alpelisib (ALP) + fulvestrant (FUL) demonstrated efficacy in this population for which achieving long-term (LT) disease control is challenging. Here, we report on pts with HR+, *PIK3CA*-altered ABC who achieved LT disease control with ALP + FUL. **Methods:** SOLAR-1 was a phase 3, randomized, double-blind study of ALP (or placebo) + FUL in HR+, HER2– ABC that progressed on/after an aromatase inhibitor. CBYL719X2101 (X2101) was a phase 1, open-label study of escalating ALP doses ± FUL in advanced solid tumors that progressed on/after anti-estrogen therapy (ET) or relapsed after adjuvant anti-ET. A cut-off ≥ median (progression-free survival [PFS] + 2 SE) was chosen based on Kaplan-Meier curves from SOLAR-1 to define LT disease control as PFS (SOLAR-1) or time on treatment (X2101) ≥18 mo. **Results:** In SOLAR-1, 51 of 169 pts (30.2%) randomized to ALP + FUL achieved LT disease control with a median PFS of 33.5 mo (95% CI, 27.4 mo-not reached). Baseline characteristics of pts in SOLAR-1 are in the table below. In pts with LT disease control, adverse events (AEs) of special interest (combined preferred terms) of GI toxicity were observed in 47 pts (92.2%; grade ≥3: 11.8%, n=6), of hyperglycemia in 41 pts (80.4%; grade ≥3: 39.2%, n=20), and of rash in 28 pts (54.9%; grade ≥3: 19.6%, n=10). Median ALP relative dose intensity was 79.9% and 82.1% for pts with LT disease control (n=51) and the overall population (n=168), respectively. In X2101, 7 of 52 pts (13.5%) with ABC who received ALP+FUL achieved LT disease control up to 47.8 mo. **Conclusions:** In this subset of pts with hard-to-treat, endocrine-resistant disease, LT disease control ≥18 mo is meaningful considering median PFS of 4.6-9.3 mo or 9.5-16.4 mo with FUL alone or with cyclin-dependent kinase 4/6 inhibitors, respectively. Here, LT disease control was observed in 2 studies of HR+, *PIK3CA*-altered ABC, including in pts with poor prognosis, diabetes/pre-diabetes at baseline, and heavy pretreatment. AE profile was consistent with prior reports and did not preclude LT disease control. Further work is needed to better understand factors influencing LT disease control. Clinical trial information: NCT01219699, NCT02437318. Research Sponsor: Novartis Pharmaceuticals Corporation.

Baseline characteristics (SOLAR-1).

Overall survival in patients with breast cancer treated with a CDK 4/6 inhibitor plus fulvestrant: A U.S. Food and Drug Administration pooled analysis. *First Author: Jennifer J Gao, US Food and Drug Administration, Silver Spring, MD*

JJG, JC, TMP contributed equally. JAB, LAK contributed equally. **Background:** Cyclin dependent kinase 4/6 inhibitors (CDKIs) are oral targeted agents approved for use in combination with endocrine therapy as first or secondline treatment of hormone-receptor positive (HR+), human epidermal growth factor receptor 2 (HER2)-negative advanced or metastatic breast cancer. We previously reported the pooled analyses of progression-free survival of patients in certain clinicopathologic subgroups, and results showed a consistent benefit from the addition of a CDKI to endocrine therapy. Here, we report the pooled overall survival (OS) results in patients treated with a CDKI plus fulvestrant. **Methods:** We pooled individual patient data (n=1948) from three phase III randomized breast cancer trials of a CDKI plus fulvestrant submitted to the FDA in support of marketing applications. All analyzed patients received at least one dose of a CDKI or placebo, plus fulvestrant. The median OS was estimated using Kaplan-Meier (KM) methods, and hazard ratios (HR) with corresponding 95% confidence intervals (CIs) were estimated using Cox regression models. **Results:** Results of OS analyses, including all pooled patients, patients treated in the first-line setting, and patients treated in the second line and later settings, are summarized in the table below. Additional subgroup analyses of OS by progesterone receptor status, site of metastases, breast cancer histology, ECOG performance status, race, and de novo metastatic presentation all favored adding a CDKI to fulvestrant. In patients age < 40, the estimated OS HR favored fulvestrant alone, but this subgroup had a small sample size (n=89), so this result must be interpreted with caution. All results are considered exploratory and hypothesis-generating. **Conclusions:** Addition of CDKIs to fulvestrant appears to confer a consistent survival benefit across all pooled patients and within most clinicopathological subgroups of interest. Research Sponsor: None.

A single-arm phase II trial of palbociclib in combination with tamoxifen as first-line therapy for metastatic hormone receptor-positive breast cancer.

First Author: Oana Cristina Danciu, University of Illinois at Chicago, Chicago, IL

Background: Palbociclib is a CDK4/6 inhibitor used to treat metastatic hormone receptor-positive (HR+) breast cancer (MBC) in combination with endocrine therapy. Tamoxifen is an effective treatment for HR+ MBC, with different toxicity profile compared with aromatase inhibitors (AI) and fulvestrant. Preclinical data demonstrated synergy for the combination of tamoxifen and palbociclib, being effective in a model of acquired tamoxifen resistance. **Methods:** We conducted an open-label, single-arm, multicenter phase II trial of palbociclib in combination with tamoxifen in patients with HR+/HER2 - advanced BC, with no prior therapy for MBC. Ovarian suppression was recommended for pre-menopausal women, but not required. Primary objective was progression free survival. Secondary objectives: objective response rate (CR or PR) based on RECIST 1.1 or MDA Criteria (for patients with bone only disease); safety and tolerability (using CTCAE v4); clinical benefit rate (CR, PR or SD lasting min 24 weeks); 2-year overall survival. Correlative objectives: proteomic analysis of plasma exosomes to identify mechanisms of primary and secondary resistance to tamoxifen/palbociclib. **Results**: Between 6/30/2016 and 7/02/2019, we enrolled 49 patients (47 evaluable): 23 pts with de-novo metastatic disease and 24 pts with recurrent BC (12 pts were on adjuvant treatment with AI at time of recurrence and 12 pts on surveillance). As of 1/5/21 data cut-off, 7 pts were still on treatment. Median follow-up time was 24 months (range 8-42). Median age was 60 (range 39-82). The median PFS was 14.6 months with 95% CI (7-41) for pts with de-novo MBC and 6 months (2-12) for pts with recurrent BC. The ORR was 30% overall, 39% for pts with de novo MBC, 21% for pts with recurrent BC. CBR was 64% overall, 78% for pts with de novo MBC and 50% for pts with recurrent BC. CBR was 65% for white pts and 55% for African American pts. Best response per RECIST1.1: 14 pts (34%) had PR, 18 pts (44%) had SD, 9 pts (22%) had PD. All 6 pts with bone only disease had SD. The most common drug related grade ≥ 3 AE was neutropenia (51%), transient and manageable by dose modifications, no cases of febrile neutropenia. Four patients developed thromboembolic events (1 grade 2, 2 grade 3, 1 grade 4). One patient died while on treatment from PD. **Conclusions**: The combination of palbociclib and tamoxifen showed tolerable, expected safety profile. This may be an alternative approach for selected patients in first line treatment of HR+ MBC, especially those who are intolerant to AI, although this small study indicates a lower PFS. Clinical trial information: 02668666. Research Sponsor: Pfizer.

A phase Ib study of xentuzumab plus abemaciclib and fulvestrant in patients (pts) with advanced hormone receptor-positive (HR+), HER2-negative breast cancer (BC) with visceral or non-visceral disease.

First Author: Douglas Yee, Masonic Cancer Center, University of Minnesota, Minneapolis, MN

Background: Cyclin-dependent kinase (CDK) 4 & 6 inhibitors plus endocrine therapy (ET) are standard of care for advanced HR+ BC. Combining xentuzumab, an insulin-like growth factor (IGF) ligand-neutralizing antibody, with ET and everolimus, suggested progression-free survival (PFS) benefit in pts with advanced HR+ BC and non-visceral disease. Activation of the IGF pathway leads to an increase in cyclin D1, providing a rationale for combining IGF and CDK4 & 6 inhibition. This prospective, open-label study is investigating xentuzumab plus abemaciclib, a CDK4 & 6 inhibitor, with fulvestrant. In dose-finding cohorts, the recommended phase II dose (RP2D) was determined as xentuzumab 1000 mg weekly intravenously plus abemaciclib 150 mg every 12h orally (Q12h). Here, we report preliminary data on disease control rate (DCR) from two expansion cohorts in pts with advanced HR+ BC with visceral (D1) or non-visceral disease (D2). **Methods:** Postmenopausal women with advanced/metastatic HR+ BC that had progressed on or after ET (including adjuvant ET) were enrolled. Pts could not have received >1 line of ET or any chemotherapy for metastatic disease. No prior CDK4 & 6 inhibitor therapy was permitted. Pts had to have ≥1 documented visceral metastasis in D1 and no visceral metastases in D2. Pts received xentuzumab weekly plus abemaciclib Q12h (at RP2D) plus fulvestrant 500 mg per label. Protocol primary endpoint was PFS rate at 18 months (mos). Secondary endpoints included DCR (complete response [CR], partial response [PR] and non-CR/non-progressive disease [PD] or stable disease [SD] lasting ≥24 weeks [wks]). **Results:** In D1/D2, 33/31 pts were treated: median age 60/53 years. 19 pts in D2 had bone-only, non-measurable disease. At data cut-off (Jan 2021), median treatment duration was 7.5/9.2 mos in D1/D2; 40 pts remain on treatment. In D1, DCR was 64%: 17 (52%) pts had PR and 4 (12%) had SD lasting ≥24 wks. In D2, DCR was 55%: 5 (16%) pts had PR, 10 (32%) had non-CR/non-PD lasting ≥24 wks and 2 (7%) had SD lasting ≥24 wks. Median duration of disease control was 10.9 mos in each cohort. Some pts had not reached 24 wks; full DCR data will be presented. Most common AEs are shown in the table (≥33% all-grade in either cohort). No hypo/hyperglycemia was reported. **Conclusions:** Xentuzumab plus abemaciclib and fulvestrant demonstrated encouraging disease control in pts with advanced HR+ BC with visceral and non-visceral disease. The safety profile was manageable, and consistent with the known profiles of the three agents. Clinical trial information: NCT03099174. Research Sponsor: Boehringer Ingelheim.

AMEERA-1: Phase 1/2 study of amcenestrant (SAR439859), an oral selective estrogen receptor (ER) degrader (SERD), with palbociclib (palbo) in postmenopausal women with ER+/ human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (mBC).

First Author: Sarat Chandarlapaty, Memorial Sloan Kettering Cancer Center, New York, NY

Background: AMEERA-1 (NCT03284957) investigates amcenestrant, an oral SERD, as monotherapy and combined with targeted therapies in ER+/HER2– mBC. Here we report data from dose escalation (Part C) and dose expansion (Part D) of amcenestrant + palbo. **Methods:** Patients (pts) were postmenopausal women with ER+/HER2– mBC and ≥ 6 mos prior advanced endocrine therapy (ET) or adjuvant (adj) ET resistance (relapse on adj ET started ≥ 24 mos ago or < 12 mos after completing adj ET). Prior chemotherapy (≤ 1) for advanced disease was allowed; targeted therapies were not except ≤ 1 CDK4/6i in Part C. Part C assessed dose-limiting toxicities (DLTs) and aimed to establish the recommended phase 2 dose (RP2D) for amcenestrant (200 or 400 mg once daily [QD], in 28-day cycles) in combination with palbo (125 mg QD for 21 days on/ 7 days off). Safety (treatment-emergent adverse events [TEAEs] and lab abnormalities per CTCAE v4.03) and pharmacokinetics (PK) were evaluated. Antitumor activity at the RP2D for amcenestrant + palbo was evaluated in a subset of Part C pts and Part D, according to RECIST v1.1, determined locally by investigators. **Results:** Feb 8, 2021 data cutoff. In Part C (n = 15; 200 mg: 9; 400 mg: 6), no DLTs occurred and amcenestrant 200 mg QD was selected as the RP2D with palbo, based on PK and safety data. In the pooled safety population at the RP2D (n = 39; Part C: 9; Part D: 30), median (range) age was 59 y (33–86) with ECOG PS 0 (74.4%) or 1 (25.6%) and 2 (1–6) organs involved. Immediate prior therapy was neo/adj (41.0%, all ET resistant) or advanced (59.0%, range 1–4 lines). Median (range) exposure was 32 wks (1–66) with 59.0% pts on ongoing therapy. No amcenestrant dose reductions occurred; 25.6% had ≥ 1 palbo dose reduction. Most common non-hematological TEAEs related to amcenestrant were Grade 1–2 nausea and fatigue (17.9% each), asthenia and hot flush (10.3% each); to palbo were fatigue (30.8%), nausea (25.6%), asthenia and dysgeusia (10.3% each). Two pts discontinued due to AEs. The majority (94.9%) had neutrophil count decrease (53.8% Grade ≥ 3). Preliminary antitumor activity after at least 6 cycles of therapy (unless early treatment discontinuation) is reported in the table below. **Conclusions:** In pts with ER+/HER2– mBC, safety at the RP2D of amcenestrant + palbo was favorable, with no safety signals of bradycardia or eye disorders. Preliminary antitumor activity was observed (ORR: 31.4% and CBR: 74.3%). Clinical trial information: NCT03284957. Research Sponsor: Sanofi.

Systematic review and meta-analysis of post-progression outcomes in ER+/HER2- metastatic breast cancer after treatment with endocrine therapy and CDK 4/6 inhibitors within randomized clinical trials.

First Author: Elisabetta Munzone, European Institute of Oncology, Milan, Italy

Background: CDK4/6 inhibitors combined with endocrine therapy (ET) deeply transformed the treatment landscape of HR+/HER2− advanced breast cancer. After progression with the combination, there are no established guidelines for an optimal sequencing of the various therapeutic options. Data from randomized clinical trials (RCT) suggest that subsequent progression free survival (PFS2) was not compromised by the use of these drugs and time to subsequent chemotherapy (TTC) may be delayed. Therefore, we performed a meta-analysis to evaluate the benefit of such treatments on PFS2 and on delaying the TTC. **Methods:** We conducted a systematic literature search using PubMed to select all available randomized clinical trials of CDK4/6-inhibitors and ET reporting PFS2 or TTC data in first- or second-line therapy of HR+/HER2- pre- or postmenopausal metastatic breast cancer. We also reviewed abstracts and presentations from all major conference proceedings. We calculated the pooled hazard ratios (HR) for PFS2 and TTC with 95% confidence intervals (CI) using fixed-effects models. The pooled HRs for PFS and OS were also calculated. I^2 was used to quantify heterogeneity between studies' results. **Results:** Seven studies (PALOMA 1-2-3, MONALEESA 3-7, MONARCH 2-3) were included in our analyses (n = 3912 patients). A clear PFS2 benefit was observed in patients who received CDK 4/6 inhibitors + ET (pooled HR = 0.67, 95% CI = 0.61 to 0.74, I^2 = 0.0%) and also a delay in subsequent TTC (pooled HR = 0.63, 95% CI = 0.58 to 0.70, I^2 = 0.0%). As previously reported, the benefit in terms of PFS (pooled HR = 0.54, 95% CI = 0.50 to 0.59, I^2= 0%) and OS (pooled HR = 0.77, 95% CI = 0.68 to 0.86, I^2= 0%) was also confirmed. **Conclusions:** CDK4/6-inhibitors plus ET compared with ET alone improve PFS2, and TTC. The delay of chemotherapy can spare the patients toxicities, potentially improving the quality of life. Thus, the observed benefit in PFS2 may postpone the onset of endocrine resistance and may offer an additional therapeutic advantage in this setting. Research Sponsor: None.

1060 **Poster Session**

Impact of duration of prior cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) therapy on alpelisib (ALP) benefit in patients (pts) with hormone receptor–positive (HR+), human epidermal growth factor receptor-2–negative (HER2–), *PIK3CA*-mutated advanced breast cancer (ABC) from BYLieve. *First Author: Stephen K. L. Chia, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: Mutations in *PIK3CA* (encoding PI3Kα) are present in ~40% of HR+, HER2– ABC tumors and are associated with relative endocrine resistance and poor prognosis. ALP inhibits and degrades PI3Kα. Primary analyses of Cohorts A and B from the phase 2 BYLieve study demonstrated that ALP + endocrine therapy (ET; fulvestrant [FUL] or letrozole [LET]) is effective and safe in pts with HR+, HER2– *PIK3CA*-mutated ABC with prior CDK4/6i therapy. Here, we evaluate if duration of prior CDK4/6i-based therapy impacts benefit of ALP + ET in these 2 cohorts. **Methods:** Cohorts A and B of BYLieve included pre/postmenopausal women who received CDK4/6i + AI or FUL, respectively, as immediate prior therapy. Cohort A received ALP 300 mg PO QD + FUL 500 mg IM Q28D + C1D15; Cohort B received ALP 300 mg PO QD + LET 2.5 mg PO QD. Within each cohort, pts were divided into 2 subgroups per duration of prior CDK4/6i therapy ("high"/"low," above/below median duration of therapy) and the association of progression-free survival (PFS) with this covariate was analyzed using stratified log-rank test and Cox PH model. This analysis included pts for whom duration of prior CDK4/6i therapy was known, and efficacy was assessed in pts with centrally confirmed *PIK3CA* mutation in tumor tissue. **Results:** Of the 126 pts in Cohort A with duration of prior CDK4/6i available, 120 had centrally confirmed *PIK3CA*-mutated disease; 60 were exposed to CDK4/6i for $>$ 380 days (high) and 60 for $<$ 380 days (low), with similar demographics/disease characteristics between subgroups. There was no significant difference in PFS between the high vs low subgroups (HR 1.03; 95% CI, 0.64-1.64; P= 0.927; median 8.0 vs 7.0 mo). Grade $\geq$3 adverse events (AEs) were experienced by 66.9% (n = 85) of all pts in Cohort A and 66.7% (n = 42)/68.3% (n = 43) in the high/low subgroups, respectively. Of the 123 pts in Cohort B with duration of prior CDK4/6i available, 113 had centrally confirmed *PIK3CA*-mutated disease; 57 were exposed to CDK4/6i for $>$ 305 days (high) and 56 for $<$ 305 days (low), with similar demographics/disease characteristics between subgroups. There was no significant difference in PFS between high vs low subgroups (HR 1.20; 95% CI, 0.78-1.84; P= 0.400; median 5.4 vs 5.9 mo). Grade $\geq$3 AEs were experienced by 69.8% (n = 88) of all pts in Cohort B and 71.0% (n = 44)/68.9% (n = 42) in the high/low subgroups, respectively. **Conclusions:** This analysis demonstrates that the benefit and safety profiles of ALP + ET are similar in pts with HR+, HER2– *PIK3CA*-mutated ABC who achieved relatively shorter duration of disease control with prior CDK4/6i vs those with longer duration of disease control, and suggests that ALP overcomes acquired resistance to CDK4/6i in these pts. Clinical trial information: NCT03056755. Research Sponsor: Novartis Pharmaceuticals Corporation.

Results from CONTESSA 2: A multinational, multicenter, phase 2 study of tesetaxel (T) plus a reduced dose of capecitabine (C) in patients (pts) with hormone receptor + (HR+), HER2- metastatic breast cancer (MBC) not previously treated with a taxane. *First Author: Lee S. Schwartzberg, West Cancer Center, Memphis, TN*

Research Funding: Odonate Therapeutics, Inc. **Background:** T is a novel, oral taxane with unique properties, including: oral administration with a low pill burden, a long (8-day) half-life in humans, once-every-3-weeks dosing, no observed hypersensitivity reactions and significant activity against chemotherapy (CT)-resistant breast cancer cell lines. T had encouraging monotherapy activity in a phase 2 study in 38 pts with HR+, HER2- MBC, with a confirmed objective response rate (ORR) per RECIST 1.1 of 45% (Seidman, 2018 ASCO Annual Meeting, Abstract 1042). In CONTESSA, a randomized phase 3 study in 685 pts with HR+, HER2- MBC previously treated with a taxane, T plus a reduced dose of C improved progression-free survival (PFS) as assessed by the Independent Radiologic Review Committee (IRC) vs. the approved dose of C alone: median of 9.8 months (mo) vs. 6.9 mo, an improvement of 2.9 mo (HR=0.716; p=0.003) (O'Shaughnessy, SABCS 2020, GS4-01). **Methods:** CONTESSA 2 is a multinational, multicenter, phase 2 study of T (27 mg/m^2 on day 1 of a 21-day cycle) plus a reduced dose of C (1,650 mg/m^2/day for 14 days of a 21-day cycle) in pts with HR+, HER2- MBC previously treated with 0-1 prior CT regimens for MBC and not previously treated with a taxane. The primary endpoint is ORR as assessed by the IRC. The secondary efficacy endpoints are duration of response (DoR), PFS and disease control rate (DCR) as assessed by the IRC, and overall survival (OS). **Results:** 150 pts were enrolled and treated. 80% had visceral disease, 46% had de novo MBC, 52% were previously treated with a CDK 4/6 inhibitor and 33% were $\geq$65 years old. At the prespecified interim analysis approx 4 mo after the last patient enrolled, the confirmed ORR was 51% (95% CI: 42%-60%), and the unconfirmed ORR was 63% (95% CI: 54%-71%). The median DoR was 9.5 mo (95% CI: 5.4-11.5 mo), the median PFS was 12.9 mo (95% CI: 8.1 mo-NR) and the DCR was 71% (95% CI: 62%-79%). OS data are immature. Grade (Gr) $\geq$3 treatment-emergent adverse events (TEAEs) occurring in $\geq$5% of pts were: neutropenia (74.0%), leukopenia (10.7%), hypokalemia (7.3%), anemia (6.7%), hand-foot syndrome (6.0%) and diarrhea (5.3%). Gr 2 alopecia occurred in 11.3% of pts, febrile neutropenia occurred in 4.7% of pts and Gr $\geq$3 neuropathy occurred in 2.0% of pts. Discontinuation of T and C due to any adverse event occurred in 13.3% of pts. **Conclusions**: An all-oral regimen of T plus a reduced dose of C demonstrated a high level of antitumor activity in pts with HR+, HER2- MBC not previously treated with a taxane. The confirmed ORR was 51%, median DoR was 9.5 mo and median PFS was 12.9 mo. Neutropenia was the most frequent Gr $\geq$3 TEAE; the rate of febrile neutropenia was 4.7%. Rates of clinically significant alopecia and neuropathy were low. Clinical trial information: NCT03858972. Clinical trial information: NCT03858972. Research Sponsor: Odonate Therapeutics, Inc.

1062 **Poster Session**

Endocrine therapy-based strategies with different endocrine sensitivity statuses for hormone receptor positive/HER2 negative metastatic breast cancer: A network meta-analysis. *First Author: Jiani Wang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Novel endocrine therapies (ETs) and targeted therapeutic regimens have been developed to dramatically improve the outcome of hormone receptor-positive (HR+), HER2-negative (HER2-) metastatic breast cancer (MBC). Since the absence of direct head-to-head comparisons for all regimens, decision-making guidelines are urgently needed for different endocrine sensitivity statuses. This study is to evaluate the efficacy of ET-based regimens in patients with HR+/HER2- MBC and to assess the heterogeneity among different compounds with a particular focus on their ability to improve survival outcomes. **Methods:** This network meta-analysis of phase II/III randomized controlled trials (RCTs) with at least one ET in HR+/HER2- MBC were enrolled. Based on the endocrine responses, participants were stratified into endocrine therapy sensitivity (ETS) and endocrine therapy resistance (ETR) groups. Primary endpoints, including progression-free survival (PFS) and overall survival (OS), were assessed by bayesian algorithms and primarily measured as surface under the cumulative ranking curve (SUCRA). **Results:** A total of 42 trials (22917 patients) were included. Regarding PFS, cyclin-dependent kinases 4/6 inhibitors (CDK4/6i) +fulvestrant 500mg (F500) was recommended for the ETS group (SUCRA = 76.92%), while chemotherapy was considered as the most effective option for the ETR group (SUCRA = 73.47%). For visceral metastases, CDK4/6i +aromatase inhibitors (AIs) could provide the extreme efficacy for the ETS group (SUCRA = 63.27%) while the CDK4/6i +F500 (SUCRA = 76.17%) as the prior regimen for the ETR group. For bone-only disease, CDK4/6i+F500 was preferred for both the ETS (SUCRA = 67.04%) and the ETR (SUCRA = 70.24%) group. Concerning OS, CDK4/6i+tamoxifen was estimated as the first-rank regimen for the ETS subgroup (SUCRA = 67.04%) and chemotherapy for the ETR subgroup (SUCRA = 60.02%). Regarding resistance category, abemaciclib +F500 was likely the best option with PFS, for both primary (SUCRA = 69.19%) and secondary ETR (SUCRA = 69.09%) settings, as well as primary ETR associated with OS improvement (SUCRA = 67.67%). Pictilisib +F500 could be the optimal treatment with OS for secondary ETR (SUCRA = 60.50%)group. **Conclusions:** The results showed that CDK4/6i + F500 was probably the most promising option in ETS, visceral ETR and bone-only disease settings in terms of PFS. OS subgroup analysis showed that different endocrine sensitivity statuses required various optimal treatment strategies. Research Sponsor: None.

Rintodestrant (G1T48), an oral selective estrogen receptor degrader, in combination with palbociclib for ER+/HER2– advanced breast cancer: Phase 1 results. *First Author: Marina Maglakelidze, LLC Arensia Exploratory Medicine, Tbilisi, Georgia*

Background: Rintodestrant, a potent, oral selective estrogen receptor degrader, competitively binds and degrades the estrogen receptor (ER), thus blocking ER signaling in tumors resistant to other endocrine therapies (ET). Results from parts 1 and 2 dose-escalation/expansion indicate that once-daily (QD) rintodestrant has a favorable safety profile and antitumor activity in patients (pts) with heavily pretreated ER+/HER2– advanced breast cancer (ABC), including those with *ESR1* variants (Aftimos et al. SABCS 2020 [PS12-04, PD8-07]). The optimal dose of rintodestrant was 800 mg. Here, we present part 3, combining rintodestrant with the CDK4/6 inhibitor palbociclib. **Methods:** This open-label study evaluated rintodestrant in pts with ER+/HER2– ABC after progression on ET (NCT03455270). Part 3 assessed rintodestrant 800 mg QD + palbociclib 125 mg QD for 21 days every 28 days. Key eligibility criteria included $\leq$1 line of chemotherapy and/or $\leq$1 line of ET in the advanced setting, with $\geq$6 months of ET in the advanced setting and/or $\geq$24 months in the adjuvant setting. Prior CDK4/6 inhibitor therapy was not allowed. Primary objectives included safety and efficacy. Secondary objectives included pharmacokinetics and antitumor activity (RECIST v1.1). Exploratory objectives included mutation profiling (cell-free DNA) at baseline and cycle 1 day 15. **Results:** Enrollment occurred Jul–Oct 2020. As of Dec 9, 2020, 40 pts were treated, with a median age of 58 years (35–76) and ECOG PS of 0 (70%) or 1 (30%); 20% had de novo stage 4 disease, 10% bone-only, and 68% visceral metastases. Median number of visceral sites was 1 (0–3): 30% of pts with lung and 40% with liver involvement. Median number of prior lines in the advanced setting was 1 (0–2), including chemotherapy (48%), fulvestrant (15%), and aromatase inhibitors (50%). Most recent ET was given in the adjuvant and metastatic settings in 28% and 73% of pts, respectively. Rintodestrant-related adverse events (AEs) were reported in 8% of pts—all nonserious and grade 2—and included nausea (3%), vomiting (3%), and neutropenia (3%). The most common ($\geq$10%) treatment-related AEs (rintodestrant and/or palbociclib) were neutropenia (88%), leukopenia (45%), anemia (10%), and thrombocytopenia (10%); grade 3/4 neutropenia was 38%/15%, in line with the safety profile of palbociclib. No deaths or treatment discontinuations due to AEs were reported. At data cutoff (median treatment duration of 3 months [1.5–4.6]), 28 pts (70%) remained on study treatment, 2 (5%) had a confirmed partial response, and 27 (68%) had stable disease. Additional efficacy and pharmacodynamic data will be presented. **Conclusions:** Rintodestrant, as monotherapy or combined with palbociclib, continues to demonstrate an excellent safety/tolerability profile with promising antitumor activity in pts with ER+/HER2– ABC, including those with *ESR1* variants. Clinical trial information: NCT03455270. Research Sponsor: G1 Therapeutics, Inc.

Alpelisib and fulvestrant efficacy in HR-positive HER2-negative *PIK3CA*-mutant advanced breast cancer: Data from the French early access program. *First Author: Diana Bello, Institut Curie, Saint-Cloud, France*

Background: In 11.2018, the PIK3CA-inhibitor alpelisib was made available in France through an early access program (EAP), in combination with fulvestrant in pre-treated PIK3CA-mutant, HR-positive, HER2-negative advanced breast cancer (ABC) patients. Patients had to received two or more prior systemic treatments for ABC, including an aromatase inhibitor and a CDK4/6 inhibitor in the absence of contraindications. This retrospective real-life, EAP-based study aimed to assess the efficacy and safety of alpelisib/fulvestrant combination in the post CDK4/6 inhibitor setting. **Methods:** The IRB-approved protocol and call for data were sent on 10.2020 to the cancer centers which participated the most in the EAP prospective registry. Eligible patients were women who started alpelisib/fulvestrant between 11. 2018 and 10.2020 as part of the EAP (which excluded patients with visceral crisis or inflammatory BC). Alpelisib and fulvestrant were used at standard doses. Primary endpoint was PFS by local investigators using RECIST1.1. Secondary endpoints included objective response rate and safety (NCI CTCAE v5.0). **Results:** 10 centers provided individual data regarding 209 consecutive patients. Patients had received a median number of 4 (1-14) previous systemic treatments for ABC, including CDK4/6 inhibitors, chemotherapy, fulvestrant (alone or in combination) and everolimus for 206 (98.8%), 159 (76.1%), 163 (78%) and 123 (58.8%) patients, respectively. With a median FU of 7.0 months, median PFS was 4.0 months (95%CI [3.5;5.0]) and 35.4% of 164 evaluable patients had an objective response. After stratification on the number of prior lines of treatment, prior exposure to everolimus had no impact on PFS (mPFS in the 123 patients pretreated with everolimus: 4.0m, 95%CI [3.5-5.5]). Of note, this population was enriched in patients who had a long disease control by everolimus (median time spent on everolimus: 7.0m, range (6.5-9.0)). In multivariable analysis, characteristics significantly associated with longer PFS were PS < 3 (HR = 0.03, 95%CI [0.02-0.29]) and prior treatment with fulvestrant (HR = 0.53, 95%CI [0.32-0.89]). N = 81(38.8%) patients discontinued alpelisib due to adverse events (AEs). Most frequent grade 3/4 AEs were hyperglycemia, skin rash, diarrhea and fatigue occurring in 13.4, 8.1, 4.8 and 1.9 % of patients, respectively. **Conclusions:** Despite heavy pre-treatments, alpelisib +fulvestrant had a clinically relevant efficacy in the French EAP population. Interestingly, prior treatment with either everolimus or fulvestrant did not overtly impair alpelisib-fulvestrant efficacy. The best treatment sequence for PI3KCA/mTOR inhibitors could be examined in future trials in PIK3CA-mutant ER+/HER2- ABC patients. Research Sponsor: None.

Landscape of *GATA3* mutations identified from circulating tumor DNA clinical testing and their impact on disease outcomes in estrogen receptor-positive (ER+) metastatic breast cancers treated with endocrine therapies. *First Author: Marko Velimirovic, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: The *GATA3* gene encodes for a transcription factor (TF) that plays a pivotal role in the development of breast tissue. Breast tumors with lower *GATA3* expression have worse prognosis compared to tumors with higher expression. However, the consequences of somatic *GATA3* mutations ($GATA3^{mut}$) on clinical outcomes in metastatic breast cancer (MBC) remain poorly understood. Further, *GATA3* TF interferes with *FOXA1* and *ER* to enhance transcription of *ER*-responsive genes, but the role of $GATA3^{mut}$ in altering downstream transcriptional activity and its effects on response to anti-estrogens remains unclear. **Methods:** We retrospectively identified ctDNA next-generation sequencing results from 101 ER+/HER2- patients with MBC treated with either selective estrogen receptor degraders (SERDs) alone or a combination of SERDs and CDK4/6 inhibitors at Massachusetts General Hospital (Boston, MA) and Northwestern University (Chicago, IL). Associations between $GATA3^{mut}$, patient and tumor characteristics, and prior treatments were assessed using logistic regression. Clinical outcomes were estimated through Cox proportional hazards regression. **Results:** $GATA3^{mut}$ were observed in 13 patients (13%), each with a single *GATA3* variant. These mutations were detected in exon 4 (M294K), exon 5 that includes Zn-finger-2 motif (T327fs, R331fs, N334K, D336fs, c.925-3_925-2del splice acceptor variant), and exon 6 (K358fs, P409fs, M416fs, G431fs, M439fs, V440fs). All mutations except for M294K were insertion/deletion frameshift mutations that result in either elongation or truncation of the protein, potentially with heterogenous downstream effects. $GATA3^{mut}$ were the only detectable alteration in 4 patients. The most commonly co-occurring mutations with $GATA3^{mut}$ were $ESR1^{mut}$ in 7/13 (53.8%) and $PIK3CA^{mut}$ in 6/13 (46%) patients. Presence of $GATA3^{mut}$ was associated with prior exposure to chemotherapy (OR = 1.09, 95%CI [1.01 - 1.10], p = 0.03). Patients with $GATA3^{mut}$ tumors had shorter PFS compared to $GATA3^{wild}$ tumors (4.1 vs. 6.7 months, in both univariate and multivariate analysis controlled for presence of $ESR1^{mut}$: HR = 2.22 95%CI [1.12 – 4.38], p = 0.02). OS was also significantly shorter in patients harboring $GATA3^{mut}$ compared to $GATA3^{wild}$ (14.1 vs. 27.1 months, multivariate analysis: HR = 2.30 95%CI [1.04 – 5.11], p = 0.04). **Conclusions:** $GATA3^{mut}$ in breast cancer tend to be grouped within exons 5 and 6, and they likely contribute to acquired resistance to endocrine-based therapies in MBC. Our study showed that patients with $GATA3^{mut}$ ER+ MBC have worse prognosis compared to those who were $GATA3^{wild}$. Larger studies are needed to further stratify and ascertain functional effects of different *GATA3* mutations and explore *GATA3* gene or its translational product as a possible druggable target. On-treatment derived neutrophil-to-lymphocyte ratio and response to palbociclib and letrozole: Analysis of a multicenter retrospective cohort and the PALOMA-2 study. *First Author: Chang Gon Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Relevant predictive biomarkers for cyclin dependent kinase 4 and 6 (CDK4/6) inhibitors have not been identified in hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer (ABC). We investigated whether dynamic changes in the peripheral immune cells can predict therapeutic response to CDK4/6 inhibitors in ABC with translational relevance. **Methods**: Postmenopausal women who received palbociclib and letrozole for HR-positive, HER2-negative ABC from tertiary referral centers were analyzed (n = 221; exploratory cohort). Pre- and on-treatment leucocyte, neutrophil, lymphocytes counts, neutrophil-to-lymphocyte ratio (NLR), and derived NLR (dNLR; neutrophil/[leucocyte-neutrophil]) were correlated with survival outcomes. Patients from the PALOMA-2 study (NCT01740427) treated with letrozole with or without palbociclib (n = 410 and 209, respectively) were analyzed for validation (validation cohort). Prospectively enrolled patients were subjected to immunophenotyping with flow cytometry to explore the immune cell dynamics after CDK4/6 inhibitor treatment. **Results**: In the exploratory cohort, palbociclib administration significantly reduced leucocyte, neutrophil, and lymphocyte counts on cycle 2 day 1. Not baseline, but on-treatment neutrophil and lymphocyte counts were associated with superior and inferior outcomes, providing predictive significance to on-treatment NLR and dNLR for progression-free survival (PFS; HR = 1.64 and 2.52; all $P< 0.001$). In the validation cohort, higher on-treatment dNLR was associated with inferior PFS in patients treated with palbociclib and letrozole (HR = 1.50 and $P= 0.009$ with 1.04 cut-off), whereas not correlated with outcome in placebo and letrozole-administered patients. Exploratory analysis revealed that CDK4/6 inhibitor prevented T cell exhaustion and diminished relative frequencies of myeloid-derived suppressor cells, both of which trigger antitumor immunity. **Conclusions**: On-treatment dNLR significantly predicted treatment outcome in HR-positive, HER2-negative ABC treated with palbociclib and letrozole, allowing early prediction of treatment response with mechanistic insights. Clinical trial information: NCT01740427. Research Sponsor: None.

Phase I safety and efficacy study of autophagy inhibition with hydroxychloroquine to augment the antiproliferative and biological effects of preoperative palbociclib plus letrozole for estrogen receptor-positive, HER2-negative metastatic breast cancer (MBC). *First Author: Akshara Singareeka Raghavendra, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Endocrine therapy with a CDK4/6 inhibitor is standard of care for patients (pts) with estrogen-receptor-positive (ER+), HER2-negative MBC, yet resistance ultimately develops. We have shown that low doses of palbociclib activates autophagy, which reverses initial G1 cell cycle arrest. High concentrations of palbociclib induce senescence, but these are off target effects of the drug. The autophagy inhibitor hydroxychloroquine (HCQ) induces senescence at a lower (i.e. on-target) continuous dosing of palbociclib, in *in vitro* and *in vivo* models. This strategy is being tested in a phase I/II trial (NCT03774472). Results from the phase I portion are reported here. **Methods:** The phase I part of this study uses a dose escalation 3+3 design testing HCQ, 400, 600 and 800 mg daily (6 pts at 800 mg) with continuously dosed palbociclib at 75 mg and letrozole 2.5 mg daily. Dose limiting toxicity (DLT) includes any study drug-related grade $\geq$ 3 nonhematological (lab) toxicity. Responding pts may continue on therapy beyond 8 weeks for up to 52 weeks. Primary objective is to determine safety, tolerability and the recommended phase 2 dose (RP2D) of HCQ. Secondary objectives are overall tumor response and time to progression. Eligible pts are $\geq$18 years of age, postmenopausal (ovarian suppression allowed) with ER+/HER2-negative MBC, ECOG performance status score of $\leq$1 and with adequate renal, hepatic, and hematologic function. Response is assessed per RECIST v1.1. **Results:** Between 9/24/18 and 12/15/20, 14 pts were evaluable for safety. Median age was 41 with Asian (1, 7.1%), Black (2, 14.3%) White (11, 78.6%) patients enrolled. No DLTs were observed. One pt progressed during the DLT period and 2 withdrew consent (one during the DLT period); two pts were replaced for DLT assessment. Reasons for coming off study were grade 3 skin toxicity (1), per protocol at 8 weeks (non-measurable or pt/physician preference, 9), and (2) full duration treatment at 50 and 52 weeks. Adverse events (AEs) of grade $\geq$3 were hematologic (29), metabolism/nutrition (2), musculoskeletal/ connective tissue (1), and skin/subcutaneous tissue (3), with no serious AEs reported. The percent of palbociclib doses held per pt due to neutrophil level ranged from 0-37.5% with no apparent relation to HCQ dose. Best response was partial (2) stable (11); and progression (1). For measurable disease, tumor decreases of 11%, 12%, 21%, 26%, 30%, 55% and increase in 1 pt by 55% were seen. **Conclusions:** This phase I study showed acceptable safety and no HCQ dose-toxicity relationship. The RP2D of HCQ is 800 mg/day with continuous dosing palbociclib at 75 mg/day and letrozole at 2.5 mg/day. The phase 2 trial will proceed in the neoadjuvant setting, with Ki67 proliferative index response as the primary endpoint. Clinical trial information: NCT03774472. Research Sponsor: U.S. National Institutes of Health.

1068 **Poster Session**

Real-world (rw) clinical outcomes on alpelisib (ALP) in patients (pts) with breast cancer (BC) and *PIK3CA* mutations (PIK3CAm). *First Author: Hope S. Rugo, University of California, San Francisco, San Francisco, CA*

Background: ALP was approved by the FDA for treatment of HR+/HER2- advanced BC with activating PIK3CAm based on the phase 3 SOLAR-1 trial. Enrollment used 11 PIK3CAm (SOLAR1m) in *PIK3CA* exons 7, 9 and 20. We report the prevalence of SOLAR1m and other predicted activating mutations elsewhere in the *PIK3CA* gene (OTHERm) in pts with BC, as well as rw clinical outcomes of ALP treatment in these pts. **Methods:** Comprehensive genomic profiling (CGP) results from 31,765 tissue and 4,147 liquid biopsies from pts with BC were analyzed. Clinical characteristics and treatment history were available for 1,579 pts with PIK3CAm in a de-identified Flatiron Health-Foundation Medicine clinico-genomic database (data obtained from ~800 US sites, 1/2011 - 9/2020, via technology-enabled abstraction of clinician notes and radiology/pathology reports). 3 cohorts were considered. Cohort A: HR+/HER2- pts receiving fulvestrant (FUL) alone (n = 124) or ALP/FUL (n = 111) in treatment line ≥2L were considered in survival analysis. Rw progression-free survival (rwPFS) from start of treatment was estimated with Kaplan-Meier analysis and hazard ratios from Cox proportional hazards models adjusted for survival bias. Cohort B: 627 HR+/HER2- pts who received a clinical report with ALP listed (report date after 5/2019) Cohort C: 36 pts with OTHERm only, any receptor subtype, treated with ALP in any combination. **Results:** Among 31,765 BC tissue biopsies, 10,869 (34%) had PIK3CAm. 8,750 (28%) had SOLAR1m, and of these 1,146 had ≥1 additional OTHERm. 2,119 pts (6.7%) had ≥1 OTHERm without any SOLAR1m. OTHERm more common in the presence of a SOLAR1m were: E726K, E418K, E365K, E453Q, and H1048R ($p < 0.0001$). OTHERm more common in absence of a SOLAR1m were: N345K, G1049R, Q546K, and indels disrupting PIK3R1 binding ($p < 0.0001$). Among 4,147 liquid biopsies, detection rates were comparable to tissue: 1,391 (34%) had PIK3CAm and 1159 (28%) had SOLAR1m. In Cohort A, median rwPFS was 4.1 mo on FUL [95%CI: 3-6.2] versus 6.5 mo on ALP/FUL [95%CI: 4.8-9.5] ($p = 0.027$). In Cohort B, 202/524 (39%) pts with a SOLAR1m were treated with ALP, compared to 28/103 (27%) pts who had OTHERm only. Pts with SOLAR1m received ALP treatment earlier: median [interquartile range] 4L [3-6] versus 5.5L [4-8]. In Cohort C, rwPFS > 6 months was observed in 5 pts bearing: N345K, Q75E, R38C, G106_108del, and N345K/N1044K. **Conclusions:** This study validates the activity of ALP among a diverse real world population, showing pts with *PIK3CA* mutations have longer rwPFS on ALP/FUL than FUL alone. Pts with SOLAR1m were more likely to be treated with ALP- and tended to be treated in earlier line settingthan pts with OTHERm. No consistent effect in a small subset of pts with OTHERm treated with ALP was observed, but there is evidence that OTHERm may differ in their degree of PI3K activation, oncogenicity, and ALP sensitivity. Liquid biopsy CGP detected PIK3CAm at similar rates to tissue biopsy. Research Sponsor: Foundation Medicine.

1069 **Poster Session**

Stereotactic radiosurgery (SRS) for brain metastasis (BM) in hormone receptor positive (HR+) HER2 negative breast cancer (BC). *First Author: Akshara Singareeka Raghavendra, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: With the increase of the utilization of SRS for the treatment of oligometastatic BM over surgical reaction or whole brain radiation therapy (WBRT), we sought to evaluate the impact of SRS on overall survival in HR+Her2- BC and prognostic factors associated with SRS. **Methods**: We reviewed prospectively collected data in the electronic data bases of the breast medical, surgical and radiation oncology departments at MD Anderson cancer center. We aimed at identifying HR+HER2- BC patients who received upfront SRS for BM's between 08/10/2009 and 02/27/2018.Overall survival was defined as the time from the first SRS to last follow-up/death. Multivariate analysis by the Cox proportional hazards regression analysis was performed to evaluate the prognostic factors (age at BM, stage, Karnofsky performance score (KPS), symptomatic BM, BM at 1stdistant metastatic presentation, extracranial Disease, treatment history, salvage therapy, number of brain lesion treated) of SRS that influenced survival. **Results:** A total of 125 patients were identified, and we are reporting on 68 with completed analysis. Median age at time of first SRS was 53.86 years. 51 patients of the 68 were deceased at the time of this analysis and 17 patients were alive at the time of last follow-up. 49 patients (72.06 %) presented with radiation necrosis after SRS; 36 patients (52.94 %) presented with BM as 1st distant metastasis including metastasis to other sites. Number of BM's lesions <4 was 60 (88.2%) and >=4 was 7 (10.3%). The median follow-up from time of first SRS for survivors was 10.84 months. 24 (35.29%) received two or more sessions of SRS and the mean time between first and second SRS sessions for these patients was 14.24 months. Median time from first SRS to second SRS for ER+HER2− patients was 10.84 months (n = 24); on multivariable analysis, higher Karnofsky performance score (KPS) was associated with better survival compared to no salvage therapy. Patients with KPS>90 (p=0.005) had better survival and reduced the hazard by a factor of 0.33 (or 67%). Receiving SRS (p=0.0003) or SRS+WBRT (0.0001) as salvage therapy reduced the hazard (risk of death) by 86% and 85%, respectively. **Conclusions:** SRS is an effective treatment modality for HR+HER2- BM from BC. Patients who received SRS or SRS and WBRT, KPS >90 had better survival than patients who didn't receive any salvage therapy. Updated data will be available at the time of the presentation. Research Sponsor: None.

Efficacy of AI and palbociclib in ER+ HER2- advanced breast cancer patients relapsing during adjuvant tamoxifen: An exploratory analysis of the PADA-1 trial. *First Author: François-Clément Bidard, Institut Curie, Paris, France*

Background: In PADA-1 (NCT03079011), a phase III trial testing the clinical utility of $ESR1_{mut}$ detection, ER+ HER2- advanced breast patients (ABC pts) received Aromatase Inhibitor (AI) and Palbociclib (Pal) +/- LHRH agonist as first line therapy. PADA-1 was open to "AI-sensitive" pts, including those with de novo stage IV disease or metastatic relapse after adjuvant endocrine therapy but also pts with metastatic relapses during adjuvant tamoxifen (TAM). In this subsidiary analysis, we report the efficacy of AI+PAL as first line therapy in patients relapsing on adjuvant TAM. **Methods:** Main inclusion criteria in PADA-1 are: pre- or post-menopausal pts with ER+ HER2- ABC, who did not receive any prior therapy for ABC and who had no adjuvant AI or completed adjuvant AI for > 12 months or who had disease recurrence while on adjuvant TAM. **Results:** From 04/2017 to 01/2019, 1017 ABC pts have been included in PADA-1, of which 115 (11.3%) had a metastatic relapse while on adjuvant TAM (TAM only (N = 112) or TAM+GnRH agonist (N = 3)). Median age at inclusion was 46 years (range 25-81), and 58 (50.4%) patients had visceral disease. The median PFS under AI+PAL was 20.4 months (95%CI16.1;27.8) in patients relapsing during adjuvant TAM. In contrast, median PFS in patients with de novo metastatic disease and metastatic relapses after the completion of adjuvant endocrine therapy were 30.6 months (95%CI26.7;Not reached) and 27.8 months (95%CI24.1;30.)], respectively. A subgroup analysis among patients relapsing on adjuvant TAM showed that those relapsing during the first two years of adjuvant TAM had a shorter PFS (11.4 months 95%CI[8.7;20.7]) than those relapsing after 2 years of adjuvant TAM (23.8 months 95%CI[20.2;Not reached]). **Conclusions:** To our knowledge, these are the first data on first line AI+CDK4/6 inhibitor in patients relapsing on adjuvant TAM. While PFS on AI + PAL appears primarily driven by endocrine resistance status, our data show that AI+PAL is a valuable option also in patients relapsing during adjuvant TAM. Clinical trial information: NCT03079011. Research Sponsor: Pfizer.

1071 **Poster Session**

Real-world quality of life (QoL) in black, indigenous and people of color (BIPOC) treated with palbociclib (PAL) and endocrine therapy for hormone receptor–positive (HR+)/human epidermal growth factor receptor 2–negative (HER2–) advanced breast cancer (ABC): A subgroup analysis from POLARIS. *First Author: Gabrielle Betty Rocque, University of Alabama at Birmingham, Birmingham, AL*

Background: Racial disparities in breast cancer incidence, mortality, and care are well documented. PAL plus endocrine therapy is indicated for patients (pts) with HR+/HER2− ABC. Findings from the PALOMA clinical trials have shown that pts receiving PAL maintained stable QoL; however, limited QoL data are available from real-world settings for BIPOC receiving PAL. **Methods:** POLARIS is a noninterventional, prospective, primarily US-based study in pts with HR+/HER2− ABC receiving PAL. QoL was assessed with the European Organisation for Research and Treatment of Cancer Quality-of-Life Questionnaire Core 30 (EORTC QLQ-C30) at baseline, monthly for the first 3 mo of treatment (Tx) with PAL, and then every 3 mo. In this interim analysis, we report Tx patterns and QoL assessments at baseline and at 6 mo and 12 mo in BIPOC from POLARIS. **Results:** Of 1280 pts treated with PAL as November 10, 2020, 233 were included in the BIPOC subgroup of whom 159 (68.2%) completed PAL Tx for ≥6 mo and 112 (48.1%) for ≥12 mo. In the BIPOC cohort, 59.2% of pts were black, 35.2% Hispanic, 3.4% American Indian or Alaskan native, 2.1% Pacific Islander. PAL in combination with letrozole/anastrozole was received by 116 pts, 94 received PAL plus fulvestrant, 13 received PAL plus exemestane, and 10 received PAL plus another Tx; 175 pts (75.1%) received PAL as first-line Tx. Mean EORTC QLQ-C30 global health QoL and functional scales scores remained stable over the first 12 mo of PAL Tx, without any changes at or above the 10-point threshold considered clinically meaningful, and were similar to those previously reported in an earlier analysis of the entire POLARIS population (Table and Rocque et al SABCS 2019). Symptom scales scores, including nausea and vomiting, pain, dyspnea, insomnia, appetite loss, constipation, and diarrhea, also remained stable over 12 mo. **Conclusions:** In this subgroup analysis, PAL had no significant adverse impact on QOL in BIPOC with HR+/HER2− ABC, consistent with previous findings from the total POLARIS study population. Pfizer (NCT03280303). Clinical trial information: NCT03280303. Research Sponsor: Pfizer Inc.

Relative risk of pneumonitis or interstitial lung disease (ILD) associated with the use of cyclin-dependent kinase inhibitors (CDK4/6i): A systematic review and meta-analysis of phase 3 randomized controlled trials. *First Author: Nusrat Jahan, Texas Tech University Health Sciences Center, Lubbock, TX*

Background: All three currently approved cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) such as palbociclib, abemaciclib, and ribociclib are reported to cause significant pulmonary toxicities including fatal pneumonitis or interstitial lung disease (ILD). We conducted a systematic review and meta-analysis of phase 3 randomized controlled trials (RCTs) to determine the relative risk of pneumonitis or ILD associated with CDK4/6i. **Methods:** We conducted a systematic search using PRISMA guidelines in PubMed, EMBASE, American Society of Clinical Oncology and San Antonio Breast Cancer Symposium meeting abstracts from inception through Jan 30, 2021. Phase 3 RCTs using CDK4/6i in the intervention arm and reporting the number of events for pneumonitis or ILD were included in the analysis. The Cochran-Mantel-Haenszel method and random effects model were used to calculate the pooled risk ratio (RR) with 95% confidence interval (CI). Heterogeneity was tested by Cochran's Q test and I^2 value. **Results:** Five phase 3 RCTs — MONALEESA-3, MONALEESA-7, MONARCH plus, monarchE, and PALLAS — reported the number of events for any grade pneumonitis or ILD and were included in the final analysis. A total of 13,191 patients — 6,758 in the CDK4/6i arm and 6,433 in the control arm — were analyzed. Following regimens were used in CDK4/6i arms — MONALEESA-3: ribociclib + fulvestrant; MONALEESA-7: ribociclib + tamoxifen or a non-steroidal aromatase inhibitor + goserelin; MONARCH plus: in cohort A, abemaciclib + anastrozole or letrozole, and in cohort B, abemaciclib + fulvestrant; MonarchE: abemaciclib + standard-of-care adjuvant endocrine therapy (ET); PALLAS: Palbociclib + ET. In the control arms, all studies used placebo and respective endocrine therapies. Any grade pneumonitis or ILD was reported in 1.64% of patients in the CDK4/6i arm versus 0.68% of patients in the control arm. The pooled RR of any grade pneumonitis or ILD was 2.26, 95% CI: 1.60-3.19, $P < 0.00001$, $I^2 = 0\%$. Grade 3/4 pneumonitis or ILD was reported in 0.28% of patients in the CDK4/6i arm and 0.06% of patients in the control arm with pooled RR of 2.35, 95% CI: 0.37-15.08, $P = 0.37$, $I^2 = 34\%$. One grade 5 pneumonitis was reported in the monarchE. **Conclusions:** Cyclin-dependent kinase 4/6 inhibitors are associated with increased risk of any grade pneumonitis or ILD. Early detection and prompt initiation of appropriate interventions are vital to reduce the morbidity and mortality associated with CDK4/6i induced pneumonitis or ILD. Research Sponsor: None.

1073 **Poster Session**

Confirmed tumor response by molecular subtype in patients with metastatic breast cancer: Sub-analysis from a phase 3 clinical study comparing oral paclitaxel and encequidar to IV paclitaxel. *First Author: Gerardo Antonio Umanzor Funez, Liga Contra El Cancer, San Pedro Sula, Honduras*

Background: Paclitaxel, a foundation treatment in MBC, is hydrophobic and must be formulated for IV administration with Cremophor EL, increasing the risk of infusion reactions and necessitating pre-treatment with corticosteroids and antihistamines. Paclitaxel cannot be administered orally because it is a substrate for P-gp. The oral bioavailability of paclitaxel is improved when administered 1 hour after the highly selective, potent, and minimally absorbed P-gp inhibitor encequidar. As oral paclitaxel is Cremophor-free there is no need for pretreatment for infusion reactions. While targeted therapies have improved outcomes in patients with HER2+ tumors there is still an unmet need for therapies that prolong survival with reduced toxicity across all tumor subtypes. **Methods:** A phase 3, open-label, randomized, multicenter study in women with histologically- or cytologically-confirmed MBC for whom treatment with IV paclitaxel monotherapy had been recommended by their oncologist randomized 402 patients 2:1 to either oral paclitaxel and encequidar (oPac+E) or IV paclitaxel (IVPac). Oral paclitaxel 205 mg/m^2 was administered once daily for 3 consecutive days, weekly. Encequidar 12.9 mg was administered 1 hour before each dose of oral paclitaxel. IV paclitaxel 175 mg/m^2 was infused over 3 hours on day 1 of every 3 weeks. **Results:** In the ITT population oPac+E was superior to IV paclitaxel with a confirmed tumor response rate of 35.8% vs 23.4% for IVPac: a difference of 12.4% ($p = 0.0107$). A post-hoc subgroup efficacy analysis was conducted based on tumor subtypes, however, the study was not powered to detect statistical differences within these subgroups. Patients in the HR+/HER2- subgroup had a better tumor response to oPac+E (44.8% vs 21.4% IVPac-response rate difference of 23.4%) as did patients in the TNBC (30.5% vs 20.2%-response rate difference of 10.3%) subgroup. Responses were similar (49% vs 47.4% IVPac) in the HER2+ subgroup. Patients with unknown HER2 status receiving oPac+E had a 58.8% response rate vs 14.3% with IVPac (response rate difference of 44.5%). **Conclusions:** oPac+E is the first oral taxane to demonstrate superiority in radiologically confirmed tumor response rate compared to IVPac in a group of 402 women with metastatic breast cancer. Patients with HR+/HER2-, TNBC, and Unknown subtypes responded considerably better to oPac+E vs IVPac—especially the HR+/HER2- subtype which represented 63% of the patients treated with oPac+E and 55% of the patients treated with IVPac. Clinical trial information: NCT 02594371. Research Sponsor: Athenex Inc.

1074 **Poster Session**

A phase Ib study of TQB2450 plus anlotinib in patients with advanced triple-negative breast cancer. *First Author: Jiayu Wang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: TQB2450 is a humanized monoclonal antibody targeting programmed death-ligand 1 (PD-L1). Anlotinib is an antiangiogenic small molecule, multi-target tyrosine kinase inhibitor that has improved clinical outcomes in various solid tumors. This phase 1b study aims to evaluate the safety and efficacy of TQB2450 plus anlotinib for patients with advanced triple-negative breast cancer (TNBC) after the failure of standard therapy. **Methods:** This ongoing study included a dose-escalation phase and an expansion phase. Advanced TNBC patients with prior anthracyclines and/or taxanes treatment and failed at least first-line therapy were enrolled. In the dose-escalation phase, eligible patients received anlotinib (8mg, 10mg, and 12mg, qd, days 1-14; 21 days per cycle) plus TQB2450 (1200mg, day 1; 21 days per cycle) following the conventional 3+3 design. If the starting dose of 10mg anlotinib led to ≥2 dose-limiting toxicities (DLTs), 8mg anlotinib would be administered. After the dose-escalating phase, eligible patients were enrolled into the expansion cohort. The primary endpoint was objective response rate (ORR), and the secondary endpoints were overall survival (OS), disease control rate (DCR), progression-free survival (PFS), and safety. **Results:** Between May 29, 2019, and December 31, 2020, in the dose-escalation phase, three patients receiving 10mg anlotinib plus 1200mg TQB2450 had no DLTs in the first cycle, neither did three patients with 12mg anlotinib plus TQB2450. Next, 28 patients with advanced TNBC received 12 mg anlotinib plus TQB2450 in the expansion phase. Finally, a total of 34 patients were included with median age of 49.5 (32-70) and median prior lines of 2 (1-6). Numbers of patients with prior platinum therapy: 16, prior anthracycline therapy: 32. The ORR was 26.47% (9/34) and DCR was 82.35% (28/34). The median PFS was 8.57 months. Seventeen patients experienced grade 3 treatment-related AEs (TRAEs). Most frequently occurring (>5%) grade 3 TRAEs were QT interval prolongation (17.65%), hypertension (14.71%), diarrhea (8.82%), hand-foot syndrome (HFS) (8.82%), and hypertriglyceridemia (5.88%). **Conclusions:** TQB2450 plus anlotinib showed an acceptable safety profile with promising activity for previously anthracyclines and/or taxanes-treated advanced TNBC patients. Clinical trial information: NCT03855358. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

List of grade 3 TRAEs.

Grade 3 TRAEs, n (%)	Anlotinib + TQB2450 n=34	Grade 3 TRAEs, n (%)	Anlotinib + TQB2450 n=34
QT interval prolongation	6 (17.65)	Neutrophil count decreased	1 (2.94)
Hypertension	5 (14.71)	Higher LDL-C levels	1 (2.94)
Diarrhea	3 (8.82)	Hyperbilirubinemia	1 (2.94)
Hand-foot syndrome	3 (8.82)	Weight loss	1 (2.94)
Hypertriglyceridemia	2 (5.88)	Hypercholesterolemia	1 (2.94)
AST elevation	1 (2.94)	Oral mucositis	1 (2.94)
White blood cell decreased	1 (2.94)

Apatinib plus vinorelbine versus vinorelbine for advanced triple-negative breast cancer with failed first or second-line treatment: The NAN trial. *First Author: Doudou Li, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: No standard treatment exists for triple negative breast cancer (TNBC) with failure of multi-line therapies. Apatinib is a small-molecule tyrosine kinase inhibitor that has promising anti-angiogenesis and antitumor activity for TNBC. We aimed to evaluate the safety and efficacy of adding apatinib to chemotherapy in patients with metastatic TNBC with failed first/second-line treatment. **Methods:** This randomized, open-label, phase 2 trial recruited patients with advanced TNBC who failed to receive first or second-line treatment. A total of 66 patients were randomly assigned, in a 1:1 ratio, to receive vinorelbine 25 mg/m^2 (days 1, 8, 15) or vinorelbine 20 mg/m^2 (days 7, 14, 21) with apatinib (250 mg once daily, days 1-5, 8-12, 15-19, if tolerable, the second cycle started with 500 mg per day) in 28-day cycles. The efficacy was evaluated every two treatment cycles (8 weeks ± 3 days). According to the RECIST criterion, patients with CR, PR and SD continued treatment until disease progression or unacceptable toxicity or withdrawal of consent. The primary end point was progression-free survival (PFS). Secondary end points included overall survival (OS), overall response rate (ORR) and safety. **Results:** Between Sep 14, 2017 and Dec 08, 2020, 66 patients underwent randomization. Median follow-up was 21.3 months. 33 received apatinib plus vinorelbine and 32 received vinorelbine (1 was withdrawal of consent). Median PFS was significantly longer in the apatinib plus vinorelbine group than in the vinorelbine group (3.8 months vs. 1.9 months; hazard ratio for disease progression or death, 1.76; 95% confidence interval [CI], 1.02 to 3.05; P= 0.039). Median OS was 14.6 months with apatinib plus vinorelbine and 14.1 months with vinorelbine (HR,1.34; 95% CI, 0.60 to 3.00; P= 0.469). The ORR was 48.5% in the apatinib plus vinorelbine group and 31.3% in the vinorelbine group (P= 0.156). The most common treatment-related hematologic grade 3–4 adverse events in those treated with apatinib plus vinorelbine versus vinorelbine, respectively, were leukopenia (42.4% vs. 34.4%), granulocytopenia (57.6% vs. 28.1%), anemia (9.1% vs. 12.5%) and thrombocytopenia (3.1% vs. 3.0%). The most frequent grade 3 nonhematologic toxicities were hand–foot syndrome (21%), proteinuria (9%), hypertension (9%) and increased ALT (9%) and which only occurred in apatinib plus vinorelbine group. No treatment-related nonhematologic grade 4 adverse events or treatment-related deaths were observed. **Conclusions:** Collectively, among patients with advanced TNBC with failed first/second-line treatment, apatinib plus vinorelbine show a promising benefit in PFS compared to vinorelbine monotherapy. Apatinib plus vinorelbine regimen shows promising efficacy and manageable toxicity, which might be a previously unappreciated therapeutic option for advanced TNBC. Clinical trial information: NCT03254654. Research Sponsor: None.

1076 **Poster Session**

Romidepsin (HDACi) plus cisplatin and nivolumab triplet combination in patients with metastatic triple negative breast cancer (mTNBC). *First Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS*

Background: Histone deacetylase inhibitors (HDACi) upregulate genes involved in antigen presentation machinery and increase expression of natural killer group 2, member D ligands (NKG2DL), thus resulting in enhanced tumor cell recognition and response to PD-1/CTLA-4 blockade. Cisplatin and HDACi combination synergistically induces cytotoxicity, apoptosis, and DNA damage. This phase I-II trial investigated combination of romidepsin (HDACi) plus cisplatin and nivolumab (PD-1 inhibitor) in mTNBC. **Patients and Methods:** Eligible patients had mTNBC with any number of prior chemotherapies. Phase I was 3+3 dose-escalation design with three dose levels of romidepsin (8, 10, 12mg/m^2, D2, 9) plus cisplatin 75mg/m^2 D 1 every 21 days. Phase II treatment included romidepsin plus cisplatin plus nivolumab 360mg every 21 days and was designed according to Simon's two stage minimax design. Primary endpoints were recommended phase 2 dose (RP2D) and objective response rate (ORR). Additional endpoints included safety, PFS, and pharmacokinetics. **Results:** 51 patients were enrolled (N=13 phase I, N=38 phase II) between 2015-2020. 69% had received ≥1 prior metastatic chemotherapy, 47% had prior platinum, 53% had liver metastasis, 12% had *BRCA1/2* mutation, and 11% had PD-L1 positive disease. There were no dose limiting toxicities in phase I. The RP2D was romidepsin 12mg/m^2 D2,9 + cisplatin 75mg/m^2 D1 + nivolumab 360mg D1 every 21 days. Thrombocytopenia (G3:27%, G4:0%), neutropenia (G3:25%, G4:0%), anemia (G3:22%, G4:0%), nausea (G3:22%, G4:0%), and vomiting (G3:20%, G4:0%) were the most common grade 3/4 adverse events. 21% of patients had immune AEs (G3-4:8%). Among 34 evaluable phase II patients, ORR was 44% (Table), median PFS was 4.4 months, and 1-year PFS was 23%. Median OS was 10.3 months and 1-year OS was 43%. No pharmacokinetic interactions were detected with co-administration of romidepsin-cisplatin-nivolumab. **Conclusions:** The triplet combination of romidepsin plus cisplatin and nivolumab was well tolerated and shows encouraging efficacy in pretreated mTNBC, including in patients with PD-L1 negative disease and in those with liver metastasis. Correlative biomarker work is ongoing. This combination warrants further evaluation in larger studies. Clinical trial information: NCT02393794. Research Sponsor: Celgene and Bristol Myers Squibb.

Objective response (phase II).

		Prior lines of metastatic chemotherapy			Liver metastasis		PD-L1[a] status

Assessment of sacituzumab govitecan (SG) versus treatment of physician's choice (TPC) cohort by agent in the phase 3 ASCENT study of patients (pts) with metastatic triple-negative breast cancer (mTNBC). *First Author: Joyce O'Shaughnessy, Texas Oncology-Baylor Sammons Cancer Center, US Oncology, Dallas, TX*

Background: In pts with pretreated mTNBC, standard-of-care chemotherapy is associated with low objective response rates (ORRs) and short median progression-free survival (PFS). SG is an antibody-drug conjugate composed of an anti–Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolyzable linker. SG received accelerated FDA approval for treatment of pts with mTNBC who have received ≥2 prior therapies for metastatic disease. The confirmatory phase 3 ASCENT study (NCT02574455) in pts with relapsed/refractory mTNBC demonstrated a significant survival benefit of SG over TPC (median PFS: 5.6 vs 1.7 mo, HR 0.41, $P< 0.0001$; median overall survival [OS]: 12.1 vs 6.7 mo, HR 0.48, $P< 0.0001$) with a tolerable safety profile. Here we summarize efficacy results for SG vs each TPC agent in ASCENT to examine how each TPC agent performed individually. **Methods**: Pts had mTNBC refractory to or progressing after ≥2 prior standard chemotherapy regimens. Pts were randomized 1:1 to receive SG (10 mg/kg intravenously on days 1 and 8, every 21 days) or single-agent TPC (eribulin, vinorelbine, capecitabine, or gemcitabine). Primary endpoint was PFS per RECIST 1.1 by independent review in brain metastases-negative (BMNeg) pts. Secondary endpoints were ORR per RECIST 1.1, duration of response, OS, and safety. Outcomes for each of the agents in the TPC arm were analyzed and compared with SG. **Results**: Of 529 pts enrolled, 468 were BMNeg. Among pts in the TPC cohort (n = 233), eribulin was the most commonly chosen chemotherapy (n = 126), followed by vinorelbine (n = 47), capecitabine (n = 31), and gemcitabine (n = 29). Treatment with eribulin, vinorelbine, capecitabine, and gemcitabine resulted in shorter median PFS vs SG (2.1, 1.6, 1.6, and 2.7 vs 5.6 mo, respectively); similar results were observed for median OS (6.9, 5.9, 5.2, and 8.4 vs 12.1 mo), ORR (5%, 4%, 6%, and 3% vs 35%), and clinical benefit rate (CBR; 8%, 6%, 10%, and 14% vs 45%). Key grade ≥3 treatment-related adverse events (TRAEs) with TPC overall vs SG included neutropenia (33% vs 51%), leukopenia (5% vs 10%), fatigue (5% vs 3%), and anemia (5% vs 8%). Key grade ≥3 TRAEs with eribulin vs SG included neutropenia (30% vs 51%), leukopenia (5% vs 10%), fatigue (5% vs 3%), anemia (2% vs 8%), and peripheral neuropathy (2% vs none), respectively. The safety profiles of vinorelbine, capecitabine, and gemcitabine combined were consistent with that of TPC overall and with eribulin. One treatment-related death was reported for the TPC arm (eribulin) and none with SG. **Conclusions**: The efficacy benefit observed with SG vs TPC in pts with mTNBC was retained when evaluating each TPC chemotherapy agent individually. These results confirm that SG should be considered as a new standard of care in pts with pretreated mTNBC. Clinical trial information: NCT02574455. A phase I/IB study of ipatasertib in combination with carboplatin or carboplatin/paclitaxel or capecitabine and atezolizumab in patients with metastatic triple-negative breast cancer. *First Author: Yuan Yuan, City of Hope National Medical Center, Duarte, CA*

Background: Ipatasertib (ipat) is an AKT inhibitor which has shown efficacy in combination with paclitaxel and atezolizumab in patients with triple negative breast cancer (TNBC). In previous trials, ipat was given 21 days on 7 days off due to gastrointestinal toxicities. The current trial was designed to test the safety and efficacy of ipat continuous dosing in combination with carboplatin (carbo) or carboplatin/paclitaxel (carbo/taxol). The trial was later amended to include an additional arm using ipat 21 days on 7 days off with capecitabine/atezolizumab (cape/atezo) to explore the safety of the combination. **Methods:** Patients with metastatic TNBC and up to 2 lines of prior chemotherapy were enrolled to receive the following: Arm A, ipat 400 mg daily, carbo AUC 2 and taxol 80 mg/m2 IV days 1, 8, 15, every 28 days; Arm B, ipat 400 mg daily, carbo AUC 2 IV days 1, 8, 15, every 28 days; Arm C, ipat 300 mg daily 21 days on 7 days off, cape 750 mg/m^2 7 days on 7 days off, atezo 840 mg IV every 28 days. Ipat continuous dosing was used for Arms A and B. Ipat 21 days on 7 days off dosing was used for Arm C. The primary endpoint is safety and recommended phase II dose (RP2D). Secondary endpoints are response rate (RR) and overall survival (OS). **Results:** Twenty-three patients with median age 49 (29-75) were enrolled from 04/2019 to 12/2020, with 9 in Arm A, 10 in Arm B, and 4 in Arm C. A total of 15/23 (65%) had dose delay and 10/23 (43%) had dose modification. 3/4 (75%) of patients in Arm A had dose limiting toxicities (DLT) including diarrhea and gastric pain, which led to de-escalation to dose -1 with ipat (300 mg daily). 5 more patients were treated at dose -1 of Arm A with only 1 DLT (maculo-papular rash). No DLTs were observed in Arm B. Of the 4 patients treated in Arm C, 1 had DLT (maculo-papular rash). The RP2D for Arms A and B are: ipat 300 mg/carbo AUC2/taxol 80 mg/m2; ipat 400 mg/carbo AUC2. RP2D for Arm C has not been determined and accrual is ongoing. There were no clinically significant G4 toxicities in Arm A; G3 toxicities included 4/9 (44%) diarrhea, 1/9 (11%) hypertension, 1/9 (11%) stomach pain, and 1/9 (11%) neutropenia. For Arm B, G3 toxicities included 2/10 (20%) diarrhea, 1/10 (10%) anemia, 1/10 (10%) maculo-papular rash, and 1/10 (10%) hyperglycemia. For Arm C, there was 1/4 (25%) G3 maculo-papular rash. Best overall responses for Arm A were: 2/9 (22%) PR, 4/9 (44%) SD, and 3/9 (33%) PD. Best responses for Arm B were 2/10 (20%) PR, 6/10 (60%) SD, and 2/10 (20%) PD. For Arm C, best responses were 3/4 (75%) SD, and 1 not evaluable (repeat biopsy showed HER2+ disease). With a median follow up of 8.1 months, the median PFS was 4.0 months (95% CI [2.6, 5.3]). **Conclusions:** Continuous dosing of ipatasertib in combination with carbo or carbo/taxol is well-tolerated with modest efficacy. Clinical trial information: NCT03853707. Research Sponsor: Genentech, Inc, City of Hope.

A phase II trial of stereotactic radiation therapy and *in situ* oncolytic virus therapy in metastatic triple-negative breast cancer (mTNBC) patients followed by pembrolizumab (STOMP). *First Author: Kai Sun, Houston Methodist Cancer Center, Houston, TX*

Background: Pembrolizumab, stereotactic body radiotherapy (SBRT), and viral vector-based gene therapy such as adenovirus-mediated expression of herpes simplex virus thymidine kinase (ADV/HSV-tk) plus ganciclovir have each shown antitumor immune activity. The combination of those modalities may represent a window of opportunity to enhance pembrolizumab efficacy in mTNBC patients. **Methods:** In this single-arm, open-label phase II trial, mTNBC patients were treated with *in situ* oncolytic ADV/HSV-tk (5 x 10^{11} vp) intratumoral injection, followed by SBRT to the injected tumor site, then pembrolizumab until progression or intolerable toxicity. Response was assessed in non-irradiated metastatic sites. The primary end point was clinical benefit rate (CR, PR and SD per RECIST version1.1). Secondary endpoints included duration on treatment (DoT) and safety. Immune correlative analysis with peripheral blood CYTOF (D1 baseline, D7 and D38), and tissue imaging mass cytometry (IMC) with 35 cell surface markers was performed on paired biopsies (D1 baseline and D17). **Results:** 28 mTNBC patients were enrolled; 18 (64.3%) had PD-L1 negative tumors. Median age was 54 years (range 34-78). Median prior lines of chemotherapy were 2 (range 0-6), with 8 (28.6%) having received >3. 3 (10.7%) had brain metastases. Clinical benefit was seen in 6 (21.43%) patients; 2 CR (7.1%),1 PR (3.57%) and 3 SD (10.7%). Patients who had clinical benefits had durable responses, with median DoT of 383 days (range 195-1195). One patient who had CR, but discontinued pembrolizumab due to Grade 3 pneumonitis, has remained disease free without any systemic therapy for 39 months. The combination was well tolerated; 9 (32.1%) patients had Grade 3- 4 AEs. Pre- and post-therapy CYTOF analysis showed significant association between immune biomarkers with clinical responses (AUC 0.75, Cohen's Kappa 0.364). Tumor PDL1 was independently associated with response (AUC 0.70, Cohen's Kappa 0.347); AUC for PDL1 together with immune biomarkers is 0.85. **Conclusions:** ADV/HSV-tk gene therapy followed by radiation therapy and then pembrolizumab is a well-tolerated promising treatment in heavily pretreated mTNBC patients. Early detection of increased effector and effector memory CD8 T cells and nonclassical monocytes correlates with response and non-response respectively. Clinical trial information: NCT03295916. Research Sponsor: Merck.

Assessment of sacituzumab govitecan (SG) in patients with prior neoadjuvant/adjuvant chemotherapy in the phase 3 ASCENT study in metastatic triple-negative breast cancer (mTNBC). *First Author: Lisa A. Carey, University of North Carolina, Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: mTNBC is a heterogenous disease with few treatment options and poor outcomes. Pts who recur ≤ 12 mo after completing (neo)adjuvant chemotherapy may represent a subset with more aggressive disease. SG is an antibody-drug conjugate composed of an anti–Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolyzable linker. SG received accelerated approval for pts with mTNBC who received ≥ 2 prior therapies for metastatic disease; clinical benefit for SG over treatment of physician's choice (TPC) was confirmed in the phase 3 ASCENT study (NCT02574455) for median progression-free survival (PFS; 5.6 vs 1.7 mo), median overall survival (OS; 12.1 vs 6.7 mo), objective response rate (ORR; 35% vs 5%), clinical benefit rate (CBR; 45% vs 9%), and median duration of response (6.3 vs 3.6 mo). This ASCENT subanalysis of pts with mTNBC who recurred ≤ 12 mo after (neo)adjuvant chemotherapy and then only received 1 line of therapy in the metastatic setting assessed the benefit of SG in this subgroup vs the overall trial population. **Methods:** In ASCENT, pts with mTNBC refractory/relapsing after ≥ 2 prior chemotherapies were randomized 1:1 to receive SG (10 mg/kg IV on days 1 and 8, every 21 days) or TPC (capecitabine, eribulin, vinorelbine, or gemcitabine). Per protocol, a pt was eligible after only 1 prior regimen in the metastatic setting if their disease recurred within 12 months of completing (neo)adjuvant therapy. Primary endpoint was PFS per RECIST 1.1 by independent review in brain metastases-negative (BMNeg) pts. Efficacy and safety was assessed in a subset of pts who recurred ≤ 12 mo after (neo)adjuvant chemotherapy and then received 1 line of therapy in the metastatic setting. **Results:** In total, 33 and 32 BMNeg pts with a median age of 49 and 51 yrs received SG and TPC in this subgroup, respectively. In this subgroup, treatment with SG (vs TPC) improved PFS (median 5.7 vs 1.5 mo; HR, 0.41; 95% CI, 0.22-0.76; P = 0.0049) and OS (median 10.9 vs 4.9 mo; HR, 0.51; 95% CI, 0.28-0.91; P = 0.0227). We also observed higher ORR (30% vs 3%) and CBR (42% vs 6%) with a median response duration of 6.7 mo with SG vs not calculable with TPC. The efficacy results from this subgroup are similar to those for SG vs TPC in the overall BMNeg population. The safety profile of SG in pts in this subgroup was consistent with prior reports. There were no treatment-related deaths with SG. **Conclusions:** Pts with mTNBC who recurred ≤ 12 mo after (neo)adjuvant therapy and then had 1 line of prior therapy in the metastatic setting may represent a subset with more aggressive disease. In this subgroup, pts had superior outcomes with SG vs TPC in the second-line metastatic setting, consistent with the benefit seen in the overall BMNeg population. Studies are ongoing (NeoSTAR, NCT04230109; SASCIA, NCT04595565) to evaluate SG as an earlier-line treatment option for TNBC. Clinical trial information: NCT02574455. Efficacy of DAN-222, a novel investigational polymeric nanoparticle with topoisomerase I inhibitor, as monotherapy in breast cancer models and when combined with PARP inhibitor. *First Author: Ashley P Wright, Dantari, Inc., Thousand Oaks, CA*

Background: Patients with BRCA-positive HER2-negative breast cancer benefit from PARP inhibitor therapy, but additional benefit is still desired. PARP inhibition alone does not prevent all mechanisms for repairing damage to DNA such as homologous recombination repair. An attractive combination for treating such patients would be combining a topoisomerase I inhibitor with a PARP inhibitor given the dual mechanism this would provide for DNA damage and inhibited repair, leading to tumor cell death. This combination has been tried in multiple phase 1 studies, but myelotoxicity prevented the combination from being evaluated further. DAN-222 is a novel investigational polymeric nanoparticle conjugated with camptothecin, a topoisomerase I inhibitor, that provides significant accumulation of drug in tumor tissues *via* the enhanced permeability and retention (EPR) effect and significantly reduced bone marrow exposure compared to native chemotherapy. These observations underscore the potential advantages of DAN-222 alone as well as in combination with other agents such as PARP inhibitors in solid tumors. Here, we report the effects of DAN-222 monotherapy and in combination with a PARP inhibitor on the growth inhibition in an HRD+ TNBC breast cancer (MDA-MB-436) and an HRD- ovarian (OVCAR3) xenograft mouse model. **Methods:** HRD+ breast cancer tumor cells (MDA-MB-436) were implanted into female NCr nu/nu mice and HRD- ovarian cancer tumor cells (OVCAR3) were implanted into female CB.17 SCID mice. Mice were randomized to vehicle or treatment arms until tumors reached 2000 mm^3 or day 45 (MDA-MB-436) or 1000mm^3 or day 45 (OVCAR3). The groups evaluated include multiple dose levels of DAN-222 as monotherapy and those also combined with niraparib. **Results:** Results were consistent in both the HRD+ and HRD- tumor models with profound dose-response of DAN-222 monotherapy inhibiting tumor growth. Additionally, synergy was demonstrated when DAN-222 was combined with niraparib, clearly evident with low doses of both products when used in combination. The table below highlights the synergy of the combination of DAN-222 at 0.3 mg/kg and niraparib at 25 mg/kg above each agent alone on the tumor growth inhibition in the MDA-MB-436 xenograft. **Conclusions:** Combining a PARP inhibitor with a topoisomerase I inhibitor delivered *via* this polymeric nanoparticle delivery system (DAN-222) has synergistic efficacy in both HRD+ and HRD- xenograft tumor models. These data support continued development of DAN-222 to treat solid tumors and its combination use with PARP inhibitors. Research Sponsor: Dantari, Inc.

Treatment	Dose (mg/kg)	Day 21 TGI (%)	Day 34 TGI (%)
DAN-222	0.3	75	82
DAN-222	1	91	98
DAN-222	3	95	99
Niraparib	25	51	59
DAN-222 + Niraparib	0.3, 25	91	97
DAN-222 + Niraparib	1, 25	94	98
DAN-222 + Niraparib	3, 25	97	99

Control arm heterogeneity in trials for unselected advanced triple-negative breast cancer (aTNBC). *First Author: Kinisha Gala, The Larvol Group, LLC, San Francisco, CA*

Background: Primary endpoints of clinical trials frequently include subgroup-analyses. Several solid cancers such as aTNBC are heterogeneous, which can lead to unpredictable control arm performance impairing accurate assumptions for sample size calculations. We explore the value of a comprehensive clinical trial results repository in assessing control arm heterogeneity with aTNBC as the pilot. **Methods:** We identified P2/3 trials reporting median overall survival (mOS) and/or median progression-free survival (mPFS) in unselected aTNBC through a systematic search of PubMed, clinical trials databases and conference proceedings. Trial arms with sample sizes ≤25 or evaluating drugs no longer in development were excluded. Due to inconsistency among PD-L1 assays, PD-L1 subgroup analyses were not assessed separately. The primary aim was a descriptive analysis of control arm mOS and mPFS across all randomized trials in first line (1L) aTNBC. Secondary aims were to investigate time-to-event outcomes in control arms in later lines and to assess time-trends in aTNBC experimental and control arm outcomes. **Results:** We included 33 trials published between June 2013-Feb 2021. The mOS of control arms in 1L was 18.7mo (range 12.6-22.8) across 5 trials with single agent (nab-) paclitaxel [(n)P], and 18.1mo (similar range) for 7 trials including combination regimens (Table). The mPFS of control arms in 1L was 4.9mo (range 3.8-5.6) across 5 trials with single-agent (n)P, and 5.6mo (range 3.8-6.1) across 8 trials including combination regimens. Control arm mOS was 13.1mo (range 9.4-17.4) for 3 trials in first and second line (1/2L) and 8.7mo (range 6.7-10.8) across 5 trials in 2L and beyond. R^2 for the mOS best-fit lines across control and experimental arms over time was 0.09, 0.01 and 0.04 for 1L, 1/2L and 2L and beyond, respectively. **Conclusions:** Median time-to-event outcomes of control arms in 1L aTNBC show considerable heterogeneity, even among trials with comparable regimens and large sample sizes. Disregarding important prognostic factors at stratification can lead to imbalances between arms, which may jeopardize accurate sample size calculations, trial results and interpretation. Optimizing stratification and assumptions for power calculations is of utmost importance in aTNBC and beyond. A digitized trial results repository with precisely defined patient populations and treatment settings could improve accuracy of assumptions during clinical trial design. Research Sponsor: None.

miR-503-5p induces doxorubicin resistance in triple-negative breast cancer. *First Author: Iris Garrido-Cano, Biomedical Research Institute INCLIVA, Valencia, Spain*

Background: Triple-negative breast cancer (TNBC) is an aggressive breast cancer (BC) subtype comprising approximately 15% of BC. Conventional cytotoxic chemotherapies continue to be the mainstay for treatment of this BC, which lacks targetable markers. In this context, microRNAs have been described to have an important role. The aim of this work was to elucidate the function of miR-503-5p in doxorubicin resistance in TNBC. **Methods:** miR-503-5p expression was evaluated in the TNBC cell line with acquired resistance to doxorubicin (MDA-MB-231R) and its parental cell line (MDA-MB-231), by qRT-PCR. Studies of gain/loss of function of miR-503-5p were carried out in MDA-MB-231 and MDA-MB-231R cells by transient transfection of mimics and inhibitors. Cells were treated with doxorubicin, and viability was measured by flow cytometry and MTT assay. The role of miR-503-5p was also evaluated *in vivo* by Chicken Chorioallantoic Membrane (CAM) assay. MDA-MB-231 cells transfected with miR-503-5p mimic or scramble miRNA were inoculated onto the CAM of fertilized chicken eggs. After 48 hours, tumours were treated with doxorubicin or supplemented media for 48 hours and tumour growth was measured. miR-503-5p expression was quantified by qRT-PCR in a retrospective cohort of 74 TNBC patients treated with anthracycline + taxane regimens. Overall survival analysis for miR-503-5p in TNBC patients from METABRIC dataset was evaluated by the KM plotter online tool. **Results:** miR-503-5p was significantly upregulated in the resistant MDA-MB-231R TNBC cell line when compared to its parental cell line MDA-MB-231 (~3.5-fold; $p< 0.0001$). Then, gain/loss function assays showed that upregulation of miR-503-5p in MDA-MB-231 cells increased resistance to doxorubicin ($p< 0.0001$) and its downregulation in MDA-MB-231R cells had the opposite effect ($p< 0.0001$). Moreover, the role of miR-503-5p was also confirmed in the CAM assay *in vivo* model, where miR-503-5p overexpression inhibited the effect of doxorubicin. In our cohort of patients, miR-503-5p expression levels in core biopsies sampled before preoperative chemotherapy were associated with residual cancer burden (RCB). miR-503-5p expression was significantly higher in patients with poor response to chemotherapy (RCB II and III; median, 95% CI: 0.00055, 0.00024 - 0.00136) than in patients with good response (RCB 0 and I; median, 95% CI: 0.00018, 0.00011 - 0.00034; $p = 0.036$). Moreover, we confirmed that TNBC patients with high expression of miR-503-5p had worse overall survival than patients with low expression ($p= 0.016$). **Conclusions:** We identified miR-503-5p as a modulator of doxorubicin resistance in TNBC. Our *in vitro* findings are supported by the clinical data of TNBC patients and *in vivo* assays. Hence, the inhibition of miR-503-5p may be a promising strategy to improve chemotherapeutic efficacy. Moreover, the expression levels of miR-503-5p may be used as a biomarker for therapy response in TNBC. Research Sponsor: None.

Distant metastases after diagnosis: Racial disparities in breast cancer outcomes. *First Author: Julia Blanter, Division of Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Black women diagnosed with breast cancer are more likely to have a poor prognosis, regardless of breast cancer subtype. Despite having a lower incidence rate of breast cancer when compared to white women, black women have the highest breast cancer death rate of all racial and ethnic groups, a characteristic often attributed to late stage at diagnosis. Distant metastases are considered the leading cause of death from breast cancer. We performed a follow up study of women with breast cancer in the Mount Sinai Health System (MSHS) to determine differences in distant metastases rates among black versus white women. **Methods:** Women were initially recruited as part of an NIH funded cross-sectional study from 2013-2020 to examine the link between insulin resistance (IR) and breast cancer prognosis. Women self-identified as black or white race. Data was collected via retrospective analysis of electronic medical records (EMR) between September 2020-January 2021. Distant metastases at diagnosis was defined as evidence of metastases in a secondary organ (not lymph node). Stage at diagnosis was recorded for all patients. Distant metastases after diagnosis was defined as evidence of metastases at any time after initiation of treatment. Univariate analysis was performed using Fisher's exact test, multivariate analysis was performed by binary logistic regression, and results expressed as odds ratio (OR) and 95% confidence interval (CI). A p value <0.05 was considered statistically significant. **Results:** We identified 441 women enrolled in the IR study within the MSHS (340 white women, 101 black women). Median follow up time for all women was 2.95 years (median = 3.12 years for white and 2.51 years for black women (p=0.017)). Among these patients, 11 developed distant metastases after diagnosis: 4 (1.2%) white and 7 (6.9%) black (p=0.004). Multivariate analysis adjusting for age, race and stage at diagnosis revealed that black women were more likely to have distant metastasis (OR 5.8, CI 1.3-25.2), as were younger women (OR for age (years) 0.9, CI 0.9-1.0), and those with more advanced stage at diagnosis. **Conclusions:** Black women demonstrated a far higher percentage of distant metastases after diagnosis even when accounting for age and stage. These findings suggest that racial disparities still exist in the development of distant metastases, independent from a late-stage diagnosis. The source of existing disparities needs to be further understood and may be found in surveillance, treatment differences, or follow up. Research Sponsor: U.S. National Institutes of Health.

The impact of radiological assessment schedules on progression-free survival in metastatic breast cancer: A systemic review and meta-analysis. *First Author: Dor Reuven Dabush, Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel*

Background: The impact of the interval of radiological assessment on the magnitude of benefit observed in randomized trials (RCTs) in metastatic breast cancer is undefined. **Methods:** All RCTs investigating anti-neoplastic drugs for metastatic breast cancer published between 2006 and 2019 were identified. Intervals for restaging were categorized as short (<9 weeks) or long ($\geq$9 weeks). Hazard ratios (HRs) and 95% confidence intervals for progression-free survival (PFS) and overall-survival (OS) were pooled in a meta-analysis and compared between trials employing short and long restaging intervals assessed as subgroup analyses. Analyses were repeated for pre-specified subgroups according to disease subtype, drug type, whether experimental therapy was added to or replaced standard treatment and whether HR for PFS was <1 or $\geq$1. **Results:** Eighty-nine studies comprising 95 comparisons and 44,901 patients were included. The magnitude of PFS benefit was non-significantly larger in trials which employed short compared to long restaging intervals (HR 0.79 vs. 0.86, p = 0.15). Short restaging interval was associated with significantly higher magnitude of effect on PFS in pre-specified subgroups including non-first line studies (HR 0.78 vs. 0.92, p = 0.04), studies with drugs replacing standard treatment (HR 0.86 vs. 1.04, p = 0.02) and studies performed exclusively in human epidermal growth factor receptor 2 (HER2) positive disease (HR 0.72 vs. 0.90, p = 0.02). Restaging interval was not associated with OS for all included studies (HR 0.92 vs. 0.93, p = 0.66) or for any of the pre-specified subgroups. **Conclusions:** Shorter restaging intervals are associated with a higher magnitude of effect of PFS, but not OS. Awareness of the impact of the restaging interval on quantification of intermediate endpoints such as PFS is important for the design and interpretation of RCTs. Research Sponsor: None.

A phase 2 study of pamiparib in the treatment of patients with locally advanced or metastatic HER2-negative breast cancer with germline *BRCA* mutation. *First Author: Tao Sun, Liaoning Cancer Hospital & Institute, Shenyang, China*

Background: Breast cancer is the most common cancer among women, with up to 37% of patients (pts) harboring germline *BRCA1/2* mutations (g*BRCA1/2*m) that appear to be sensitive to poly (ADP-ribose) polymerase proteins 1 and 2 (PARP1/2) inhibition. Pamiparib is an orally administered selective PARP1/2 inhibitor that has the potential to cross the blood-brain barrier. This study evaluated the efficacy and safety of pamiparib in pts with locally advanced/metastatic human epidermal growth factor receptor 2-negative (HER2-) breast cancer, with deleterious or suspected deleterious g*BRCA1/2*m, who received $\leq$ 2 prior lines of chemotherapy. **Methods:** In this open-label, phase 2, multi-center study in China (NCT03575065), pts with locally advanced/metastatic HER2- breast cancer with deleterious or suspected deleterious g*BRCA1/2*m triple negative breast cancer (TNBC cohort) or hormone receptor-positive (HR+)/HER2- breast cancer (HR+ cohort) were enrolled. Pts received pamiparib 60 mg orally twice daily in 28-day cycles. The primary endpoint was objective response rate (ORR; RECIST v1.1) by independent review committee (IRC). Secondary endpoints included duration of response (DOR) and progression free survival (PFS) by IRC, overall survival (OS), safety and tolerability. **Results:** 88 pts were enrolled (median age 45.5 years), 76 pts (TNBC cohort n = 55; HR+ cohort n = 21) had measurable disease at baseline per IRC. 60 pts (68.2%) received 1 or 2 prior lines of chemotherapy; 42 pts (47.7%) were treated with platinum previously. Median follow-up was 13.77 months (TNBC cohort, 10.87 months; HR+ cohort, 18.45 months). In the TNBC cohort: confirmed ORR was 38.2% (95% CI: 25.4–52.3); median DOR (mDOR) was 6.97 months (95% CI: 3.94–not estimable[NE]); median PFS (mPFS) was 5.49 months (95% CI: 3.65–7.33); median OS (mOS) was 17.08 months (95% CI:13.70–NE). In the HR+ cohort: confirmed ORR was 61.9% (95% CI: 38.4–81.9); mDOR was 7.49 months (95% CI: 5.55–14.75); mPFS was 9.20 months (95% CI: 7.39–11.93); mOS was not reached (NR; 95% CI 18.10–NE). $\geq$ Grade 3 treatment emergent adverse events (TEAEs) occurred in 54 pts (61.4%); anemia was the most common TEAE, occurring in 77 pts (87.5%). Dose reduction due to TEAEs occurred for 57 pts (64.8%); discontinuations due to TEAEs occurred for 2 pts (2.3%). **Conclusions:** Pamiparib showed a promising response in pts with locally advanced/metastatic HER2- breast cancer with a g*BRCA1/2*m. The safety profile of pamiparib was considered acceptable and was generally consistent with therapies in the same class. Clinical trial information: NCT03575065. Research Sponsor: This trial is sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Yasmin Issop, PhD, and Shannon Galgani, MSci, of Ashfield Medcomms, an Ashfield Health company, and was funded by BeiGene, Ltd.

Efficacy by cohort.

	TNBC (N = 62)	HR(+)/HER2(-) (N = 26)

Survival time in urban center breast cancer patients with CNS metastasis with or without visceral metastasis. *First Author: Miriam Pearl Klahr, Albert Einstein College of Medicine, Bronx, NY*

Background: There is limited data about the role of isolated central nervous system (CNS) metastasis (mets) in patients with breast cancer (BC), since prior studies evaluated BC patients with CNS plus visceral mets. Furthermore, though Black race is associated with worse BC outcomes, there are few studies on CNS mets that predominantly included racial and ethnic minorities in their cohorts. Our study compares overall survival (OS) in BC patients with CNS involvement with and without visceral mets in an underrepresented patient population. **Methods:** This is a retrospective case series study. We used Montefiore's Clinical Looking Glass software to identify patients. Inclusion criteria were females age $\geq$18 years at our institution with the diagnosis of BC and CNS mets between 3/31/1997 to 3/31/2019. Chart review was conducted to obtain clinical-pathological features, including date of diagnosis, treatment, clinical course, and survival status. Patients with BC and CNS mets were divided into two cohorts, those with additional mets limited to bone and lymph nodes but without further visceral spread (CNS-NV), and those with CNS mets plus visceral mets (CNS-V). Kaplan-Meier methods were used to analyze the median OS. **Results:** Our study included a high proportion of underrepresented minorities (n=177); 46.3% were Black, 10.7% were White, and 34.5% were Other Race; besides, 28% were Hispanic. Mean age at diagnosis of CNS mets was 58 years (SD = 12.9). 62.1% were estrogen receptor (ER) and/or progesterone receptor (PR) positive, 27.1% were HER2 positive; and 19.8% were ER, PR and HER2 negative. Mean number of chemotherapy and endocrine therapy lines before CNS mets were 2 (IQR = 1-2) and 1 (IQR = 1-2), respectively. CNS-NV and CNS-V cohorts included 35 and 142 patients, respectively. Patients with CNS-NV had longer OS than CNS-V (2118 vs. 1120 days, p=0.02). Further subgroup analysis for group CNS-NV was performed based on treatment modality. In this cohort, OS was not significantly different between patients who did and did not receive chemotherapy (n =35, mean OS 1509 vs. 960 days, p = 0.49). In addition, OS was not significantly different between patients who received and did not receive endocrine therapy (n = 24, mean OS 857 vs. 1394 days, p = 0.4). Finally, OS did not significantly differ between patients who did and did not receive anti HER2 treatment (n = 11, 1753 vs. 849 days, p = 0.15). **Conclusions:** Minimal research has been conducted on breast cancer patients with CNS mets and distal involvement limited to the bones or lymph nodes. In a heterogenous racial and ethnic population, patients with BC and CNS mets have prolonged OS if the extent of distal involvement is limited to the bones or lymph nodes, compared to those with visceral mets. More research with larger sample sizes is needed to confirm our findings, which may help to de-escalate and tailor treatment for patients with CNS mets. Research Sponsor: None.

1089 **Poster Session**

Clinical and pathological characteristics of breast cancer with resected brain metastasis. *First Author: Shiyuan Anabeth Liu, Washington University School of Medicine, St. Louis, MO*

Background: Breast cancer brain metastasis (BCBM) has poor prognosis and limited therapeutic options. Studies have shown that BCBM may differ from their matched primary tumors in receptor subtypes and genomic characteristics. However, studies have been limited by the tissue availability of BCBM. Taking advantage of our institutional database of resected BCBM with matched primary breast samples, this study aimed to investigate the clinical and pathological characteristics of patients with resected BCBM. **Methods:** We performed retrospective chart review for all breast cancer patients who had resected BCBM samples at our institution over the last 20 years. Hormone receptor (HR) and human epidermal growth factor receptor 2 (HER2) status of the primary breast and BCBM samples, location of BCBM, and extracranial metastases at time of BCBM diagnosis were categorized. Overall survival (OS) from time of BCBM diagnosis was calculated using the Kaplan-Meier method. Progression interval and receptor subtype switching from primary diagnosis to brain metastasis were computed and compared using Wilcoxon rank sum test and Fisher's exact test, respectively. **Results:** Eighty-six patients were included in this study (median age at time of BCBM diagnosis 54.3 [range 28.3-84.0] years, median follow up 26.0 months). These included 47 HR+, 15 HER2+, 20 triple negative (TN), 4 unknown subtype breast samples, and 42 HR+, 18 HER2+, 17 TN and 9 unknown subtype brain samples. OS was significantly shorter in patients with TN compared to HR+ or HER2+ subtype, whether the TN status was in the primary breast tumor (median 20.5 vs 34.0 months, p = 0.04, thresholded at year 2) or in the brain metastasis (median 16.0 vs 34.0 months, p = 0.02, thresholded at year 2). No significant difference in OS was observed between HR+ and HER2+ groups. There was no significant difference in the progression interval from primary diagnosis to brain metastasis among receptor subtypes. From primary tumor to brain metastasis, receptor subtype switching occurred in 10 out of 73 patients (13.7%) for estrogen, 20 out of 70 (28.6%) for progesterone (PR), and 6 out of 72 (8.3%) for HER2. Receptor subtype switching did not significantly correlate with OS. Presence of extracranial metastases at time of BCBM diagnosis corresponded to significantly lower OS compared to no extracranial metastasis (16.5 vs 36.0 months, p = 0.01). No significant difference in OS was observed between patients with cerebral vs cerebellar brain metastases. **Conclusions:** These data indicate that patients with TN BCBM disease have the worst overall survival among all receptor subtypes. Metastases in extracranial sites at time of BCBM diagnosis significantly decreased survival. Location of the brain metastasis and receptor subtype switching from primary diagnosis to BCBM, which was relatively infrequent outside of the PR group, did not significantly correlate with OS in this limited data set. Clinical outcomes in patients (pts) with a history of central nervous system (CNS) metastases receiving talazoparib (TALA) or physician's choice of chemotherapy (PCT) in the phase 3 EMBRACA trial. *First Author: Jennifer Keating Litton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In the EMBRACA trial (NCT01945775) of pts with germline *BRCA1/2*-mutated HER2-negative locally advanced/metastatic breast cancer (ABC), the poly(ADP-ribose) polymerase (PARP) inhibitor TALA significantly improved progression-free survival (PFS) vs PCT (8.6 vs 5.6 mo; HR [95% CI] 0.54 [0.41-0.71]; $P < 0.0001$). Patient-reported outcomes favored TALA, and most common adverse events included anemia, fatigue, and nausea. Previous subgroup analyses found that pts with a history of CNS metastases had improved PFS for TALA vs PCT (HR [95% CI] 0.32 [0.15-0.68]; $P = 0.0016$) and improved objective response rate (ORR) 63.2% vs 15.8%, respectively (odds ratio [95% CI] 8.95 [1.86-52.26]; $P = 0.0013$). This retrospective subgroup analysis further explored the clinical characteristics and outcomes in pts with a history of CNS metastases in EMBRACA. **Methods:** Pts were randomized 2:1 to TALA or PCT. Pts with adequately treated and stable CNS metastases not requiring corticosteroids were included. This analysis assessed intracranial ORR and best overall response (BOR) based on investigator assessment per RECIST 1.1 in pts with intracranial disease at baseline (data cutoff 15-Sep-17), and overall survival (OS; data cutoff 30-Sep-19). **Results:** In the intent-to-treat (ITT) population, 63 pts (43/287 [15.0%] TALA and 20/144 [13.9%] PCT) had a history of CNS metastases, of which 33 (11.5%) pts (TALA) and 15 (10.4%) pts (PCT) had intracranial disease at baseline. Additional baseline characteristics are shown in the table. Intracranial ORR in pts with intracranial disease at baseline and unconfirmed complete or partial response was 18.2% (TALA) vs 20.0% (PCT) (odds ratio [95% CI] 0.78 [0.13-5.80]; $P = 0.765$). In pts with intracranial disease at baseline, an intracranial BOR of stable disease was 69.7% for TALA vs 33.3% for PCT. Median OS in pts with a history of CNS metastases was 12.9 mo (95% CI 9.4-15.6) for TALA and 13.4 mo (95% CI 8.8-17.6) for PCT (HR [95% CI] 0.67 [0.37-1.2]; $P = 0.1936$ [stratified log-rank test]). In the safety population ([n = 43, TALA]; [n = 19, PCT]), median treatment duration (range) with TALA was 5.0 (0.1-36.0) mo compared with 2.1 (0.4-6.9) mo for PCT. **Conclusions:** In this subgroup analysis, baseline characteristics between pts with a history of CNS metastases treated with TALA or PCT were comparable. More pts with intracranial disease at baseline treated with TALA vs PCT experienced stable disease. Intracranial ORR in pts with intracranial disease was 18.2% for TALA vs 20.0% for PCT. Treatment options for pts with a history of CNS metastases are limited and further investigation in larger data sets is warranted. Clinical trial information: NCT01945775. Research Sponsor: Pfizer.

Genomic evaluation of tumor mutational burden-high (TMB-H) versus TMB-low (TMB-L) metastatic breast cancer to reveal unique mutational features. *First Author: Sarah Sammons, Duke University Medical Center, Duke Cancer Institute, Durham, NC*

Background: Tumor mutational burden (TMB) has emerged as an imperfect biomarker of immune checkpoint inhibition (ICI) outcomes in solid tumors. Despite the approval for pembrolizumab in all TMB-high (TMB-H) solid tumors, the optimal clinical approach to TMB-H or hypermutated advanced/metastatic breast cancer (MBC) is unknown with sparse prospective data. We hypothesize that TMB-H MBC will have unique genomic alterations compared to TMB-low (TMB-L) breast cancer that could inform novel therapeutic approaches. **Methods:** Tumor samples (N = 5621) obtained from patients with MBC were analyzed by next-generation sequencing (NGS) of DNA (592-gene panel or whole exome sequencing) and RNA (whole transcriptome sequencing) at Caris Life Sciences (Phoenix, AZ). TMB was calculated based on recommendations from the Friends of Cancer Research TMB Harmonization Project (Merino et al., 2020), with the TMB-H threshold set to ≥ 10 muts/Mb. IHC was performed for PD-L1 (Ventana SP142 ≥1% immune cells). Deficient mismatch repair (dMMR)/high microsatellite instability (MSI-H) was tested by IHC and NGS, respectively. **Results:** TMB-H was identified in 8.2% (n = 461) of MBC samples, with similar frequencies observed across molecular subtypes (7.8-8.6%, p = 0.85): HR+/HER2- (n = 3087) 7.8%, HR+/HER2+ (n = 266) 8.3%, HR-/HER2+ (n = 179) 7.8%, TNBC (n = 1476) 8.6%. The frequency of TMB-H was significantly increased in lobular (16%) versus ductal (5%) MBC ($p < 0.01$). TMB-H samples were enriched in genitourinary (42%), soft tissue (20%), and gastrointestinal non-liver (16%) biopsy specimens. Compared to TMB-L tumors, TMB-H tumors exhibited significantly higher mutation rates for TP53 (60 v 52%), PIK3CA (55 vs 31%), ARID1A (34 vs 11%), CDH1 (27 vs 11%), NF1 (22 vs 9%), RB1 (14 vs 5%), KMT2C (12 vs 7%), PTEN (12 vs 7%), ERBB2 (7 vs 2.9%), and PALB2 (3.3 vs 1%) genes ($p < 0.05$ each). Copy number alteration and fusion rates did not differ between TMB-H and TMB-L breast cancers. PI3K/AKT/MTOR, TP53, Histone/Chromatin remodeling, DNA damage repair (DDR), RAS, and cell cycle pathway alterations were detected in > 25% TMB-H MBCs ($p < 0.05$ each). dMMR/MSI-High (7.2 vs 0.3%, $p < 0.01$) and PD-L1 positivity (36 vs 28%, $p < 0.05$) frequencies were significantly increased in TMB-H tumors. DNA signature analyses including APOBEC and homologous recombination repair deficiency, as well as gene expression profiling to assess immune-related signatures and tumor microenvironment are underway. **Conclusions:** TMB-H breast cancers contain a unique genomic profile enriched with targetable mutations such as PIK3CA, ARID1A, NF1, PTEN, ERBB2, and PALB2. Concurrent predictive biomarkers of response to immune checkpoint inhibition such as MSI-H and PDL-1 positivity are also more prevalent in TMB-H MBC. These findings suggest novel combination strategies within TMB-H MBC could be explored. Research Sponsor: None.

Decreased enrollment of patients with advanced lobular breast cancer compared to ductal breast cancer in interventional clinical trials. *First Author: Mary Kathryn Abel, University of California, San Francisco School of Medicine and Department of Surgery, San Francisco, CA*

Background: Response Evaluation Criteria in Solid Tumors (RECIST) criteria are often used to measure tumor response in cancer trials, especially in the stage IV setting. However, RECIST requires measurable disease, which is less common in invasive lobular breast carcinoma (ILC) of the breast, a diffusely growing tumor type, compared to invasive ductal carcinoma (IDC). We examined the prevalence of RECIST in breast cancer clinical trials, and whether there are differential trial enrollment rates by histology and stage. **Methods:** We analyzed the *clinicaltrials.gov* database to evaluate the proportion of interventional, stage IV clinical trials that require measurable disease as inclusion criteria or outcome measures. We then performed an institutional cohort study comparing the proportion of patients in the University of California, San Francisco (UCSF) OnCore clinical trials management system (CTMS) to the UCSF Cancer Registry between 2000-2018, stratified by histology and stage. We hypothesized that the proportion of patients with ILC in the CTMS would be significantly lower than in the cancer registry. **Results:** There were 146 actively-recruiting, interventional clinical trials for stage IV breast cancer that were identified in our search on *clinicaltrials.gov*. Overall, 108 (74%) required measurable disease for study participation. The UCSF Cancer Registry included 8,679 patients, while the UCSF OnCore CTMS included 1,511 patients (Table). In those with early stage disease, where RECIST is not typically used, there was no difference in the proportion of ILC patients enrolled in clinical trials versus in the cancer registry. However, among those with stage IV disease, there was a significantly lower proportion of patients with ILC in the CTMS than in the cancer registry (9.2% versus 17.9%, p = 0.005). In contrast, patients with stage IV IDC were overrepresented in the clinical trials database compared to the cancer registry. **Conclusions:** Patients with metastatic ILC were significantly less likely to be enrolled in clinical trials than those with metastatic IDC. This decreased enrollment may be due to the widespread use of RECIST, and further investigation is needed to ensure equity in access to clinical trials. Research Sponsor: None.

Two-sample tests of proportion evaluating patients enrolled in the UCSF Cancer Registry compared to the OnCore clinical trial management system (CTMS) by histology and stage.

	UCSF Cancer Registry	OnCore CTMS	P-Value Using Two-Sample Test of Proportions
Study Population	8,697	1,511	0.0486
IDC (n, %)	7320 (84.3%)	1304 (86.3%)	
ILC (n, %)	1359 (15.7%)	207 (13.7%)	
Early Stage (Stage I-III)	8,187	1,337	0.063
IDC (n, %)	6,916 (84.4%)	1,146 (85.7%)	
ILC (n, %)	1271 (15.5%)	191 (14.3%)	
Metastatic (Stage IV)	492	174	0.005

Systemic chemotherapy in patients with brain only metastatic breast cancer: A retrospective analysis. *First Author: Akshjot Puri, Houston Methodist Cancer Center, Houston, TX*

Background: The treatment of patients with brain only metastatic breast cancer (BO-MBC) remains very challenging. There is also very limited literature informing on appropriate treatment or natural history of this entity. Systemic chemotherapy in addition to targeted therapy and/or anti-estrogen treatment is often used, but little is known if it adds to the overall or disease free survival. In this retrospective study, we examine this, as well as other factors which may be associated with increased risk of CNS or systemic recurrence in these patients. **Methods:** A database search at a single institution identified 178 patients with brain metastases (BM) from breast cancer out of which 45 patients had BO-MBC between 2007-2020. We collected demographic, clinical, radiographic and other treatment data. Leptomeningeal disease (LMD) was diagnosed by cerebrospinal fluid (CSF) cytology, neuroimaging, or both. We used the Brookmeyer and Crowley method. **Results:** The patients were followed for a median of 17.9 months; 36 out of 45 patients (80%) received local treatment for BM (surgery/radiation/both) and HER2 directed antibodies or tyrosine kinase inhibitors and/or anti-estrogen treatment, whereas 9 out of 45 patients (20%) received systemic chemotherapy in addition. There were 22 out of 45 (49%) HER2 +, 5 out of 45 (11%) HR + and 18 out of 45 (40%) triple negative breast cancer (TNBC) patients. There were 17 out of 45 patients (38%) who were deemed to have low burden of BM (defined as one to three BM and largest being ≤3 cm) whereas there were 24 out of 45 patients (53%) who had high burden of BM (defined as four or more BM or largest being > 3 cm). **Conclusions:** Patients with BO-MBC represent a distinct entity. Despite having better survival than patients with BM and extra CNS disease these patients have a high risk of developing LMD, CNS and systemic recurrences. The addition of chemotherapy to targeted therapy and/or anti-estrogens does not decrease the rates of systemic or CNS recurrence. The ER+ subset have a lower rate of development of systemic disease, as expected due to their relatively indolent biology. The CNS and systemic recurrence seem to be higher in patients with HER2+ cancers and counterintuitively even in those with low burden of BM; albeit these were statistically insignificant. Research Sponsor: None.

One year estimated time to recurrence	Chemotherapy	No chemotherapy		
Extra CNS	87.5% (95% CI: 38.7%, 98.1%)	81.8% (95% CI: 63.8%, 91.4%)	p=0.64

Metastasectomy versus radiation of secondary sites in stage IV breast cancer. *First Author: Nadeem Bilani, Cleveland Clinic Florida, Weston, FL*

Background: Prospective trials have yielded mixed results on the utility of surgery in metastatic breast cancer (mBC). Thus far, however, studies have focused primarily on the impact of lumpectomy or mastectomy. We previously showed that a combined approach involving resection of primary *and* secondary sites (i.e. 'metastasectomy') in patients with limited mBC was associated with improved overall survival (OS). We sought to evaluate the effect on OS of two approaches to loco-regional therapy (LRT) at secondary sites: metastasectomy versus radiation therapy. **Methods:** This is a retrospective analysis of patients diagnosed with mBC from 2010-2017 using the National Cancer Database. We identified 5 cohorts of patients by site of metastasis: mBC involving only 1) bone, 2) brain, 3) liver, or 4) lung; and 5) patients with metastasis involving >1 site. For each cohort, we used Kaplan-Meier (KM) models with log-rank testing to evaluate differences in OS, by the LRT approach at secondary sites (radiation versus metastasectomy). Prior to KM modeling, chi-squared statistics were used in each cohort to assess whether age, race, Charlson/Deyo score (CDS) for comorbidity, and receptor subtype were potential confounders of survival. The KM models were adjusted accordingly, as per the table below. **Results:** 53.4%) were between 50-70 years old, White (n=53,409, 78.9%), and had hormone receptor (HR)-positive/HER2 receptor-negative breast cancer. N=12,362 patients received radiation therapy at either the bone, brain, liver, or lung; while n=2674 underwent surgical resection of a metastatic site. Of patients with metastasis to 1 site (n=44,451), n=30,341(68.3%) involved the bone, n=1,119 (2.5%) involved the brain, n=5,227 (11.8%) involved the liver, and n=7,764 (17.5%) involved the lung. N=24,017 patients had metastatic disease involving > 1 site. KM modeling revealed superior OS of patients undergoing metastasectomy versus radiation of secondary sites in all 5 cohorts ($p<0.05$). The difference in median OS (ΔmOS) by LRT approach was more pronounced when metastasis involved only the liver (41.6 months) or lung (48.6 months), versus only the brain (9.7 months) or bone (8.7 months). **Conclusions:** Metastasectomy appears to confer a superior benefit for OS compared to radiation of secondary sites, particularly in patients with secondary site involvement limited to the liver or lung. More research is needed from prospective trials investigating surgical resection of metastatic sites. Research Sponsor: None.

		KM Median OS (months)			Log-rank
		Radiation	Metastasectomy	ΔmOS (months)	p-value
1 site of metastasis	Bone only*	39.2	47.9	8.7	0.012
	Brain only	11.9	21.6	9.7	0.006
	Liver only	39.2	80.8	41.6	<0.001
	Lung only	18.2	66.8	48.6	<0.001
>1 site of metastasis**		21.5	31.4	9.9	<0.001

*KM adjusted for age (50-70). **KM adjusted for age (50-70), receptor status (HR+/HER2-), and CDS (0-1).

Survival among patients with untreated metastatic breast cancer. *First Author: Jennifer Kay Plichta, Department of Surgery, Duke University Medical Center, Durham, NC*

Background: Treatments for metastatic breast cancer (MBC) have significantly improved survival for patients who receive treatment, yet data describing the prognosis for untreated patients is lacking. Therefore, we sought to assess the survival outcomes of patients with de novo MBC who did not receive treatment. **Methods:** Adults with MBC at diagnosis (clinical M1 or pathologic M1) were selected from the NCDB (2010-2016) and stratified based on receipt of treatment (treated = received at least one treatment; untreated = received no treatments). Differences between patient groups were tested using Chi-square tests for categorical variables and t-tests for continuous variables. Overall survival (OS) was estimated using the Kaplan-Meier method for the overall cohort and stratified by select patient and/or disease characteristics, and groups were compared with log-rank tests. Cox Proportional Hazards models were used to identify factors associated with OS in the untreated MBC subgroup. **Results:** Of the 53,240 patients with de novo MBC, the median age was 61y (IQR 52-71), and the majority had a comorbidity score of 0 (81.2%). Within this cohort, 49,040 (92.1%) received at least one treatment (treated) and 4,200 (7.9%) had no documented treatments (untreated). Untreated patients were more likely to be older (median 68y vs 61y, $p < 0.001$) and have higher comorbidity scores ($p < 0.001$). Patients with untreated MBC were more likely to have triple negative disease (17.8% vs 12.6%), and a higher disease burden (≥2 metastatic sites: 38.2% untreated vs 29.2% treated, $p < 0.001$). The median unadjusted OS in the untreated subgroup was 2.5mo vs 36.4mo in the treated subgroup ($p < 0.001$). For those who survived at least 1mo post-diagnosis, the median unadjusted OS in the untreated subgroup was 6.9mo vs 37.3mo in the treated subgroup ($p < 0.001$), which increased to 18.6mo and 40.3mo for those who survived at least 3mo post-diagnosis ($p < 0.001$). In the untreated population, unadjusted OS varied by breast cancer subtype (median 3.8mo for HR+/HER2-, vs 2.6mo for HER2+, vs 2.1mo for triple negative, $p < 0.001$) and number of metastatic sites (4.1mo for 1 site, vs 1.8mo for 2 sites, vs 1.1mo for 3 sites, vs 1.2mo for ≥4 sites, $p < 0.001$). After adjustment, variables associated with a worse OS in the untreated cohort included older age, higher comorbidity scores, higher tumor grade, and triple negative (vs HR+/HER2-) tumor subtype (all $p < 0.05$), while the number of metastatic sites was not associated with survival; these same findings were also noted when the analysis was limited to those who survived at least 1mo post-diagnosis. **Conclusions:** Patients with de novo MBC who do not receive treatment are more likely to be older, present with comorbid conditions, and have clinically aggressive disease. Similar to those who do receive treatment, survival in an untreated population is associated with select patient and disease characteristics. However, the prognosis for untreated MBC is dismal. Research Sponsor: None.

Trastuzumab deruxtecan (T-DXd) combinations in patients with HER2-positive advanced or metastatic breast cancer: A phase 1b/2, open-label, multicenter, dose-finding and dose-expansion study (DESTINY-Breast07). *First Author: Fabrice Andre, Gustave Roussy, Université Paris-Sud, Villejuif, France*

Background: HER2-targeted therapies have improved survival in patients (pts) with HER2+ advanced/metastatic breast cancer (mBC) but challenges remain, including resistance to current HER2-targeted therapies. Also, additional treatment options are needed in pts with brain metastases (BM). In the phase 2 DESTINY-Breast01 trial, T-DXd demonstrated efficacy, with an objective response rate (ORR) of 61.4% and median progression-free survival (mPFS) of 19.4 mo in pts with previously treated HER2+ advanced/mBC (Modi SABCS 2020); data from an earlier cutoff of this trial supported approval of T-DXd in the US, Europe, and Japan. In a subgroup analysis of 24 pts with stable BM, T-DXd showed preliminary efficacy, with mPFS of 18.1 mo (Jerusalem ESMO Breast Cancer 2020). Here, we describe a phase 1b/2 trial evaluating the safety and preliminary antitumor activity of T-DXd monotherapy and combinations in pts with HER2+ advanced/mBC, including pts with stable and active BM. **Methods:** DESTINY-Breast07 (NCT04538742) is a global, multicenter, open-label, phase 1b/2 trial designed to evaluate the safety, tolerability, and preliminary antitumor activity of T-DXd monotherapy and combinations in pts with HER2+ advanced/mBC. This study consists of a T-DXd monotherapy module (module 0) and 5 combination modules of T-DXd plus (1) durvalumab, (2) pertuzumab, (3) paclitaxel, (4) durvalumab + paclitaxel, or (5) tucatinib, all in pts with no or stable BM. Two additional modules consisting of (6) T-DXd + tucatinib and (7) T-DXd monotherapy will include pts with untreated BM not requiring local therapy or previously treated BM that have progressed since local therapy (active BM). The need for chronic steroids or local therapy to manage BM symptoms is exclusionary. Modules 2 to 5 will each consist of 2 parts: dose finding (part 1) and dose expansion (part 2). Modules 0, 1, 6, and 7 will include part 2 only. Part 1 of individual modules will enroll pts who have had disease progression while receiving ≥1 prior line of therapy in the metastatic setting. In part 2, pts who have received no prior therapy (modules 0 to 5) or ≤1 prior therapy (modules 6 to 7) for metastatic disease will be randomized to receive a T-DXd combination regimen or monotherapy. The primary endpoints are determination of the recommended phase 2 doses (part 1 only) and safety and tolerability of T-DXd and combinations (parts 1 and 2). Secondary endpoints include ORR, PFS, PFS2, duration of response (DoR), and overall survival (all assessed in part 2 only) and pharmacokinetics and immunogenicity (parts 1 and 2). To assess central nervous system (CNS) activity, exploratory endpoints were added, including CNS-ORR, CNS-DoR, and CNS-PFS (by RECIST version 1.1 and RANO-BM criteria) as well as cognitive and symptom assessment using CANTAB, MDASI-BT, and NANO. Clinical trial information: NCT04538742. Research Sponsor: AstraZeneca.

TPS1097 **Poster Session**

HER2CLIMB-04: Phase 2 open label trial of tucatinib plus trastuzumab deruxtecan in patients with HER2+ unresectable locally advanced or metastatic breast cancer with and without brain metastases (trial in progress). *First Author: Ian E. Krop, Dana-Farber Cancer Institute, Boston, MA*

Background: Tucatinib (TUC) is an oral, reversible, small molecule tyrosine kinase inhibitor highly selective for human epidermal growth factor receptor 2 (HER2) with minimal inhibition of human epidermal growth factor receptor (EGFR). In the pivotal, randomized HER2CLIMB trial (NCT02614794), the combination of TUC + trastuzumab (T) + capecitabine (C) demonstrated statistically significant and clinically meaningful improvements in progression free survival (PFS), overall survival (OS), and PFS in patients (pts) with brain metastases (BM), compared to T + C alone. These data supported regulatory approvals in the US and internationally for TUC in combination with T + C in pts with HER2+ metastatic breast cancer (MBC). Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate of trastuzumab and a topoisomerase I inhibitor payload approved in the US for treatment of HER2+ MBC in pts who have received 2 or more prior anti-HER2 regimens in the metastatic setting. Approval was based on data from the single arm Destiny-Breast01 trial (NCT03248492) where treatment with T-DXd resulted in a confirmed objective response rate (cORR) of 61.4% (95% CI: 54.0, 68.5) in pts with HER2+ MBC who had prior ado-trastuzumab emtansine treatment. Despite these advances, HER2+ MBC remains incurable, and pts will eventually progress on currently available therapies. Combining TUC and T-DXd may result in further improvement on the efficacy seen with either agent alone. **Methods:** HER2CLIMB-04 (NCT04539938) is a single arm, open-label phase 2 trial evaluating safety and antitumor activity of TUC + T-DXd in pts with HER2+ unresectable locally-advanced or MBC who have received 2 or more prior HER2-based regimens in the metastatic setting. Pts with BM, including active BM, may be enrolled. Ten pts will be enrolled in the safety lead-in portion of the trial and followed for at least 1 cycle. If safety of the combination is acceptable, the trial will continue until approximately 60 response-evaluable pts have been enrolled, approximately evenly distributed between pts with and without BM. The primary endpoint is cORR by investigator (INV) per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Secondary endpoints are PFS, duration of response (DOR), and disease control rate (DCR) by INV per RECIST v1.1, OS, and safety. Exploratory endpoints will include cORR, PFS, DOR, DCR by independent central review per RECIST v1.1, pharmacokinetic analyses, biomarker analyses, and changes in patient-reported outcomes using the European Quality of Life 5-Dimension 5-Level instrument. Enrollment began in late 2020 in the United States. Clinical trial information: NCT04539938. Research Sponsor: Seagen Inc.

TPS1098 **Poster Session**

Trial in progress: A phase 1b/2 study of the PARP inhibitor niraparib in combination with trastuzumab in patients with metastatic HER2+ breast cancer (TBCRC 050). *First Author: Erica Michelle Stringer-Reasor, University of Alabama at Birmingham, Birmingham, AL*

Background: Approximately 20% of breast cancers (BC) express the human epidermal growth factor receptor 2 (HER2). Although HER2-directed therapies result in improved patient outcome, resistance ultimately occurs. Poly (ADP-Ribose) polymerase (PARP) inhibitors are currently indicated in cancers that express germline mutations in the DNA repair proteins BRCA1/2 due to their synthetic lethality against the homologous recombination repair (HR) pathway. In addition to its role in DNA damage repair, PARP1 has also been implicated in other cellular functions, including co-activation of genes such as NF-κB, which regulate tumor proliferation and HER2 drug resistance. Our group identified that HER2+ BC overexpress the PARP1 and phospho-p65 protein. In HER2+ BC cells and animal models, PARP inhibitors initiated apoptosis independent of a DNA repair deficiency, via inhibition of NF-kB signaling. Key proteins (p65, IKK-α) of the NF-κB-mediated growth pathways were reduced and IκBα was increased in the presence of PARPi, implicating another oncologic pathway in which HER2+ BC cells may be dependent. **Methods**: The study is a phase 1b/2, multicenter, single arm clinical trial evaluating the safety and efficacy of niraparib 200 mg orally days 1-21 with trastuzumab 6 mg/kg (cycle 1 loading dose of 8 mg/kg) intravenously on day 1 of a 21-day cycle for patients with unresectable or metastatic HER2+ BC. Eligible patients include metastatic HER2+ BC, progression on at least 1 prior HER2-targeted therapy, measurable disease, ECOG PS 0-1, and LVEF $\geq$ 50%. Stable/treated CNS disease allowed. Prior PARPi and known germline BRCA 1/2 excluded. Forty patients will be enrolled at 7 US sites within the Translational Breast Cancer Research Consortium. The primary objectives are determining the dose-limiting toxicity (DLT) of the combination and assessing the objective response rate. The phase 1b cohort has been completed (N=6). Enrollment in phase 2 began February 2021 with a total accrual goal of 40. Gehan's two-stage design will be used assuming the response rate is at least 24% and the response rate will be estimated with Clopper-Pearson exact method. Correlative aims include assessing blood and tissue biomarkers (e.g. PARP1, p65, phosphor-p65, let-7a miRNA, NF-kB, ctDNA, etc.) for association with clinical benefit and to predict response to therapy. Clinical trial information: NCT03368729. Research Sponsor: TESARO/GSK, Other Foundation.

TPS1099 **Poster Session**

Trial in progress: Phase I/II study of radiation therapy followed by intrathecal trastuzumab/pertuzumab in the management of HER2$^+$ breast leptomeningeal disease. *First Author: Kamran A. Ahmed, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: HER2$^+$ breast cancer patients with leptomeningeal disease (LMD) represent a poor prognosis population with a high unmet clinical need. Although a multitude of treatment options are available for the management of systemic disease, once metastases travel to the leptomeninges, patients have a lack of treatment options aside from traditional local approaches. Data from a phase I/II study reveals intrathecal (IT) trastuzumab to be well tolerated with improved overall survival (OS) compared to historical controls in HER2$^+$ breast LMD. Radiotherapy can improve the flow of IT therapy through the cerebrospinal fluid (CSF) and provide symptomatic relief. The monoclonal antibody pertuzumab is used in conjunction with trastuzumab in the management of metastatic and localized HER2$^+$ breast cancer. Given the role of radiotherapy in the management of LMD along with the role of pertuzumab in the management of HER2$^+$ breast cancer, there is a strong clinical rationale to combine radiotherapy with IT trastuzumab/pertuzumab in the management of HER2$^+$ breast LMD. **Methods:** The study is designed as a prospective, single-arm, nonrandomized, open-label, phase I/II trial of radiation therapy followed by IT trastuzumab/pertuzumab in the management of HER2$^+$ breast LMD. HER2$^+$ LMD patients identified by magnetic resonance imaging (MRI) and/or CSF cytology, $\geq$ 18, with a life expectancy $>$ 8 weeks are eligible. Treatment is initiated with radiotherapy, whole brain radiotherapy and/or focal brain/spine radiation followed by IT trastuzumab/pertuzumab. Safety and feasibility will be monitored by a modified toxicity probability interval-2 (mTPI-2) design. Dose reductions of IT trastuzumab will not be allowed. Once the maximum tolerated dose of IT pertuzumab is determined, the phase II portion of the study will commence to determine OS. Secondary objectives involve defining the CSF pharmacokinetics of IT trastuzumab/pertuzumab, evaluating the response rate (leptomeningeal and parenchymal), and progression free survival (leptomeningeal and parenchymal) following IT trastuzumab/pertuzumab. In the phase 2 portion, a single-arm two-stage trial is designed using the Restricted-Kwak-and-Jung's Method. The primary endpoint is one-year OS. An interim analysis will be performed after 20 patients are enrolled. This study is open with 1 patient enrolled at the time of submission. Clinical trial information: NCT04588545. Research Sponsor: Genentech.

TPS1100 **Poster Session**

acelERA Breast Cancer (BC): Phase II study evaluating efficacy and safety of giredestrant (GDC-9545) versus physician's choice of endocrine monotherapy in patients (pts) with estrogen receptor-positive, HER2-negative (ER+/HER2-) locally advanced or metastatic breast cancer (LA/mBC). *First Author: Miguel Martin, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: The standard-of-care therapy for ER+ BC typically involves modulation of estrogen synthesis and/or ER activity. Despite disease progression with standard treatments, growth and survival of the majority of tumors are thought to remain dependent on ER signaling; therefore, pts with ER+ BC can still respond to second- or third-line endocrine treatment (ET) after progression on prior therapy (Di Leo 2010; Baselga 2012). *ESR1* mutations may drive estrogen-independent transcription and proliferation leading to resistance. The highly potent, nonsteroidal oral selective ER degrader, giredestrant, achieves robust ER occupancy and is active regardless of *ESR1* mutation status. Phase I data have shown that giredestrant is well tolerated and active both as a single agent and in combination with the cyclin-dependent kinase 4/6 inhibitor (CDK4/6i), palbociclib (Lim 2020). Single-agent giredestrant has also shown encouraging antitumor activity in pts previously treated with fulvestrant and/or a CDK4/6i. **Methods:** acelERA BC (NCT04576455) is a randomized, open-label, multicenter phase II study evaluating the efficacy and safety of giredestrant vs. physician's choice of ET (fulvestrant or aromatase inhibitor) in males, or postmenopausal or pre/perimenopausal females with ER+/HER2– LA/mBC who have received 1–2 prior lines of systemic therapy in the LA or mBC settings, at least one of which must be ET. Randomization: 1:1 to receive giredestrant (30 mg PO QD on Days 1–28 of each 28-day cycle) or physician's choice of ET per local guidelines. Men and pre-/perimenopausal women will receive a luteinizing hormone-releasing hormone agonist. Eligibility: $\geq$18 years, ECOG PS 0–1, histologically or cytologically confirmed diagnosis of LA (recurrent or progressed) or metastatic adenocarcinoma of the breast, measurable disease (per modified RECIST v1.1) or evaluable bone lesions, and ER+/HER2– tumors (locally assessed). Primary endpoint: progression-free survival (PFS; investigator-assessed per RECIST v1.1). Secondary endpoints: overall survival, objective response rate, duration of response, clinical benefit rate, PFS in pts with baseline *ESR1* mutations, and quality of life. Safety, pharmacokinetics, biomarkers, and health status utility will also be assessed. Stratification: site of disease (visceral vs. nonvisceral), prior treatment with CDK4/6i (yes vs. no), and prior treatment with fulvestrant (yes vs. no). PFS will be compared using a stratified log-rank test; median PFS, using Kaplan–Meier analyses. Recruitment for the global enrollment phase is ongoing, the first patient was enrolled November 27, 2020. Clinical trial information: NCT04576455. Research Sponsor: F. Hoffmann-La Roche Ltd.

TPS1101 **Poster Session**

SERENA-4: A phase 3 comparison of AZD9833 (camizestrant) plus palbociclib, versus anastrozole plus palbociclib, for patients with ER-positive, HER2-negative advanced breast cancer who have not previously received systemic treatment for advanced disease. *First Author: Seock-Ah Im, Seoul National University Hospital, Seoul, South Korea*

Background: More than two thirds of patients with advanced breast cancer (ABC) have estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2−) tumors. Current standard-of-care first-line treatments include an aromatase inhibitor (AI) or fulvestrant, a selective ER degrader (SERD), combined with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors. Concurrent use of luteinizing hormone-releasing hormone (LHRH) agonists is recommended for men and premenopausal women with ABC. Nevertheless, almost all ABCs eventually become resistant to endocrine therapy (ET) and the disease is incurable. New therapies are needed to combat ET resistance, maintain patient quality of life (QoL), and delay the need for chemotherapy. AZD9833 (camizestrant) is an orally bioavailable, highly potent, next-generation SERD that demonstrated anti-cancer properties across a range of preclinical models, including those with ER-activating mutations (Scott *et al*, 2020). A phase I study (SERENA-1) has demonstrated that AZD9833 is well tolerated and has a promising antitumor profile when administered alone or in combination with palbociclib, a CDK4/6 inhibitor (Baird *et al*, *SABCS* 2020). SERENA-4 (NCT04711252) is a randomized, multicenter, double-blind, phase III trial to evaluate the safety and efficacy of AZD9833 in combination with palbociclib for patients with ER+ HER2− ABC who have not received any systemic treatment in the advanced disease setting. **Methods:** SERENA-4 will enroll 1,342 patients with *de novo* or recurrent ER+ HER2– ABC who have not previously received systemic treatment for their locoregionally recurrent or metastatic disease. Patients with recurrent disease must have received adjuvant AI or tamoxifen therapy for at least 24 months without relapse. Patients will be randomized 1:1 to receive orally either (a) AZD9833 (75 mg, once daily), palbociclib (125 mg, once daily for 21 days followed by 7 days off treatment) and anastrozole-matching placebo (once daily) or (b) anastrozole (1 mg, once daily), palbociclib (same as active arm), and AZD9833-matching placebo (once daily). Premenopausal women and men will also receive LHRH agonists. The primary endpoint will be progression-free survival (PFS; up to 5 years). Secondary endpoints will include overall survival (up to 8 years), length of second PFS period, objective response, time to chemotherapy, and changes in QoL measures. Enrollment began in January 2021. Acknowledgments: We thank Rose Goodchild, PhD, of Oxford PharmaGenesis, UK, for providing medical writing assistance. Funding: The SERENA-4 trial is funded and overseen by AstraZeneca. Clinical trial information: NCT04711252. Research Sponsor: AstraZeneca.

TPS1102 **Poster Session**

Saci-IO HR+: Randomized phase II trial of sacituzumab govitecan (SG) +/- pembrolizumab in PD-L1+ hormone receptor-positive (HR+) / HER2- metastatic breast cancer (MBC). *First Author: Ana Christina Garrido-Castro, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune checkpoint inhibitors (ICIs) have not yet benefited most patients with MBC. In HR+ MBC, the first randomized trial combining an ICI with chemotherapy demonstrated no clinical benefit with the addition of pembrolizumab to eribulin.[1] The optimal ICI combination agent to overcome primary resistance in HR+ MBC is unknown. One promising agent is the anti-Trop-2-SN-38 antibody drug conjugate (ADC) SG, which led to median progression-free survival (PFS) of 5.5 months in HR+ MBC refractory to endocrine therapy.[2] This ADC may boost anticancer immunity by binding immune cell receptors to promote antibody-dependent cellular cytotoxicity.[3] In addition, the SN-38 payload of SG is the active metabolite of irinotecan, which depletes regulatory T cells, upregulates MHC class I and PD-L1 expression, and augments the antitumor activity of anti-PD-1/L1 antibodies in murine tumor models.[4] The irinotecan analogue camptothecin also enhances CD8+ cytotoxic T cell effector functions and antitumor immune responses by inhibiting NR4A transcription factors,[5] which have recently been shown to play a central role in inducing the T cell dysfunction associated with chronic antigen stimulation in solid tumors. **Methods**: This is a multi-center 1:1 randomized phase II trial to investigate whether the addition of pembrolizumab (200 mg IV every 3 weeks) to SG (10 mg/kg IV days 1+8 every 21 days) improves PFS compared to SG alone in HR+ HER2- MBC that is PD-L1+ by central assessment with 22C3 combined positive score (CPS) $\geq$ 1 (NCT04448886). Key eligibility criteria include at least 1 prior hormonal therapy and no more than 1 prior chemotherapy for HR+ MBC. Eligible patients must have evaluable disease, and previously treated brain metastases are permitted. Exclusion criteria include prior treatment with SG, irinotecan, and PD-1/L1 inhibitors. Based on a sample size of 110 patients, the trial has 80% power to detect a 3-month difference in median PFS from 5.5 months in the SG-alone cohort to 8.5 months in the SG + pembrolizumab cohort with a one-sided alpha of 0.1. Participants undergo mandatory baseline and on-treatment research biopsies if their disease is safely accessible. Tumor biopsies will be evaluated for Trop-2, immune cells, inhibitory checkpoints, transcriptomic signatures, and genomic alterations. Stool specimens will be submitted for microbiome analyses, and health-related quality of life will be assessed. The trial is currently open and enrolling patients. TPS1103 **Poster Session**

persevERA Breast Cancer (BC): Phase III study evaluating the efficacy and safety of giredestrant (GDC-9545) + palbociclib versus letrozole + palbociclib in patients (pts) with estrogen-receptor-positive, HER2-negative locally advanced or metastatic BC (ER+/HER2– LA/mBC). *First Author: Nicholas C. Turner, Royal Marsden Hospital, London, United Kingdom*

Background: Modulating estrogen synthesis and/or ER activity is the mainstay of treatment for pts with ER+ BC. Despite substantial progress, many pts experience relapse during/after adjuvant endocrine therapy. However, even though resistant to aromatase inhibitors (AIs) or tamoxifen, growth and survival of the majority of tumors are thought to remain dependent on ER signaling. Therefore, pts with ER+ BC can still respond to second- or third-line endocrine treatment after progression on prior therapy (Di Leo 2010; Baselga 2012). Therapeutic resistance can arise from mutations in *ESR1*, which can drive estrogen-independent transcription and proliferation. The highly potent, non-steroidal oral selective ER degrader giredestrant achieves robust ER occupancy and is active regardless of *ESR1* mutation status. Phase I data indicate that giredestrant is well tolerated, with encouraging activity as a single agent and in combination with the CDK4/6 inhibitor palbociclib (Lim 2020). Single-agent activity was observed after prior treatment with fulvestrant and/or a CDK4/6 inhibitor (Jhaveri 2019). **Methods:** persevERA BC (NCT04546009) is a double-blind, placebo-controlled, randomized, multicenter phase III study designed to evaluate the efficacy and safety of first-line giredestrant + palbociclib in pts with ER+/HER2– LA/mBC. Randomization: 1:1 to either giredestrant (30 mg PO) plus letrozole placebo QD or letrozole (2.5 mg PO) plus giredestrant placebo QD on Days 1–28 of each 28-day cycle, with palbociclib (125 mg PO QD) on Days 1–21 of each 28-day cycle. Men and premenopausal women will receive an LHRH agonist. Eligibility: females or males $\geq$18 years old with measurable disease or evaluable bone disease and no prior treatment for advanced disease. Pts who received prior fulvestrant or who have relapsed within 12 months of completion of (neo)adjuvant therapy with an AI and/or prior therapy with CDK4/6 inhibitor are not eligible; relapse during tamoxifen therapy but $>$ 24 months after the start of tamoxifen therapy is allowed. Stratification: site of disease, disease-free interval since the end of (neo)adjuvant therapy, menopausal status, and geographic region. Primary efficacy endpoint: progression-free survival (determined locally by the investigator per RECIST v1.1). Secondary endpoints include overall survival, objective response rate, duration of response, clinical benefit rate, QoL, and safety. Enrollment is open (first patient in: Oct 9, 2020); target recruitment is 978 pts across all sites in a global enrollment phase. After completion of the global enrollment, additional pts may be enrolled in China. Clinical trial information: NCT04546009. Research Sponsor: F. Hoffmann-La Roche Ltd, Basel, Switzerland.

TPS1104 **Poster Session**

AMEERA-5: A randomized, double-blind phase III study of amcenestrant (SAR439859) + palbociclib versus letrozole + palbociclib for previously untreated ER+/HER2- advanced breast cancer. *First Author: Aditya Bardia, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Selective estrogen receptor degraders (SERDs) block estrogen receptor (ER) associated signaling and have created interest for treating patients (pts) with advanced ER+ breast cancer (BC). Fulvestrant is currently the only SERD available for advanced BC but requires intramuscular administration, limiting the applied dose, exposure and receptor engagement. Amcenestrant (SAR439859) is an oral SERD that binds with high affinity to both wild-type and mutant ER, blocking estradiol binding and promoting up to 98% ER degradation in preclinical studies. In the phase I AMEERA-1 study of pretreated pts with ER+/HER2- advanced BC, amcenestrant 150–600 mg once daily (QD) showed a mean ER occupancy of 94% with plasma concentrations $>$ 100 ng/mL and a favorable safety profile (Bardia, 2019; data on file). Combination therapy with amcenestrant + palbociclib (palbo) was also evaluated as part of this ongoing phase I study. CDK 4/6 inhibitors (CDK4/6i) combined with an aromatase inhibitor (AI), the gold standard for first line treatment for advanced breast cancer, prolong progression free survival (PFS) in pts with no prior treatment for ER+/HER2- advanced BC, but OS benefit has not been shown yet in postmenopausal pts. There remains a clinical need for more effective treatments in this setting. **Methods:** AMEERA-5 (NCT04478266) is an ongoing, prospective, randomized, double-blind phase III study comparing the efficacy and safety of amcenestrant + palbo with that of letrozole + palbo in pts with advanced, locoregional recurrent or metastatic ER+/HER2- BC who have not received prior systemic therapy for advanced disease. The study includes men, pre/peri-menopausal (with goserelin) and post-menopausal women. Pts with progression during or within 12 months of (neo)adjuvant endocrine therapy using any of the following agents are excluded: AI, selective estrogen receptor modulators, CDK4/6i. Pts are randomized 1:1 to either continuous amcenestrant 200 mg or letrozole 2.5 mg QD orally with matching placebos; both combined with palbo 125 mg QD orally (d1–21 every 28-d cycle). Randomization is stratified according to disease type (de novo metastatic vs recurrent disease), the presence of visceral metastasis, and menopausal status. The primary endpoint is investigator assessed progression free survival (PFS) (RECIST v1.1). Secondary endpoints are overall survival, PFS2, objective response rate, duration of response, clinical benefit rate, pharmacokinetics of amcenestrant and palbo, health-related quality of life, time to chemotherapy, and safety. Biomarkers will be measured in paired tumor biopsies and cell free deoxyribonucleic acid (cfDNA) over time. Target enrolment = 1066 pts; enrolment as of 1/2021 = 33 pts. Bardia A, et al., *J Clin Oncol*. 2019; 37 (15 suppl):1054 Clinical trial information: NCT04478266. Research Sponsor: Sanofi.

TPS1105 **Poster Session**

BEGONIA: Phase 1b/2, open-label, platform study of the safety and efficacy of durvalumab (D) ± paclitaxel (P) with novel oncology therapies for first-line metastatic triple-negative breast cancer (mTNBC): Addition of arm 7, D + datopotamab deruxtecan (Dato-DXd; DS-1062). *First Author: Peter Schmid, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

Background: Patients (pts) with mTNBC have limited treatment options and poor prognosis. The combination of immune checkpoint inhibitors with chemotherapy shows promise, but only a subset of pts with mTNBC derive benefit, highlighting the need for new combinations. BEGONIA is an ongoing Simon 2-stage, multicenter, multi-arm platform study evaluating the safety and efficacy of D, an anti–PD-L1 monoclonal antibody, with or without P, in combination with novel oncology therapies as first-line treatment for mTNBC (NCT03742102). Dato-DXd is an antibody-drug conjugate (ADC) consisting of a humanized anti-trophoblast cell surface antigen 2 (TROP2) IgG1 monoclonal antibody, a stable tetrapeptide-based cleavable linker, and a topoisomerase I inhibitor payload. Dato-DXd displayed encouraging clinical activity with a manageable safety profile in heavily pretreated pts with metastatic NSCLC in the phase 1 TROPION-PanTumor01 (NCT03401385) study. TROP2 is highly expressed on breast and other epithelial tumors, and a TROP2 ADC showed activity in heavily pretreated pts with mTNBC (Bardia, *NEJM* 2019). **Methods:** Eligible female pts are aged ≥18 years with untreated unresectable, locally advanced or mTNBC, ≥12 months since prior taxane therapy, ECOG PS 0/1, adequate organ function, and ≥1 nonirradiated measurable lesion. For Arm 7, pts are excluded if they have clinically significant corneal disease, history of interstitial lung disease/pneumonitis, underlying pulmonary disorder, or prior treatment with an ADC containing a topoisomerase I inhibitor. Arm 7 will evaluate D (1120 mg) + Dato-DXd (6 mg/kg) given intravenously every 3 weeks until disease progression or unacceptable toxicity. Part 1 of each arm includes a total of 30 pts with a safety run-in (n=6) to observe dose-limiting toxicities, identify the recommended phase 2 dose (RP2D), and detect an efficacy signal for part 1 expansion. The primary endpoint of part 1 is safety and tolerability. Secondary endpoints include investigator-assessed objective response rate (ORR), duration of response, progression-free survival (PFS), and overall survival (OS). Once the RP2D has been established for part 1, a futility analysis will be performed with an option to expand the cohort to an additional 27 pts if expansion criteria are met. The primary endpoint for part 1 is ORR. Tumors will be assessed every 6 weeks per RECIST v1.1. Kaplan-Meier analysis will be used for PFS and OS. PD-L1 and TROP2 expression will be assessed by immunohistochemistry. Enrollment is ongoing. Clinical trial information: NCT03742102. Research Sponsor: AstraZeneca, Pharmaceutical/Biotech Company.

TPS1106 **Poster Session**

Saci-IO TNBC: Randomized phase II trial of sacituzumab govitecan (SG) +/- pembrolizumab in PD-L1– metastatic triple-negative breast cancer (mTNBC). *First Author: Ana Christina Garrido-Castro, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune checkpoint inhibitors (ICIs) have not yet benefited most patients with breast cancer. In mTNBC, ICIs combined with chemotherapy have improved survival only in PD-L1+ mTNBC. The optimal ICI combination agent to overcome primary resistance in PD-L1– mTNBC is unknown. One promising agent is the anti-Trop-2-SN-38 antibody drug conjugate (ADC) SG, which led to median progression-free survival (PFS) of 5.6 months in mTNBC with ≥2 prior lines of chemotherapy.[1] This ADC may boost anticancer immunity by binding immune cell receptors to promote antibody-dependent cellular cytotoxicity.[2] In addition, the SN-38 payload of SG is the active metabolite of irinotecan, which depletes regulatory T cells, upregulates MHC class I and PD-L1 expression, and augments the antitumor activity of anti-PD-1/L1 antibodies in murine tumor models.[3] The irinotecan analogue camptothecin also enhances CD8+ cytotoxic T cell effector functions and antitumor immune responses by inhibiting NR4A transcription factors,[4] which have recently been shown to play a central role in inducing the T cell dysfunction associated with chronic antigen stimulation in solid tumors. **Methods**: This is a multi-center 1:1 randomized phase II trial to investigate whether the addition of pembrolizumab (200 mg IV every 3 weeks) to SG (10 mg/kg IV days 1+8 every 21 days) improves PFS compared to SG alone in mTNBC that is PD-L1– by standard of care testing with 22C3 CPS < 10 or SP142 immune cells $< 1\%$ (NCT04468061). Key eligibility criteria include no prior systemic therapy for mTNBC and evaluable disease. Previously treated brain metastases are permitted. Exclusion criteria include prior treatment with SG, irinotecan, and PD-1/L1 inhibitors. Based on a sample size of 110 patients per arm, the trial has 80% power to detect a 3-month difference in median PFS from 5.5 months in the SG-alone cohort to 8.5 months in the SG + pembrolizumab cohort with a one-sided alpha of 0.1. Participants undergo mandatory baseline and on-treatment research biopsies if their disease is safely accessible. Tumor biopsies will be evaluated for Trop-2, immune cells, inhibitory checkpoints, transcriptomic signatures, and genomic alterations. Stool specimens will be submitted for microbiome analyses, and health-related quality of life will be assessed. The trial is currently open and enrolling patients. TPS1107 **Poster Session**

Trial in progress: A phase 3, randomized, double-blind trial of trilaciclib versus placebo in patients receiving first- or second-line gemcitabine and carboplatin for locally advanced unresectable or metastatic triple-negative breast cancer (PRESERVE 2). *First Author: Shom Goel, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Trilaciclib is an intravenous (IV), highly potent and selective, reversible cyclin-dependent kinase (CDK) 4/6 inhibitor that protects hematopoietic stem and progenitor cells during chemotherapy (myeloprotection) and may directly enhance antitumor immunity (anticancer efficacy). In a randomized phase 2 trial of trilaciclib administered prior to gemcitabine and carboplatin (GC) versus GC alone in advanced/metastatic triple-negative breast cancer (mTNBC), although the primary endpoint of myeloprotection was not met, the addition of trilaciclib resulted in a substantial improvement in median overall survival (OS; 19.8 months with trilaciclib vs 12.6 months with placebo, hazard ratio [95% CI] = 0.37 [0.21–0.63]; O'Shaughnessy et al. SABCS 2020 [PD1-06]). Clinically meaningful improvements in OS and progression-free survival (PFS) were also observed in both programmed death ligand-1 (PD-L1)–positive and –negative subsets. **Methods:** The PRESERVE 2 trial (EudraCT: 2020-004930-39) is a randomized, double-blind, placebo-controlled, international phase 3 trial evaluating the efficacy of trilaciclib administered prior to GC in patients with mTNBC. Two mTNBC patient populations will be studied and analyzed separately: cohort 1 (N = 170) will evaluate first-line, PD-1/PD-L1 inhibitor–naïve patients with ≥6 months between completion of last curative treatment and first recurrence; cohort 2 (N = 80) will evaluate second-line PD-L1–positive patients following ≥4 months of PD-1/PD-L1 inhibitor therapy in the advanced setting. Key eligibility criteria for both cohorts include age ≥18 years, Eastern Cooperative Oncology Group performance status of 0/1, and available tumor tissue. Patients will be randomized (1:1) to trilaciclib 240 mg/m^2 or placebo prior to gemcitabine 1000 mg/m^2 and carboplatin area under the curve 2 IV on days 1 and 8, every 21 days. Stratification factors (cohort 1 only) include tumor PD-L1 status by Ventana SP-142 IVD assay, disease-free interval, and country. Study treatment will continue until progressive disease per RECIST v1.1, unacceptable toxicity, or investigator/patient decision, after which, patients will be followed every 3 months for survival. Up to 80 patients will be consented for optional paired baseline and on-treatment biopsies. Archival tissue and serial peripheral blood will be collected from all patients. The primary endpoint is OS, and the key secondary endpoint is time to confirmed deterioration in fatigue. Other secondary endpoints include PFS, myeloprotection, and safety/tolerability. Exploratory endpoints will assess pharmacodynamic parameters, including those related to immune-based mechanisms, and efficacy by CDK4/6-dependence signatures. Study enrollment is open. Clinical trial information: 2020-004930-39. Research Sponsor: G1 Therapeutics, Inc.

TPS1108 **Poster Session**

NBE-002: A novel anthracycline-based antibody-drug conjugate (ADC) targeting ROR1 for the treatment of advanced solid tumors—A phase 1/2 clinical trial. *First Author: Anthony W. Tolcher, NEXT Oncology, San Antonio, TX*

Background: The receptor tyrosine kinase-like orphan receptor 1 (ROR1) is highly expressed during embryonic development, but is minimally present or absent on postpartum healthy tissues. ROR1 is expressed in a variety of hematological and solid tumors and is associated with aggressive cancer phenotype and poor clinical outcomes. NBE-002 is an ADC targeting ROR1, obtained by site-specific, enzymatic conjugation of the anthracycline-derivative PNU-159682, modified with a non-cleavable linker to a humanized recombinant IgG1 monoclonal antibody, based on a novel anti-human ROR1 monoclonal antibody XBR1-402 (Peng et al. (2017) J. Mol. Biol. 429: 2954-73). Direct anti-tumor activity of NBE-002 was evaluated in immunodeficient, ROR1 expression-low/-intermediate/-high PDX models of several carcinoma and sarcoma subtypes. The most pronounced anti-tumor effect was achieved in triple-negative breast cancer (TNBC), at doses as low as 0.033 mg/kg, suggesting a best-in-class therapeutic index in light of the high tolerability in preclinical toxicology models. Administration in a fully immune competent setting (EMT6/ROR1 orthotopic breast cancer model) led to a strong anti-tumor response and a long-lasting anti-tumor immune protection dependent on CD8 T cells. **Methods:** NBE-002-01 (NCT04441099) is a first-in-human, open-label, multi-center, phase (Ph) 1/2 study of NBE-002 in adult patients with advanced solid tumors. Ph 1 of the study consists of a Dose Escalation Cohort (DEC), utilizing an accelerated titration design, followed by a traditional 3+3 design, and an optional Safety Expansion Cohort (SEC). Ph 2 will include two parallel Expansion Cohorts (EC), enrolling patients with advanced TNBC (EC1) or other solid tumors (EC2), with Simon's two-stage design. Key eligibility criteria include Eastern Cooperative Oncology Group performance status of 0-2 (Ph 1) or 0-1 (Ph 2), adequate organ function defined as: hemoglobin ≥9.0 g/dL, neutrophils ≥1500 /μL, platelets ≥100000/μL, aspartate and alanine aminotransferases ≤2.5x the upper limit of normal (ULN), total bilirubin ≤1.5x ULN, creatinine ≤1.5x ULN, left ventricular ejection fraction ≥50%. The primary objectives are to assess safety and tolerability and to establish the recommended dose for further development (Ph 1), and to evaluate anti-tumor activity of (Ph 2). Secondary and exploratory objectives include characterization of immunogenicity as well as pharmacokinetic and pharmacodynamic profiles. NBE-002 is given intravenously once every three weeks until disease progression, unacceptable toxicity, withdrawal of consent, or other protocol-specific criteria are met. Ph 1 dose escalation was initiated on 17 JULY 2020 and is still recruiting in the US. Ph 2 is planned to be initiated in 2022. Clinical trial information: NCT04441099. Research Sponsor: NBE-Therapeutics.

TPS1109 **Poster Session**

A phase II clinical trial of talazoparib monotherapy for PALB2 mutation-associated advanced breast cancer. *First Author: Joshua James Gruber, Stanford University, Palo Alto, CA*

Background: PALB2 (Partner and Localizer of BRCA2) plays a critical role in the maintenance of genomic integrity through its role in the Fanconi anemia and homologous recombination DNA repair pathways. Our recently reported phase II clinical trial (Gruber, et al. JCO 2019) showed that talazoparib monotherapy was associated with single agent activity in germline PALB2 (gPALB2) mutation-associated advanced breast cancers. Of 5 patients with a germline PALB2 mutation, all 5 had reduction in target lesions $>$ 20% with 3 of 5 achieving a RECIST 1.1 response. All patients had visceral metastases and were heavily pretreated; one response occurred in a patient with 8 prior lines of therapy for metastatic breast cancer. Clinical activity of the PARP inhibitor olaparib was also demonstrated in breast cancer patients with gPALB2 mutations in the Olaparib Expanded trial (TBCRC 048). Thus, we believe there is significant value in generating additional PARP inhibitor monotherapy data in subjects with advanced PALB2 mutation-associated breast cancer. We propose this phase II trial to better estimate the rate of RECIST 1.1 objective response in this patient population. **Methods**: This is a single-arm, two-stage, non-randomized study to assess the objective response rate (ORR) of talazoparib monotherapy in patients with PALB2 mutation-associated advanced breast cancer. Eligible subjects will be adults with inoperable locally advanced or metastatic breast cancer with a germline or somatic PALB2 mutation with 0-3 prior therapies for advanced disease. Eligible patients must have a deleterious or suspected deleterious mutation in PALB2 on a CLIA approved commercial germline or next generation sequencing tumor assay. Study treatment is talazoparib 1 mg PO daily. In stage 1, ORR will be assessed after 15 patients; if at least 2 responses are observed then an additional 15 patients will be enrolled; if less than 2 responses are observed the study will be terminated. The primary objective is to evaluate whether talazoparib monotherapy can induce a 30% ORR in subjects with advanced breast cancer associated with a PALB2 mutation. Response will be assessed by RECIST 1.1. Secondary objectives include safety, PFS, clinical benefit rate, and patient-reported quality-of-life. Exploratory endpoints will assess for the presence of PALB2 loss-of-heterozygosity, biallelic mutations, correlation of ctDNA profile with treatment response and the correlation of germline versus somatic mutations with response rate. This trial is currently activated and enrolling at Stanford Cancer Center and it is expected that 4 additional sites will be added. **Conclusion**: This trial will evaluate gPALB2 as a biomarker for PARP inhibitor monotherapy in advanced or metastatic HER2- breast cancer. Clinical trial information: pending. Research Sponsor: Pfizer.

TPS1110 **Poster Session**

Phase II multicenter study of talazoparib for somatic *BRCA1/2* mutant metastatic breast cancer. *First Author: Neelima Vidula, Massachusetts General Hospital, Boston, MA*

Background: PARP inhibitors are approved for the treatment of HER2 negative metastatic breast cancer (MBC) with germline *BRCA1/2* mutations, based on phase III studies demonstrating an improvement in progression-free survival (PFS) compared to chemotherapy in this population and better patient reported outcomes (Robson, NEJM, 2017; Litton, NEJM, 2018). However, germline *BRCA1/2* mutations account for only 5-10% of breast cancer, limiting the current clinical applicability of PARP inhibitors. Somatic *BRCA1/2* mutations are detectable in circulating cell-free DNA (cfDNA) in ~13.5% of patients with MBC; in pre-clinical models, pathogenic somatic *BRCA1/2* mutations have been shown to respond to PARP inhibition (Vidula, CCR, 2020). The purpose of this study is to evaluate the efficacy of talazoparib, a PARP inhibitor, in patients with MBC who have somatic *BRCA1/2* mutations detectable in cfDNA, in the absence of a germline *BRCA1/2* mutation, which we hypothesize will be effective in this setting. This study may help expand the population of patients with MBC who benefit from PARP inhibitors. **Methods:** This is an investigator initiated multicenter, single arm, phase II clinical trial studying the efficacy of talazoparib in 30 patients with MBC who have pathogenic somatic *BRCA1/2* mutations detected in cfDNA. Patients with MBC who are found to have pathogenic somatic *BRCA1/2* mutations detected in cfDNA in the absence of a germline *BRCA1/2* mutation are eligible. Patients may have triple negative (with $\geq$ 1 prior chemotherapy), or hormone receptor positive/HER2 negative breast cancer (with $\geq$ 1 prior hormone therapy). Patients may have received any number of prior lines of chemotherapy, including a prior platinum (in the absence of progression). They must have adequate organ function and ECOG performance status $\leq$2, and should not have previously received a PARP inhibitor. Patients are treated with talazoparib 1 mg daily until disease progression or intolerability, with serial imaging using CT chest/abdomen/pelvis and bone scan performed at baseline and every 12 weeks, and cfDNA collection every 4 weeks. Primary endpoint is PFS by RECIST 1.1. Patients are being enrolled in a two-stage design with 80% power to demonstrate that the treatment is associated with "success" (PFS $>$ 12 weeks) in $\geq$53% patients (4% alpha). Secondary endpoints include objective response rate and safety (NCI CTCAE v 5.0). Exploratory analyses include studying serial changes in cfDNA *BRCA1/2* mutant allelic frequency and comparing pre-and post-treatment cfDNA for the emergence of *BRCA1/2* reversion and resistance mutations. This study is activated and open at Massachusetts General Hospital, where 2 patients are completing screening. It is also opening soon at 6 other academic centers (NCT03990896). Grant support includes a Pfizer ASPIRE award and 2020 Conquer Cancer Foundation of ASCO – Breast Cancer Research Foundation – Career Development Award. Clinical trial information: NCT03990896. Research Sponsor: Pfizer Aspire Award and Conquer Cancer Foundation of ASCO CDA.

TPS1111 **Poster Session**

Multi-center randomized study of pembrolizumab/carboplatin versus carboplatin alone in patients with chest wall disease from breast cancer: TBCRC 044. *First Author: Neelima Vidula, Massachusetts General Hospital, Boston, MA*

Background: Chest wall recurrence is a subtype of breast cancer that is challenging to treat, and associated with a short duration of response to treatment and an increased risk of development of distant metastases. Given the inflammatory nature of this disease and the association of chest wall disease with lymphovascular invasion, which is correlated with higher programmed cell death 1 (PD-1) expression, we hypothesized that immunotherapy may be beneficial as treatment. Combinations of immunotherapy and chemotherapy have a synergistic effect and demonstrated efficacy in the treatment of metastatic triple negative breast cancer (TNBC). This study is evaluating the efficacy of pembrolizumab, an anti-PD-1 antibody, in combination with carboplatin, in patients with chest wall infiltration from breast cancer. This drug combination has shown efficacy in advanced lung cancer. **Methods:** This is a multicenter, 2:1 randomized phase II study of pembrolizumab/carboplatin (Arm A, 56 patients) vs. carboplatin (Arm B, 28 patients) in 84 patients with chest wall disease from breast cancer, with or without distant metastases. Patients may have TNBC, hormone receptor positive/HER2 negative (following receipt of 2 prior hormone therapies), or HER2 positive breast cancer (with option to continue trastuzumab on study). Pembrolizumab is administered as 200 mg IV every 3 weeks, and carboplatin as AUC 5 IV every 3 weeks. Patients on Arm A may continue pembrolizumab +/- carboplatin (Arm Ax) after completion of 6 cycles of treatment, while patients in Arm B can cross-over to pembrolizumab (+/- carboplatin) on progression (Arm Bx). Patients must have adequate organ function, performance status $\leq$ 2, and may have received any number of lines of prior chemotherapy. Patients undergo serial chest wall photography and imaging (CT chest, abdomen, and pelvis, and bone scan) at baseline and every 6 weeks, as well as blood collection for correlative studies and chest wall biopsies at baseline and after 2 cycles of treatment. The primary endpoint is disease control rate (RECIST 1.1) at 18 weeks of treatment, and the study is powered to determine a 20% difference in disease control rates between arms (HR 0.52, a = 0.10, ß = 0.20). An interim analysis will occur for Arm B after 18 patients are enrolled, with a stopping rule for futility. Secondary endpoints include progression-free survival, toxicity (NCI CTCAE), and response based on irRECIST and tumor programmed death ligand 1 (PD-L1) expression. Exploratory objectives include evaluating changes in soluble PD-L1, tumor and peripheral blood immune composition, circulating tumor cells and cell-free DNA, and MYC oncogene expression. This study (NCT03095352) is open at 7 sites in the Translational Breast Cancer Research Consortium (TBCRC). 52 patients are enrolled. Grant funding is provided by Merck and UCSF. Clinical trial information: NCT03095352. Research Sponsor: Merck and UCSF Breast Oncology Program Development Grant.

Outcomes of COVID-19 in cancer patients: Report from the National COVID Cohort Collaborative (N3C). *First Author: Noha Sharafeldin, Department of Hematology & Oncology, School of Medicine, University of Alabama at Birmingham, Birmingham, AL*

Background: The impact of COVID-19 has disproportionately affected every aspect of cancer care and research—from introducing new risks for patients to disrupting the delivery of treatment and continuity of research. Variation in risk of adverse clinical outcomes in COVID-19 patients by cancer type has been reported from relatively small cohorts. Gaps in understanding effects of COVID-19 on cancer patients can be addressed through the study of a well-constructed representative cohort. The NCATS' National COVID Cohort Collaborative (N3C) is a centralized data resource representing the largest multi-center cohort of COVID-19 cases and controls nationwide. We aimed to construct and characterize the cohort of cancer patients within N3C and identify risk factors for all-cause mortality from COVID-19. **Methods:** From the harmonized N3C clinical dataset, we used 3,295,963 patients from 39 medical US centers to construct a cancer patient cohort. We restricted analyses to adults ≥18 yo with a COVID-19 positive PCR or antigen test or ICD-10-CM diagnostic code for COVID-19 between 1/1/2020 and 2/14/2021. We followed N3C definitions where each lab-confirmed positive patient has one single index encounter. A modified WHO Clinical Progression Scale was used to determine clinical severity. All analyses were performed in the N3C Data Enclave on the Palantir platform. **Results:** A total of 372,883 adult patients with cancer were identified from the N3C cohort; 54,642 (14.7%) were COVID-19 positive. Most common represented cancers were skin (11.5%), breast (10.2%), prostate (8%), and lung cancer (5.6%). Mean age of COVID-19 positive patients was 61.6 years (SD 16.7), 47.3% over 65yo, 53.7% females, 67.2% non-Hispanic White, 21.0% Black, and 7.7% Hispanic or Latino. A total of 14.6% were current or former smokers, 22.3% had a Charlson Comorbidity Index (CCI) score of 0, 4.6% score of 1 and 28.1% score of 2. Among hospitalized COVID-19 positive patients, average length of stay in the hospital was 6 days (SD 23.1 days), 7.0% patients had died while in their initial COVID-19 hospitalization, 4.5% required invasive ventilation, and 0.1% extracorporeal membrane oxygenation. Survival probability was 86.4% at 10 days and 63.6% at 30 days. Older age over 65yo (Hazard ratio (HR) = 6.1, 95%CI: 4.3, 8.7), male gender (HR = 1.2, 95%CI: 1.1, 1.2), a CCI score of 2 or more (HR = 1.15, 95%CI: 1.1, 1.2), and acute kidney injury during hospitalization (HR = 1.3, 95%CI: 1.2, 1.4) were associated with increased risk of all-cause mortality. **Conclusions:** Using the N3C cohort we assembled the largest nationally representative cohort on patients with cancer and COVID-19 to date. We identified demographic and clinical factors associated with increased all-cause mortality in cancer patients. Full characterization of the cohort will provide further insights on the effects of COVID-19 on cancer outcomes and the ability to continue specific cancer treatments. Research Sponsor: None.

The association of the affordable care's Medicaid expansion on survival in gynecologic cancer: A National Cancer Database study. *First Author: Anna Jo Smith, Johns Hopkins Department of Gynecology and Obstetrics, Baltimore, MD*

Background: Under the Affordable Care Act's 2014 Medicaid expansion, more than 12 million Americans gained health insurance. Whether such gains in insurance improve survival in gynecologic cancer is unknown. This study aims to determine whether Medicaid expansion is associated with improved survival among women with gynecologic cancers. **Methods:** We conducted a retrospective cohort study using a difference-in-differences study design comparing insurance status, stage at diagnosis, delays in treatment, and one-year survival before and after the ACA's Medicaid expansion in Medicaid expansion states (intervention group) compared to women in non-expansion states (control group). Using hospital-reported data from the 2010-2016 National Cancer Database, we compared outcomes overall for women ages 40-64 years old with endometrial, cervical, ovarian, or vulva/vaginal cancer and then stratified by cancer type, stage, race, and rural/urban status. We adjusted for patient (area-level income, area-level education, distance traveled for care, comorbidities), clinical (co-morbidities, grade) and hospital (academic facility) characteristics. **Results:** Our sample included 241,713 women with gynecologic cancer, 119,392 in expansion states and 122,321 in non-expansion states. Post-Medicaid expansion, there was a statistically significant 0.8 % increase in 1-year survival among patients in expansion states compared to non-expansion states (95% CI 0.1-1.5). There was also a significant reduction in uninsurance (-1.1%, 95%CI, –1.5, -0.7) and delays of 30+ days from diagnosis to treatment (-2.4%, 95%CI -3.4, -1.2). There was no significant change in early-stage diagnosis (0%; 95%CI -0.7-0.7). Improvements in one-year survival after Medicaid expansion were driven by ovarian cancer (difference-in-differences 2.2%, 95%CI 0.6-3.8) and in white women (difference-in-differences 0.8%, 95%CI 0.1-1.5), while there was no significant difference in one-year survival for non-white or rural women. **Conclusions:** The Affordable Care Act's Medicaid expansion was significantly associated with 1-year survival and insurance access among patients with gynecologic cancer. Insurance expansion efforts in non-Medicaid expansion states may improve survival for women with gynecologic cancer. Research Sponsor: Kelly Society Grant, Johns Hopkins Department of Gynecology and Obstetrics.

1502 **Oral Abstract Session**

Association between Medicaid expansion under the Affordable Care Act and survival among newly diagnosed cancer patients. *First Author: Xuesong Han, American Cancer Society, Atlanta, GA*

Background: Medicaid expansion under the Affordable Care Act (ACA) is associated with increased insurance coverage and early stage at diagnosis among patients with cancer. Whether these gains translate to improved survival is largely unknown, however. This study examines changes in one-year survival rates among persons newly diagnosed with cancer following the ACA Medicaid expansion. **Methods:** Patients aged 18-62 years from 41 population-based state cancer registries diagnosed pre-(2010-2012) and post-(2014-2016) ACA Medicaid expansion were followed through October 1, 2013 and December 31, 2016, respectively. Difference-in-differences (DD) analysis was conducted to estimate changes in one-year overall and cause-specific survival rates associated with Medicaid expansion, adjusting for age group, sex, race/ethnicity, area-level poverty, urban/rural status and region. Stratified analysis was conducted by cancer type, sex and area-level poverty. **Results:** A total of 2,537,818 patients diagnosed with cancer were included from Medicaid expansion (N = 1,492,729) and non-expansion (N = 1,045,089) states. During follow-up, 291,854 patients died including 246,660 deaths from cancer. The one-year overall survival rate (%) increased from 88.1 pre-ACA to 89.1 post-ACA in Medicaid expansion states and from 85.6 to 86.4 in non-expansion states for both sexes combined, resulting in a net increase of 0.4 (95%CI = 0.3-0.6) in expansion states after adjusting for sociodemographic factors. By cancer site and for both sexes combined, the increase in adjusted one-year overall survival in expansion states versus non-expansion states was greater for cancers of lung (DD = 1.6; 95%CI = 0.8-2.5), pancreas (DD = 2.2; 95%CI = 0.5-3.9) and liver (DD = 3.4; 95%CI = 1.7-5.1); as were the increases for cervix (DD = 1.3; 95%CI = 0.1-2.5), melanoma (DD = 0.4;95%CI = 0.04-0.9), non-Hodgkin lymphoma (DD = 1.2; 95%CI = 0.1-2.2) and esophagus (DD = 7.1; 95%CI = 0.5-13.7) among women. The improvement in one-year overall survival was larger among patients residing in the poorest areas (DD = 0.7; 95%CI = 0.3-1.1) compared to those in the richest areas (DD = 0.2; 95%CI = -0.2 to 0.5), leading to a narrowing survival disparity by area-level poverty. Patterns in one-year cause-specific survival were similar. **Conclusions:** Medicaid expansion was associated with greater increase in one-year overall survival rates, largely driven by the improvements in survival for cancer types with poor prognosis, suggesting improved access to timely and effective treatments. Furthermore, the increase was largest in poorest areas, highlighting the promising role of Medicaid expansion in reducing health disparities. Future studies should monitor changes in longer-term health outcomes following the ACA. Research Sponsor: None.

1503 **Oral Abstract Session**

Association of use of remote patient monitoring (RPM) with reduced hospitalizations in cancer patients with COVID-19. *First Author: Joshua Pritchett, Mayo Clinic Rochester, Rochester, MN*

Background: Patients with cancer and COVID-19 are at risk for poor clinical outcomes. An established multi-site remote patient monitoring (RPM) service was rapidly adapted to support a novel, interdisciplinary COVID-19 program for outpatient management of patients at high-risk for severe illness. The goal of this study was to assess the impact of the RPM program on clinical outcomes and acute care utilization in cancer patients diagnosed with COVID-19. **Methods:** This is a cross-sectional analysis following a multi-site prospective observational study performed at Mayo Clinic Cancer Center (MCCC). All adult patients with active cancer – defined as currently receiving cancer-directed therapy or in recent remission on active surveillance – and PCR-confirmed SARS-CoV-2 infection between March 18 and July 31, 2020 were included. RPM was comprised of in-home technology to assess symptoms and physiologic data with centralized nurse and physician oversight. **Results:** During the study timeframe 224 cancer patients were diagnosed with COVID-19 at MCCC. Initial management included urgent hospitalization (within 48 hours of diagnosis) in 34 patients (15%). Of the remaining 190 patients (85%) initially managed in the outpatient setting, those who did not receive RPM were significantly more likely to experience hospitalization than those receiving RPM (OR 3.6, 95% CI 1.036 to 12.01, P = 0.044). Following balancing of patient characteristics by inverse propensity weighting, rates of hospital admission for RPM and non-RPM patients were 3.1% and 11% respectively, implying that RPM was associated with an 8% reduction in hospital admission rate (-0.077; 95% CI: -0.315 to -0.019, P = 0.009). Use of RPM was also associated with lower rates of prolonged hospitalization, ICU admission, and mortality, though these trends did not reach statistical significance. **Conclusions:** In the midst of a global pandemic associated with inpatient bed, ventilator, and PPE shortages, the RPM program provided an effective strategy for outpatient clinical management and was associated with decreased rates of hospitalization, ICU admission, and mortality in cancer patients with COVID-19. This care model enabled simultaneous opportunity to mitigate the increased risks of exposure, transmission, and resource utilization associated with conventional care. Research Sponsor: None.

1504 **Oral Abstract Session**

Oncology patients' perspectives on remote patient monitoring for COVID-19. *First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Oncology patients are particularly vulnerable to adverse outcomes from COVID-19 and require careful monitoring to identify early deterioration and render higher level care when indicated. Several institutions launched remote patient monitoring programs (RPMPs) to care for patients with COVID-19. We describe patients' perspectives on a COVID-19 RPMP at a National Comprehensive Cancer Center. **Methods:** Adult patients who had either tested positive for COVID-19 on an outpatient microbiology test or were discharged after hospitalization for the virus were eligible. Patients enrolled in the RPMP received a daily 10-question electronic patient-reported outcome assessment of COVID-19 symptoms and their responses generated alerts to a centralized monitoring team for new or worsening symptoms. A subset of high-risk patients also received a pulse oximeter which alerted when blood oxygen levels dropped below 93%. RPM was discontinued 14 days after a patient's positive test result and following 3 days without worsening symptoms or fever. Patients who exited the program and had completed at least one assessment were sent a patient engagement survey. The objective of the survey was to evaluate the patient's experience with digital monitoring and symptom management for COVID-19. The assessment was structured with objective response questions, including a net promoter score, and free text questions to elicit patient perspectives on RPM value. Free text responses were analyzed using grounded theory to identify primary themes regarding perceived value. **Results:** The survey was distributed to 452 patients; 241 responded as of June 10, 2020 (53% completion rate). The net promoter score was 91%. The table provides responses to objective questions. Qualitative analysis of free text responses identified the primary themes regarding patient perceived value which included: 1) Security: patients appreciated that the RPMP provided a clinical safety net; 2) Connection: patients appreciated the link to their clinical team during a period of isolation; 3) Empowerment: patients appreciated that the RPMP provided education on the virus and symptom management. **Conclusions:** RPMPs are perceived to be of value to oncology patients with COVID-19. A key barrier to maintaining these programs is cost. Policymakers should consider how these programs can be reimbursed in the future so that they can continue to provide care to vulnerable patients and keep them at home out of the acute care setting. Research Sponsor: None.

N=241	Strongly agree	Agree	Neither agree nor disagree	Disagree	Strongly disagree
The time and effort it took to report symptoms was worth it	67%	25%	7%	0%	1%
By participating in the RPMP, I felt better able to manage my COVID-19 symptoms	48%	31%	18%	2%	1%
The RPMP helped me cope with my COVID-19 diagnosis	45%	30%	22%	2%	1%
Taking part in the RPMP made me feel more connected to my clinical team	55%	34%	8%	2%	1%
The RPMP helped prevent visits to the emergency room	38%	24%	30%	5%	3%

CORONET; COVID-19 in Oncology evaluatiON Tool: Use of machine learning to inform management of COVID-19 in patients with cancer. *First Author: Rebecca Lee, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Patients (pts) with cancer are at increased risk of severe COVID-19 infection and death. Due to COVID-19 outcome heterogeneity, accurate assessment of pts is crucial. Early identification of pts who are likely to deteriorate allows timely discussions regarding escalation of care. Likewise, safe home management will reduce risk of nosocomial infection. To aid clinical decision-making, we developed a model to help determine which pts should be admitted vs. managed as an outpatient and which pts are likely to have severe COVID-19. **Methods:** Pts with active solid or haematological cancer presenting with symptoms/asymptomatic and testing positive for SARS-CoV-2 in Europe and USA were identified following institutional board approval. Clinical and laboratory data were extracted from pt records. Clinical outcome measures were discharge within 24 hours, requirement for oxygen at any stage during admission and death. Random Forest (RF) algorithm was used for model derivation as it compared favourably vs. lasso regression. Relevant clinical features were identified using recursive feature elimination based on SHAP. Internal validation (bootstrapping) with multiple imputations for missing data (maximum $\leq$2) were used for performance evaluation. Cost function determined cut-offs were defined for admission/death. The final CORONET model was trained on the entire cohort. **Results:** Model derivation set comprised 672 pts (393 male, 279 female, median age 71). 83% had solid cancers, 17% haematological. Predictive features were selected based on clinical relevance and data availability, supported by recursive feature elimination based on SHAP. RF model using haematological cancer, solid cancer stage, no of comorbidities, National Early Warning Score 2 (NEWS2), neutrophil:lymphocyte ratio, platelets, CRP and albumin achieved AUROC for admission 0.79 (+/-0.03) and death 0.75 (+/-0.02). RF explanation using SHAP revealed NEWS2 and C-reactive protein as the most important features predicting COVID-19 severity. In the entire cohort, CORONET recommended admission of 96% of patients requiring oxygen and 99% of patients who died. We then built a decision support tool using the model, which aids clinical decisions by presenting model predictions and explaining key contributing features. **Conclusions:** We have developed a model and tool available athttps://coronet.manchester.ac.uk/ to predict which pts with cancer and COVID-19 require hospital admission and are likely to have a severe disease course. CORONET is being continuously refined and validated over time. Research Sponsor: The Christie Charitable Foundation.

The future of tele-oncology: Trends and disparities in telehealth and secure message utilization in the COVID-19 era. *First Author: Elad Neeman, San Francisco Medical Center, Kaiser Permanente Northern California, San Francisco, CA*

Background: The COVID-19 pandemic created an imperative to re-examine the role of telehealth in oncology. Herein we report trends and demographic disparities in utilization of telehealth and secure messaging (SM; i.e., email via portal/app), before and during the pandemic, at a large integrated healthcare system. **Methods:** This population-based retrospective cohort study examines utilization of various patient-provider visit types (office, video, telephone) and SM from 1/1/2019-9/30/2020 at 22 Kaiser Permanente Northern California Hematology and Oncology practices. We explored changes associated with the pandemic (i.e., since 03/2020, when stay home orders were introduced) as well as demographic differences, using Chi-square for categorical and the Mann-Whitney U Test for non-parametric comparisons. **Results:** During the study period, there were 334,666 visits and 1,161,239 SM sent between patients and providers. Since the pandemic, total monthly average of visits declined only slightly by 4.1%, but monthly average office visits decreased by 80% from 11,001 to 2,170, monthly average video visits increased from 40 to 4,666, and monthly average telephone visits increased by 69% from 5,114 to 8,663. The monthly average SM increased by 26% from 50,788 to 64,315. The trend of increasing telehealth utilization was sustained and stabilized between 07-09/2020. New consultations initially decreased from a mean of 1,995 per month (12.4% of all visits) in 2019, to a minimum of 1,179 (8.6%) by 05/2020, returning to 1,619 (11.7%) by 09/2020. Pandemic era video visits were a significantly higher fraction of all visits ($p < 0.01$) in: (1) younger patients (Gen Z 48%, Gen Y/Millennials 46%; Gen X 40%; Baby Boomers 34.4%; Pre-Boomers 24.5%); (2) patients with commercial insurance (39%) compared to those with Medicaid (32.7%) or Medicare (28.1%); (3) Primary English speakers (33.7%) compared to those who require an interpreter (24.5%);(4) Asians (35%) and non-Hispanic Whites (33.7%) compared to Blacks (30.1%) and Hispanic Whites (27.5%); (5) married/ domestic partner patients (35%) compared to single/divorced/widowed patients (29.9%); (6) patients with a Charlson comorbidity index $\leq$3 (36.2%) compared to $>$ 3 (31.3%); and (7) males (34.6%) compared to females (32.3%). Similar statistically significant SM utilization patterns were also seen. **Conclusions:** In the pandemic era, utilization of telehealth and SM rapidly increased in all demographic categories, shifting the landscape and resource allocation of hematology/oncology practices in a manner that is feasible and sustained. New consultations decreased early in pandemic with return to pre-pandemic levels by 09/2020. Utilization of video visits and SM significantly differ between various demographic populations with disparities seen by age, insurance plan, English proficiency, race/ethnicity, marital status, comorbidities, and gender. Research Sponsor: None.

1507 **Oral Abstract Session**

Documentation of goals of care (GOC) by medical oncologists is associated with improved oncology patient end-of-life (EOL) care outcomes. *First Author: Han Xiao, Memorial Sloan Kettering Cancer Center, Basking Ridge, NJ*

Background: Documenting GOC is integral to patient care and quality performance but has been underutilized by oncologists due to many barriers. As oncologists play a key role in initiating GOC discussions, we implemented a clinical initiative to improve their GOC documentation and evaluated the impact of such documentation on patient care during the EOL (last 30 days of life). **Methods:** We launched the initiative among 270 medical oncologists in an academic cancer center in 4/2020. A newly formulated GOC note to ease documentation was embedded in oncology outpatient and inpatient notes. Oncologists completed components in the GOC note that applied to their communication about GOC with the patient: 1) cancer natural history, 2) patient goals, and 3) EOL discussion: patient resuscitation preferences and, when pertinent, receptivity to hospice referral. GOC notes were pulled to a centralized location in the electronic health record (EHR) that displays documents relevant to patients' values, goals and preferences. A dashboard allowed continual monitoring of documentation performance. We evaluated the association between GOC notes and outcomes of patient care at EOL. We further analyzed the impact of EOL discussion on EOL care. **Results:** The GOC note completion rate steadily rose after implementation. GOC notes were present in EHR for 46% of 10,006 patients who were either seen in outpatient clinic or discharged from hospital during the 1st week of January 2021. Among 1790 patients who died between 7/1/20 and 12/31/20 and had either at least an outpatient visit or hospitalization during EOL, the median days from first GOC note and first EOL discussion to the patient's death were 71 days and 24 days, respectively. Linear regression analysis demonstrated that patients who had GOC note 60 days before death spent less time as inpatient during EOL (0.4 day less/patient, from 8.1 to 7.7, $P = 0.01$). When EOL discussion was documented 30 days before death, patients also spent less time in the hospital (1.2 days less/patient, from 9.7 to 8.5, $P < 0.001$) and in the ICU (0.3 days less/patient, from 1.7 to 1.4 ICU days, $P = 0.04$), and were 4% less likely to receive chemotherapy (from 38% to 34%, $P = 0.004$) at EOL. During the same period, among 1,009 patients with hospital admission in the last 30 days of life, those with a prior documented EOL discussion had shorter inpatient stay (7.7 vs 13.1 days, $P < 0.001$) and were more likely to be discharged to hospice (34% vs 22%, $P = 0.003$). **Conclusions:** During the COVID-19 pandemic, we successfully implemented GOC documentation by medical oncologists that is easily visible by the full care team. Documentation of GOC including EOL discussion was associated with fewer days in the hospital and ICU, increased hospice referral, and lower likelihood of receiving chemotherapy during patients' last 30 days of life. Research Sponsor: None.

1508 **Oral Abstract Session**

The effect of a lay health worker intervention on acute care use, patient experiences and end-of-life care: Results from a randomized clinical trial. *First Author: Manali I. Patel, Division of Oncology; Clinical Excellence Research Center; Stanford University School of Medicine, Stanford, CA*

Background: Previously, among Veterans with cancer, lay health workers (LHWs) trained to discuss patients' goals of care reduced acute care use, improved patient experiences and reduced total costs of care at the end-of-life. Among Medicare-Advantage beneficiaries with cancer, LHWs trained to proactively assess patient symptoms reduced symptom burden, acute care use and total costs of care. It is unknown whether LHWs can assist with both goals of care and symptom assessments in community settings. The objective of this randomized clinical trial was to determine the effect of a LHW-led goals of care and symptom assessment intervention on acute care use and secondarily goals of care documentation, satisfaction and end-of-life healthcare use among patients with advanced cancer in a community practice. **Methods:** Newly diagnosed patients with advanced stages of solid and hematologic malignancies who planned to receive care at the oncology practice were randomized from 8/11/2016 through 2/5/2020 into intervention and control groups. Patients completed validated satisfaction surveys at randomization and 9 months follow-up and were followed for 12 months. We compared risk of death using Cox Models, healthcare use and satisfaction using generalized regression models adjusted for length of follow-up. **Results:** 128 patients were randomized; 64 in the intervention and 64 in the control. The mean age was 67 years; 22% identified as Hispanic/Latino; 57% White, 30% Asian Pacific Islander, 8% Black or African American, 1% Native Hawaiian, 1% American Indian/Alaskan Native, 3% multiple races/ethnicities. There were no survival differences. Intervention patients were less likely to utilize the emergency department (OR: 0.35; 95% CI 0.17-0.72) and hospital (OR: 0.48; 95% CI 0.23-0.98) and had lower mean emergency department visits (1.05 +/- 1.74 versus 1.84 +/- 2.55, p = 0.04) and hospitalizations per year (0.63 +/- 1.28 versus 1.26 +/- 2.23, p = 0.04) as compared to control patients. More intervention patients had their goals of care documented (94% versus 52% $p < 0.001$) and used hospice (35% versus 14% p = 0.004) as compared to control patients. There were no differences in palliative care use (89% versus 77% p = 0.09). At 9 months follow-up as compared to baseline, intervention patients experienced greater improvements in satisfaction with care (difference-in-difference: 0.41, 95% CI 0.22-0.60, $p < 0.001$). Among 30 patients who died (n = 16 intervention; n = 16 control), more patients in the intervention used hospice (81% versus 43%) and fewer used acute care in the last month (37% versus 81%, p = 0.012) than in the control. **Conclusions:** An LHW intervention reduced acute care use among patients with cancer, improved patient experiences and end-of-life care. This intervention may be a scalable approach to improve care delivery and experiences for patients after a diagnosis of cancer. Clinical trial information: NCT03154190. Research Sponsor: U.S. National Institutes of Health.

Impact of machine learning-directed on-treatment evaluations on cost of acute care visits: Economic analysis of SHIELD-RT. *First Author: Divya Natesan, Duke University Medical Center, Department of Radiation Oncology, Durham, NC*

Background: SHIELD-RT was a randomized controlled quality improvement study (NCT03775265) that implemented electronic health record-based machine learning (ML) to direct supplemental visits for high risk (HR) patients undergoing radiotherapy (RT). Acute care visits (ER visits or hospitalizations) were reduced from 22% to 12%. We evaluated the costs associated with acute visits in this study. **Methods:** Patients who initiated RT between 1/7/19 and 6/30/19 at a single institution were evaluated by a ML algorithm to identify HR courses (>10% risk of acute visit during RT). HR patients were randomized to standard weekly (S)*or* intervention of twice weekly (TW) evaluation during RT. Cost data associated with acute visits were obtained and compared between patients who underwent S or TW evaluations. Missing cost data were imputed using disease related groups (DRGs). Mean costs (standard deviation) were compared between arms with non-parametric Wilcoxon Rank Sum tests. **Results:** 311 HR courses were identified and randomized to either S (n=157) or TW (n=154) evaluations during RT. 85 patients (S: 51; TW: 34) had 121 distinct acute care visits (S: 74; TW: 47). Patients in the TW evaluation arm had fewer hospitalizations (29 vs 41) and ER visits (18 vs 33) than those in the S arm. There were fewer acute visits per patient in the TW arm (0.34) compared to S arm (0.49). Actual cost data was available for 102 visits at our institution, and imputed for 19 outside hospital visits. Mean cost associated with acute visits was lower in the TW arm ($1939, SD $5912) compared with the S arm ($4002, SD $11568; p=0.03). Differences in mean cost between arms are presented in the table. **Conclusions:** ML-directed evaluations for HR patients undergoing RT resulted in decreased costs of ER visits and hospitalizations. Costs were decreased across revenue centers, with the largest difference related to inpatient room costs. Future analyses will incorporate intervention costs, which are currently bundled with RT reimbursement. Research Sponsor: Duke Radiation Oncology Residency, Adam Olson Fund.

Cost of acute care during RT or within 15 days of RT completion.

Augmenting machine learning algorithms to predict mortality using patient-reported outcomes in oncology. *First Author: Ravi Bharat Parikh, University of Pennsylvania, Philadelphia, PA*

Background: Machine learning (ML) algorithms based on electronic health record (EHR) data have been shown to accurately predict mortality risk among patients with cancer, with areas under the curve (AUC) generally greater than 0.80. While patient-reported outcomes (PROs) may also predict mortality among patients with cancer, it is unclear whether routinely-collected PROs improve the predictive performance of EHR-based ML algorithms. **Methods:** This cohort study included 8600 patients with cancer who had an outpatient encounter at one of 18 medical oncology practices in a large academic health system between July 1st, 2019 and January 1st, 2020. 4692 (54.9%) patients completed assessments of symptoms, performance status, and quality of life from the PRO version of the Common Terminology Criteria for Adverse Events and the Patient-Reported Outcomes Measurement Information System Global v.1.2 scales. We hypothesized that ML models predicting 180-day all-cause mortality based on EHR + PRO data would improve AUC compared to ML models based on EHR data alone. We assessed univariate and adjusted associations between each PRO and 180-day mortality. To train the EHR-only model, we fit a Least Absolute Shrinkage and Selection Operator (LASSO) regression using 192 EHR demographic, comorbidity, and laboratory variables. To train the EHR + PRO model, we used a two-phase approach to fit a model using EHR data for all patients and PRO data for those who completed assessments. To test our hypothesis, we compared the bootstrapped AUC, area under the precision-recall curve (AUPRC), and sensitivity at a 20% risk threshold for both models. **Results:** 464 (5.4%) patients died within 180 days of the encounter. Decreased quality of life, functional status, and appetite were associated with greater 180-day mortality (Table). Compared to the EHR-only model, the EHR + PRO model significantly improved AUC (0.86 [95% CI 0.85-0.86] vs. 0.80 [95% CI 0.80-0.81]), AUPRC (0.40 [95% CI 0.37-0.42] vs. 0.30 [95% CI 0.28-0.32]), and sensitivity (0.45 [95% CI 0.42-0.48] vs. 0.33 [95% CI 0.30-0.35]). **Conclusions:** Routinely collected PROs augment EHR-based ML mortality risk algorithms. ML algorithms based on EHR and PRO data may facilitate earlier supportive care for patients with cancer. Association of PROs with 180-day mortality. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Identification of patients at high risk for preventable emergency department visits and inpatient admissions after starting chemotherapy: Machine learning applied to comprehensive electronic health record data. *First Author: Dylan J. Peterson, Stanford University School of Medicine, Stanford, CA*

Background: Acute care use is one of the largest drivers of cancer care costs. OP-35: Admissions and Emergency Department Visits for Patients Receiving Outpatient Chemotherapy is a CMS quality measure that will affect reimbursement based on unplanned inpatient admissions (IP) and emergency department (ED) visits. Targeted measures can reduce preventable acute care use but identifying which patients might benefit remains challenging. Prior predictive models have made use of a limited subset of the data available in the Electronic Health Record (EHR). We hypothesized dense, structured EHR data could be used to train machine learning algorithms to predict risk of preventable ED and IP visits. **Methods:** Patients treated at Stanford Health Care and affiliated community care sites between 2013 and 2015 who met inclusion criteria for OP-35 were selected from our EHR. Preventable ED or IP visits were identified using OP-35 criteria. Demographic, diagnosis, procedure, medication, laboratory, vital sign, and healthcare utilization data generated prior to chemotherapy treatment were obtained. A random split of 80% of the cohort was used to train a logistic regression with least absolute shrinkage and selection operator regularization (LASSO) model to predict risk for acute care events within the first 180 days of chemotherapy. The remaining 20% were used to measure model performance by the Area Under the Receiver Operator Curve (AUROC). **Results:** 8,439 patients were included, of whom 35% had one or more preventable event within 180 days of starting chemotherapy. Our LASSO model classified patients at risk for preventable ED or IP visits with an AUROC of 0.783 (95% CI: 0.761-0.806). Model performance was better for identifying risk for IP visits than ED visits. LASSO selected 125 of 760 possible features to use when classifying patients. These included prior acute care visits, cancer stage, race, laboratory values, and a diagnosis of depression. Key features for the model are shown in the table. **Conclusions:** Machine learning models trained on a large number of routinely collected clinical variables can identify patients at risk for acute care events with promising accuracy. These models have the potential to improve cancer care outcomes, patient experience, and costs by allowing for targeted preventative interventions. Future work will include prospective and external validation in other healthcare systems. Research Sponsor: None.

Evaluating a high-dimensional machine-learning model to predict hospital mortality among elderly cancer patients. *First Author: Edmund M. Qiao, Department of Radiation Medicine and Applied Sciences, University of California San Diego, La Jolla, CA*

Background: Elderly hospitalized cancer patients face high risks of inpatient hospital mortality. Identifying patients at high risk of hospital mortality could help with risk stratification, and potentially help inform future interventions aimed at improving outcomes. We evaluated the predictive capacity of a high-dimensional machine-learning prediction tool to predict inpatient mortality, and compared the performance of this new tool to existing prediction indices. **Methods:** We identified cancer patients 75 and over who presented to an emergency department (ED) and were subsequently hospitalized from the National Emergency Department Sample (NEDS) between 2016 and 2018. We used an extreme gradient boosting approach to predict the risk of death during hospitalization. Model covariates included patient demographics, hospital characteristics, and International Classification of Diseases, version 10 (ICD-10) diagnosis codes recorded during the ED visit. The data were split 75%/25% into training/testing datasets. We constructed the model with training data and evaluated performance within the test data using area under the curve (AUC), with an AUC of 1.0 indicating perfect prediction. We compared the performance of this risk prediction model to standard prediction indices including the Hospital Frailty Risk Score, modified 5-item frailty index, and Charlson comorbidity index. **Results:** We identified 1,892,690 weighted-hospitalizations among elderly cancer patients, of which 133,379 (7.0%) who died in the inpatient setting. Our final predictive model included 238 features, which contained 5 demographic variables, 3 hospital characteristics, and 230 ICD-10 diagnosis codes. The predictive model achieved an AUC of 0.92. Our comparator models including the Hospital Frailty Risk Score, modified 5-item frailty index, and Charlson comorbidity index achieved AUCs of 0.67, 0.56, and 0.60, respectively. **Conclusions:** Using a high-dimensional machine-learning model enabled a high level of precision in predicting hospital mortality among elderly cancer patients, substantially out-performing existing prediction indices. High-dimensional prediction models show promise in helping to identify patients at risk of severe adverse outcomes, though additional validation is needed as well as research studying how to implement these tools into practice. Research Sponsor: U.S. National Institutes of Health.

Risk for SARS-CoV-2 infection in patients with breast cancer treated with chemotherapy, biologic therapy or active surveillance: Patient outcomes from multicenter institution in New York. *First Author: Nibash Budhathoki, Perlmutter Cancer Center at NYU Langone Hospital-Long Island, Mineola, NY*

Background: In high-risk estrogen-receptor positive, HER2 positive, or triple negative breast cancer (BC), chemotherapy can increase cure rates in early-stage disease and prolong survival in setting of advanced disease. Real world data specific to BC is needed to counsel patients (pts) with BC on their risk for SARS-CoV-2 infection and mortality in the context of the SARS-CoV-2 pandemic. **Methods:** In this retrospective study, we abstracted clinical data including demographics, tumor histology, cancer treatment, and COVID-19 testing results status from the electronic medical record of 3778 BC patients who received cancer care from 02/01/2020 – 05/01/2020 in New York City at our cancer center. The primary endpoint of the study was incidence of SARS-CoV-2 infection by treatment type (cytotoxic chemotherapy (CT) vs non-cytotoxic therapies (endocrine and/or HER2 directed therapy (E/H)) diagnosed by either serology, RT-PCR, or documented clinical diagnosis. Probability of Treatment Weighting (IPTW) and Mann-Whitney Test were used to assess risk of SARS-CoV-2 infection by treatment and assess outcomes based on oncologic and non-oncologic risk factors respectively. **Results:** 3062 patients met inclusion criteria with 379 pts in CT, 2343 pts in E/H and 340 in NT groups. During study period 641 patients (20.9%) were tested by either PCR or serology with 64 patients (2.1%) diagnosed with COVID-19. All pts who tested positive by PCR and subsequently had serology testing were positive for IgG. The weighted risk of SARS-COV-2 infection was 3.5% in CT vs. 2.7% in E/H (p=0.523). 27 patients (0.9%) expired over follow up, with 10 deaths attributed to SARS-CoV-2 infection. The weighted risk for death was 0.7% with CT vs. 0.1% with E/H, p=0.24 (Table A). Age, BMI,CCI and advanced cancer stage were associated with increased mortality following SARS-CoV-2 infection (Table). **Conclusions:** CT was not associated with increased risk of infection with SARS-CoV-2 infection or death following infection. BC cancer treatment, including CT, can be safely administered with enhanced infectious precautions and should not be withheld particularly when given for curative intent. Research Sponsor: Departmental Funds.

Association of the COVID-19 pandemic with patterns of cancer services. *First Author: K Robin Yabroff, American Cancer Society, Atlanta, GA*

Background: The COVID-19 pandemic led to delays in medical care in the United States. We examined changes in patterns of cancer diagnosis and surgical treatment in 2020 using real-time electronic pathology report data from population-based SEER cancer registries in Georgia and Louisiana. **Methods:** Bi-weekly numbers, distributions, and patterns of pathology reports were compared between January 1st and December 31st in 2020 and the same period in 2019 by age group and cancer site. **Results:** During 2020, there were 29,905 fewer pathology reports than in 2019, representing a 10.2% decline. Absolute declines were greatest among adults aged ≥50 years (N=23,065); percentage declines were greatest among children and young adults ≤18 years (38.3%). By cancer site, percentage declines were greatest for lung cancer (17.4%), followed by colorectal (12.0%), breast (9.0%) and prostate (5.8%) cancers. Biweekly reports were statistically significantly lower in 2020 than in 2019 from late March through the end of December in most biweekly periods. The nadir was the month of April 2020 – the number of reports was at least 40% lower than in April 2019. The number of reports in 2020 compared with 2019 also declined sharply in early November (26.8%) and late December (32.0%). Numbers of reports in 2020 never consistently exceeded those in 2019 after the first decline. Patterns were similar by cancer site, with variation in magnitude and duration of declines. **Conclusions:** Significant declines in cancer pathology reports from population-based registries during 2020 suggest substantial delays in screening, evaluation of signs and symptoms, diagnosis, and treatment services for cancers with effective screening tests as well as in cancer sites and age groups without effective screening tests as an indirect result of the COVID-19 pandemic. Ongoing evaluation will be critical for informing public health efforts to minimize any lasting adverse effects of the pandemic on cancer screening, diagnosis, treatment, and survival. Research Sponsor: None.

Growth in eligibility criteria content and failure to accrue among National Cancer Institute (NCI)-affiliated clinical trials. *First Author: John Stuart Peterson, University of Utah School of Medicine, Salt Lake City, UT*

Background: Cancer clinical trial accrual across diverse socioeconomic and demographic groups is a national priority, yet up to 20% of trials fail due to poor accrual. Eligibility criteria content may contribute to poor accrual, but effects are challenging to measure. We sought to evaluate growth of eligibility criteria within NCI-affiliated cancer trials and the impact on trial accrual over the past decade. **Methods:** We conducted a retrospective study with the Aggregate Analysis of ClinicalTrials.gov (AACT) (abstracted: 02/02/2021). We included NCI-affiliated, interventional Phase II or III trials that initiated between 01/01/2008 and 12/13/2018. We excluded active and recruiting trials that lacked accrual data on the Cancer Trials Support Unit website. Trials whose status was "Withdrawn", "Terminated", or "Suspended" due to low accrual, or had less than 50% target accrual after two years active were deemed accrual failures. Eligibility criteria were extracted from inclusion and exclusion criteria and complexity was estimated by the number of unique content words, calculated by removing duplicates and stop words from the word count. Association of unique word count with accrual failure was evaluated by univariable and multivariable logistic regressions, adjusting for other predictors of low accrual identified in earlier research. **Results:** Of 1197 trials included, 231 (19.3%) failed due to low accrual. Eligibility criteria increased in length from a median of 214 (IQR [23, 282]) unique content words in 2008 to 417 (IQR [289, 514]) in 2018. The rate of trial accrual failure increased with unique word count decile from 11.8% in the first decile (12 to 112 words) to 29.4% in the tenth decile (445 to 750 words) (P = 0.004). On multivariable analysis, unique word count remained independently associated with low accrual (OR: 1.07 per decile, 95%CI [1.01-1.13], P = 0.02), as did Phase III and metastatic disease settings (Table). **Conclusions:** Eligibility criteria content has increased dramatically in the last decade in NCI-affiliated trials. Increasing eligibility criteria content associates strongly with accrual failure, even after adjusting for multiple known predictors of accrual. These findings underscore the need for efforts to simplify eligibility criteria to improve trial accrual. Further investigation is ongoing to determine specific criteria qualities that portend accrual failure. Research Sponsor: None.

Multivariable Logistic Regression for Accrual Failure	OR (95% CI)
Number of unique content words (per decile)	1.07 (1.01, 1.13)
Common solid cancer	1.01 (0.69, 1.45)
Common liquid cancer	1.40 (0.93, 2.10)
NCI-approved targeted therapy as intervention	1.31 (0.90, 1.93)
Metastatic disease	1.53 (1.09, 2.16)
Tissue sample required	1.01 (0.74, 1.37)
Radiation therapy as intervention	0.85 (0.24, 2.35)
Phase III	1.78 (1.15, 2.70)

1516 **Poster Discussion Session**

The validity of progression-free survival (PFS) 2 as a surrogate endpoint for overall survival (OS) in randomized controlled trials (RCTs) of advanced solid tumors. *First Author: Rachel Woodford, St George Hospital, Lisarow, Australia*

Background: OS is the gold-standard endpoint for treatment efficacy in oncology RCTs. However, prolonged follow-up is required to obtain mature data, which impedes regulatory approval of potentially beneficial therapies. Furthermore, increasing therapeutic options including cross over to investigational agents at disease progression often confound OS findings. PFS-2, defined as time from randomization to progression on second-line therapy, has been proposed as a potential surrogate endpoint for OS. Using a meta-analytic approach, we aimed to assess the association between OS and PFS-2, and its validity compared with other surrogate endpoints. **Methods:** We performed an electronic literature search to identify RCTs of systemic therapies that reported PFS-2 as a pre-specified endpoint with defined follow up protocols. Articles were screened for eligibility and outcome data were extracted. Correlations in the relative treatment difference between treatment arms for OS vs PFS-2, PFS-1, and objective response rate (ORR) were assessed as the comparison of hazard ratios (HR) and odds ratio (OR) respectively. **Results:** 38 eligible RCTs comprising of 44 analysis units, with 19,031 patients across 8 unique tumor types were identified. The majority received targeted therapies (72.2%), followed by immunotherapy (IO; 26.3%). The correlations of HR-OS/HR-PFS-2, HR-OS/HR-PFS-1 and HR-OS/OR-ORR were $r = 0.67$ (95% CI 0.08-0.69), $r = 0.12$ (95% CI 0.00-0.13) and $r = 0.21$ (95% CI 0.00-0.33) respectively. Correlations between OS with surrogates was assessed in different subgroups according to post-progression survival times (SPP), types of treatment agents and rate of subsequent therapy after progression (table). **Conclusions:** Across diverse tumors and therapies, treatment effect on PFS-2 has modest to strong correlation with OS, but poor correlations were observed between OS-PFS-1 and OS-ORR respectively. Across all subgroups, PFS-2 performs consistently better than traditional surrogates of PFS-1 and ORR, validating and providing support for use in future RCTs. Research Sponsor: None.

Impact of the Oncology Care Model on use of bone supportive medications, antiemetics, and growth factors. *First Author: Gabriel A. Brooks, Dana-Farber Cancer Institute, Boston, MA*

Background: The Oncology Care Model (OCM) is a voluntary, episode-based alternative payment model for cancer care launched by the Centers for Medicare & Medicaid Services in July 2016. OCM incentivizes participating practices to reduce spending during chemotherapy treatment while maintaining quality of care. We evaluated the impact of OCM on the use of costly supportive care medications. **Methods:** Using 100% Medicare claims (2013-2019), we evaluated use of outpatient supportive care medications during chemotherapy episodes assigned to OCM practices (n = 186) or propensity-matched comparison practices (n = 534). For bone supportive medications, we evaluated use of bisphosphonates and/or denosumab in beneficiaries with bone metastases from breast, lung, or prostate cancer. For anti-emetic drugs, we evaluated prophylactic use of neurokinin-1 (NK1) antagonists and long-acting (LA) serotonin antagonists. For white blood cell growth factors (GCSFs), we evaluated prophylactic use in beneficiaries starting chemotherapy for breast, lung, or colorectal cancer; we separately evaluated use of biosimilar (vs originator) filgrastim. Analyses employed the difference-in-differences (DID) approach, excepting the filgrastim biosimilar analysis where we assessed the adoption trend. **Results:** There was no OCM impact on receipt of any bone supportive medication (denosumab or bisphosphonate) among beneficiaries with bone metastases; however, OCM led to a relative decrease in use of denosumab for breast cancer (DID = -5.0 percentage points [90% CI -7.1, -2.8]), prostate cancer (-4.0 percentage points [90% CI -5.9, -2.2]), and lung cancer (-4.1 percentage points [90% CI -7.4, -0.9]). In beneficiaries starting chemotherapy regimens with high or moderate emetic risk, OCM led to reductions in prophylactic use of NK1 antagonists and LA serotonin antagonists (e.g. 6.0 percentage point reduction in use of NK1 antagonists during high emetic risk chemotherapy [90% CI -9.0, -3.1]); there was no impact on antiemetic use during low emetic risk chemotherapy. There was no OCM impact on use of prophylactic WBC growth factors among beneficiaries receiving chemotherapy with high risk for febrile neutropenia (FN). Among beneficiaries receiving chemotherapy with intermediate risk for FN, OCM led to a 7.6 percentage point reduction in prophylactic GCSF use for patients with breast cancer (90% CI -12.6, -2.7); however, there was no OCM impact on prophylactic GCSF use in patients with lung or colorectal cancer. Among beneficiaries receiving filgrastim, OCM led to faster adoption of biosimilar vs. originator filgrastim (differential trend estimate 2.6%, 90% CI 1.0, 4.4). **Conclusions:** OCM led to reduced use of some high cost supportive care medications, with patterns suggesting more value-conscious care. Alternative payment models have potential to drive value-based changes in medication use during cancer care. Research Sponsor: Centers for Medicare and Medicaid Services.

Baseline and short-term financial burden (FB) in colorectal cancer (CRC) treated with curative intent: Early results of ECOG-ACRIN EAQ162CD. *First Author: Sheetal Mehta Kircher, Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL*

Background: Cancer therapy costs continue to rise, resulting in FB. FB in CRC treated with curative intent remains unexplored, particularly in the community oncology setting. We assess baseline FB and 3-month change, including predictors. **Methods:** Patients with newly diagnosed CRC treated with curative intent were enrolled through NCI Community Oncology Research Program (NCORP) Community Sites in a longitudinal study and completed the validated FACIT Comprehensive Score for Financial Toxicity (COST) instrument at baseline and 3 months. Higher COST score (range 0-44) indicates greater financial well-being. Pearson correlation compared baseline and 3-month measurements. Effects of patient demographics, clinical, self-efficacy variables (Table) and practice safety net affiliation were assessed using linear regression for baseline COST and COST difference at 3 months. F-tests identified covariates significantly predicting FB. **Results:** 450 and 296 participants completed the baseline and 3-month survey with a mean COST score 23.5 ± 11.9 and 24.6 ± 12.4, respectively ($r=0.80$, $p<0.001$), considered grade 1 or mild. Financial resource indicators such as income, insurance type, high-deductible insurance and savings, along with self-efficacy strongly predicted baseline FB (Table). No assessed covariates predicted COST difference. Safety-net affiliation (54/450, 12%) did not predict COST outcomes. **Conclusions:** Among those with CRC treated with curative intent in community settings, FB at treatment initiation and 3-month follow-up are highly correlated. Financial resources predict FB at treatment initiation. Self-efficacy to manage finances predicted FB, suggesting interventions such as financial counseling and navigation delivered early in the treatment course may minimize downstream FB. Clinical trial information: NCT03516942. Research Sponsor: U.S. National Institutes of Health.

Patient factors associated with time to medication receipt of oral anti-cancer drugs. *First Author: Morgan Rachel Lieberman Lichtenstein, Massachusetts General Hospital, Boston, MA*

Background: The past decade has seen a dramatic increase in the number of Food and Drug Administration approvals of oral anti-cancer drugs (OACDs). Most OACD prescriptions require coordination between providers, payers, specialty pharmacists, and financial assistance organizations, which can delay drug receipt. We evaluated median time to OACD receipt (TTR) from initial OACD prescription submission and assessed clinical and process-related factors associated with TTR. **Methods:** We prospectively collected data on all new OACD prescriptions for adult oncology patients at a large, urban outpatient cancer center from 1/1/2018 to 12/31/2019. We collected patient demographic, medical, and insurance data; prescription submission and delivery dates; and interactions with payers and financial assistance groups. TTR was defined as the number of days from OACD initial prescription to patient receipt of the drug. We estimated the median TTR across all patients and used multivariable logistic regression to identify factors associated with TTR above the median. **Results:** The cohort included 1080 patients who were prescribed 1269 new OACDs. Of these prescriptions, 84% (N=1069) were received, and 71% (N=896) required prior authorization. The median patient age was 66, 44% identified as Non-Hispanic White (White), 25% of patients had commercial insurance, 16% had Medicaid alone, and 58% had Medicare alone or in combination with another plan. The median TTR per patient was 7 days (IQR 0 – 142; 25% ≥ 14 days and 5% ≥ 30 days). In unadjusted analyses, insurance and race/ethnicity were associated with TTR. Compared with patients covered by Medicaid, those with Medicare and supplemental insurance (a partial, not free-standing plan) had nearly 2.5 times the odds of TTR >7 days controlling for other factors. Race/ethnicity showed a trend toward longer TTR with Non-Hispanic Black (Black) patients having a longer TTR compared to White patients, controlling for other factors. We did not observe statistically significant effects of either comorbidity or prior authorization requirement on TTR. **Conclusions:** Though the majority of oncology patients prescribed OACDs receive the drug, 71% of prescriptions required prior authorization and a quarter of patients waited at least two weeks. Disparities in TTR are primarily driven by financial factors, specifically insurance type. Research Sponsor: NCI.

Multivariable analysis: Factors associated with TTR > 7 days.

Insurance coverage and care affordability in cancer survivors in 2016-2019. *First Author: Justin Michael Barnes, Saint Louis University School of Medicine, St. Louis, MO*

Background: The Affordable Care Act (ACA) led to improvements in insurance coverage and care affordability in cancer patients. However, the uninsured rate for the general US reached its nadir in 2016 and has been increasing since. We aimed to quantify the changes in insurance coverage and rate of care unaffordability in cancer survivors from 2016 to 2019. **Methods:** We queried data from the Behavioral Risk Factor Surveillance System (2016-2019) for cancer survivors ages 18-64 years. Outcomes of interest were the percentage of cancer survivors reporting insurance coverage and the percentage reporting cost-driven lack of care in the previous 12 months. Survey-weighted linear probability models adjusted for covariates (age, sex, race/ethnicity, income, education, marital status, and state Medicaid expansion status) were utilized to estimate the average yearly change (AYC) in the outcomes across 2016-2019. Mediation analyses evaluated the mediating effect of insurance coverage changes on changes in cost-driven lack of care. **Results:** A total of 178,931 cancer survivors were identified among the survey respondents. The percentage of insured cancer survivors between 2016 and 2019 decreased from 92.4% to 90.4% (AYC: -0.54, 95% CI = -1.03 to -0.06, P = .026). This translates to an estimated 164,638 cancer survivors in the United States who lost insurance coverage in the study period. There were decreases in private insurance coverage (AYC: -1.66, 95% CI = -3.1 to -0.22, P = .024) but increases in Medicaid coverage (AYC: 1.14, 95% CI = 0.03 to 2.25, P = .043). The decreases in any coverage were largest in individuals with income $<$ 138% federal poverty level (FPL) (AYC: -1.14, 95% CI = -2.32 to 0.04, P = .059; compared to $>$ 250% FPL, $P_{interaction}$= .03). Cost-driven lack of care in the preceding 12 months among cancer survivors increased from 17.9% in 2016 to 20% in 2019 (AYC: 0.67, 95% CI = 0.06 to 1.27, P = .03), which translates to an estimated 167,184 survivors in the US who skipped care due to costs. Changes in insurance coverage mediated 27.5% of the observed change in care unaffordability overall (p = .028) and 65.7% in individuals with income $<$ 138% FPL relative to $>$ 250% FPL (p = .045). **Conclusions:** Between 2016 and 2019, about 165,000 cancer survivors in the United States lost their insurance coverage and a similar number may have skipped needed care due to cost. Loss of insurance coverage was mostly among individuals with low socioeconomic status. Interventions to improve health insurance coverage among cancer survivors, such as the recent executive order to strengthen the ACA and further efforts promoting Medicaid expansion in additional states, may be important factors to mitigate these trends. Research Sponsor: None.

Comparing FOLFOX delivery in trial and real-world populations using longitudinal cumulative dose. *First Author: Michael Webster-Clark, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Patterns of chemotherapy delivery are likely to differ between trial and real-world populations. Typical measures used to compare these patterns are calculated at treatment completion, potentially missing key differences in the timing and trajectory of delays and dose reductions. We used a new measure, longitudinal cumulative dose (LCD), to compare treatment delivery over time in trial and real-world populations. **Methods:** We compared chemotherapy delivery in patients with stage II-III colon cancer enrolled in the MOSAIC trial of 5-fluorouracil (5FU) vs oxaliplatin + 5FU (FOLFOX4) to patients treated from 2008-2019 in the US Oncology Network with FOLFOX4, FOLFOX6, or mFOLFOX6. For each patient, we computed oxaliplatin LCD as the cumulative oxaliplatin dose received at a given timepoint (t) divided by the final standard oxaliplatin dose. We then estimated the median and 25th and 75th percentiles for oxaliplatin LCD within each regimen at day 68 (before the standard timing of the 7th dose), 168 (two weeks after the standard end of treatment), and 250. **Results:** The table shows the number of patients receiving each treatment regimen and the median and interquartile range for oxaliplatin LCD at each time. Higher LCDs in the trial show delivery closer to standard treatment, meaning fewer delays, dose reductions, and discontinuations. Differences between the medians, 25th percentiles, and 75th percentiles of LCD in each regimen were small at day 68 but grew considerably by days 168 and 250. **Conclusions:** Divergence from the standard dosing schedule was larger in real-world versus trial settings and varied by oxaliplatin regimen. LCD, as a longitudinal measure, showed that differences in delivery between trial and real-world populations grew substantially over time (even after 168 days and the standard end of treatment) possibly as real-world patients experienced more side effects and barriers to treatment than trial participants. These discrepancies in LCD may cause poorer outcomes in real-world settings than expected based on randomized trials. Research Sponsor: Patient Centered Outcomes Research Institute.

Regimen	Number receiving regimen	Median (IQR) oxaliplatin LCD, day 68 (ideal = 50%)	Median (IQR) oxaliplatin LCD, day 168 (ideal = 100%)	Median (IQR) oxaliplatin LCD, day 250 (ideal = 100%)
MOSAIC

Impact of a regimen-level prior authorization tool on provider adherence to clinical guidelines' and cost savings in a Medicare advantage population. *First Author: Heeseon Yeon, CVS Health, Wellesley, MA*

Background: In 2019, a large national health system developed a comprehensive approach to improve the quality and cost of cancer care; this solution included a Web-based clinical decision support prior authorization (PA) tool, Novologix (NLX), which approves at the regimen rather than drug level to reduce administrative burden and elevate the quality of care. Evidence-based guidelines in NLX are updated in real-time via a partnership with the National Comprehensive Cancer Network (NCCN). The purpose of this study is to evaluate the NCCNconcordance of PAs submitted via NLX and total cost of care for Medicare Advantage (MA) patients with non-small cell lung cancer (NSCLC) who received NCCNconcordant versus non-concordant therapies. **Methods:** Eligible patients included MA patients diagnosed with NSCLC; our initial analysis included only the NSCLC subset of patients. NCCN regimen concordance was identified from pharmacy and medical claims and defined as concordant if the entire prescribed treatment regimen matched an NCCNregimen; patients not receiving an NCCN recommended regimen were deemed to be non-concordant. Total cost of care for MA patients with NSCLC were calculated. **Results:** From April-December 2020, 279 PAs were submitted via NLX and 83% were automatically approved in real-time. PAs not automatically approved were deemed concordant after peer-to-peer consultations that led to NCCN concordance; no PA denials were made. In the first half of 2020, 2,690 MA patients with NSCLC were identified; 2,166 (81%) patients were defined as NCCN concordant. Beginning with and including the first treatment and for 30-days thereafter, total cost of care for concordant patients averaged $19,321 while non-concordant patients averaged $26,405, a statistically significant savings of $7,084 (p $<$ 0.001). **Conclusions:** Preliminary findings with a MA NSCLC population suggest engaging oncology practices through an enhanced payer-provider collaboration and implementing an automated regimen-level precertification process with real-time NCCNupdates can facilitate lower cost, and more efficient oncology care. Financial savings by encouraging providers to follow NCCN guidelines may lead to a 27% reduction in total cost of care with further proper adjustment on population bias; this may lead to similar findings in other cancer types. Future studies are needed to measure the long-term impact of this program on total cost of care for other care models and cancer types. Research Sponsor: None.

Germline testing in community oncology patients with somatic BRCA1/2 mutations. *First Author: Kate Principe, Texas Oncology, Houston, TX*

Background: The primary purpose of tumor mutation profiling (TMP) is to molecularly characterize tumors to identify targeted treatments and improve outcomes, but it may also uncover germline mutations with implications for patients and families. In September 2016, the National Comprehensive Cancer Network (NCCN) added "BRCA1/2 mutation detected by TMP" as a criterion for germline BRCA1/2 testing. This study aims to assess rates of germline testing, with and without genetic consultations, for individuals with a somatic BRCA1/2 finding in community oncology centers. **Methods:** Retrospective data was abstracted from an internal database of results from four TMP laboratories. Individuals with a somatic BRCA1/2 pathogenic/likely pathogenic (P/LP) variant reported from January 1, 2017 to December 31, 2019 were included. Clinical data was obtained from electronic medical records. The project was approved by the Texas Oncology Privacy Board. **Results:** 221 patients had a P/LP somatic BRCA1/2 result on TMP, 138 of which were BRCA1/2 spectrum tumors (breast, ovary, pancreas, prostate). 144/221 patients (65.2%) had BRCA1/2 germline testing. 133/221 (60.2%) met NCCN guidelines for germline BRCA1/2 testing independent of their somatic results; they were statistically more likely to undergo germline testing than patients who did not otherwise meet germline BRCA1/2 testing criteria (p=2.3e-16) (Table). 70/144 (48.6%) had a germline P/LP BRCA1/2 mutation identified. At locations with genetic providers versus those without, there was a significant difference in rates of genetic consultation (p=0.02) but not in the rate of germline testing (p=0.3). This indicates patients were more likely to receive pre- and post-test counseling at clinics offering in-house genetic consultations. **Conclusions:** Most individuals who had a P/LP somatic *BRCA1/2* mutation identified on TMP underwent germline genetic testing. As 60.2% of our cohort qualified independently for germline testing, somatic*BRCA1/2*results may not have been the driving force behind germline testing. However, individuals who had a non-*BRCA1/2*-spectrum tumor were significantly less likely to have the recommended confirmatory germline testing. Quality improvement initiatives can focus on improving rates of counseling and germline testing for patients with somatic*BRCA1/2* mutations, regardless of tumor type. Research Sponsor: None.

Rate of germline testing, genetic consultation, and pathogenic germline *BRCA1/2* mutations.

	Met NCCN criteria independent of somatic result (n= 133)	Did not meet NCCN criteria independent of somatic result (n= 88)	*BRCA1/2* spectrum tumor (n=138)	Non-*BRCA1/2* spectrum tumor (n=83)
Had germline genetic testing	116 (87.2%)	28 (31.8%)	118 (85.5%)	26 (31.3%)
Had genetic consultation	74 (55.6%)	21 (23.9%)	73 (52.9%)	22 (26.5%)

Patient navigation plus hospital at home to improve COVID-19 outcomes for cancer patients. *First Author: Brittany K. Ragon, Levine Cancer Institute, Charlotte, NC*

Background: Reports suggested cancer patients were at greater risk for increased morbidity and mortality from COVID-19. A process to mitigate these risks was established at Levine Cancer Institute (LCI) in partnership with Atrium Health's (AH) Hospital at Home (HAH) initiative. This virtual health navigation process employed expertise from the departments of Hematologic Oncology and Blood Disorders, Oncology, and Supportive Oncology, including a specialized nurse navigation team, to rapidly identify COVID-19 positive LCI patients, monitor them under physician supervision, and escalate care as needed with AH HAH program. **Methods:** AH Information Services created an automated list of LCI COVID-19 positive patients with a daily database. Each patient was reviewed by a nurse navigator. Review included hematologic or oncologic diagnosis, outpatient or inpatient status, and any COVID-19 symptoms. Once a malignant diagnosis was confirmed, a diagnosis-specific navigator contacted and screened the patient with a COVID assessment tool. Documentation was forwarded to the primary oncologist/hematologist. The tool scored patients for surveillance and treatment needs. A score of 0-2 prompted phone assessment every 48-72 hours, and score of 3-5 required every 24-48 hour calls with physician involvement when appropriate. If score of ≥6, care was escalated to LCI nurse/physician for admission to AH acute care HAH or conventional inpatient admission. **Results:** From inception on 3/20/2020 to data review date of 12/2/2020, 974 LCI patients were identified as COVID-19 positive and reviewed for nurse navigation (Table). Of the 974, 488 were navigated. Given limited resources, patients with benign conditions were not assigned a navigator, though a similar process was created for sickle cell disease. Of the 974, 75 are now deceased. Only 25 are deceased among the 488 navigated. **Conclusions:** The COVID-19 pandemic presented unprecedented circumstances to our patients and their clinicians. LCI expeditiously put policies and procedures in place to mitigate the intersection of COVID-19 and cancer. The multidisciplinary response strategy liaising between AH HAH and LCI followed, assessed, and assisted LCI COVID-19 positive patients. With our embedded nurse navigation team's specialized attention along with enhanced physician oversight and close collaboration with AH HAH, opportunities for care escalation or adjustments in cancer-focused care were promptly identified. Analysis is ongoing to elucidate the lower mortality rate observed among navigated patients. Research Sponsor: None.

The influence of race on financial toxicity among cancer patients. *First Author: John Panzone, SUNY Upstate Medical University, Syracuse, NY*

Background: Studies show that cancer patients and survivors are likely to endure financial toxicity long after being diagnosed. **Methods:** To examine the influence of race on financial toxicity among individuals with a history of cancer, a US based cross sectional study was conducted using data on 1,328 cancer patients collected from the Health Information National Trends Survey. Multivariable logistic regression analyses were used to analyze the relationship between race and financial toxicity, adjusting for known confounders. **Results:** Blacks, Hispanics and other races were shown to have a lower rate of insurance compared to Whites. Whites were also more likely to receive cancer treatment than other races (6.1% received no treatment vs 15.0% of Blacks, 17.8% of Hispanics, and 9.7% of other races, $p<0.001$). Considerably more Whites underwent surgical treatment of their cancer (77%) vs. 60% of Blacks, 55% of Hispanics and 74.2% of other races, $p<0.001$. Blacks were found to be over 5 times more likely to be denied insurance (OR 5.003, 95% CI 2.451-10.213, $p<0.001$) and more than twice as likely to be hurt financially than Whites (OR 2.448, 95% CI 1.520-3.941, $p<0.001$). Other racial minorities were also more than twice as likely to be hurt financially than Whites (OR 2.421, 95% CI 1.248-4.698, p=0.009) (Table). **Conclusions:** These data suggest that race is significantly associated with increased rates of being hurt financially and being denied insurance due to cancer. Awareness of race inequality should be raised so that equal cancer treatment can be provided, irrespective of race, gender or socioeconomic status. Research Sponsor: None.

Additional variables included in the analyses but not shown were US Census region, age of diagnosis, survey year, gender, education, rural vs. metro residence, marital status, and health insurance.

1526 **Poster Session**

Successful implementation of an ePRO remote monitoring system in patients receiving chemotherapy in a community oncology practice. *First Author: Michael A. Kolodziej, ADVI, Washington, DC*

Background: Remote symptom monitoring of patients receiving cancer treatment has been shown to improve patient outcomes in the research setting. However, there is little evidence that this technology can be implemented and scaled in the real world with the same benefits. **Methods**: Highlands Oncology Group (HOG) is a 19 physician medical oncology group in Northwest Arkansas. Beginning in June 2020, HOG offered patients receiving parenteral cancer therapy enrollment onto Expain: an EMR-integrated, electronic patient-reported outcomes (ePRO) system which enables remote symptom monitoring during systemic cancer therapy. Patients reported distress and symptoms using the NCCN Distress Thermometer and Problem List instrument. The practice prospectively defined patient reporting intervals based on disease and treatment protocol, as well as thresholds for each symptom that would trigger a nursing notification. Following clinical review, nurses initiated interventions including a telephone call, urgent office visit, or referral to an emergency room when necessary. **Results**: From June 2020 – January 2021, HOG treated 1261 patients with IV chemotherapy. 769 patients were offered enrollment and 569 (73.9%) were successfully enrolled onto the ePRO system. At the time of enrollment 419 (73.6%) of enrolled patients were in an Oncology Care Model (OCM) episode. Common reasons for declined enrollment were: low symptom burden, non-English speaker, and approaching the end of treatment. Of enrolled patients, the most common tumor types were: gastrointestinal (21.8%), breast (17.5%), and thoracic (16.1%). Patients reported using Expain's mobile app (89.1%) or Interactive Voice Response interface (IVR, 10.1%) with the following frequency: once a month (12%), twice a month (30%), 3 reports a month (35%), and 4 reports or more (23%); Of patients successfully enrolled 52.72% were still reporting after 3 months. The most common reasons specified for opting-out were: death, hospice admission, and completion of the treatment course. 50% of reports exceeded the practice-defined threshold for a nursing notification. The nurses initiated a follow-up call in response to 78.8% of notifications, and of these calls, 21.2% resulted in an urgent office evaluation. The most common problems triggering an office evaluation were: high NCCN Distress Thermometer score (17.1%), fatigue (16.1%), pain (11.5%), nausea (9.4%), and dyspnea (4.5%). **Conclusions**: ePRO-based remote monitoring of patients receiving parenteral cancer therapy in routine clinical care is feasible. Patient enrollment and retention are high across all tumor types. Symptoms reported by patients were concordant with previous publications, and a small percent (7% of reports) required an acute office visit. It is expected that office intervention will reduce the use of ER and inpatient services. Research Sponsor: None.

The role of experience and clinical decision support in clinical trial accrual within oncology. *First Author: Waqas Haque, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Patient accrual for cancer clinical trials is suboptimal. The complexity of applying eligibility criteria and enrolling patients may deter oncologists from recommending patients for a trial. As such, there is a need to understand how experience, training, and clinical decision support impact physician practices and intentions related to trial accrual. **Methods:** From May to September 2017, we conducted a survey on clinical trial accrual in a national sample of medical, surgical, and radiation oncologists. The 20-minute survey assessed barriers and facilitators to clinical trial accrual, including experience (e.g., "In the past 5 years, have you been a study or site PI of a trial?"), training (e.g., "Did you receive training about trial design and recruitment as part of medical school, residency, or fellowship? After fellowship?"), and clinical decision support (e.g., "What kind of clinical decision support has your practice implemented?). We used logistic regression to identify factors associated with frequency of discussing trials (with ≥25% of patients) and likelihood of recommending a trial to a patient (likely or very likely) in the future. **Results:** Survey respondents (n = 1,030) were mostly medical oncologists (59%), age 35-54 years (67%), male (74%), and not in academic practice (58%). About 18% of respondents (n = 183) reported discussing trials with ≥25% of their patients, and 80% reported being likely or very likely to recommend a trial to a patient in the future. Prior experience as principal investigator of a trial was associated with both frequency of discussing trials (OR 3.27, 95% CI 2.25, 4.75) and likelihood of recommending a trial in the future (OR 5.22, 95% CI 3.71, 7.34), as was receiving additional training in clinical trials after fellowship (discussion with patients: OR 2.48, 95% CI 1.80, 3.42; recommend in future: OR 1.92, 95% CI 1.37, 2.69). Implementing clinical decision support was not associated with discussing trials with ≥25% of patients (OR 1.12, 95% CI 0.76, 1.67), but was associated with being likely to recommend a trial in the future (OR 1.73, 95% CI 1.11, 2.71). **Conclusions:** In a national survey of oncologists, we observed differences in physician practices and intention related to clinical trial accrual. Whereas the vast majority (80%) reported being likely or very likely to recommend trials in the future, far fewer (20%) reported discussing trials with their patients within the past 5 years. Implementation of clinical decision support – electronic tools intended to optimize patient care and identification of patient eligibility – was not associated with frequency of past discussion of clinical trials but was associated with recommending a trial in the future. Given the stronger association between experience as a site Principal Investigator and recommending a trial, future research should explore how improving opportunities to lead a clinical trial impact trial accrual. 1528 **Poster Session**

Impact of COVID-19 pandemic on time to treatment initiation for patients with advanced cancer. *First Author: Samuel U Takvorian, University of Pennsylvania, Philadelphia, PA*

Background: The COVID-19 pandemic has disrupted US healthcare delivery and led to delays in life-prolonging therapy for some conditions. Its impact on diagnosis and timely care delivery for patients (pts) with cancer is unknown. We assessed the pandemic's impact on time from advanced diagnosis to systemic treatment initiation (TTI) for pts with newly diagnosed advanced solid cancers. **Methods:** We performed a controlled interrupted time series analysis using the nationwide Flatiron Health electronic health record-derived de-identified database, which originated from ~280 US cancer clinics. The study sample included pts ≥ 18 years diagnosed with advanced solid cancers from Jan 1-Jul 31 in 2019 or in 2020, excluding a 30-day period (Mar 8-Apr 7) encompassing the start of most state stay-at-home orders. We used Cox proportional hazards models to estimate standardized predicted probabilities of TTI within 30 days of advanced diagnosis before (Jan-Mar) and during (Apr-Jul) the pandemic in 2020, compared to historical controls in 2019, adjusted for age, sex, race, insurance, performance status, and cancer type. Interactions by cancer type and race examined heterogeneity of effects. **Results:** The study included 12,977 pts (median age 69 yrs [IQR 61-77]; 47.4% female; 59.4% non-Hispanic white). At the time of analysis, fewer advanced cancer diagnoses were recorded in 2020 (Jan-Mar 2,409; Apr-Jul 3,027) than in 2019 (Jan-Mar 2,910; Apr-Jul 4,631). Compared to Apr-Jul 2019, pts diagnosed with advanced cancer during the COVID-19 period were more likely to have de novo (vs recurrent) disease (67.3% vs 56.8%). In adjusted models, the COVID-19 period was associated with an increased probability of treatment within 30 days (adjusted difference-in-differences +5.2 percentage points [ppts]). TTI improvements were not observed for pts with advanced breast cancer or Black pts, but effect differences across subgroups were not statistically significant (Table). **Conclusions:** Among pts diagnosed with advanced cancer, the COVID-19 pandemic was associated with shorter time to systemic therapy initiation. These treatment patterns may reflect the fewer advanced cancer diagnoses and higher proportion of de novo cancers observed during this period. Longer follow-up and data maturity are needed to understand the impact of the pandemic on clinical outcomes. Research Sponsor: None.

Adjusted probability of treatment within 30 days of advanced diagnosis (%).

	Jan-Mar 2019	Apr-Jul 2019	Jan-Mar 2020	Apr-Jul 2020	Adjusted difference-in-differences, ppts

Socio-economic disparities and accessibility to age-appropriate screening tools. *First Author: Noha Soror, Western Reserve Health Education, Warren, OH*

Background: Pervasive racial and ethnic health disparities continue to be reported throughout the U.S. population. An increasing number of studies have discussed racial disparities in cancer statistics as well as socio-economic differences. The purpose of this study is to investigate sociodemographic health care disparities and the prevalence of cancer diagnosis in the context of challenges in medical services accessibility due to financial burden. **Methods:** Analysis of pooled cross-sectional data using 2017 Behavioral Risk Factor Surveillance System (BRFSS). Differences between our comparison groups were computed using chi square test for categorical values and t-test for continuous variables. Demographic factors were analyzed through weighted regression for accessibility to cancer treatment and prior cancer screening. **Results:** We report data from a total of 436,198 respondents to the 2017 BRFSS survey, with cancer prevalence 9.8% and higher prevalence of cancer among females and elderly population (70 years and older). Racial disparities differed significantly between respondents with and without history of cancer, with higher prevalence in Hispanic and multiracial minorities, 19% and 14%, respectively. We also report, differences in annual income are significantly associated with increased cancer prevalence in lower socioeconomic populations. Nineteen percent of participants who had annual income less than 25k were diagnosed with cancer. Additionally, analyzing the association between delayed medical care due to financial burden and its correlation with accessibility to age-appropriate cancer screening tools. We report significant differences in receipt of cancer screening among respondents, with consistently lower probabilities of receiving age-appropriate screening tools among participants who experienced delays in medical care due to cost, that applies to all screening tools. Among respondents who did not receive screening mammograms, 17% reported delays in medical care due to medical cost. Twelve percent of participants who did not receive screening colonoscopy suffered delays in medical care due to cost. Also, among participants who did not receive screening for prostate cancer with PSA testing, 11% reported delays in medical care due to cost. **Conclusions:** Health care disparities in cancer screening continue to persist including differences in socioeconomic classes and access to medical services. In this study, we report that patients with delayed access to medical services due to cost are not adequately receiving age-appropriate screening for cancer. Given the deleterious effects of delayed diagnosis and treatment of cancer, it is important that public health and clinical professionals utilize tools to improve cancer screening accessibility to minorities with socio-economic disparities. Research Sponsor: None.

Comparison of clinician and model estimates of risk for hospitalization during systemic therapy for advanced cancer. *First Author: Lukas P Emery, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: Patients receiving treatment for advanced cancer are at substantial risk for unplanned hospitalization. A validated two-variable risk model can identify patients at increased risk for hospitalization. However, little is known about how model-based estimates of hospitalization risk compare with assessments of treating clinicians. **Methods:** We identified patients initiating a new line of systemic therapy for advanced non-hematologic cancer. For each patient, we assigned three categorical estimates of 30-day hospitalization risk. The first risk estimate was generated by a validated two-variable risk prediction model with inputs of pretreatment plasma sodium and albumin (PMID: 30995122); continuous risk scores were converted to risk tertiles. We solicited a second risk estimate by real-time survey of a treating oncology clinician; clinicians were instructed to estimate hospitalization risk as low, intermediate, or high, as compared with other patients. A third hybrid risk estimate retained the highest risk category from either the clinician or model risk assessment. We describe the agreement of clinician and model-based estimates of 30-day hospitalization risk, and we compare the sensitivity and specificity of clinician, model, and hybrid high-risk assessments, using McNemar's test. We compared discrimination of the three risk estimates via the area under the ROC curve (AUC). **Results:** We identified 104 patients with valid clinician and model hospitalization risk estimates and complete 30-day follow-up. The most common cancer type was lung cancer (27%), the median age was 68 years, and 62% of patients were male. 30-day hospitalization occurred in 21 patients (20.2%). There was moderate to poor agreement between clinician and model categorical estimates of hospitalization risk (weighted kappa = 0.245). The proportion of patients identified as high-risk by the clinician, model, and hybrid assessments was 15.4%, 26.0%, and 33.7%. Sensitivity and specificity of the high-risk categorization for 30-day hospitalization were 38% and 90% for the clinician assessment, 57% and 82% for the model assessment (NSS for comparison with clinician assessment), and 76% and 77% for the hybrid assessment (greater sensitivity [p = 0.008] and lesser specificity [p = 0.001] than clinician assessment). The AUC values for the clinician, model, and hybrid assessments were 0.674, 0.757, and 0.764, respectively. **Conclusions:** Compared with the estimate of a treating clinician, a two-variable risk model exhibited similar sensitivity and specificity for 30-day hospitalization risk. A hybrid risk assessment incorporating information from the risk model significantly improved on the sensitivity of the clinician risk assessment. Future research should test strategies to prevent hospitalizations by targeting interventions to high-risk patients. People with cancer are likely to accept the COVID-19 vaccine, but politics tracks with attitudes: An inspire and COSMO survey. *First Author: Don S. Dizon, Lifespan Cancer Institute and Brown University, Providence, RI*

Background: Vaccines are a major step towards control of the COVID-19 pandemic. Estimates from multiple surveys of the general public indicate that 40 to 60% plan to be vaccinated, with some data suggesting that uptake differs by political leanings. The views of people with cancer on COVID-19 vaccination have not been reported. We report survey results of people with cancer, evaluating intent and attitudes toward COVID-19 vaccinations. **Methods:** An online survey included self-identified patients with cancer, ≥18 years old, in the Inspire Online Community (www.inspire.com). Invitation was restricted to only members of Inspire's cancer support groups who agreed to be contacted for research. Quantitative data were summarized with descriptive statistics. Data were analyzed by chi-square, ANOVA, and post hoc Tamhane' T2 testing. **Results:** 750 responded with the most common cancers represented being prostate (30%), thyroid (24%) ovarian (20%), bladder (8%) and breast (4%). 44% were between 46 and 65 years old and 48% were over 65. Of these, 38% reported being on active treatment. The majority were white (91%), female (56%) and had a bachelor's degree or higher (72%). Respondents represented the South (38%), West (28%), Midwest (20%), and Northeast (18%). Nearly half of respondents lived in a suburb near a large city. Almost 40% reported an annual income of > $100,000 and 13% reported income < $50,000/year. The proportion that would "definitely" or "most probably" get the COVID-19 vaccine was 80%, with significantly greater interest in people with prostate (85%), bladder (82%) and ovarian cancer (81%). Those with breast cancer reported the highest levels of being uncertain (23%) and 30% of those with thyroid cancer reported they would "probably" or "definitely" not get vaccinated. Older age, male sex, and college graduates were significantly more likely to get vaccinated. Concerns about side effects were reported by 54%, with younger patients significantly more concerned than those 66 years and older. Of 158 participants who listed other reasons they would not get vaccinated, 23% were concerned that the research and development was rushed and 11% worried about how it might interact with a compromised immune system. Using the 2020 Electoral College map to indicate political leaning at the state level, there was no significant difference in vaccine uptake, although significantly more people from blue states agreed that vaccination was the best defense against COVID-19 compared to those from red states (67 vs 33%, p < .05). **Conclusions:** People with cancer are much more interested in COVID-19 vaccination compared to the general public. Despite this, a large percentage of people with cancer reported distrust in either the government and/or the healthcare industry. Although vaccine attitudes tracked with political leanings at the state level, intention to get vaccinated did not. Research Sponsor: None.

Choosing unwisely: Low-value care in older adults with a diagnosis of myelodysplastic syndrome. *First Author: Sudipto Mukherjee, Leukemia Program, Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH*

Background: In tandem with the Choosing Wisely initiative, ASCO's Cost of Care Task Force has proposed a list of low-value (LV) procedures and therapies that may be of limited benefit to patients. Myelodysplastic syndrome (MDS) is the most common myeloid malignancy in the US. A complete diagnostic evaluation (CDE) of MDS requires a bone marrow biopsy, fluorescence in situ hybridization and chromosomal analysis. As a potential LV procedure, we evaluated receipt of CDE in MDS patients with isolated or no cytopenias and no transfusion dependence. **Methods:** Using national 2011-2014 Medicare data, we identified fee-for-service Medicare patients 66 years of age or older with an MDS diagnosis, one or no cytopenias, and no blood transfusions in the 16 weeks before or after an MDS diagnosis (n = 16,779). We examined the following variables that may have provided a clinical context to (or not to) pursue CDE – demographics (age, race, sex); number of Elixhauser comorbid conditions (< 5 vs >5); nursing home status, prior history of lymphoma, myeloma, MGUS and other cancers; chronic kidney disease (CKD); colonoscopy; and therapies received including erythropoiesis stimulating agents (ESAs), hypomethylating agents (HMAs) or lenalidomide. We conducted Classification and Regression Tree (CART) analysis, a machine learning approach to identify combinations of factors in patients with little clinical justification for CDE, and Cox proportional hazards regression analysis to compare survival outcomes between those with or without CDE. **Results:** Over half of our study population (51%) received CDE. Of those, 46.6% were 80 years of age or older, 4.8% were nursing home residents; and 33.6% had 5 or more chronic conditions. Results from CART analysis showed that among patients with an isolated cytopenia (e.g., isolated anemia), 46.0% of patients >80 years (n = 860), and 57.7% (n = 1,156) of those in the 66-79 age group underwent CDE in the absence of CKD, colonoscopy, HMA, or ESA. Among those with no cytopenia (n = 3890), 866 patients received CDE in the absence of HMA, ESA, or history of lymphoma or progression to leukemia. In adjusted analyses, no survival benefit was associated with receipt of CDE (p = 0.24). **Conclusions:** A substantial number of patients with an MDS diagnosis, isolated or no cytopenias, and no transfusion dependence received a CDE in the absence of other diagnoses, procedures, or therapies that may have explained the clinical decision to perform CDE. These procedures entail costs, pain and anxiety, but do not appear to yield useful information to guide clinical management, as evidenced by the comparable survival outcomes between patients who did and did not undergo CDE. To promote patient-centered care, careful patient selection that reduces unnecessary CDE in MDS patients should be a priority in clinical decision-making. Research Sponsor: Celgene (now Bristol Myers Squibb).

1533 **Poster Session**

The impact of COVID-19 on clinical cancer care: An individual-patient level analysis. *First Author: Lynsey M Drewett, Department of Oncology, University of Cambridge and Cambridge Breast Cancer Research Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom*

Background: At the outset of the COVID-19 pandemic, concerns for the safety of patients receiving anti-cancer treatment coupled with pressures on healthcare services prompted review of standard clinical care pathways in the UK. Revised consensus treatment guidelines were generated. Individual patient-level data regarding actual treatment modifications implemented in clinical practice are lacking. **Methods:** All anti-cancer treatment plans of patients with breast, lung, renal, hepatopancreatobiliary, CNS cancers and melanoma attending a single academic cancer centre in the UK between 16 March and 31 May 2020 were reviewed and any modifications to standard practice were documented. The effect of patient (age, ECOG performance status [PS], sex) and cancer (site, stage, treatment intent) characteristics on likelihood of treatment modifications were analysed using univariable and multivariable models. **Results:** Treatment plans for 925 patients were reviewed: median patient age was 63 (range 19-97); 66% were female; 73% were PS 0-1; 45% were on a curative pathway. Overall, 47% of all patients had one or more modifications made to their treatment plans: 53% of surgeries (primarily being delayed); 41% of radiotherapy (primarily reduced fractions delivered); 39% of systemic therapy prescriptions. 96-100% of all systemic therapy modifications resulted in treatment de-escalation, excluding endocrine therapy used as a bridge to defer primary breast cancer surgery. Biological therapy was predominantly interrupted (49%), immunotherapy was mostly omitted entirely (36%), and chemotherapy varied between interruptions (39%) or omissions (31%). Relative to the likelihood of modification to chemotherapy, surgery was significantly more likely to be modified (OR 1.69 95%CI 1.20-2.38). Chemotherapy, radiotherapy, biological therapy and immunotherapy were all modified to a similar degree. Multivariate analysis identified PS ≥ 2 (OR 1.79, 95% CI 1.18–2.75), but not patient age, as a predictor of treatment modification. Some tumour types were less likely to undergo any modification: stage 1-3 lung (OR 0.13, 95%CI 0.04-0.37), stage 4 lung (OR 0.26 95%CI 0.24–0.60) and stage 4 renal cancer (OR 0.22 95%CI 0.09-0.52). **Conclusions:** This single centre analysis demonstrated almost half of cancer patients had their treatment modified, the overwhelming majority resulting in treatment de-escalation. The impact of the treatment modifications on overall cancer patient outcomes remains to be determined. Research Sponsor: None.

Are National Cancer Institute Cancer Centers (NCI-CC) providing adolescents and young adults (AYA) with cancer focused clinical services? A national survey. *First Author: Katherine Daunov, Case Western Reserve University, Cleveland, OH*

Background: AYA patients with cancer have inferior outcomes compared to their pediatric and adult counterparts. The NCI recommends they be treated by AYA focused healthcare professionals within an AYA oncology program. This survey captures the current landscape of AYA oncology care in the United States. **Methods:** An online survey was sent to 272 cancer centers in September 2020, in coordination with Teen Cancer America and included all clinically designated NCI-CC. The survey asked about the presence of an AYA program, types of patients, dedicated resources, clinical space, type of providers, associated support services, educational efforts, importance of AYA oncology care, and how well these services are provided. **Results:** In total, we received 93 responses, a 34% response rate, including 50 NCI centers, a 72% response rate. Only half (49%) of NCI-CC reported having an AYA program, and 70% were started in the past 5 years. One-third (32%) of centers reported plans to start an AYA program. Most programs included patient ages from $\geq$15 (56%) to $\leq$39 (63%) with a variety of cancers – most commonly hematologic (49%) and sarcoma (49%) and least commonly lung (36%), breast (38%), and head and neck cancer (38%). AYA programs are generally embedded in both adult and pediatric oncology services (63%). On average, cancer centers reported seeing 25-50 new AYA patients/month and 100-200 follow-up visits/month. Few programs reported a dedicated inpatient space (4%) or outpatient space (9%). Most NCI-CC have supportive services available for all oncology patients, but fewer of these services were dedicated specifically to AYA patients: navigators (92% vs. 71%), social work (98% vs. 57%), psycho-oncology (96% vs. 54%), dietician (98% vs. 24%), physical therapy (98% vs. 18%), chaplaincy (98% vs. 18%), and child life (83% vs. 26%). Other services available to the AYA population included sexual health (62%), academic support (62%), and career resources (36%). A minority of centers (30%) provided AYA training to their staff. A majority of NCI-CC felt AYA programs were important-very important (60%). They reported providing good-excellent overall AYA care (59%), but this dropped to 22% for sexual health and education of staff, which was relatively consistent across centers (Table). **Conclusions:** This survey is the first ever national survey to assess AYA oncology programs. Despite greater emphasis on the AYA cancer population, only half of NCI-CC report having a dedicated program, and areas of improvement include education of staff and sexual health services for patients. Self-report of providing good to excellent AYA care in specific areas. Research Sponsor: None.

	Overall	Fertility	Psycho-Oncology	Survivorship	Symptoms	End of Life	Research	Education	Sexual Health
NCI-CC	58%	65%	65%	65%	57%	49%	37%	22%	22%
Academic	67%	71%	83%	61%	67%	67%	44%	22%	39%

Patterns in cancer management changes for patients with COVID-19 in northern California. *First Author: Michael Glover, Stanford University Medical Center, Stanford, CA*

Background: The COVID-19 pandemic affected oncology practice in ways that are still evolving. In particular, COVID-19 has led to changes in cancer treatment for patients (pts) infected with COVID, which may have long-term implications for both COVID and cancer-related outcomes. In this retrospective analysis, we describe changes in cancer management over time for cancer pts diagnosed with COVID-19 at two academic institutions in Northern California. **Methods:** Adult and pediatric pts diagnosed with COVID-19 receiving active cancer management, defined as therapy/surgery/diagnostics within 3 weeks of COVID diagnosis, were identified through the EMR. Patients whose care was affected by COVID-19 were identified and analyzed for significant intra-group differences with regards to management type, treatment intent, and the time of COVID-19 diagnosis ("early" was defined as March to June 2020 and "late" as July 2020 to January 2021). The duration and characteristics of such changes were compared across subgroups. Chi-squared test was used to compare the incidence of delays between subgroups. **Results:** Among 134 COVID-positive pts on active cancer management, 83 (62%) had significant changes in management that consisted primarily of treatment delays. More delays were identified in patients treated with curative intent earlier in the course of the pandemic compared to later (OR 4.1, p=0.022). This difference was not seen among pts treated with palliative intent. In addition, pts on oral (PO) therapy were significantly less likely to have treatment changes than those on IV/IM therapy (OR 0.32, p=0.005). This difference was driven by a decrease in management changes for those on PO therapy in the later time period (OR 0.27, p=0.026). Pts diagnosed later were more likely to have delays due to clinical reasons rather than institutional policy (OR 6.2, P<.005). The median delay in both time frames was 21 days. Comparison of subgroups is shown in the table. **Conclusions:** We found significant changes in management of cancer pts with COVID-19 that evolved over time. Oncologists have become increasingly willing to continue therapy for cancer pts treated with curative intent and pts on oral therapy. Changes in cancer therapy have become more frequently related to patient clinical status, and less so due to institutional policies. It will be important to analyze how these changes in management are ultimately reflected in cancer outcomes in order to equip patients and oncologists to react to the next pandemic. Research Sponsor: Stanford Cancer Center.

Characteristic	Active cancer management (N=134)	Incidence of delay in management (N=83)	P Value for delays (N=83)
Date			
March-June	55 (41%)	38 (46%)	0.21
July-January	80 (60 %)	45 (54%)	
Management			
IV/IM Therapy	56 (42%)	40 (48%)	.04*
PO therapy	58 (43%)	26 (31%)	
Other	20 (15%)	17 (20%)	
Intent			
Curative	51 (38%)	27 (33%)	0.09
Palliative	83 (62%)	56 (67%)

Feasibility of fully remote administration of problem-solving skills training (PSST) to adult cancer survivors in community settings. *First Author: Katia Noyes, University of Rochester Medical Center, Rochester, NY*

Background: Cancer survivors experience significant stress throughout cancer treatment and especially during transition back to normal life. These stressors are particularly severe for rural or socially disadvantaged patients with limited access to care. Improving their problem-solving skills is known to help patients make reasoned and timely decisions about survivorship care that reduce stress and enhance quality of life, physical and social functioning, and overall cancer prognosis. This pilot implementation study examined barriers to and facilitators of providing Problem-Solving Skills Training (PSST) to adult cancer survivors and their caregivers in community settings. **Methods:** Patients (n = 50) who completed their definitive cancer treatment and cancer survivorship visit within the previous 6 months were recruited from two regional cancer centers and affiliated community cancer clinics. Patients with NCCN distress level >2 were randomly assigned to either care as usual (CAU) or 8 weekly PSST sessions using the Bright IDEAS system of teaching problem solving. Training was offered by a trained therapist in person at the patient's preferred location or remotely. Patients were invited but not required to include a supportive other (SO). Patient outcomes were assessed at baseline (T1), the end of the intervention/3 months (T2), and 3 months post intervention/6 months (T3). We examined patient and caregiver preferences for mode of communication and therapy, barriers to PSST participation, and adherence rates. An independent consultant interviewed patients and caregivers about factors that promote or inhibit intervention sustainability and its wider adaptation and usefulness. **Results:** Average age of the participants was 63 years (45-87) with gender, racial and ethnic distributions representative of the local population (64% women, 88% white). Women were 80% less likely to include a SO than men. Among the third of the patients recruited fully remotely, 50% preferred receiving consent materials via regular mail and 18% preferred electronic communication. Among the two patients lost to follow-up before PSST completion and one patient who withdrew despite reporting significant distress, none had a SO in the study. Seventy-six percent of the PSST patients completed the training (defined as > 6 sessions). After study completion, all patients and caregivers reported high satisfaction with Bright IDEAS and high probability of continuing to use the skills learned. **Conclusions:** Despite significant distress and numerous reported social challenges, patients and caregivers in the PSST arm demonstrated high adherence, skill retention and overall satisfaction. Future research should be tailored to accommodate the preferred type of communication and recruitment approaches of the targeted population and emphasize the positive role of informal caregivers. Clinical trial information: NCT03567850. Research Sponsor: U.S. National Institutes of Health.

The HOLA COVID-19 study: Evaluating the impact of caring for patients with COVID-19 on cancer care delivery in Latin America. *First Author: Carolina Bernabe Ramirez, Essen Medical Group, Bronx, NY*

Background: The severe acute respiratory syndrome 2 (SARS-cov-2) virus causing COVID-19 has brought great challenges to global health services affecting cancer care delivery, outcomes, and increasing the burden in oncology providers (OP). Our study aimed to describe the challenges that OP faced while delivering cancer care in Latin America. **Methods:** We conducted an international cross-sectional study using an anonymous online survey in Spanish, Portuguese, and English. The questionnaire included 43 multiple choice questions. The sample was stratified by OP who have treated patients with COVID-19 versus those who have not treated patients with COVID-19. Data was analyzed with descriptive statistics and Chi-square tests. **Results:** A total of 704 OP from 20 Latin American countries completed the survey (77% of 913 who started the survey). Oncologists represented 46% of respondents, followed by 25% surgical-oncologists. Of the respondents, 56% treated patients with COVID-19. A significant proportion of OP reported newly adopting telemedicine during COVID-19 (14% vs 72%, p=0.001). More than half (58%) of OP reported making changes to the treatments they offered to patients with cancer. As shown in the table, caring for patients with COVID-19 significantly influenced practice patterns of OP. Access to specialty services and procedures was significantly reduced: 40% noted significantly decreased or no access to imaging, 20% significantly decreased or no access to biopsies, 65% reported delays in surgical oncology referrals, and 49% in radiation oncology referrals. A vast majority (82%) reported oncologic surgeries were delayed or cancelled, which was heightened among those treating patients with COVID-19 (87% vs 77%, p=0.001). **Conclusions:** The COVID-19 pandemic has significantly affected the way cancer care is delivered in globally. Although changes to healthcare delivery are necessary as a response to this global crisis, our study highlights the significant disruption and possible undertreatment of patients with cancer in Latin America that results from COVID-19. Research Sponsor: None.

	Cared for patients with COVID-19 (%)	Did not care for patients with COVID-19 (%)	P-value
Changed to a less effective CT regimen with less side effects	53	39	0.006
Stopped CT in patients previously on treatment	29	18	0.001
Delayed CT start	45	28	0.001
Cancelled or stopped adjuvant CT	25	18	0.026
Discontinued palliative CT	40	28	0.001
Cancelled adjuvant RT	22	19	0.265
Used less multi-drug CT regimens	41	32	0.013
Increased use of oral CT	53	41	0.002
Cancelled or delayed concurrent chemoradiation	35	25	0.004

Abbreviations: CT = chemotherapy; RT = radiation therapy.

Bridging the gaps between tertiary and community care networks: Results from a southern California survey research analysis. *First Author: Alex Chehrazi-Raffle, City of Hope National Medical Center, Duarte, CA*

Background: Although many tertiary cancer centers offer access to myriad research protocols, the majority of patients nevertheless receive treatment at community practices. We sought to examine the barriers that hamper clinical collaboration between tertiary and community practice environments in Southern California. **Methods:** A 31-item survey was distributed to community and tertiary oncologists using REDCap, a browser-based electronic data capture system. Survey questions assessed the following attributes: demographics and features of clinical practice, referral patterns, availability and knowledge pertaining to clinical trials, strategies for knowledge acquisition, and integration of community and tertiary practices. **Results:** The survey was distributed to 98 oncologists, 85 (87%) of whom completed it in full. The most common institutional affiliations were City of Hope Comprehensive Cancer Center (58%), University of California, Los Angeles (10%), and Cedars Sinai Medical Center (8%). In total, 52 (61%) respondents were community practitioners and 33 (38%) were tertiary oncologists. A majority (56%) of community oncologists defined themselves as general oncologists whereas almost all (97%) tertiary oncologists reported a subspecialty. Clinical trial availability was the most common reason for pt referrals to tertiary centers (73%). The most frequent barrier to tertiary referral was financial considerations (59%). Clinical trials were offered by 97% of tertiary practitioners as compared to 67% of community oncologists (p = 0.001). Of note, while a majority of tertiary center providers (52%) described the primary value of community practices to be a source of referrals for clinical trials, most community oncologists (82%) reported only a minimal-to-moderate understanding of clinical trials available at regional tertiary centers. **Conclusions:** Community oncologists refer patients to tertiary centers primarily with the intent of clinical trial enrollment; however, significant gaps exist in their knowledge of trial availability. Our results identify the need for enhanced communication and collaboration between community and tertiary providers to expand patients' access to clinical trials. Research Sponsor: None.

An automated EHR-based tool to facilitate patient identification for biomarker-driven trials. *First Author: Shailendra Lakhanpal, Birmingham Hem Onc, Mountain Brk, AL*

Background: Clinical trial eligibility increasingly requires information found in NGS tests; lack of structured NGS results hinders the automation of trial matching for this criterion, which may be a deterrent to open biomarker-driven trials in certain sites. We developed a machine learning tool that infers the presence of NGS results in the EHR, facilitating clinical trial matching. **Methods:** The Flatiron Health EHR-derived database contains patient-level pathology and genetic counseling reports from community oncology practices. An internal team of clinical experts reviewed a random sample of patients across this network to generate labels of whether each patient had been NGS tested. A supervised ML model was trained by scanning documents in the EHR and extracting n-gram features from text snippets surrounding relevant keywords (i.e. 'Lung biomarker', 'Biomarker negative'). Through k-fold cross-validation and l2-regularization, we found that a logistic regression was able to classify patients' NGS testing status. The model's offline performance on a 20% hold-out test set was measured with standard classification metrics: sensitivity, specificity, positive predictive value (PPV) and NPV. In an online setting, we integrated the tool into Flatiron's clinical trial matching software OncoTrials by including in each patient's profile an indicator of "likely NGS tested" or "unlikely NGS tested" based on the classifier's prediction. For patients inferred as tested, the model linked users to a test report view in the EHR. In this online setting, we measured sensitivity and specificity of the model after user review in two community oncology practices. **Results:** This NGS testing status inference model was characterized using a test sample of 15,175 patients. The model sensitivity and specificity (95%CI) were 91.3% (90.2, 92.3) and 96.2% (95.8, 96.5), respectively; PPV was 84.5% (83.2, 85.8) and NPV was 98.0% (97.7, 98.2). In the validation sample (N = 200 originated from 2 distinct care sites), users identified NGS testing status with a sensitivity of 95.2% (88.3%, 98.7%). **Conclusions:** This machine learning model facilitates the screening for potential patient enrollment in biomarker-driven trials by automatically surfacing patients with NGS test results at high sensitivity and specificity into a trial matching application to identify candidates. This tool could mitigate a key barrier for participation in biomarker-driven trials for community clinics. Research Sponsor: This study was sponsored by Flatiron Health, which is an independent subsidiary of the Roche Group.

Transitioning ifosfamide based chemotherapy to the outpatient setting: A model of implementation of transitioning chemotherapy outpatient in a safety net hospital. *First Author: Cindy Banh, University of Arizona College of Pharmacy, Tucson, AZ*

Background: Ifosfamide displays clinical activity against germ cell tumors as well as soft-tissue and bone sarcomas. It is used in different oncology regimens and commonly administered inpatient due to patient monitoring and side effect management. Transitioning certain chemotherapy regimens to the outpatient setting provides a novel approach to treating patients while maximizing patient satisfaction and decreasing total patient care costs[1]. There is limited data and protocol development to transition ifosfamide regimens to the ambulatory setting. This study's purpose is to characterize a pharmacy managed ambulatory oncology workflow for transitioning ifosfamide based-regimens to the outpatient setting. **Methods:** A retrospective cohort chart review was conducted at a single center and included patients 18 years and older receiving at least one cycle of ifosfamide therapy between September 1, 2013 and July 31, 2019. The primary outcome was to evaluate the side effect profile and cost of treatment of ifosfamide. The secondary endpoint included number of hospitalizations. The adverse event grading system was defined using the Common Terminology Criteria for Adverse Events (CTCAE) Version 5.0. The highest grade observed for adverse effects was documented for every cycle of each patient. The cost was evaluated by labs ordered, drug used, length of stay in the hospital for chemotherapy or adverse reactions. **Results:** Ifosfamide therapy of 86 patients (57 OP, 29 IP) was reviewed. The predominant OP regimens were adriamycin-ifosfamide-mesna (AIM) with 43.9% and ifosfamide-etoposide (IE) with 29.8%. Grade 4 anemia, thrombocytopenia, and neutropenia were most frequent in IP vs OP therapies (22.9% IP vs 4.3% OP, 21.6% IP vs 9.2% OP, and 22.8% IP vs 19.6% OP respectively). Neutropenic fever (NF) occurred in 20 OP patients which were predominantly treated with AIM or IE, and led to average hospital stay of 6 days. Neurotoxicity, treated with methylene blue (MB), occurred in 4 OP patients. OP therapy saved a total of 783 hospital days, leading to a cost savings of $2,103,921. **Conclusions:** Transitioning to outpatient therapy is feasible for academic and community infusion centers. Administration of chemotherapy in the outpatient setting has shown to be safe, well-tolerated, and associated with decreased total cost of care, thereby lowering costs under the oncology care model when compared with inpatient chemotherapy costs. Research Sponsor: None.

Trends of cancer associated with modifiable behavior in the U.S.: Is there a difference based on age, gender, or race? *First Author: Cheng-I Liao, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*

Background: To examine trends in modifiable behaviorally related cancers among men and women in the United States. **Methods:** Data were obtained from the United States Cancer Statistics (USCS) database for all cancers diagnosed between 2001 and 2017. Alcohol-associated cancers, HPV-associated, obesity-associated, physical inactivity-associated, and tobacco-associated were defined using ICD-O-3 site codes. SEER*Stat 8.3.8 and Joinpoint regression program 4.8.0.1 were used to calculate the trends of associated cancers expressed per 100,000. **Results:** In 2017 the incidence of cancers in women associated with alcohol, smoking and obesity were 168/100,000, 134/100,000 and 121/100,000 respectively. Based on analysis of trends of women from 2001 to 2017, alcohol, smoking and physical inactivity related cancers decreased with an annual percent change (APC -0.51%, -0.96%, -0.92% respectively, $p < 0.001$). However, there was no significant change in obesity, HPV, or post menopausal female breast cancer related cancers (APC: 0.07%, 0.09%, -0.08% respectively, $p = 0.303$, 0.181, 0.569). Based on age, in women less than 65, rates of obesity related cancers are increasing. Based on racial groups, all rates of cancer associated with modifiable factors are decreasing, however Hispanic women have an increasing rate of obesity related cancers (APC 0.46%, $p < 0.001$). When examining differences in region, all rates of cancer are decreasing or unchanged except the south has an increasing rate of obesity related cancer (APC 0.28%, $p < 0.001$). Using a projection model, obesity will become the highest incidence cancer in Hispanic women by 2035, surpassing alcohol and tobacco. In 2017 the incidence of cancers in men associated with tobacco, obesity, and alcohol were 209/100,000, 111/100,000 and 81/100,000 respectively. Based on analysis of trends in men alcohol, smoking, physical inactivity and obesity related cancers decreased (APC -1.42%, -1.59%, -3.15%, -0.41% respectively, $p < 0.001$). HPV related cancers have increased (APC 2.36%, $p < 0.001$). In men less than 60 years old, the rates of obesity related cancers are increasing. Using a prediction model, obesity is predicted to surpass tobacco as the most common social cause of cancer in 2020 for men 35-39, 2024 in men 40-44 and in 2030 in men 45-49. **Conclusions:** In women, most modifiable factors associated with cancer are decreasing except in obesity and HPV related cancers. In men, these rates of cancer are decreasing except HPV related cancers. However, rates of obesity related cancers are on the rise in Hispanic women and younger men. Obesity is set to become the major modifiable factor for many associated cancers. Research Sponsor: Fisher Foundation and Denise Cobb Hale.

Dedicated clinical trial tissue tracking database to improve turn-around time at high-volume center. *First Author: Peter Blankenship, Sarah Cannon Research Institute, Nashville, TN*

Background: Tissue requirements in oncology clinical trials are increasingly complex due to prescreening protocols for patient selection and serial biopsies to understand molecular-level treatment effects. Novel solutions for tissue processing are necessary for timely tissue procurement. Based on these needs, we developed a Tissue Tracker (TT), a comprehensive database for study-related tissue tasks at our high-volume clinical trial center. **Methods:** In this Microsoft Access database, patients are assigned an ID within the TT that is associated with their name, medical record number, and study that follows their request to external users: pathology departments, clinical trial coordinators and data team members. To complete tasks in the TT, relevant information is required to update the status. Due to the high number of archival tissue requests from unique pathology labs, the TT has a "Follow-Up Dashboard" that organizes information needed to conduct follow-up on all archival samples with the status "Requested". This results in an autogenerated email and pdf report sent to necessary teams. The TT also includes a kit inventory system and a real-time read only version formatted for interdepartmental communication, metric reporting, and other data-driven efforts. The primary outcome in this study was to evaluate our average turnaround time (ATAT: average time from request to shipment) for archival and fresh tissue samples before and after TT development. **Results:** Before implementing the TT, between March 2016 and March 2018, we processed 2676 archival requests from 235 unique source labs resulting in 2040 shipments with an ATAT of 19.29 days. We also processed 1099 fresh biopsies resulting in 944 shipments with an ATAT of 7.72 days. After TT implementation, between April 2018 and April 2020, we processed 2664 archival requests from 204 unique source labs resulting in 2506 shipments (+28.0%) with an ATAT of 14.78 days (-23.4%). During that same period, we processed 1795 fresh biopsies (+63.3%) resulting in 2006 shipments (+112.5%) with an ATAT of 6.85 days (-11.3%). **Conclusions:** Oncology clinical trials continue to evolve toward more extensive tissue requirements for prescreening and scientific exploration of on-treatment molecular profiling. Timely results are required to optimize patient trial participation. During the intervention period, our tissue sample volume and shipments increased, but the development and implementation of an automated tracking system allowed improvement in ATAT of both archival and fresh tissue. This automation not only improves end-user expectations and experiences for patients and trial sponsors but this allows our team to adapt to the increasing interest in tissue exploration. Research Sponsor: None.

Oncology patient and provider preferences regarding rapid radiology result release to online portals. *First Author: Jonathan Bleeker, Sanford Health, Sioux Falls, SD*

Background: Spurred by changes in legislation and technology, rapid patient access to medical results has never been higher. Many health systems now release results of radiology tests within 24 hours of completion, meaning patients may see results before being able to discuss them with the ordering provider. Generally, surveys have demonstrated that patients are in favor of rapid result availability, but research on rapid result release to oncology patients with distinct concerns is scant. **Methods:** Starting in February 2020, oncology providers throughout Sanford Health, a multi-site primarily rural integrated practice in the upper Midwest were invited to complete an online survey regarding their opinions on rapid result release. Starting in February 2020, oncology patients were invited to complete a similar survey. This survey was open until August 2020, when 100 patients had completed the survey; both surveys contained both categorical and narrative results. **Results:** Oncology providers had a generally more negative opinion of rapid radiology result release to online portals compared to patients. 65% of patients believed radiology results should be released within 24 hours of resulting; only 12% of providers shared this view. 66% of providers shared that they did not feel comfortable with patients' ability to interpret radiology results and only 13% felt that "normal" results should be released immediately to an online portal; this number decreased to 3% when results were "abnormal". Patient opinions on appropriate result release were impacted by test results as well. For "normal" radiology results, 50% of patients favored initial communication be via online portal without discussion with a provider; for "abnormal" results, this number decreased to 28%. 43% of patients had learned of an "abnormal" result via online portal before discussion with a provider; 66% of these patients felt that this was a positive which allowed them to process information prior to the visit; 33% felt that it created undue anxiety. 94% of providers reported having a patient contact them regarding a test result prior to a planned visit, with 60% providers sharing this happens at least once weekly. When asked what improvements could be made to the system currently in place at Sanford, 80% of providers suggested holding radiology results until direct communication with the provider can occur; only 8% of patients suggested the same intervention. **Conclusions:** Rapid result release is generally a patient satisfier, although oncology patients do distinguish abnormal from normal results in terms of rapid release. It is a dissatisfier for providers both due to concerns regarding patients' ability to interpret results and due to excess work created by rapid release. Ongoing work should focus on ways to allow patients to access resources to make medical results more interpretable if reviewed prior to provider visits. Research Sponsor: None.

Veterans on anticancer medications in rural and community environment support (VA CARES) program: A pharmacist-led telemedicine medication management program for veterans receiving oral antineoplastic therapies through the MISSION Act. *First Author: Regan Healy, George E. Wahlen Department of Veterans Affairs Medical Center, Salt Lake City, UT*

Background: Cancer therapies are leveraging oral targeted treatments over traditional cytotoxic chemotherapy (CT) at an increasing rate. Compared to CT, use of oral antineoplastic treatments (OATs) shift some of the burden of medication management onto patients. To address these challenges, several health systems have developed multidisciplinary OAT management teams or 'clinics' whereby an Oncology Clinical Pharmacist (OCP) collaborates with oncology teams to ensure optimal use of these agents. Through the VA MISSION Act of 2018, Veterans can be prescribed treatments in the community which are dispensed by VA. These Veterans often live in rural areas and may lack access to comprehensive medication management resources. **Methods:** The VA CARES Program is a telemedicine medication management 'clinic' and care delivery model for patients receiving OATs leveraging custom designed health information technology (HIT) tools to remotely coordinate OAT related care. Veterans are automatically enrolled in the program if they have OATs prescribed by community providers which are to be dispensed by VA . An OCP provides telemedicine medication management services. The OCP performs a screening assessment, ensures appropriate indication and dosing, reviews baseline laboratory results, and performs a thorough drug-drug interaction analysis. The OCP then provides OAT education. Throughout the duration of therapy the OCP ensures necessary therapeutic monitoring, and regularly follows up with the Veterans. Subsequent encounters are to assess knowledge, adherence, toxicities, new drug-drug interactions, and need for OAT refills. The outcome measures for the VA CARES Program include safety (number and type of pharmacist interventions), economic benefits (cost savings or cost avoidance), and patient satisfaction. **Results:** In the initial 13 months, the VA CARES Program screened N = 78 and enrolled N = 64 (82%) Veterans from three VA medical facilities in VISN-19 from January 2020 to January 2021. The CPS performed n = 342 telemedicine visits and n = 80 interventions leading to improved safety, effectiveness, and/or an economical benefit. The most common interventions included detection and/or prevention of drug-drug interactions (n = 45) and adverse events (n = 18), drug not indicated (n = 13), alternative therapy suggested (n = 7), and limited-quantity dispensed (n = 7). The CPS interventions saved an estimated $210,864 in medication-related costs or avoidance. The Veterans surveyed were highly satisfied with the program services. **Conclusions:** Telemedicine delivery of oncology medication management by an OCP across systems is feasible, and provides clinical and economic benefits. Research Sponsor: U.S. Dept. of Veterans Affairs, Health Services Research and Development Service (RVR 19-483).

Utilization of preoperative breast MRI among women with newly diagnosed breast cancer. *First Author: I-Wen Pan, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The use of preoperative (pre-op) breast MRI remains controversial. Current practice may rely on patient characteristics and providers' clinical judgment. This national study examined factors associated with pre-op breast MRI among women with newly diagnosed breast cancer (BC) and explored sources of variations. **Methods:** We applied the Nattinger algorithm to identify women with incident BC diagnosed between Mar 2008 and Dec 2018 from OPTUM Clinformatics database. Patients who had 26 months of full enrollment, 14 months before and 12 months after the first (index) BC surgery, and no pre-op radiotherapy were included. We defined pre-op MRI as patients who had an MRI between the date of BC diagnosis and date of index surgery. We conducted multivariable logistic regression models to examine factors associated with pre-op MRI and performed separate analyses for elderly (age > = 65) and non-elderly (age < 65) women. **Results:** 61,865 women (non-elderly: 27,309, elderly: 34,556) were included in the analysis. The crude rate of pre-op MRI increased from 7.4% in 2008 to 14.6% in 2018 (p-value < .001). For the non-elderly, women who were older (adjusted rates: 60-64, 10% vs 20-49, 12.1%), had no distant metastasis (10.6% vs. 12.3% with metastasis), no neoadjuvant chemotherapy (9.9% vs 15.0% with neoadjuvant), and 2 or more comorbidities (9.0% vs. 11.1% with zero comorbidity) were less likely to undergo pre-op MRI (all p-value < .001). Compared to white women (adjusted rate 10.6%), African Americans were more likely to have pre-op MRI (12.7%, p < .001) and Hispanics were less likely (8.14%, P < .001). There was no association between Health Management Organization (HMO) status and receipt of pre-op MRI among non-elderly. For elderly women, older age, more comorbidities, no distant metastasis, and no neoadjuvant chemotherapy were similarly associated with less pre-op MRI use. There was no significant association between race and receipt of pre-op MRI. Moreover, elderly women with HMO insurance were less likely to receive pre-op MRI. In both age groups, we observed wide geographic variations, with significant interaction between census division and HMO enrollment among elderly group only (Table). **Conclusions:** The use of pre-op MRI nearly doubled from 2008 and 2018. In addition to demographic and clinical characteristics, regional practice pattern variations and insurance type played a key role in the receipt of pre-op MRI among newly diagnosed breast cancer patients. Future study to understand this phenomenon is warranted. Research Sponsor: Alliance.

Census division	Age < 65 (%)	Non HMO, Age > = 65 (%)	HMO, Age > = 65 (%)

Combining hematoxylin and eosin (H&E) stained images and RNA sequencing (RNA-Seq) data to predict overall survival (OS) in patients with non-small cell lung cancer (NSCLC). *First Author: Teresa M Karrer, Roche, Basel, Switzerland*

Background: IMpower150 was a phase 3 clinical trial that evaluated the efficacy of atezolizumab in patients with metastatic nonsquamous NSCLC; it demonstrated no significant OS benefit in the ACP (atezolizumab+carboplatin+paclitaxel) arm vs the BCP (bevacizumab+carboplatin+paclitaxel) control arm (hazard ratio [HR]=0.85; 95%CI, 0.71-1.03). The objective of this analysis was to identify a subpopulation of patients that benefits from ACP using H&E stained images and RNA-Seq data. **Methods:** Spatial statistics algorithms were applied to the coordinates of tumor cells and lymphocytes of the H&E stained images to capture spatial heterogeneity of the tumor microenvironment. The normalized and log-transformed RNA-Seq data underwent a nested feature selection procedure using a Cox proportional hazard model with L1 regularization and stability selection. Cutoffs for gene selection were determined using a permutation strategy with a false discovery rate <0.001. To investigate the association between the 41 derived spatial features, significant genes and OS, a Cox proportional hazard model with L2 regularization was fitted only for the ACP group. Survival groups were further identified using nested Monte Carlo Cross Validation to prevent over-fitting. **Results:** A total of 236 ACP and 235 BCP patients who had both H&E stained images and RNA-Seq data were analyzed. In the predicted long survival group, ACP patients had significantly longer median OS vs BCP patients based on H&E stained images (HR=0.61; 95%CI, 0.41-0.90;*P*=0.013) and RNA-Seq data (HR=0.64; 95%CI, 0.41-0.99;*P*=0.042). The combination of both modalities further improved the OS benefit between the arms (HR=0.44; 95%CI, 0.27-0.73;*P*=0.001). Data-driven selection of genes relevant for the prediction of OS included-*MAML3*,*AC024475.4*,*RGPD1*,*LCE3D* and*AC004156.1*. **Conclusions:** Our approach was able to stratify a subpopulation of patients that significantly benefited from ACP compared with BCP treatment, particularly when integrating both H&E stained images and RNA-Seq data, which demonstrated the complementary value of both modalities. Our results could inform the development of a companion diagnostic that predicts individualized treatment response. Clinical trial information: NCT02366143. Research Sponsor: Roche.

Use of deep learning frameworks to detect super-responder and super-survivor stage IV squamous non-small-cell lung cancer (NSCLC) patients treated with a gemcitabine and cisplatin combination. *First Author: Carlos Maria Maria Galmarini, Topazium Artificial Intelligence, Madrid, Spain*

Background: Synthetic fingerprints integrate clinical data within computational models allowing the identification of particular clinical subpopulations at a given moment. We here describe a deep learning strategy to detect super-responder and super-survivor patients with squamous NSCLC by setting up synthetic fingerprints and using unsupervised deep learning frameworks (UDLF). **Methods:** Through www.projectdatasphere.org, we accessed the control arm clinical data (N = 548) of the randomised phase III SQUIRE trial (NCT00981058). This trial included patients with stage IV squamous NSCLC who had not received previous chemotherapy. These patients were treated with gemcitabine 1,250 mg/m^2 (IV, 30-min infusion, d1/d8) and cisplatin 75 mg/m^2 (IV, 120 min infusion, d1) on a 3-week cycle for a maximum of six cycles. Synthetic fingerprints resulted of the integration of 180 features collected during the first 3 cycles including demographics, medical history, physical exam, concomitant medication, histopathology, PK parameters, adverse events and common labs. These fingerprints were used as input for the UDLF. The resultant clusters were correlated with overall-response rate (ORR) and overall survival (OS). **Results:** After missing data removal and feature standardization, 192 patients were eligible for the study. The UDLF was able to generate two different clusters: P0 (n = 107) and P1 (n = 84). ORR was higher in the P1 than in the P0 cluster (mean 41.6% [95% CI 31.7-52.3] vs. 28.0% [95% CI 20.4-37.2]; p = 0.04). OS was significantly longer in the P1 than in the P0 cluster (median 13.2 months vs. 9.7 months; hazard ratio 1.56 [95% CI 1.12-2.17; p = 0.008]). Feature contribution analysis showed that P1 had more patients and more events of grade III/IV neutropenia. In contrast, P0 had more patients and more events of grade III/IV nausea and vomiting. Other major differences were observed on vital signs (SBP, DBP, HR, RR, Temp), concomitant medication (osmotically-active laxatives, dexamethasone, furosemide, granisetron and ondansetron) and in hematological (RBC, HGB, HCT, MCV, WBC, neutrophils, monocytes, lymphocytes) and biochemistry (albumin, globulins, ALP, LDH, creatinine, BUN, urea, sodium, magnesium and phosphate) tests. **Conclusions**: Our findings show that synthetic fingerprints and subsequent deep learning analysis can be of use to identify patients with clinical characteristics associated with high-response rate and long-term survival. Predicting disease progression and mortality in metastatic colorectal cancer patients (mCRC) through an artificial intelligence-based analytical tool. *First Author: Carlos Maria Maria Galmarini, Topazium Artificial Intelligence, Madrid, Spain*

Background: Predicting the clinical course of metastatic disease remains a key challenge in CRC. Estimating prognosis of these late-stage patients can avoid undertreatment or overtreatment and also guide the follow-up intensity. This study has investigated the ability of an artificial intelligence-based analytical tool to identify those mCRC patients with high risk of disease progression and mortality based on their clinical parameters. **Methods:** Throughwww.projectdatasphere.org we accessed datasets of two randomised phase III trials including chemo-naïve (NCT00364013, n = 1183 patients) and chemo-refractory (NCT00113763, N = 483) mCRC patients. We generated synthetic fingerprints (SF) for each patient through the integration of 44 clinical features (demographics, anthropometrics, medical history, blood tests and treatment characteristics) collected, respectively, during the screening phase and the first month of inclusion in each trial. These SF were then input into a deep learning framework (DLF) to identify subgroup of patients based on their similarities. The resultant clusters were correlated with progression-free survival (PFS) and overall survival (OS). **Results:** After discarding missing data, 861 chemo-naïve and 341 chemo-resistant mCRC patients were eligible for the study. In the chemo-naïve cohort, the SF/DLF system was able to detect two different clusters: C0 (n = 31) and C1 (n = 830). Patients in C0 had a higher risk of progression (median PFS 6.2 months vs. 9.1 months; hazard ratio 1.83, 95% CI 1.16-2.88; p = 0.008) and death (median OS 13.2 months vs. 20.1 months; hazard ratio 2.84, 95% CI 1.68-4.80; p < 0.001) compared to patients in C1. When applied to the chemo-resistant cohort, the SF/DLF system was again able to identify two different clusters: P0 (n = 159) and P1 (n = 182). Patients in P0 had a higher risk of progression (median PFS 1.7 months vs. 1.8 months; hazard ratio 1.32, 95% CI 1.05-1.67; p < 0.001) and death (median OS 6.1 months vs. 6.8 months; hazard ratio 1.34, 95% CI 1.07-1.68; p = 0.01) compared to patients in P1. In both cases, feature contribution analysis showed that major differences between clusters were related to clinical status, anthropometrics and haematological and biochemistry tests. **Conclusions:** Our SF/DLF system can identify mCRC subtypes based on distinct clinical features that correlate with higher risk of progression and death. Further work is required to validate this approach as a novel prognostic biomarker tool for monitoring mCRC patients. Research Sponsor: None.

Impact of a deep learning model to reduce variation and costs of federally mandated breast density legislation. *First Author: Katherine Cavallo Hom, Massachussetts General Hospital, Boston, MA*

Background: Dense breast tissue is an independent risk factor for malignancy and can mask cancers on mammography. Yet, radiologist-assessed mammographic breast density is subjective and varies widely between and within radiologists. Our deep learning (DL) model was implemented into routine clinical practice at an academic breast imaging center and was externally validated at a separate community practice, with both sites demonstrating high clinical acceptance of the model's density predictions. The aim of this study is to demonstrate the influence our DL model has on prospective radiologist density assessments in routine clinical practice. **Methods:** This IRB-approved, HIPAA-compliant retrospective study identified consecutive screening mammograms without exclusion performed across three clinical sites, over two time periods: pre-DL model implementation (January 1, 2017 through September 30, 2017) and post-DL model implementation (January 1, 2019 through September 30, 2019). Clinical sites were as follows: Site A (the academic practice where the DL model was developed and was implemented in late 2017); Site B (an affiliated community practice which implemented the DL model in late 2017 and was used for external validation); and Site C (an affiliated community practice which was never exposed to the DL model). Patient demographics and radiologist-assessed mammographic breast densities were compared over time and across sites. Patient characteristics were evaluated using Wilcoxon test and Pearson's chi-squared test. Multivariable logistic regression models evaluated the odds of a dense breast classification as a function of time period (pre-DL vs post-DL), race (White vs non-White) and site. **Results:** A total of 85,865 consecutive screening mammograms across the three clinical sites were identified. After controlling for age and race, adjusted odds ratios (aOR) of a mammogram being classified as dense at Site C compared to Site B before the DL model was implemented was 2.01 (95% CI 1.873, 2.157,p<0.001). This increased to 2.827 (95% CI 2.636, 3.032,p< 0.001) after DL implementation. The aOR of a mammogram being classified as dense at Site A after implementation compared to before implementation was 0.924 (95% CI 0.885, 0.964,p<0.001). **Conclusions:** Our findings suggest implementation of the DL model influences radiologist's prospective density assessments in routine clinical practice by reducing the odds of a screening exam being categorized as dense. As a result, clinical use of our model could reduce downstream costs of supplemental screening tests and limit unnecessary high-risk clinic evaluations. Research Sponsor: Massachusetts General Hospital.

Site:	Percent Mammograms classified as dense in 2017	Percent Mammograms classified as Dense in 2019	Post-DL:Pre-DL aOR of a Dense Mammogram classification (95%CI)
A	42.9%	40.6%	0.924 (0.885,0.964)
B	47.0%	41.2%	0.808 (0.739,0.883)
C	65.5%	67.7%	1.132 (1.084, 1.182)

Automated identification of immune related adverse events in oncology patients using machine learning. *First Author: Wenxin Xu, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Immune related adverse events (irAEs) are a major cause of morbidity among cancer patients treated with immune checkpoint inhibitors (ICIs). irAEs are difficult to identify systematically, which represents a major barrier to the conduct and reproducibility of irAE research. Automated approaches would facilitate cohort identification and understanding of risk factors for irAEs following ICI therapy. **Methods:** Patients treated with one or more ICIs at a single tertiary cancer center were identified. Patients who received ICIs outside the clinical trial context were used as a development cohort. For each date containing clinical documentation, proxy outcomes expected to correlate with grade 2+ irAEs including irAE related diagnosis codes, key laboratory values, prescriptions for topical and systemic steroids, and irAE keywords were extracted. Intermediate machine learning models were trained to predict the presence of each proxy outcome using structured and unstructured patient data. We used clinical trial irAEs extracted from adverse event tables found in the electronic health record as the "gold standard" outcome for a final training and evaluation cohort. A logistic regression model was used to combine predictions from each intermediate model and generate an overall probability score for each irAE type on a given encounter date. Ten-fold cross-validation was used to evaluate the final machine learning model on a held-out sample of clinical trial patients. Encounter level models were evaluated for predicting the onset of a given irAE on a given date, and patient level models for predicting irAE onset within 6 months of ICI initiation. **Results:** We identified 3,765 patients treated with ICIs off-trial and 1106 patients treated on ICI clinical trials. Among trial patients, overall incidence of any grade 2+ irAE was 21%. The combined irAE models were able to predict prospective gold standard irAE labels with accurate discrimination at both the encounter and patient level (Table). **Conclusions:** Machine learning models can identify irAEs among cancer patients in an automated manner, which may facilitate research to mitigate toxicities and optimize clinical outcomes. Validation of these methods in an external institutional cohort is underway. Research Sponsor: None.

Automated imaging-based stratification of early-stage lung cancer patients prior to receiving surgical resection using deep learning applied to CTs. *First Author: Felipe Soares Torres, University of Toronto, Toronto, ON, Canada*

Background: Computed tomography (CT) imaging is an important tool to guide further investigation and treatment in patients with lung cancer. For patients with early stage lung cancer, surgery remains an optimal treatment option. Artificial intelligence applied to pretreatment CTs may have the ability to quantify mortality risk and stratify patients for more individualized diagnostic, treatment and monitoring decisions. **Methods:** A fully automated, end-to-end model was designed to localize the 36cm x 36cm x 36cm space centered on the lungs and learn deep prognostic features using a 3-dimensional convolutional neural network (3DCNN) to predict 5-year mortality risk. The 3DCNN was trained and validated in a 5-fold cross-validation using 2,924 CTs of 1,689 lung cancer patients from 6 public datasets made available in The Cancer Imaging Archive. We evaluated 3DCNN's ability to stratify stage I & II patients who received surgery into mortality risk quintiles using the Cox proportional hazards model. **Results:** 260 of the 1,689 lung cancer patients in the withheld validation dataset were diagnosed as stage I or II, received a surgical resection within 6 months of their pretreatment CT and had known 5-year disease and survival outcomes. Based on the 3DCNN's predicted mortality risk, patients in the highest risk quintile had a 14.2-fold (95% CI 4.3-46.8,p < 0.001) increase in 5-year mortality hazard compared to patients in the lowest risk quintile. **Conclusions:** Deep learning applied to pretreatment CTs provides personalised prognostic insights for early stage lung cancer patients who received surgery and has the potential to inform treatment and monitoring decisions. Research Sponsor: None.

Trajectories of machine learning-predicted mortality risk among patients with cancer and associated end-of-life utilization. *First Author: Manqing Liu, University of Pennsylvania, Philadelphia, PA*

Background: Machine learning (ML) algorithms outperform traditional tools used for prognostication and may facilitate earlier discussions between oncologists and patients (pts) about hospice enrollment and treatment modification. Identifying longitudinal trajectories of mortality risk may help clinicians and health systems understand which populations such algorithms are likely to benefit. **Methods:** We identified trajectories of mortality risk and their association with existing metrics of end-of-life care quality, using electronic health and registry data from a prospective cohort of 3,280 pts with cancer who were seen in 18 tertiary or community medical oncology practices within a large academic health system between January 2018 and May 2020 and died prior to November 2020. A validated ML algorithm (c-statistic 0.89; Parikh et al, JAMA Oncol, 2020) prospectively generated mortality risk predictions prior to all encounters. Functional principal component analysis (FPCA) identified modes of variation for all patient-level mortality risk predictions associated with encounters prior to death. Adjusted logistic regression analyses tested associations between mortality risk trajectory and metrics of high-quality end-of-life care. **Results:** FPCA revealed 2 trajectories that represented 36% and 64% of all pts in the cohort. The first cluster ("unpredictable") consisted of pts whose ML-predicted mortality risk rose sharply within 30 days of death. The second cluster ("predictable") consisted of pts whose ML-predicted mortality risk was higher at baseline and rose gradually until death. Individuals with predictable mortality risk trajectories were more likely to have worse performance status, high comorbidity burden, and gastrointestinal (GI) malignancies (Table). Predictable trajectories were associated with higher hospice enrollment (adjusted odds ratio [aOR] 1.87, 95% CI 1.48-2.37), less inpatient death (aOR 0.72, 95% CI 0.56-0.92), less end-of-life intensive care unit admissions in the last 30 days of life (aOR 0.74, 95% CI 0.57-0.95), and less chemotherapy in the last 14 days of life (aOR 0.77, 95% CI 0.55-1.08). **Conclusions:** Over one-third of deaths among pts with cancer follow an unpredictable trajectory. For pts with unpredictable trajectories, overreliance on ML predictions could perpetuate aggressive end-of-life care. Research Sponsor: National Palliative Care Research Center, U.S. National Institutes of Health.

Use of remote patient monitoring in the care of COVID-positive patients in oncology. *First Author: Laura Pugliese, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cancer patients face an increased risk of developing acute complications from COVID-19. Remote monitoring can help with the critical need for early detection of symptoms among those diagnosed with COVID-19, enabling timely symptom management that can mitigate clinical deterioration. In response to this need, Memorial Sloan Kettering Cancer Center fast-tracked a program to monitor patients with COVID-19 from home, using an electronic symptom-tracking questionnaire and digital pulse oximeter to track patients' status and alert care teams to intervene if symptoms worsened. A multi-disciplinary group composed of Oncology providers, advanced practice providers, nursing, nursing informatics and biomedical informatics formed to manage the program. **Methods:** Memorial Sloan Kettering launched a remote monitoring program for patients diagnosed with COVID-19 on March 25, 2020. All patients testing positive for COVID-19 were enrolled in the program and asked to complete a daily symptom tracking questionnaire accessed through their patient portal or administered verbally over the phone. A subset of high risk patients were also provided with a digital pulse oximeter linked to their patient portal and capable of transmitting readings directly to the care team. Clinicians received alerts for patients reporting symptoms or an oxygen saturation below 92%. Alerts resulted in an immediate response from the care team to determine if the patient needed additional care. We retrospectively evaluated the program usage, outcomes and learnings from March 25, 2020 to December 22, 2020. **Results:** In total, 1,721 patients were enrolled in the program from March 25, 2020 to December 22, 2020. Among these, 210 were deemed high risk patients who received a pulse oximeter in addition the daily symptom questionnaire. Over this period, 27% of patients triggered an alert from an electronic symptom questionnaire, and 63% of patients with a pulse oximeter triggered an alert from their device. Among patients who triggered an alert of any kind, 3% were triaged to a higher level of care. Patients reported that the program was highly valued and alleviated anxiety about their care. Iterative improvements were made to the program over time in response to the evolving knowledge about care for patients with COVID-19. **Conclusions:** Memorial Sloan Kettering was able to quickly implement a program to detect and triage symptoms among patients with COVID-19 and cancer. Refinements were made over time to many aspects of the program in response to learnings about care related to COVID-19, including to clinical eligibility, alert criteria, monitoring duration and workflows. The program also demonstrated value for patients who felt more comfortable with their care while being monitored remotely. This program established a successful model for remote monitoring of patients with COVID-19 with the potential to be scaled to other institutions or clinical areas. Research Sponsor: None.

A natural language processing tool for automatic identification of new disease and disease progression: Parsing text in multi-institutional radiology reports to facilitate clinical trial eligibility screening. *First Author: Eric J. Clayton, Oncology Hematology Care, Cincinnati, OH*

Background: Screening every patient for clinical trials is time-consuming, costly and inefficient. Developing an automated method for identifying patients who have potential disease progression, at the point where the practice first receives their radiology reports, but prior to the patient's office visit, would greatly increase the efficiency of clinical trial operations and likely result in more patients being offered trial opportunities. **Methods:** Using Natural Language Processing (NLP) methodology, we developed a text parsing algorithm to automatically extract information about potential new disease or disease progression from multi-institutional, free-text radiology reports (CT, PET, bone scan, MRI or x-ray). We combined semantic dictionary mapping and machine learning techniques to normalize the linguistic and formatting variations in the text, training the XGBoost model particularly to achieve a high precision and accuracy to satisfy clinical trial screening requirements. In order to be comprehensive, we enhanced the model vocabulary using a multi-institutional dataset which includes reports from two academic institutions. **Results:** A dataset of 732 de-identified radiology reports were curated (two MDs agreed on potential new disease/dz progression vs stable) and the model was repeatedly re-trained for each fold where the folds were randomly selected. The final model achieved consistent precision (>0.87 precision) and accuracy (>0.87 accuracy). See the table for a summary of the results, by radiology report type. We are continuing work on the model to validate accuracy and precision using a new and unique set of reports. **Conclusions:** NLP systems can be used to identify patients who potentially have suffered new disease or disease progression and reduce the human effort in screening or clinical trials. Efforts are ongoing to integrate the NLP process into existing EHR reporting. New imaging reports sent via interface to the EHR will be extracted daily using a database query and will be provided via secure electronic transport to the NLP system. Patients with higher likelihood of disease progression will be automatically identified, and their reports routed to the clinical trials office for clinical trial screening parallel to physician EHR mailbox reporting. The over-arching goal of the project is to increase clinical trial enrollment. 5-fold cross-validation performance of the NLP model in terms of accuracy, precision and recall averaged across all the folds. Research Sponsor: US Oncology Research.

Extracting non-small cell lung cancer (NSCLC) diagnosis and diagnosis dates from electronic health record (EHR) text using a deep learning algorithm. *First Author: Alexander S. Rich, Flatiron Health, New York, NY*

Background: Identifying patients with a particular cancer and determining the date of that diagnosis from EHR data is important for selecting real world research cohorts and conducting downstream analyses. However, cancer diagnoses and their dates are often not accurately recorded in the EHR in a structured form. We developed a unified deep learning model for identifying patients with NSCLC and their initial and advanced diagnosis date(s). **Methods:** The study used a cohort of 52,834 patients with lung cancer ICD codes from the nationwide deidentified Flatiron Health EHR-derived database. For all patients in the cohort, abstractors used an in-house technology-enabled platform to identify an NSCLC diagnosis, advanced disease, and relevant diagnosis date(s) via chart review. Advanced NSCLC was defined as stage IIIB or IV disease at diagnosis or early stage disease that recurred or progressed. The deep learning model was trained on 38,517 patients, with a separate 14,317 patient test cohort. The model input was a set of sentences containing keywords related to (a)NSCLC, extracted from a patient's EHR documents. Each sentence was associated with a date, using the document timestamp or, if present, a date mentioned explicitly in the sentence. The sentences were processed by a GRU network, followed by an attentional network that integrated across sentences, outputting a prediction of whether the patient had been diagnosed with (a)NSCLC and the diagnosis date(s) if so. We measured sensitivity and positive predictive value (PPV) of extracting the presence of initial and advanced diagnoses in the test cohort. Among patients with both model-extracted and abstracted diagnosis dates, we also measured 30-day accuracy, defined as the proportion of patients where the dates match to within 30 days. Real world overall survival (rwOS) for patients abstracted vs. model-extracted as advanced was calculated using Kaplan-Meier methods (index date: abstracted vs. model-extracted advanced diagnosis date). **Results:** Results in the Table show the sensitivity, PPV, and accuracy of the model extracted diagnoses and dates. RwOS was similar using model extracted aNSCLC diagnosis dates (median = 13.7) versus abstracted diagnosis dates (median = 13.3), with a difference of 0.4 months (95% CI = [0.0, 0.8]). **Conclusions:** Initial and advanced diagnosis of NSCLC and dates of diagnosis can be accurately extracted from unstructured clinical text using a deep learning algorithm. This can further enable the use of EHR data for research on real-world treatment patterns and outcomes analysis, and other applications such as clinical trials matching. Future work should aim to understand the impact of model errors on downstream analyses. Research Sponsor: This study was sponsored by Flatiron Health, which is an independent subsidiary of the Roche Group.

Metric	Initial	Advanced
Diagnosis Sensitivity	.98	.95
Diagnosis PPV	.95	.85
Date of diagnosis 30-Day Accuracy	.90	.84

Clinical accuracy of information extracted from prostate needle biopsy pathology reports using natural language processing. *First Author: Risa Liang Wong, University of Washington, Seattle, WA*

Background: Patients with prostate cancer are diagnosed through a prostate needle biopsy (PNB). Information contained in PNB pathology reports is critical for informing clinical risk stratification and treatment; however, patient comprehension of PNB pathology reports is low, and formats vary widely by institution. Natural language processing (NLP) models trained to automatically extract key information from unstructured PNB pathology reports could be used to generate personalized educational materials for patients in a scalable fashion and expedite the process of collecting registry data or screening patients for clinical trials. As proof of concept, we trained and tested four NLP models for accuracy of information extraction. **Methods:** Using 403 positive PNB pathology reports from over 80 institutions, we converted portable document formats (PDFs) into text using the Tesseract optical character recognition (OCR) engine, removed protected health information using the Philter open-source tool, cleaned the text with rule-based methods, and annotated clinically relevant attributes as well as structural attributes relevant to information extraction using the Brat Rapid Annotation Tool. Text pre-processing for classification and extraction was done using Scispacy and rule-based methods. Using a 75:25 train:test split (N = 302, 101), we tested conditional random field (CRF), support vector machine (SVM), bidirectional long-short term memory network (Bi-LSTM), and Bi-LSTM-CRF models, reserving 46 training reports as a validation subset for the latter two models. Model-extracted variables were compared with values manually obtained from the unprocessed PDF reports for clinical accuracy. **Results:** Clinical accuracy of model-extracted variables is reported in the Table. CRF was the highest performing model, with accuracies of 97% for Gleason grade, 82% for percentage of positive cores ($<$ 50% vs. $\geq$50%), 90% for perineural or lymphovascular invasion, and 100% for presence of non-acinar carcinoma histology. On manual review of inaccurate results, model performance was limited by PDF image quality, errors in OCR processing of tables or columns, and practice variability in reporting number of biopsy cores. **Conclusions:** Our results demonstrate successful proof of concept for the use of NLP models in accurately extracting information from PNB pathology reports, though further optimization is needed before use in clinical practice. Research Sponsor: American Cancer Society, Fred Hutchinson Cancer Research Center, University of Washington.

Machine learning prediction of COVID-19 mortality in cancer patients. *First Author: Rodrigo Dienstmann, Oncoclínicas, São Paulo, Brazil*

Background: COVID-19 is a challenge for clinical decision-making in cancer patients and the allocation of healthcare resources. An accurate prognosis prediction to effectively triage patients is needed, especially in the community oncology practice. **Methods:**Nationwide cohort from Oncoclínicas Brazil was used to validate previously developed multivariable logistic regression (mLR) model (Ferrari et al, JCO GO 2021) and to construct a machine learning Random Forest (RF) algorithm as predictor of 30-day mortality after SARS-CoV-2 detection by RT-PCR in cancer patients diagnosed in an outpatient setting. To find the most important baseline clinical determinants of early COVID-19-related death via Gini index, a RF with 100,000 trees was trained in 75% of the dataset, and the performance was assessed in the remaining 25%. We then compared the accuracy of different models in terms of sensitivity, specificity and area under the receiver operating characteristics curves (AUC). **Results:**From March to December 2020, 533 patients with COVID-19 were prospectively registered in the database. Median age was 60 years (19-93) and 67% were female. Most frequent cancers were breast in 34%, hematological in 16%, and gastrointestinal in 15%. Comorbidities were common (52%), as was current/former smoking history (17%). Most patients were on active systemic therapy or radiotherapy (84%) in the advanced or metastatic disease setting (55%). The overall mortality rate was 15% (CI95% 12%-18%). We validated the original mLR model trained in the first 198 patients: management in a non-curative setting (odds ratio [OR] 3.7), age $\geq$ 60 years (OR 2.3), and current/former smoking (OR 1.9) were significant predictors of death in the expanded cohort. Presence of comorbidities (OR 1.9) also defined poor outcome in the updated mLR model, which yielded low sensitivity (74%), specificity (68%) and AUC (0.78). With RF modeling, the most significant predictors of 30-day death after COVID-19 (in decreasing order) were older age, treatment of advanced or metastatic disease, tumor type (respiratory tract, brain and unknown primary cancers had higher mortality), COVID-related symptom burden at baseline evaluation and treatment regimen (immunotherapy combinations had higher mortality). The RF model demonstrated high sensitivity (89%), specificity (88%) and AUC (0.96). **Conclusions:**The results highlight the possibility that machine learning algorithms are able to predict early mortality after COVID-19 in cancer patients with high accuracy. The proposed prediction model may be helpful in the prompt identification of high-risk patients based on clinical features alone, without having to wait for the results of additional tests such as laboratory or radiologic studies. It can also help prioritize medical resources and redefine vaccination strategies. A web-based mortality risk calculator will be created for clinical decision support. Research Sponsor: None.

Improving tumor mutational burden calibration in non-European patients. *First Author: Elio Adib, The Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: Tumor mutational burden (TMB), has been recently granted FDA approval as a biomarker for ICI treatment in tumors with a high mutation load ($\geq$ 10/MB). To leverage this biomarker in the clinical setting, it is necessary to evaluate its application in diverse patient populations. In particular, tumor-only sequencing may overestimate TMB in non-EUR populations for which reference panels are small or unavailable, and thus have poorer predictive performance. Herein, we investigate the effect of TMB overestimation in non-EURs on patient diagnosis and clinical outcomes in a real world patient cohort. **Methods:** TMB was computed using a tumor-only NGS platform (Oncopanel) for 8349 cancer patients (pts) of 7 cancer types (Table). Genetic ancestry was inferred directly from tumor sequencing data and confirmed for a subset of pts using germline SNP arrays. TMB was compared using Wilcoxon rank-sum test between European (EUR) and non-EUR pts. TMB percentile rank by ancestral group (East Asian, African, European) and tumor histology was computed. In non-EUR pts, TMB was calibrated by reassigning its value to the corresponding percentile rank in EUR pts having the same cancer (AH-TMB). Tumors with raw TMB $\geq$ 10/MB were assigned as TMB-high (TMBH; with the rest referred to as TMBL for TMB-low) and those with calibrated AH-TMB $\geq$ 10/MB as AH-TMBH. A subset of pts treated with ICIs at DFCI and of EUR ancestry were analyzed. TMB was intentionally mis-calibrated in EURs (MC-TMB), to mimic the TMB overestimation observed in non-EURs. Associations between TMBH status and overall survival (OS) was assessed using Cox regression. **Results:** Uncalibrated TMB was significantly higher in tumors from non-EUR pts overall (p $<$0.0001, Table) as anticipated, whereas this difference was not observed in tumors with matched germline filtering. We reassigned non-EUR pts into low/high groups using calibrated AH-TMB, which changed the assignment of 67/670 non-EURs, most of which (65/67) were downgraded from TMBH to AH-TMBL. In the ICI-treated cohort, there was a strong association between TMBH status and OS (p = 2e-11, HR = 0.6) whereas MC-TMBH (mimicking the miscalibration in non-EUR samples) had a weaker association with OS (p = 0.0013, HR = 0.8). Importantly, pts assigned to TMB-H due to miscalibration (90 TMB-L/MC-TMBH pts) had shorter OS compared to the true TMBH group (p = 3e-6, HR = 1.9). **Conclusions:** In this analysis, we showed that tumor-only sequencing platforms can overestimate TMB in non-EUR pts, impacting treatment decisions and outcomes. Replacing raw TMB counts with an ancestry-adjusted measure could optimize TMB application in the clinical setting when germline sequencing is not available. Accurate ancestry inference can be performed using tumor-only sequencing. Research Sponsor: None.

A machine learning tool to predict mortality risk among patients with metastatic cancer in outpatient oncology care. *First Author: Brandon Butler, McKesson Corporation, The Woodlands, TX*

Background: End-of-life management is a well-known challenging aspect of cancer care. In particular, timely hospice enrollment is a leading quality metric in the Oncology Care Model that has substantial room for improvement. An automated algorithmic tool that can incorporate the wealth of available EHR data and rapidly identify patients with a high risk of imminent mortality could be a valuable asset to supplement important clinical decisions and improve timely hospice care. **Methods:** A retrospective study cohort was formed using patients with metastatic cancer from US Oncology Network (USON) practices participating in the Oncology Care Model (OCM) between January 1, 2017 and June 30, 2019. Patients were required to have at least one record for lab values and vital signs in the EHR database. Patients were excluded from the study cohort if they were not enrolled in the OCM program or did not have a diagnosis for metastatic cancer. The patients satisfying the selection criterion were used to train and optimize the model. The training dataset was also used for internal validation and hyperparameter tuning until the final model was produced. As external validation, the final model was independently tested on 3 separate holdout datasets including OCM patients between July 1, 2019 and March 31, 2020. To avoid bias, all holdout datasets used for validation were excluded from the model. **Results:** A multivariable model to predict 90-day mortality was developed using a retrospective dataset derived from EHR data and Medicare claims data. A logistic regression algorithm using L1 (lasso) regularization yielded the best performance compared to other model candidates. The performance on the training cohort was given by a cross-validated AUC score of 0.85 (95% CI, 0.84 to 0.86). Further, external validation conducted using 3 independent holdout datasets demonstrated impressive generalizability marked by stable performance scores across multiple time periods (AUC between 0.84 and 0.85). **Conclusions:** This study builds upon previous work and further establishes the utility of machine learning to predict risk of imminent mortality for advanced cancer patients using available EHR data. A data-driven tool that estimates the probability of 90-day mortality could be leveraged as a powerful supplementary aid to clinicians managing end-of-life care at oncology practices. Research Sponsor: McKesson / US Oncology Network (USON).

The surgical oncology clinical trial landscape: A cross-sectional analysis of ClinicalTrials.gov from 2008-2020. *First Author: Nirosha D. Perera, School of Medicine, Stanford University, Stanford, CA, and Department of Internal Medicine, Mayo Clinic, Rochester, MN*

Background: Surgical interventions are studied less often than medical or radiation interventions in oncology clinical trials. We characterized surgical oncology trials registered on ClinicalTrials.gov, analyzed funding sources and identified features associated with early discontinuation and results reporting. **Methods:** We employed a cross-sectional study design with descriptive, logistic regression, cox regression, time series and survival analyses. We downloaded all 270,172 studies registered on the Aggregate Analysis of the ClinicalTrials.gov database from October 1, 2008 to March 9, 2020. After excluding non-interventional trials, applying cancer/oncology specific Medical Subject Heading terms to the remaining trials and excluding phase 1 trials, 27,915 trials were identified for manual review. Primary exposure variables were trial focus: neoplasia site and treatment modality (surgical interventions included investigations of outcomes from surgical resection or intra-operative/peri-operative changes), and funding: industry, U.S. government, academic. **Results:** 26,815 trials were found to have true oncology content; 1,661 (6.2%) involved surgical oncology, representing 311,789 patients. Funding sources were: 82.7% by academic institutions, 10.9% by industry, and 6.2% by U.S. government. The most studied neoplasia sites were colorectal (17.4% of trials), breast (10.7%), gastric (10.5%), hepatic (8.6%), lung (7.5%), brain/CNS (6.7%) and cervical (6.6%). U.S. government funded surgical oncology trials had the lowest risk of early discontinuation (adjusted HR 0.65, 95% CI: 0.58-0.73, p<0.001) and the highest odds of results reporting (adjusted OR 1.35, 95% CI: 1.08-1.68, p=0.008) (Table). **Conclusions:** There is a paucity of surgical oncology clinical trials compared to other treatment modalities, especially in context of surgery's role in overall cancer care. From 2008-2020 only 6.2% of trials focused on surgical oncology, and U.S. government funded trials displayed the lowest hazard of early discontinuation and highest odds of results reporting. Stakeholders should look to government funded trials as models of improvement, but must increase representation and results dissemination of surgical oncology trials to guide treatment recommendations. Surgical oncology trial features and associated early discontinuation/results reporting. Research Sponsor: Stanford Medical Students Association - funding for the abstract submission fee only.

NCI's national treatment trial networks: Experience and adaptations during COVID-19. *First Author: Margaret M. Mooney, National Cancer Institute, Rockville, MD*

Background: The National Cancer Institute supports several national trial networks which responded rapidly to the COVID-19 pandemic to overcome operational barriers to clinical cancer research. The National Clinical Trials Network (NCTN) focuses on late phase treatment trials, while the Experimental Therapeutics Clinical Trials Network (ETCTN) conducts early phase treatment trials. We report findings on the experience and adaptations of these networks during COVID-19. **Methods:** Using 2019 and 2020 accrual data, we analyzed changes in accrual levels and demographics. We also evaluated changes in trial activation numbers and timelines. In July 2020, we surveyed 255 investigators from academic and community sites to assess changes in research practices and get feedback on modified processes implemented by NCI to address trial conduct during the pandemic. **Results:** Accrual across the NCTN and ETCTN fell significantly in mid-March 2020, dropping from a weekly average of 307 patients in February to 169 the week of March 23-29. Accrual began to recover in June and July but did not return to pre-pandemic levels until September. Accrual in November and December 2020 followed the patterns seen in 2019, with short-term drops around major holidays. Non-White participants were enrolled to NCTN and ETCTN trials at similar monthly rates throughout 2019 and 2020, with slightly higher overall enrollment in 2020 (23.7% vs. 22.7%). New trials continued to be developed and activated throughout 2020. Between 2017 and 2019, an average of 71 trials were activated per year (NCTN = 46, ETCTN = 25), compared to 84 activated in 2020 (NCTN = 58, ETCTN = 26). The average time to trial activation was similar or slightly longer in 2020 compared to 2019. The investigator survey yielded 111 responses (43.5% response rate). 43% of respondents' sites paused enrollment to phase 1 trials during the pandemic, compared to 18% for phase 3 trials. Many sites temporarily stopped opening new trials and processing specimens. Sites were more likely to keep enrolling to trials offering clear potential benefit and pause complex trials that required more patient contact. Respondents attributed some of the decline in accrual to a reduction in overall patient volume, increased patient concerns, and reduced research staff on site. Respondents were asked to rate the usefulness of modified trial processes NCI put in place during the pandemic. Telehealth was rated most useful (avg. 4.6/5), followed by shipping oral IND agents to enrolled patients (4.5/5), remote informed consent (4.2/5), coordinating care with local providers (3.9/5), and remote auditing (3.7/5). **Conclusions:** The cancer trials community has an opportunity to learn from working through the challenges of COVID-19. NCI will seek to continue and expand on modifications to clinical trial processes that have the potential to improve operational efficiency, reduce cost, and help bring trials to more patients. Research Sponsor: None.

1563 **Poster Session**

The TIME Trial Network to facilitate rapid clinical trial activation, patient screening, and enrollment in molecularly targeted trials. *First Author: Stephanie OLeary, Tempus Labs, Chicago, IL*

Background: Clinical trials that require patients to have specific actionable mutations based on next generation sequencing (NGS) present unique problems, such as recruiting patients with rare mutations, low enrollment rates, and distance between patients and trial sites. Such barriers can slow the pace of trial enrollment and delay the development of new therapeutic options. **Methods:** Tempus Labs has partnered with experienced research sites and pharmaceutical companies with molecularly targeted clinical trials to create the TIME Trial Network. The study portfolio includes pharmaceutical sponsored phase I-III clinical trials across solid tumors and hematological malignancies, targeting actionable mutations. This network was established to ensure rapid just-in-time (JIT) activation of trials by streamlining start-up activities (i.e., execution of CTAs and study budgets/financial exhibits, regulatory paperwork, SIV planning and conduct, drug and study supply shipments, submission to the central IRB, and sponsor-specific requirements). Rapid activation begins upon receipt of an activation form from a site partner. "Site Activated" describes a site that has fulfilled all regulatory, documentation, contracting requirements, and has sponsor approval to screen and enroll patients. **Results:** In Q4 2020, JIT activations were completed for 6 unique interventional clinical trials across 10 sites in 8 US states in the TIME Trial Network. On average, sites were activated in 9.4 business days. Patients enrolled had rare NGS mutations and were from geographically diverse locations. In one urgent case, trial activation, patient consent, screening, and treatment were achieved in 5 business days. In total, 91.7% of patients consented to trial. The average timeline from activation to consent was 4.5 days (range 0 - 24 days), with half of patients consenting within 1 business day. 45.5% of patients who consented to trial received the study drug within 1 day of consent; 2 patients dosed on day of consent. **Conclusions:** Over a 3-month period, on average, TIME Trial sites were activated in 9.4 days (compared to the 20+ week industry-wide average), and patient consent was completed in 4.5 days. Rapid JIT activations through the TIME program provide significant improvements in trial enrollment timelines and increase access to therapies nationwide. JIT activations may be especially useful for rural, underserved communities, as sites can enroll diverse patient populations and help address the equity gap in clinical trials across ethnic groups. Nodule net: A prospective safety net program to reduce loss to follow-up and increase early detection of lung cancer. *First Author: Harpreet Singh, Froedtert and Medical College of Wisconsin, Milwaukee, WI*

Background: Inadequate follow-up of suspicious lung nodules can result in a delay in diagnosis and potential progression to advanced staged lung cancer. A multidisciplinary lung nodule program entitled "Nodule Net" was implemented in 2017 to provide a safety net, increase the rate of follow-up, streamline management. The program consisted of a multidisciplinary team with EMR notification by the radiologist to a centralized nurse navigator for inclusion in a follow-up database, outreach with reminders to the primary care provider if follow-up was not completed, and referral for management where appropriate. In this study, we sought to evaluate program effectiveness in tracking and rate of follow-up imaging of suspicious pulmonary nodules. **Methods:** 2,398 chest CT scans were reviewed between January and May 2018 for the presence of a lung nodule that required follow-up. Nodules known to be inflammatory or associated with a metastatic malignancy were excluded. Baseline demographics, medical history, primary care affiliation, type of imaging scan, nodule characteristics, and presence and specifics of follow-up recommendations were collected. For reports that did not include a follow-up recommendation, Fleischner's recommendations were applied or an independent pulmonologist's review was completed. The rate of follow-up imaging was recorded and compared with historical rates prior to Nodule Net implementation. Prevalence ratios were generated for each comparison. **Results:** 1,367 (57%) reported lung nodules. Recommendations for follow-up imaging were recorded in 632 (46.2%), and 523 (82.8%) of these were reported to the program navigator. The rate of follow-up completion of those referred to the program was significantly higher [408 (78%)] than standard of care prior to program implementation [442/1202 (36.8%), (2.90, 95% CI: 2.65-3.18)]. Out of 408 patients who completed follow-up, nodule net outreach was required in 116 (28.4%). Of these 116, malignancy was identified in 4/116 (3.4%). Increased nodule size requiring referral was identified in 17 (14.7%). Out of 109 who were not transmitted to the program navigator and not present in the database, 57 (52.3%) had completed the recommended follow-up compared with 78% among those referred (1.49, 95% CI:1.23-1.79). **Conclusions:** Management of lung nodules is a complex process with poor follow-up completion reported in prior studies (29%-33%). Implementation of a multidisciplinary lung nodule care program for tracking lung nodules led to a significant increase in completion of recommended follow-up imaging. Developing a comprehensive lung nodule management program using software and navigation may further enhance detection, reduce human errors, augment the necessary follow-up for suspicious lung nodules, and ultimately the prevalence of advanced stage lung cancer. Research Sponsor: None.

Oncology trial enrollment trends following the first wave of the COVID-19 pandemic. *First Author: Elizabeth W. Lamont, Acorn AI at Medidata, a Dassault Systèmes Company, Boston, MA*

Background: The first wave of the COVID-19 pandemic was associated with a negative effect on global oncology clinical research and development including documented decreases in new trial launches and patients enrolling on existing trials. We sought to evaluate secular trends in patient enrollment on global oncology trials of drugs and/or biological agents coincident with trends in the pandemic through 10/31/2020. **Methods:** This time-series study of global oncology clinical trial patient enrollment relied on data from the Medidata Enterprise Data Store, which comprises studies using the RAVE electronic data capture platform, and eCDC. We quantified the number of patients enrolling on oncology trials according to contiguous pandemic waves between 01/05/2020 and fixed right censoring at 10/31/2020. For this study, we defined pandemic waves empirically through review of peaks and nadirs of global case counts/week from eCDC data: wave 1 (01/05/2020-05/02/2020), wave 2 (05/03/2020-08/22/2020), wave 3 (08/23/2020-10/31/2020). We used negative binomial regressions to evaluate associations between time periods (i.e., waves) and counts of new trial enrollees and time periods and counts of new COVID-19 patients. **Results:** A total of 54,752 patients enrolled in 1,176 oncology trials world-wide during the observation period: 14,888 patients during wave 1, 19,631 patients during wave 2, and 20,233 patients during wave 3 of the pandemic. Compared to wave 1, the incidence of new trial enrollees increased by 10% in wave 2 (incidence rate ratio [IRR] 1.10, 95% confidence interval [CI] 0.95-1.26) and by 29% in wave 3 (IRR 1.29, 95% CI: 1.10-1.52). Over the same period, 47,336,995 people were diagnosed with COVID-19 infection: 3,481,165 patients during wave 1, 20,205,244 patients during wave 2, and 23,650,586 patients during wave 3. Compared to wave 1, the incidence of new COVID-19 patients increased by 617% in wave 2 (IRR 6.17, 95% CI: 2.76-13.77) and by 1,155% (IRR 11.55, 95% CI: 4.61-28.95) in wave 3. **Conclusions:** Despite substantial increases in the incidence of COVID-19 following the first wave of the pandemic, the number of patients enrolled in oncology clinical trials increased notably during the same period. Future research seeks to understand the mechanism through which the oncology research and development enterprise adapted to the shock of the COVID-19 pandemic. eCDC Source: European Centre for Disease Prevention and Control. Efficacy analysis of a remote symptom management platform. *First Author: Paris A. Kosmidis, Care Across, London, United Kingdom*

Background: Quality of life of cancer patients is a critical part of cancer care. Symptom management is evolving as a multidisciplinary approach, and is increasingly delivered through a combination of physical and remote interactions. CareAcross is an online platform offering personalized, guidelines-based support to cancer patients, that complements physicians' support and enables remote monitoring. This analysis investigated the improvement in the quality of life of cancer patients delivered through such remote support. **Methods:** Patients engage with an online interactive platform to receive personalized support based on a variety of parameters, through algorithms incorporating their exact diagnoses, treatments and comorbidities, and more. For symptom management, patients report the presence of specific side-effects via brief questionnaires; for each side-effect reported, they receive tailored support (text and multimedia) to help overcome it. These online questionnaires are repeated periodically to capture the outcome of the supportive process, and provide additional support as necessary. A retrospective analysis evaluated the efficacy of the personalized support: each patient's reported side-effects were compared before versus after receiving the support, hence calculating the reduced incidence. **Results:** 2203 patients from 8 countries, with breast, lung, prostate or colorectal cancer (1563, 404, 159 and 77, respectively) reported side-effects, received support, and updated their reports at least once. The median follow-up period was 4.9 months. The patient-reported outcomes on their quality of life revealed substantial improvement, regardless of cancer type (lowest recorded improvement = 25.7%). Commonly reported side-effects included sleep problems, dry mouth, constipation, changes in food taste, and more (see Table). Side-effects reported in specific cancer types also showed substantial improvement, including hot flushes (breast; 32.0% improvement), dyspnea (lung; 38.1%), bowel dysfunction (prostate; 80%) and others. The efficacy of the support to breast, prostate or colorectal cancer patients was similar; support to lung cancer patients exhibited the lowest efficacy ($p < 0.05$). Fatigue was the most common side-effect. It was also the most resistant to improvement compared to all others ($p < 0.05$). **Conclusions:** Digital remote support of cancer patients is a realistic option to improve quality of life. Randomized controlled trials can help quantify its impact on health economics, hospital admissions, resource utilization, and other aspects. Research Sponsor: None.

Side-effect & Improvement rates per cancer type	Breast	Lung	Prostate	Colorectal
Fatigue	37.1%	25.7%	44.7%	38.5%
Sleep problems	41.9%	55.8%	49.2%	33.3%
Dry mouth	62.0%	51.7%	65.9%	52.0%
Constipation	56.3%	52.0%	73.5%	81.0%
Food taste	72.4%	58.2%	91.7%	80.0%
Diarrhea	71.6%	63.4%	84.0%	77.3%
Reduced appetite	75.4%	62.6%	78.6%	53.8%
Mouth sores	83.6%	71.1%	75.0%	78.6%

Risk factors associated with skeletal-related events following denosumab cessation among patients with bone metastases from solid tumors: A real-world machine learning approach. *First Author: Alison Stopeck, Stony Brook Cancer Center, Stony Brook University, Stony Brook, NY*

Background: The anti-RANKL monoclonal antibody denosumab has been shown to be superior to the bisphosphonate zoledronate for the prevention of skeletal-related events (SREs) in patients with incident bone metastases (BM) from solid tumors (ST). Clinical guidelines recommend the use of a bone-targeting agent for SRE prevention for ≥ 2 years. However, real-world treatment patterns in the U.S. suggest that the denosumab treatment duration is often < 1 year. Applying a machine learning approach, we sought to identify risk factors associated with SRE incidence following cessation of denosumab to help inform optimal clinical SRE prevention strategies. **Methods:** Using the Optum PanTher Electronic Health Record repository, patients diagnosed with incident BM from a primary ST between 1 Jan 2007 and 1 Sep 2019 were evaluated for inclusion in the study. Eligible patients had to receive ≥ 2 consecutive 120 mg denosumab doses on an every 4-week (± 14 days) schedule and have a minimum follow-up ≥ 1 year after the last denosumab dose or an SRE occurring between days 84 and 365 after denosumab cessation. Extreme gradient boosting was used to develop an SRE risk prediction model evaluated on a test dataset. Impact and relative importance of available medical, clinical, and treatment factors on SRE risk following denosumab cessation were extracted from the model using Shapley additive explanations (SHAP). Univariate analyses on risk factors with the highest importance from pooled and tumor-specific models were also conducted. **Results:** A total of 1,414 patients (breast, n = 563 [40%]; prostate, 421 [30%]; lung, 180 [13%]; other cancers, 250 [17%]) met inclusion criteria, with a median of 253 (min, 88; max, 2726) days of denosumab treatment; 490 (35%) experienced ≥ 1 SRE following denosumab cessation. With a meaningful model performance based on an area under the receiver operating characteristic (AUROC) score of 77%, SHAP identified several significant factors that predicted an increased SRE risk following denosumab cessation, including prior SREs, shorter denosumab treatment duration, and a higher number of clinic visits as the top-ranked factors (Table). **Conclusions:** A machine learning approach to SRE risk factor identification may help clinicians better assess the individualized patient's need for denosumab treatment persistence and improve patient outcomes. Results from tumor-specific groups will be presented at the meeting. Research Sponsor: Amgen Inc.

SHAP risk factors that increase risk of SRE 3 to 12 months after denosumab cessation in ST with BM (declining importance).

AI-based imaging biomarker in mammography for prediction of tumor invasiveness. *First Author: Hyeonseob Nam, Lunit Inc., Seoul, South Korea*

Background: The preoperative diagnosis of ductal carcinoma in situ (DCIS) by core needle biopsy (CNB) can be upstaged in the final pathology, and this possibility is linked to the controversy over whether axillary staging is necessary in primary operation. In this study, we developed an artificial intelligence (AI)-powered Imaging Biomarker in Mammography (IBM) that can predict tumor invasiveness in preoperative mammography and evaluated its performance in an external validation cohort. **Methods:** A total of 151,764 exams of 4-view mammograms were collected from five institutions of three countries to develop the AI algorithm for breast cancer detection, where 31,776 were cancer exams. In previous studies, the performance of this breast cancer detection algorithm has already been evaluated, and in this study, we further developed the AI-powered IBM for predicting tumor invasiveness on top of the AI algorithm for breast cancer detection. To develop the AI-powered IBM for predicting invasiveness, final diagnosis information was collected for 8,251 cancer exams (472 DCIS, 388 ductal carcinoma in situ (DCIS-MI), and 7,391 invasive ductal carcinoma (IDC)), and 886 cancer exams (44 DCIS, 51 DCIS-MI, 791 IDC) were additionally collected for internal validation. The AI-powered IBM was developed via two stages of training – 1) training with diagnosis labels (cancer vs non-cancer), followed by 2) fine-tuning with invasiveness labels (DCIS, DCIS-MI, IDC). The AI-powered IBM also tested in an external validation cohort of 699 cancer exams (68 DCIS, 19 DCIS-MI, 612 IDC) and all the exams were confirmed by surgical biopsy. **Results:** The AI-powered IBM showed an area under the curve (AUC) values of 0.968 for breast cancer detection and it successfully distinguished IDC from DCIS and DCIS-MI with AUC values of 0.898 and 0.851, respectively (Table). In addition, the AUC value in terms of discriminating between DCIS and DCIS-MI was 0.752. When the AI-powered IBM was tested in the external cohort, it could detect breast cancer with the AUC of 0.952 and, its performance in terms of invasiveness prediction was similar that of the internal validation (IDC vs DCIS, 0.810; IDC vs DCIS-MI, 0.846), which supports the AI-powered IBM is applicable to the unseen mammography exam. **Conclusions:** The AI-powered IBM can distinguish IDC from DCIS and DCIS-MI in mammography. The results support that the AI-powered IBM can be used as a biomarker to help determine the surgical plan that includes whether or not to perform the axillary dissection. Research Sponsor: Lunit Inc.

The performance of AI-powered IBM for differentiating cancer subtype.

Continuous unobtrusive assessment of meaningful change in older adults with cancer: The Pacific Aging & Cancer Study Collaborative—PACS collaborative. *First Author: Chao-Yi Wu, Oregon Center for Aging & Technology (ORCATECH), Oregon Health & Science University, Portland, OR*

Background: Knowledge of changes in health that precede a cancer diagnosis is challenging because of a lack of longitudinal, objective measurement techniques. Current approaches rely on periodic assessment via self-report which may miss when and how health changes, particularly when changes may appear subtly over time. Remote-monitoring technologies provide a mechanism to continuously, passively, and unobtrusively monitor changes in health so that trajectories of change in relation to a life event (i.e., cancer diagnosis, treatment) can be detected and described. We examined the changes in*digital* indicators of health and life events 1 year before and after a self-reported cancer diagnosis in community-dwelling adults aged 65 and older. **Methods:** This is a secondary, retrospective data analysis of older adults who self-reported a new cancer diagnosis in the Oregon Center for Aging & Technology (ORCATECH) cohort. Ten older adults (age = 71.8±4.9 years, 30% women) were included with various cancer types (esophageal, prostate, uterine, pancreatic, b-cell follicular lymphoma, multiple myeloma, basal cell melanoma, basal and/or squamous cell carcinoma). Daily physical activity was measured using step counts derived from an actigraph watch. Weekly health and life events (pain severity, loneliness, hospitalization/emergency room (ER) visits, days away from home overnight) were self-reported from weekly online surveys. **Results:** A total of 3,624 days of actigraphy data (210 ± 88 days pre-cancer; 153 ± 81 days post-cancer) and 750 weeks of self-reported online survey data (36 ± 12 weeks pre-cancer; 39 ± 14 weeks post-cancer) were collected. Longitudinal linear mixed-effects models revealed that the trajectory of step counts was different pre- and post-cancer (β = -1.52, $p < .001$), with a gradual decrease in step counts before a cancer diagnosis. The trajectory of pain severity was different pre- and post-cancer (β = 0.01, $p < .001$), with a gradual increase in pain severity before a cancer diagnosis. There was a gradual increase in the occurrence of hospitalization/ER visits (OR = 1.07, p = 0.02) and days away from home overnight (OR = 1.04, p = 0.01) before a cancer diagnosis. Feelings of loneliness increased over time, regardless of pre- or post-cancer (OR = 1.04, $p < .001$). **Conclusions:** Changes in health and life events 1-year before a cancer diagnosis in older adults with varying cancer types and severity were unobtrusively observed. This study suggests that a remote-monitoring technology platform deployed in homes can detect meaningful intra-individual changes before and after a cancer diagnosis. Future studies can employ this technology as a pathway for improving the timeliness of detection and more effective therapeutic follow-up for older adults. Feasibility of integrating the Outcomes4Me smartphone navigation application into the care of breast cancer patients (FIONA). *First Author: Steven J. Isakoff, Massachusetts General Hospital, Boston, MA*

Background: Patients diagnosed with breast cancer (BC) face complex decisions about their care and many studies have shown that improved patient engagement results in increased satisfaction and better outcomes. Patient engagement includes education, treatment option selection, symptom tracking and reporting, and clinical trial opportunities. We conducted a pilot study to determine the feasibility of introducing the Outcomes4Me patient engagement app into the standard of care experience of BC patients. **Methods:** This was a pilot study (NCT04262518) conducted at an academic medical center. Eligible patients had any subtype of stage 1-4 BC and were on any type of chemo-, hormonal-, targeted-, or radiation-therapy for BC during the study period. Participants downloaded the app on their smartphone and their app usage was evaluated. Surveys were administered at baseline and end of study. Clinicians caring for patients using the app were surveyed at the end of the study. The primary endpoint was feasibility, defined as at least 40% of patients engaging with the app at least 3 times over the 12-week study period. Additional endpoints included usability, satisfaction, correlation of patient reported data with the EHR, clinical trial matching, and patient experience. **Results:** Between June 2020 and December 2020, 107 patients enrolled; results are reported for 90 patients with complete data as of 1/24/21. Baseline demographics: median age 53 (range: 27-77); 90% White, 4% Black, 3% Asian; 66% had hormone positive/HER2-, 20% HER2+, and 13% triple negative BC; 31% had stage 4 disease. At study entry, 93% had never used an app to help with their disease or treatment options. Over the 12 week study period, 58% of patients engaged with the app at least 3 times, meeting the primary feasibility endpoint. Patients engaged with the app on average 5.5 days (range: 0-40) with 20% engaging on more than 10 days during the study. The mean System Usability Score was 71 (median = 76) and was similar across age groups. The 5 app features deemed most ('somewhat' or 'very') helpful were: background about their BC (76%), information about treatment options (74%), newsfeed about their BC (70%), symptom tracking (65%), and clinical trial information (65%). 53% said that the app helped them keep track of symptoms and 33% said they are more likely to explore or enroll in a clinical trial after using the app. **Conclusions:** Integration of the Outcomes4Me app into the care management of BC patients is feasible with acceptable usability. Our results suggest that use of a patient smartphone app may be helpful for many aspects of patient education and engagement for patients with BC. The results also suggest that this type of intervention can help patients better track their symptoms and make them aware of clinical trials, potentially facilitating the management of side effects and accelerating clinical trials recruitment. Clinical trial information: NCT04262518. Research Sponsor: Outcomes4Me.

Daily step counts to predict hospitalizations during chemoradiotherapy for head and neck cancer. *First Author: Elena S. Izmailova, Koneksa Health, NY, NY*

Background: Wearable activity trackers could provide useful data for managing cancer patients with respect to treatment selection, toxicity monitoring, and implementation of supportive care measures. Here, we seek to evaluate the association between daily step counts and hospitalizations in a cohort of patients with head and neck cancer (HNC). **Methods:** This analysis consists of patients enrolled in one of three prospective trials involving activity monitoring (NCT02649569, NCT03115398, NCT03102229) during chemoradiation. Study subjects were asked to wear a commercial fitness tracker continuously during the therapy. ECOG performance status (PS) was assessed at baseline, and quality of life (QoL) EORTC QLQ-C30 questionnaires were completed weekly. Multivariable Cox regression models with time-dependent covariates (average step count over the past 3 days, most recent QoL score) and time-fixed covariates (age, sex, baseline PS, study number, baseline tumor volume, and treatment setting [definitive versus postoperative]) were used to identify predictors of first hospital admission during the chemoradiotherapy course. In addition to the Cox regression models, linear mixed models were fitted with daily step count as the dependent variable to examine its relationship with certain independent variables including age, sex, weekend status, days after treatment initiation, and study number. **Results:** Sixty-six HNC patients who received chemoradiotherapy between 2015 and 2019 were included in the analysis. Median age was 60 (range: 27-88). 47% of patients had ECOG PS score 0, 47% ECOG score 1, and 6% ECOG score 2. 29% of patients had HPV-positive oropharyngeal tumors, and the most common other tumor subsites were larynx (27%), and nasopharynx (12%). The Cox regression survival model demonstrated a 26% reduction in the short-term hospitalization risk for every 1000 daily steps (averaged over the past 3 days, hazard ratio 0.74; 95% confidence interval (CI) 0.55-0.98, p = 0.0367). Hospitalizations were not significantly associated with most recent QoL or baseline ECOG PS. Additionally, according to the linear mixed model results, daily step count was not associated with age (p = 0.8048). Study subjects moved less on weekends (on average 245 fewer steps on weekends than weekdays, 95% CI 134-357, $p < 0.0001$). Also, an increase in most recently measured ECOG PS was associated with a decrease in daily step count (167 fewer steps for every increase in ECOG PS, 95% CI -289 to -45, $p < 0.0072$). **Conclusions:** Daily step counts are a dynamic predictor of hospitalizations in patients undergoing chemoradiotherapy for head and neck cancer. Interventional studies are needed to demonstrate feasibility of leveraging physical activity data to optimize supportive care during cancer therapy and enhance cancer care quality. Clinical trial information: NCT02649569, NCT03115398, NCT03102229. Research Sponsor: None.

Towards reducing cancer burden within the Medicaid program: Impact of Medicaid expansion on cancer stage at diagnosis. *First Author: Siran M. Koroukian, Case Western Reserve University, Cleveland, OH*

Background: Studies to date have shown post-Medicaid expansion (M-exp) decreases in the percentage of cancer patients who are uninsured and improvements in cancer stage at diagnosis in states that expanded Medicaid as part of the Affordable Care Act. However, most studies have examined impact of M-exp on stage outcomes at the population level, or among Medicaid and uninsured, rather than solely in the Medicaid population. Using cancer registry data from a non M-exp state (Georgia (GA)) and two M-exp states (Ohio (OH) and New Jersey (NJ)), we compared changes in cancer stage in patients on Medicaid, accounting for individual- and contextual-level characteristics at the Zip Code Tabulation Area (ZCTA) level. **Methods:** We used GA, OH, and NJ cancer registry data for individuals 20-64 years of age and diagnosed with incident invasive female breast (BC), cervical (CC), and colorectal cancer (CRC). Data spanned from 2010-2017 for GA and OH, and from 2011-2016 for NJ (for BC and CRC only), with 2014 marking the year in which Medicaid was expanded in OH and NJ. We retrieved demographic data (age, race/ethnicity, sex for CRC, insurance status, and cancer stage from the cancer registries), and obtained ZCTA-level data from the American Community Survey (e.g., income, education, and female-headed households). We defined late-stage diagnosis as regional- or distant- stage. We conducted multivariable logistic regression models by state and cancer site to examine changes in late-stage cancer diagnosis pre- and post-M-exp, accounting for individual- and ZCTA-level covariates. **Results:** The number of patients with incident cancer who were on Medicaid increased by 41.7% (n = 1757 to 2490), 59.6% (327 to 522), and 76.4% (953 to 1681) for BC, CC, and CRC cancers, respectively, in Ohio; by 92.4% (433 to 833) for BC and by over 100% for CRC (232 to 496) in NJ; but by 12.7% (662 to 746) among CRC patients in GA, where the number of BC and CC patients on Medicaid remained relatively stable. Adjusting for individual and contextual-level factors, the adjusted risk ratio (ARR and (95% Confidence Interval)) for late-stage disease was lowest for BC patients in OH (0.93 (0.87, 0.99)) and for CRC patients in GA (0.94 (0.89, 0.99)). The ARR for BC and CRC in NJ were not statistically significant, though they trended towards improvement. Similarly, changes in late-stage for CC were not statistically significant in OH or in GA. **Conclusions:** The increased number of cancer patients in Medicaid and the reductions in late-stage diagnosis observed may potentially translate into reduced, or at least stabilized, cancer-related morbidity and mortality burden among Medicaid beneficiaries over time. However, reductions in late-stage diagnosis were not consistent across cancer sites or states, possibly due to differences in population demographics, health behaviors, healthcare seeking patterns, and state-level cancer prevention efforts. Disparities in government and nonprofit organization funding may hinder clinical trial development for underfunded cancers. *First Author: Suneel Deepak Kamath, Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH*

Background: National Cancer Institute (NCI) and nonprofit organization (NPO) funding is critical for research and advocacy, but may not be equitable across cancers. This could negatively impact clinical trial development for underfunded cancers. **Methods:** This study evaluated funding from the NCI and NPOs with > $5 million in annual revenue supporting leukemia, lymphoma, melanoma, lung, breast, colorectal, pancreatic, hepatobiliary, prostate, ovarian, cervical and endometrial cancers from 2015-2018 based on publically available reports and tax records. The primary objectives were to assess for disparities in NCI and NPO funding across different cancers compared to their median incidence and mortality from 2015-2018, and to determine if underfunding correlates with fewer clinical trials found in clinicaltrials.gov. Correlations between combined NCI and NPO funding for each cancer and its incidence, mortality and number of clinical trials were evaluated using descriptive statistics and Pearson correlation coefficients. **Results:** Diseases with the largest combined NCI+NPO funding were breast ($3.75 billion), leukemia ($1.99 billion) and lung cancer ($1.56 billion). Those with the least funding were endometrial ($94 million), cervical ($292 million), and hepatobiliary cancers ($348 million). These data are summarized in the Table. Disease-specific NCI+NPO funding correlated well with incidence, but less so with mortality (Pearson correlation coefficients: 0.74 and 0.63, respectively). Disease-specific NPO funding correlated moderately well with incidence, but was poorly correlated with mortality (Pearson correlation coefficients: 0.54 and 0.39, respectively). Breast cancer, leukemia and lymphoma were consistently well-funded compared to their incidence and mortality, while colorectal, lung, hepatobiliary and uterine cancers were consistently underfunded. The amount of NCI funding, NPO funding and combined NCI+NPO funding for a particular cancer each correlated strongly with the number of clinical trials for that disease (Pearson correlation coefficients: 0.88, 0.87 and 0.91, respectively). **Conclusions:** Many cancers with high incidence and mortality are underfunded. Cancers with higher mortality rates receive less funding, particularly from NPOs. Underfunding strongly correlates with fewer clinical trials, which could impede future advances in underfunded cancers. Research Sponsor: None.

	Leukemia	Lymphoma	Breast	Lung	Colon	Pancreas	Liver	Melanoma	Uterine	Cervix	Ovary	Prostate

Determinants of enhanced vulnerability to Covid-19 in U.K. cancer patients: Results from the OnCovid study. *First Author: David James Pinato, Department of Surgery and Cancer, Imperial College, London, United Kingdom*

Background: Despite high contagiousness and rapid spread, SARS-Cov-2 has led to heterogeneous outcomes across affected nations. Within Europe, the United Kingdom is the most severely affected country, with a death toll in excess of 100.000 as of February 2021. We aimed to compare the national impact of Covid-19 on the risk of death in UK cancer patients versus those in continental Europe (EU). **Methods:** We performed a retrospective analysis of the OnCovid study database, a European registry of cancer patients consecutively diagnosed with Covid-19 in 27 centres from February 27 to September 10, 2020. We analysed case fatality rates and risk of death at 30 days and 6 months stratified by region of origin (UK versus EU). We compared patient characteristics at baseline, oncological and Covid-19 specific therapy across cohorts and tested these in multivariable Cox regression models to identify predictors of adverse outcome in UK versus EU patients. **Results:** Compared to EU patients (n = 924), UK patients (n = 468) were characterised by higher case fatality rates (40.38% versus 26.5%, $p < 0.0001$), higher risk of death at 30 days (hazard ratio, HR 1.64 [95%CI 1.36-1.99]) and 6 months after Covid-19 diagnosis (47.64% versus 33.33%, $p < 0.0001$, HR 1.59 [95%CI 1.33-1.88]). UK patients were more often males, of older age and more co-morbid than EU counterparts ($p < 0.01$). Receipt of anti-cancer therapy was lower in UK versus EU patients ($p < 0.001$). Despite equal proportions of complicated Covid-19, rates of intensive care admission and use of mechanical ventilation, UK cancer patients were less likely to receive anti-Covid-19 therapies including corticosteroids, anti-virals and interleukin-6 antagonists ($p < 0.0001$). Multivariable analyses adjusted for imbalanced prognostic factors confirmed the UK cohort to be characterised by worse risk of death at 30 days and 6 months, independent of patient's age, gender, tumour stage and status, number of comorbidities, Covid-19 severity, receipt of anti-cancer and anti-Covid-19 therapy. Rates of permanent cessation of anti-cancer therapy post Covid-19 were similar in UK versus EU. **Conclusions:** UK cancer patients have been more severely impacted by the unfolding of the Covid-19 pandemic despite societal risk mitigation factors and rapid deferral of anti-cancer therapy. The increased frailty of UK cancer patients highlights high-risk groups that should be prioritised for anti-SARS-Cov-2 vaccination. Continued evaluation of long-term outcomes is warranted. Research Sponsor: None.

Time intervals between U.S. Food and Drug Administration (FDA) and European Medicines Agency (EMA) new cancer therapy approvals. *First Author: Mark Lythgoe, Imperial College London, London, United Kingdom*

Background: Novel therapies are transforming cancer care. Regulatory review and approval are essential to deliver safe and efficacious innovations to patients. Studies prior to 2010 describe quicker approval decisions for new oncology drug registrations with the FDA compared to the EMA (median delay 238 days). Both regulatory agencies have subsequently improved procedures to expedite approval times. We compared regulatory market authorisation dates at the FDA and EMA for new oncology therapies from 2010-2020. **Methods:** New oncology therapeutic approvals between 2010-2020 were identified from the FDA and EMA regulatory databases. We analysed only initial approvals (not supplementary licenses) for active anti-cancer therapies (excluding biosimilars and supportive drugs). The delay in regulatory approval between the FDA and EMA was calculated in calendar days. We further analysed therapies by therapeutic class, evaluating for significant differences. **Results:** We identified 108 new therapy registrations during the study period. 104 (96.3%) therapies were approved by the FDA and 90 (83.3%) had EMA market authorisation. 4 (3.7%) drugs were not FDA registered, including 3 unsuccessful applications and 1 which sought licensing in a different indication. 18 (16.5%) drugs were not EMA registered, including 9 (8.8%) which did not pursue EMA licensing, 3 (2.9%) withdrawn licensing applications, 3 (2.9%) sought licensing in different tumour group/indication, 1 (0.9%) rejected application and 2 (1.9%) with applications under review at submission date. Of the 86 drugs approved by both agencies, 80 were approved first by the FDA and 6 by the EMA. The median delay in approval between the FDA and EMA was 227 days (IQR:124-354 days). Table shows approvals by therapeutic class. The shortest median time difference for approval was for monoclonal antibodies (171 days) with the longest for kinase inhibitors (281 days). **Conclusions:** This study shows more new oncology therapies are approved by the FDA than the EMA. Patients in the US typically have access to approved therapies earlier than in Europe. From 2010 to 2020 the median delay between FDA and EMA approval was 227 days, falling by 11 days compared to 2003-10, [non-statistically significant]. Such lengthy delays could exceed the life expectancy of many patients with advanced cancer. Innovations for accelerated approval at both the FDA (e.g. Project Orbis) and EMA (e.g., PRIME) have potential to lead to faster approval. Research Sponsor: None.

Therapeutic Class	Approved First by FDA	Approved First by EMA	Median Time difference between approvals in days (IQR)
Kinase Inhibitor	37	0	281 (137-367)
Monoclonal Antibody	18	2	171 (100-265)
Antibody Drug Conjugate	4	1	266 (220-395)
Cytotoxic Chemotherapy	5	1	245 (145-336)
Other*	16	2	242 (179-328)
Total	80	6	227 (124-357)

Implementation of insurance marketplaces and changes in diagnosis stage in low-income cancer patients. *First Author: Uriel Kim, Case Western Reserve University, Cleveland, OH*

Background: Millions of low-income Americans gained insurance coverage through Medicaid expansion and the "Marketplaces" of the Affordable Care Act (ACA). How Marketplaces have specifically improved cancer outcomes among these individuals is unclear. Thus, we examined changes in insurance status and diagnosis stage following the ACA among low-income (139-250% of the Federal Poverty Level [FPL]), non-elderly patients (ages 30-64). **Methods:** In Ohio's cancer registry, we identified patients diagnosed with one of the top 16 cancers before (2011-2013, "Pre-ACA") and after (Q3 of 2014-2016, "Post-ACA") the implementation of the ACA's insurance Marketplaces and either had private insurance or no insurance. Low-income patients were isolated using a novel, geographically-driven approach called probability weighting. **Results:** The uninsured percentage dropped from 12.9% to 4.9% between the Pre- and Post-ACA periods in the study sample (N = 10,747). An estimated 11.1% of individuals had Marketplace insurance Post-ACA. A significant but modest Post-ACA (versus Pre-ACA) shift toward non-metastatic disease was identified (Adjusted Odds Ratio [AOR]: 0.95, 95%CI: 0.90-0.99). The largest site-specific shifts were observed for thyroid (AOR: 0.50, 95%CI: 0.30-0.83) and ovarian (AOR: 0.74, 95%CI: 0.58-0.93) cancers. In a control analysis of wealthier (400%+ FPL), privately insured individuals, no significant shifts were identified (AOR: 0.97, 95%CI: 0.92-1.02). **Conclusions:** This is the first study to show an effect in cancer stage at diagnosis from the Affordable Care Act's Insurance Marketplaces. We found that the Marketplaces greatly reduced the number of low-income, uninsured cancer patients, translating to significant improvements in cancer stage at diagnosis. As policy makers contemplate modifications to the ACA, they should carefully consider the impact of those changes on the highly vulnerable population of low-income cancer patients. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Pre-screening as a tool for increasing oncology trial enrollment. *First Author: Jennifer J. Wu, Laura and Isaac Perlmutter Cancer Center, NYU Langone Health, New York, NY*

Background: Recruiting underserved patients onto therapeutic oncology trials is imperative in light of cancer disparities. Many institutions have increased enrollment with data mining tools that match patients to clinical trials, but such expensive tools are unavailable in a public safety net healthcare system. **Methods:** The NYU Perlmutter Cancer Center Clinical Trials Office implemented a quality improvement program aimed to increase therapeutic trial enrollment at Bellevue Cancer Center (BCC), an affiliated public hospital. The initiative utilized one employee to manually pre-screen patients via the EMR, cancer registries, and conferences. The program aimed to identify eligible patients for therapeutic trials and those subsequently enrolled. **Results:** During the two years preceding the pre-screening program, 31 patients were enrolled onto therapeutic clinical trials at BCC. For a period of two years (7/2017-7/2019) following the initiation of this program, 255 patients were identified, of which 143 (56.1%) enrolled onto trials. Of those enrolled, 55 were referred to NYU for trials not open at BCC. Among the 143 enrolled patients, 64% were female, 56% were non-white, and 57% did not speak English (spanning 16 languages). The median age was 55, and the top three disease groups were breast, GI, and thoracic. 83% of our patients reside in low-income areas, with 62% in both low income and Health Professional Shortage Areas (HPSA). **Conclusions:** Dedicating one employee to screening led to a 4.6 fold increase in accruals, successfully augmenting therapeutic trial enrollment in a healthcare setting with scarce resources, providing broader access to clinical trials for underserved populations. Research Sponsor: None.

Demographics of enrolled patients.

Category		Count	Percent of Total
Gender	Female / Male	91 / 52	63.64 / 36.36
Age	<60 / >60	92 / 51	64.34 / 35.66
Race	Asian Indian	46	32.17
	Black or African American	26	18.18
	Other / Unknown	13	9.09
	White	58	40.56
Ethnicity	Hispanic or Latino	49	34.27
	Not Hispanic or Latino	89	62.24
	Unknown	5	3.50

Improvement in incident resolution time with implementation of an electronic patient management solution at a community oncology practice. *First Author: Lalan S. Wilfong, Texas Oncology/The US Oncology Network, Dallas, TX*

Background: Value-based care models such as the Oncology Care Model incentivize practices to reduce hospitalizations and emergency department (ED) visits. Texas Oncology found that most ED visits occurred during regular business hours. Prolonged patient call back times were consistently rated poorly on satisfaction surveys and often led to ED visits for symptoms that could be managed in our offices. We partnered with Navigating Cancer (NC) to implement an electronic patient management technology solution. **Methods:** For each of our 200 locations, call volume was estimated based on clinic volume. We then reallocated or hired dedicated triage nurses and operators. Incoming calls were entered into the NC dashboard by operators as incidents which were routed based on symptom priority following system generated prompts. Incident volumes and resolution times were tracked. We instituted PDSA cycles at all locations with a goal of less than 90-minute resolution of symptom-related incidents Utilizing the electronic dashboard allowed us to continue this initiative during the COVID-19 public health emergency as our staff could work remotely. Nurses were able to document if a potential ED visit was avoided. These data points allowed our practice to establish comprehensive and strategic actions plans for quality improvement. **Results:** We finalized implementation of the system in February of 2020. Total incidents for 2020 were over 1 million, averaging over 5000 per location. Resolution time for all incidents started at 3.2 hours pre-implementation and improved to 2.2 hours in December of 2020. Resolution times for symptom-related incidents started at 2.3 hours pre-implementation and ended at 1.5 hours in December of 2020 with over 60% resolved under one hour. 8% of symptom-related incidents resulted in definite or probable ED avoidances by nursing assessment. Shortness of breath, vomiting, chills, and weakness were the top symptom types addressed for ED avoidances. **Conclusions:** An electronic patient management solution with PDSA cycles of quality improvement can markedly reduce call back times, especially for symptom related calls. We believe managing symptoms in a timely fashion will lower ED visits and hospitalizations as well as improve patient satisfaction. We will report on these outcomes once available. Research Sponsor: None.

Cancer patient satisfaction with telehealth: Survey results from a large NCI-designated cancer institute. *First Author: Divya Natesan, Duke University Medical Center, Department of Radiation Oncology, Durham, NC*

Background: Telehealth (TH) utilization for patients at our cancer institute increased in 2020 in response to the COVID-19 pandemic, however oncology-specific TH patient satisfaction is unknown. **Methods:** Monthly TH utilization at a single large NCI-designated institute from 3/1/2020-11/30/2020 was reviewed. Utilization was calculated as chargeable TH visits (new video, established video, phone) as a proportion of all consult/follow up visits. Patient satisfaction surveys for oncology TH visits for MD/PA/NP providers were reviewed from 4/1/2020-11/30/2020. Surveys were sent after every TH visit, unless the patient had a prior visit in the past 3 months. Percent (%) top box score (TBS) was defined as proportion of responses in the highest possible response category (i.e. very good). % TBS was reported for 14 survey items in 4 domains: technology, access, care provider (CP), and overall assessment. Satisfaction was assessed over time and according to patient factors: generation, gender, insurance type, employment status, and clinic site. The Cochrane-Armitage trend test was used to compare proportions of TBS responses across monthly time points. **Results:** TH comprised 21% (22,055/103,461) of all encounters in the study period. TH use increased from 9% in 3/2020 to a peak of 47% in 4/2020. In 11/2020, TH use was 18%. 28.0% (2,286/8,173) of TH patient surveys were returned. Multiple patient satisfaction metrics were improved over time (Table). Patients had higher satisfaction with phone compared to video visits with regards to technology (86% vs 76%) and access (80% vs 72%). Millennials (born 1981-1995) had higher satisfaction with access to TH (87%) compared to Gen X (1965-1980) (77%), Baby Boomer (1946-1964) (74%), and Silent Generation (1928-1945) (72%), however all generations had similar levels of satisfaction with technology (range 77-80%). Disabled patients had higher overall satisfaction of TH (82%) versus those working full time or retired (71%). Patients with commercial insurance had worse overall satisfaction of TH compared to other insurance types (65% vs 72%). Patients with encounters in genitourinary, thoracic, and endocrine oncology clinics had the highest levels of overall satisfaction (75%) compared to other clinics (69%). There were no observed differences in TH satisfaction according to gender. **Conclusions:** TH cancer patient satisfaction is high and has improved over time, however satisfaction differs by patient demographics. Further data are needed to best select patients appropriate for TH. Research Sponsor: None.

Patterns of telehealth utilization during the COVID-19 pandemic and preferences for post-pandemic telehealth use: A national survey of oncology clinicians. *First Author: Christopher Manz, University of Pennsylvania, Philadelphia, PA*

Background: Rarely used in routine practice pre-pandemic, telehealth utilization for cancer care rose significantly during the COVID-19 pandemic. Increased familiarity with telehealth has led to calls to continue its use after the pandemic ends. Yet national patterns of oncology telehealth utilization by visit type, preferences for telehealth use post-pandemic and barriers to telehealth for patients with cancer have not been described. **Methods:** 9,336 survey invitations were emailed to US-based ASCO members who have agreed to receive communications. Survey distribution was equally divided over five US regions, and practice type (e.g., academic, community) was reflective of ASCO membership proportions. The survey was open and data collected from January 4-28, 2021. Non-respondents received two reminder emails at week intervals. Analysis is descriptive. **Results:** 200 respondents completed the survey (2%). Respondents were 72% medical oncologists, 66% urban, 64% academic-affiliated, and from 42 states. 99% currently offered telehealth. 63% used telehealth for <=30% of all patient visits in the last 30 days; 18% used telehealth for more than half of visits. Telehealth utilization varied by visit type (table). 64% reported that the care delivered in telehealth visits was similar quality to in-person visits (29% worse). Assuming no regulatory or financial barriers to telehealth use after the pandemic, 92% would like to use telehealth for at least some visit types; only 8% prefer not to use telehealth. 20% would like to use telehealth for all visits types, and 64%, 54%, 33% and 17% would like to use telehealth for survivorship, symptom management, evaluation of patients receiving treatment and new patient visits, respectively (multiple selections allowed). Major barriers to telehealth were lack of patient access to technology (reported by 81%), limited patient technological proficiency (80%), language barriers (45%), uncertainty about future reimbursement (41%) and lack of administrative resources to support clinicians (33%). 68% agreed that the barriers increase cancer care disparities. **Conclusions:** Telehealth utilization was widespread during the COVID pandemic and varied by visit type. Most respondents plan to use telehealth in the future, but report barriers to continued use that worsen disparities. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Telehealth visits in last 30 days by type.

% reporting for each visit type	No telehealth visits	< half	≥ half
New patient	28	50	22
Consent	33	52	16
Evaluation for patients receiving systemic therapy	23	53	24
Post surgery/radiation	35	44	21
Survivorship	9	40	51
Symptom management	7	55	37
Discussion of important results	10	54	36
Discussion of goals of care	26	55	19

*Each cell is the percent of respondents who reported none, < half, or ≥ half of visits of the visit type in the last 30 days occurred as telehealth. Rows may not sum to 100 due to rounding.

Improving cancer patient care with a digital telemonitoring platform: The ConnectPatienToDoctor study. *First Author: Carole Helissey, Clinical Research Unit, Military Hospital Begin, Saint-Mandé, France*

Background: During COVID19 pandemic, clinicians have had to face two challenges in an unprecedented context: ensuring continuity of patient care for a disease that involves a life-threatening prognosis while reducing patients' vulnerability to this virus. The ConnectPatientToDoctor study aimed to evaluate a connected telemonitoring platform,*Cureety*, in cancer patient care. **Patients and Methods:** This prospective study was conducted at the Military Hospital Bégin. Each cancer patient was allowed to respond to a personalized symptomatology questionnaire based on CTCAE v.5.0, and personalized to their pathology and treatment. An algorithm evaluated the health status of the patient based on the reported adverse events and provided adapted recommendations. The calculated score allows to classify the patient into four different levels: (1) Correct State (green) (2) Compromised State (yellow) (3) State to be monitored (orange) (4) Critical State (red) In the case of orange or red classification, the patient was invited to call the hospital. In case of green or yellow classification, the patient received therapeutic advice set by the doctor, for each of the adverse events reported. The primary endpoint was to assess the feasibility of monitoring cancer patient with the connected platform. The secondary endpoint was to assess patient and caregivers' satisfaction. **Results:** There were 108 patients included in the program between July 1st, 2020 and January 31st, 2021. The median age was 70 and 77% presented a metastatic stage. The most represented cancer was prostate (50%), followed by lung (24%) and breast (15%). Overall, 1864 questionnaires were completed by the patients, resulting in 543 yellow alerts and 133 orange or red alerts. More than 60% of the alerts was managed through outpatient care or with a rapid intervention to resolve the adverse events. On a satisfaction scale from 1 to 10, where 10 was the highest, 72% of the patients responded with a 9 or 10. And all caregivers were satisfied because they could offer a better care, prioritize care, and save time. **Conclusions:** Participants in ConnectPatientToDoctor study reported that they had a clear benefit from using a connected platform to monitor their treatment. Patients felt less isolated and felt that they benefited from personalized care. This solution makes it possible to streamline the patient care process. Research Sponsor: None.

Telehealth: Reducing or increasing cancer care disparities? *First Author: Patricia Jewett, University of Minnesota, Minneapolis, MN*

Background: During the COVID-19 pandemic, most cancer care in the United States transitioned to telehealth (phone or video visits) to reduce infection risks for patients and providers. Telehealth may simplify care logistics (e.g. reduce travel and waiting times), but it may also unintentionally exacerbate existing disparities in healthcare utilization by race/ethnicity, age, or rural/urban status. As telehealth will likely continue long-term, we examined telehealth use at a comprehensive cancer center during the COVID-19 pandemic across patient populations with established disparities in cancer treatment and outcomes. **Methods:** We retrospectively reviewed telehealth visits from March until December 2020 among individuals diagnosed with cancer at the University of Minnesota Masonic Cancer Center (MCC). We used Chi-squared tests and GEE logistic regression to compare video vs. phone visits by age, urban/rural status, and race/ethnicity (American Indian / American Native [AIAN], Asian, Non-Hispanic Black/African American [NH Black/AA], Hispanic, Multiple, Native Hawaiian / Pacific Islander [NHPI], NH White). **Results:** Over the study period, 42,171 telehealth visits were performed with 11,097 patients at the MCC. Patients had a mean age of 62.7±13.9 years; 59.2% were female; 88.7% lived in urban areas; 90.0% of patients were NH White, 4.4% NH Black/AA, 3.0% Asian, 1.5% Hispanic, 0.8% AIAN, 0.3% of multiple races, and 0.1% NHPI. The most common cancer sites were breast (24.1%), hematological (21.0%), gynecologic (10.0%), and lung (8.4%). NH White individuals were more likely (53.9%) to use video than AIAN (39.7%), Black/AA (37.8%), or NHPI individuals (34.9%). Video use was less common among rural (45.3%) than urban (53.7%; $p<.0001$) residents, and among individuals aged 65 or older (45.2%) vs. younger than 65 (59.5%; $p<.0001$). In a logistic regression, adjusted for continuous age and urban/rural status, all race/ethnic groups except Multiple were less likely to use video than NH White individuals (vs. phone; Table). **Conclusions:** Our findings underscore disparities in telehealth use for cancer care across historically underserved populations. Future research should evaluate potential underlying contributors to these disparities such as technology access, internet capability, and fear of discrimination. Additional research is also needed to determine whether video vs. phone visits affect cancer outcomes, therefore indicating true disparity. Research Sponsor: None.

Logistic regression, adjusted for age and urban/rural status: use of video vs. phone, University of Minnesota Masonic Cancer Center, March-December 2020.

Can COV Direct: Effectiveness of a tele-medicine self- care interventions for cancer survivors during COVID 19 pandemic. *First Author: Narayanankutty Edavalath Warrier, Malabar Institute of Medical Sciences, Calicut, India*

Background: Good mental health improves the overall quality of life. Anxiety and depression in post-treatment cancer survivors is common and can affect adversely on the individual. CanCovDirect is a novel, tele-medicine self-care intervention for cancer survivors. We practiced a randomized controlled superiority trial to compare CanCovDirect with usual standard care (SC) in this population.**Methods:** Individuals completing cancer treatment within the past 3 years who had symptoms with or without anxiety or depression were recruited from clinical and community settings in Northern Kerala. We allocated the participants using block randomization (CanCovDirect plus SC or to SC alone). Assessments of anxiety and depression severity (Centre for Epidemiological Studies-Depression scale [CES-D]; primary outcome) and secondary outcomes anxiety symptoms (Hospital Anxiety and Depression Scale) health-related quality of life (Short Form Survey-12 mental and physical component summaries), were conducted at baseline, as well as 3 and 6 months (primary time point). Analyses of outcomes were adjusted for covariates using linear regression. **Results:** Participants recruited between June 2020 and November 2020 were randomly assigned to CanCovDirect (n = 152) or SC (n = 152). Among 350 participants randomly assigned, 304 (86.85%) completed the primary outcome at 6 months. CanCovDirect participants reported less severe anxiety and depressive symptoms on the CES-D than SC participants at 6 months, adjusted effect size (ES) 1.68 (95% CI, 1.28 to 2.05). CanCovDirect participants also had significantly greater quality of life compared with SC. Exploratory analysis suggested that types of cancer was a modifier of the primary outcome (interaction term P value = .04); the intervention was effective in women (ES, 0.62; 95% CI, −0.45 to 0.89). **Conclusions:** CanCovDirect is an essential method of managing mild-moderate depression and anxiety symptoms in cancer survivors. Research Sponsor: None.

mPalliative Care Link: Examination of a mobile solution to palliative care coordination among Tanzanian cancer patients. *First Author: Mamsau Ngoma, Ocean Road Cancer Institute Cancer Institute, Dar Es Salaam, Tanzania, United Republic of*

Background: Cancer is a growing public health concern in Tanzania (and throughout sub-Saharan Africa), with a majority of cases presenting in late stage with associated distress, ie, pain. Access to specialty palliative care (PC) is a national priority in Tanzania; however, there are limited numbers of PC specialists (hereafter, specialists). Mobile health promises to extend the reach of a limited pool of specialists through inter-professional, community-based care coordination. This work assessed the effectiveness of a smartphone-/web-based application, mobile Palliative Care Link (mPCL), to extend specialist access via shared data and communication with local health workers (LHWs). Central to mPCL is the African Palliative care Outcome Scale (POS), adapted for automated, scheduled mobile symptom assessment and response. **Methods:** Following consent, incurable adult cancer patients were randomized at hospital discharge from a large urban, government-supported Tanzanian cancer institute to one of two study arms—mPCL or phone-contact POS collection. Baseline sociodemographic, clinical and POS data were recorded. Twice-weekly POS responses were collected and managed via mPCL or by phone-contact with clinician study personnel for up to 4-months depending on respective study arm. Patient end-of-study care satisfaction was assessed via phone-survey. **Results:** Forty-nine patients per arm participated. Comparison of baseline characteristics showed a trend toward more women (p= 0.07) and higher discharge morphine use (p= 0.09) in the mPCL versus phone-contact groups, respectively, and significant between-group differences in cancer types (p= 0.003). Proportion of deaths were near-equal comparing groups [26% (n= 13) mPCL versus 28% (n= 14) phone-contact]. Overall symptom severity was lower in the phone-contact group (p <0.0001) and symptom severity decreased over time in both groups (p= 0.0001); however, between-group change in overall symptoms over time did not vary (p= 0.34). Care satisfaction was high overall in both groups with few between-groups differences, ie, greater provider response to questions and concerns in the phone-contact arm and greater provision of spiritual support in the mPCL arm. **Conclusions:** Higher symptom severity scores in the mPCL arm likely reflecting between-group sociodemographic/clinical differences and clinical support of phone-contact arm participants. Similar rates of care satisfaction in both groups suggest that, compared to phone-based support, mPCL may facilitate effective symptom-focused care in a more efficient and scalable manner. Study limitations include a small sample of patients from a single urban hospital and lack of a true usual care arm. Broader study of mPCL's cost-efficiency and utility in Tanzania is needed. This work promises to close a large PC gap in under-resourced settings throughout Tanzania and other LMICs. Research Sponsor: U.S. National Institutes of Health.

Implementing virtual mind-body programming to support cancer patients during COVID-19. *First Author: Jun J. Mao, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite growing evidence of mind-body therapies for physical and psychological health among patients with cancer, their access remains limited. The COVID-19 pandemic has further disrupted the delivery of necessary cancer and supportive care; thus, the need to support patients with cancer is unprecedented. To expand the reach and access of mind-body therapies, we developed, implemented, and evaluated a novel virtual mind-body program for patients with cancer. **Methods:** We rapidly developed a 7-day a week virtual mind-body program, Integrative Medicine at Home (IM@Home), for patients with cancer (ages ≥18 years) and deployed it on April 1st, 2020. IM@Home included mind-body group therapy classes in fitness, meditation, yoga, dance, tai chi, and music delivered using Zoom video conferencing. Classes ranged from 30-45 minutes and were led by an integrative medicine clinician. Patients had the option to register for a 1-month, 3-month, or 6-month membership to gain unlimited access to all virtual mind-body classes. Multimethod evaluation was conducted using the RE-AIM conceptual framework to guide surveys and qualitative interviews. Surveys were analyzed using descriptive statistics and interviews were analyzed using grounded theory. **Results:** Between April 2020 and January 2021, IM@Home registered over 32,000 class participants, with a weekly average attendance of 700-800 participants. In a 4-month post-deployment survey (n = 131), nearly all participants were satisfied with IM@Home (93.9%) and would recommend the program to friends and family (95.4%). A majority of participants also found IM@Home to be simple to use (87.0%) and said the program had a variety of classes that interested them (93.1%). Three-quarters of participants (74.8%) were taking 3 to 7 classes a week (range: 1 to 15 classes), among which the most popular classes were fitness (88.7%), chair yoga (37.1%), and tai chi (33.1%). Most participants preferred a 3-month membership (51.6%), followed by a 6-month membership (19.5%). In qualitative interviews (n = 30), participants reported IM@Home helped them to: 1) maintain structured routines and stay motivated to exercise; 2) cope with COVID-19-related and cancer-related stressors; and 3) connect with their fellow cancer patient community and foster social relationships during a time of isolation. **Conclusions:** Virtual mind-body programming, through IM@Home, reached many patients with cancer to address their physical and psychological challenges during COVID-19. As patients with cancer experience high physical and psychological symptom burden following diagnosis, future clinical trials are needed to evaluate the specific effects of IM@Home when integrated into active treatment and survivorship care. Research Sponsor: Translational and Integrative Medicine Research Fund at Memorial Sloan Kettering Cancer Center, U.S. National Institutes of Health.

Exploring the role of digital health coaching for men with prostate cancer. *First Author: Nathan Handley, Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia, PA*

TPS1586Background: Toxicity leading to impaired quality of life is common among men receiving treatment for Prostate Cancer (PCa). Digital interventions may be beneficial in enhancing health self-efficacy in managing symptom burden. This study evaluates the feasibility and preliminary outcomes of digital health coaching intervention on men with PCa. **Methods:** This pilot study aims to recruit up to 100 adult, English-speaking men with PCa who in the last 2 years have required active treatment, defined as cancer management via active surveillance, surgery, radiation, androgen deprivation, chemotherapy, hormonal therapy, immunotherapy or a combination of these modalities. Men will be enrolled across the catchment area of Jefferson Health using social media and a variety of other outreach tools approved by the Institutional Review Board. Consented patients are enrolled in a 3-month digital health coaching program which combines weekly calls with up to 4 nudges of evidence-based content delivered via text or email weekly. The program focuses on a weekly health topic, such as physical, mental, social, or financial health, and managing symptoms, and empowers participants to set health goals of importance to them. Primary endpoints include feasibility, defined as 60% of participants completing the 3-month program. The main secondary endpoints measured are health self-efficacy as measured by the Cancer Behavior Inventory-Brief (CBI-B), quality of life, as measured by the Expanded Prostate Cancer Index Composite for Clinical Practice (EPIC-CP), financial toxicity as measured by the Comprehensive Score of Financial Toxicity (COST) and physical and mental health as measured by the Patient Reported Outcomes Measurement Information System-Global Health 10 (PROMIS-10). Outcomes are captured on enrollment and monthly through program completion for a total of 4 data points. Summary statistics will be used to describe patient demographic and clinical characteristics of the study population. Summary statistics will also be used to describe CBI, EPIC-CP, PROMIS and COST by assessment time. The change in CBI-B scores from baseline to 3 months will be calculated along with 95% confidence intervals. Additional LMMs will be created to assess the relationship between self-efficacy (CBI) and quality of life (EPIC-CP), financial toxicity (COST) and global health (PROMIS- SF10). Research Sponsor: Philadelphia Prostate Cancer Biome Project.

Primary care oncology model (PCOM): Implementation of a model integrating primary and oncology care for patients taking oral anticancer agents. *First Author: Emily R. Mackler, University of Michigan Health System, Ann Arbor, MI*

TPS1587Background: Non-adherence to oral anticancer agents (OAA) has been reported among 30% of individuals. Often, individuals with cancer are not just managing their new OAA but also medications to treat multiple chronic conditions (MCC). Multiple factors contribute to the extent patients on OAAs and MCC medications adhere to therapy. The objective of this study is to improve medication, symptom, and disease management of patients with hematological malignancies and MCC through care coordination between pharmacists. **Methods:** Design. This is a multi-center prospective single arm pilot study at two academic medical centers in Michigan and Tennessee. Subjects. Ninety participants will be recruited, 60 from site 1 and 30 from site 2. Inclusion criteria are: adults > 18 years, diagnosed with and initiating oral treatment for chronic myeloid leukemia, chronic lymphocytic leukemia, or multiple myeloma, diagnoses of at least 2 chronic conditions, where one is type 2 diabetes, hypertension, congestive heart failure, depression/anxiety, gastroesophageal reflux disease, hyperlipidemia, or chronic obstructive pulmonary disease, taking at least two chronic medications, and able to provide electronic consent. Exclusion criteria are: inability to speak English, and diagnosis of type 1 diabetes or HIV. Intervention. Participants will complete two Patient Reported Outcome Measures (PROMs) for their OAA that will be reviewed by the oncology pharmacist, with follow-up to the care team if needed. Participants will be scheduled for a Comprehensive Medication Review with a primary care pharmacist for up to two visits for their chronic medications. The intervention over 2 months, and the oncology and primary care pharmacists communicate via electronic health record about medications, symptoms, and disease control. Outcomes. The primary endpoints are (a) dose-adjusted adherence by proportion days covered (PDC) for the OAA and (b) PDC for chronic condition medications, assessed using 6 months of prescription claims. Data will be collected from patients using REDCap surveys and abstracted data will be entered into REDCap. Implementation by pharmacists and patient acceptability will be examined. Analysis. The association of OAA and chronic medication adherence (PDC) will be examined via correlation. Participant demographics ,clinical characteristics, and the symptom experience from the PROM will be described. Using CMR results, medication problems, recommendations, and changes will be provided. Program implementation will be assessed and patient perceptions obtained from post-CMR interviews. A joint display for the quantitative and qualitative data for feasibility, appropriateness, and acceptability from pharmacists will be completed. Results: Screening and recruitment has begun. Clinical trial information: NCT04595851 and NCT04663100. Research Sponsor: AstraZeneca.

TPS1588 **Poster Session**

A study evaluating targeted therapies in participants who have advanced solid tumors with genomic alterations or protein expression patterns predictive of response (MyTACTIC). *First Author: Axel Grothey, West Cancer Center and Research Institute, OneOncology Research Network, Germantown, TN*

TPS1588Background: Cancer treatment is evolving toward a more personalized approach in which the intersection of genomics, pathology and imaging methods leads to individualized care. Furthermore, identification of novel genomic alterations and other biomarkers has the potential to lead to customized, targeted treatments. Matching specific therapies to tumor biomarkers has the potential to yield valuable clinical information. Here we present a multiarm basket trial that matches patients with a broad array of metastatic solid cancers to investigational therapies alone or in combination based on specific, targetable genomic alterations or protein expression patterns that are potentially predictive of response (MyTACTIC). Historically, such trials have been conducted at large academic medical centers rather than community centers, where most US patients with cancer receive treatment. Prioritizing community centers for this study presents an exciting opportunity to generate data from a more representative patient population. **Methods:** This phase II, multicenter, nonrandomized, open-label study is enrolling approximately 200 participants with advanced solid tumors that harbor alterations including mutations, fusions, amplifications and protein loss in specific biomarkers that include human epidermal growth factor receptor 2 (HER2), phosphoinositide 3-kinase (PI3K), anaplastic lymphoma kinase (ALK), proto-oncogene tyrosine-protein kinase (ROS1), protein kinase B (AKT), phosphatase and tensin homolog (PTEN), high tumor mutational burden (TMB), high microsatellite instability (MSI) and deficient mismatch repair (dMMR). Patients aged ≥18 years with positive local biomarker results from tissue or blood samples will be enrolled from community oncology centers and practices. Eligibility criteria have been broadened to allow enrollment of a diverse population of patients, including those with nonmeasurable disease, HIV or viral hepatitis infections, and to allow for previous treatment with anticancer agents in the same class. Once general and arm-specific criteria are met, patients will be assigned to 1 of 10 treatment arms to receive mono- or combination therapy with targeted agents, immunotherapy and/or chemotherapy (≤25 patients per arm). The primary objective is to evaluate confirmed objective response rate, as assessed by the investigator according to RECIST version 1.1 or RANO criteria for primary central nervous system tumors. Progression-free survival, duration of response, overall survival and safety will also be assessed. Special attention has been paid to the study design and implementation to ensure equitable access, along with flexibility to add additional baskets. Enrollment is ongoing. Clinical trial information: NCT04632992. Research Sponsor: Genentech, Inc.

TPS1589 **Poster Session**

Comprehensive ambulatory monitoring during immunotherapy in patients with advanced melanoma: A prospective trial (CAMP-IT). *First Author: Milan Kos, Amsterdam UMC, University of Amsterdam, Department of Medical Oncology, Cancer Center Amsterdam, Amsterdam, Netherlands*

TPS1589Background: The emergence of immune checkpoint inhibitors has improved survival outcomes for patients with advanced melanoma. However, these treatment modalities are also associated with specific immune-related toxicities. These are often reversible after prompt recognition and initiation of appropriate management, but can result in severe morbidity and hamper health-related quality of life (HRQoL) if left undetected. Hence, accurate and regular monitoring of these patients is critical. Recent advances in*mHealth* technologies and the rapidly expanding armamentarium of wearable devices allow for real-time objective (vital signs and physical activity) data and patient-reported outcome measurement (PROMs) collection and, hence, serve this purpose. We hypothesize that collection of real-time objective data adds to the early detection of disease- and treatment-related adverse events. The primary objective of this study is to determine the feasibility of collecting real-time PROMs, vital signs, and physical activity data in advanced melanoma patients receiving immunotherapy using a comprehensive ambulatory monitoring platform (CAMP) that consists of a smartphone app, activity monitor, digital thermometer, and online dashboard for physicians. **Methods:** In this prospective multi-center trial, patients (n = 50) with advanced melanoma, scheduled to receive immunotherapy with immune checkpoint inhibitors, and with access to a smartphone are eligible for inclusion. Consenting patients will be asked to wear a FitBit Versa 2.0 during waking hours, collect daily temperature measurements using a Withings Smart Temporal thermometer, and answer weekly toxicity questionnaires (NCI PRO-CTCAE) using the smartphone app for the duration of the study (12 weeks). Primary outcome is feasibility in terms of (i) participation rates, (ii) wear-time, (iii) compliance rates with in-app questionnaires and temperature measurements, and (iv) satisfaction with the platform. Secondary exploratory outcomes include associations between CAMP-derived parameters and clinical outcomes: performance status (PS), HR-QoL scores (EORTC QLQ-C30 questionnaire), unplanned hospitalizations, physician-assessed adverse events, and 1-year survival outcomes. PS and HR-QoL will be rated at baseline, mid-study, and end-of-study. The occurrence of adverse events will be documented up to 12 months from baseline. Survival outcomes will be compared to a propensity score matched group from the Netherlands Cancer Registry. Accrual has started in February 2021. Clinical trial information: NL8827. Research Sponsor: BMS.

2000 **Oral Abstract Session**

Alliance A071601: Phase II trial of BRAF/MEK inhibition in newly diagnosed papillary craniopharyngiomas. *First Author: Priscilla Kaliopi Brastianos, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Craniopharyngiomas, a rare brain tumor along the pituitary-hypothalamic axis, can cause significant clinical sequelae. Surgery and radiation, the only effective treatments, can cause significant morbidity. Genetic analysis of craniopharyngiomas revealed that 95% of papillary craniopharyngiomas (PCP) have BRAF *V600E* mutations (Brastianos et al. Nature Genetics 2014). We evaluated the efficacy of BRAF/MEK inhibition in patients (pts) with previously untreated PCP. **Methods:** Eligible pts without prior radiation whose PCP screened positively for BRAF mutations were treated with oral vemurafenib/cobimetinib in 28-day cycles. The primary endpoint of response rate (RR) based on centrally determined volumetric data was evaluated in 16 pts, where a partial response was defined as >20% decrease in volume. This single arm, Simon two-stage phase 2 trial had 89% power to detect a true RR of at least 30% (vs. the null RR 5%; alpha=0.04). In this design, 3 or more observed volumetric responses in 16 evaluable pts would be considered promising activity. **Results:** In the 16 pts evaluated, 56% were female, and the median age was 49.5 years. Median follow-up was 22 months (95% CI: 16-26.5) and median number of treatment cycles was 8. Three patients progressed after therapy was discontinued and none have died. Based on volumetric response criteria, 14 of 15 pts with volumetric data available for central review had response to therapy (93%; 95% CI: 68% to 99.8%). Of 16 patients evaluable based on local review, 15 had response to therapy (93.75%; 95% CI: 70% to 99.8%). The median tumor reduction was -83% (range: -52% to -99%). The one nonresponder received 2 days of treatment before coming off therapy due to toxicity. Median progression-free survival was not reached. Grade 3 toxicities at least possibly related to treatment occurred in 12 pts (rash in 6 pts). Grade 4 toxicities were observed in two pts: hyperglycemia (n=1) and increased CPK (n=1). Three pts discontinued treatment for adverse events. **Conclusions:** Vemurafenib/cobimetinib resulted in an objective response in all pts who received 1 or more cycles of therapy. Our study indicates that BRAF/MEK inhibitors could be a powerful tool in the treatment of previously untreated PCP and warrants further evaluation in larger studies. A second arm of this study is enrolling pts with progressive PCP after prior radiotherapy. Support: U10CA180821, U10CA180882; U24CA196171, U10CA180868 (NRG); Genentech; https://acknowledgments.alliancefound.org. Clinical trial information: NCT03224767. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

ALK inhibitors for treatment of adult-onset neuroblastoma. *First Author: Jessica Stiefel, MSKCC, New York, NY*

Background: Neuroblastoma (NB), a rare malignancy of the sympathetic nervous system, is a tumor of early childhood with > 90% of cases diagnosed before 5 years of age. Adult-onset NB (AON) is extremely rare and differs significantly from childhood disease. AON, while more indolent, is usually metastatic at diagnosis, generally chemotherapy-resistant, and almost invariably lethal. Additionally, standard therapies for NB such as dose-intensive chemotherapy and anti-GD2 antibody are poorly tolerated by adults. Prior studies have shown AON is enriched for genomic aberrations especially *ALK* (Suzuki *et al* 2018). Although *ALK* inhibitors (ALKi) are effective for therapy of lymphoma and non-small cell lung cancer, their use in AON has not previously been reported. **Methods:** Retrospective review of patients > 18 years old at diagnosis seen at Memorial Sloan Kettering Cancer Center (MSKCC) was performed after IRB approval. Response to ALKi was evaluated using International Neuroblastoma Response Criteria; objective responses were also noted. Progression-free (PFS) and overall survival (OS) was calculated using Kaplan-Meier methods. **Results:** Since 1979, 52 patients with AON were seen at MSKCC. Of 23 patients evaluated, 14 (61%), harbored somatic *ALK* mutations. Seven were treated with FDA-approved ALKi. One patient initially diagnosed at 12 years of age was treated with ALKi following a relapse 15 years later. Overall, all ALKi were well-tolerated; reported adverse events included grade 1-2 nausea and vomiting (n = 6), and neurologic symptoms including hallucinations, drowsiness, and dizziness (n = 1 patient each) which resolved after stopping ALKi. Four patients received > 1 ALKi either due to progressive disease or intolerance. Most patients responded to the first ALKi with objective though partial response (n = 5) while one had progressive disease (PD). Median time to progression for initial ALKi was 15.5 months (10-45). One patient with no evaluable disease after four prior relapses was treated with alectinib for 36 months without PD. Of the patients treated with a second ALKi (n = 4), 1 had CR and 2 had PR after not having progressed previously, while the other had stable disease. Median OS from beginning treatment with first ALKi was 46.5 (17-74) months. **Conclusions:** AON is a rare disease which is a therapeutic challenge. Enrichment of *ALK* mutations permits consideration of targeted therapy. ALKi were well tolerated, often associated with significant responses, and treatment with serial ALKi led to ongoing benefit. Given this, ALKi should be considered for treatment in future AON cases. Research Sponsor: None.

Efficacy and safety of larotrectinib in adult and pediatric patients with tropomyosin receptor kinase (TRK) fusion-positive primary central nervous system tumors. *First Author: Sébastien Perreault, Department of Neurosciences, CHU Hopital Sainte-Justine, Montréal, QC, Canada*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are oncogenic drivers in various tumor types, including central nervous system (CNS) tumors. Larotrectinib is a first-in-class, highly selective TRK inhibitor approved for the treatment of adult and pediatric patients with TRK fusion cancer, with an objective response rate (ORR) of 78% across 175 adult and pediatric patients with various non-CNS cancers (McDermott et al, ESMO 2020). We report data on patients with TRK fusion-positive primary CNS tumors. **Methods:** Patients with primary CNS tumors harboring an *NTRK* gene fusion enrolled in two clinical trials (NCT02637687, NCT02576431) were identified. Larotrectinib was administered until disease progression, withdrawal, or unacceptable toxicity. Response was investigator assessed. **Results:** As of July 2020, 33 patients with TRK fusion-positive CNS tumors were identified: 19 high-grade gliomas (HGG), 8 low-grade gliomas (LGG), 2 glioneuronal tumors, 2 neuroepithelial tumors, 1 CNS neuroblastoma, and 1 small round blue cell tumor. The patients had gene fusions involving *NTRK2* (n = 24; 73%), *NTRK1* (n = 5; 15%), and *NTRK3* (n = 4; 12%). Median age was 8.9 years (range 1.3–79.0); 26 patients were pediatric (< 18 years). Patients were heavily pre-treated with 45% having 2 or more prior lines of systemic therapy. The ORR in all patients was 30% (95% CI 16–49): 3 complete responses (all in pediatric patients), 7 partial responses (2 pending confirmation), 20 stable disease (including 15 pts > 6 months), and 3 progressive disease. The ORR in patients with HGG and LGG were 26% (95% CI 9–51) and 38% (95% CI 9–76), respectively. In all patients, the 24-week disease control rate was 73% (95% CI 54–87). Twenty-three of 28 patients (82%) with measurable disease had tumor shrinkage. The median time to response was 1.9 months. Median duration of response (DoR) was not reached (95% CI 3.8–not estimable [NE]) at a median follow-up of 12.0 months. The 12-month DoR rate was 75% (95% CI 45–100). Median PFS was 18.3 months (95% CI 6.7–NE) at a median follow-up of 16.5 months. Median overall survival (OS) was not reached (95% CI 16.9–NE) at a median follow-up of 16.5 months, with a 12-month OS rate of 85% (95% CI 71–99). Duration of treatment ranged from 1.2 to 31.3+ months. Treatment-related adverse events (TRAE) were reported by 20 patients and were Grade 3–4 in 3 patients (9%). There were no treatment discontinuations due to TRAEs. **Conclusions:** In patients with TRK fusion-positive CNS tumors, larotrectinib demonstrated rapid and durable responses, high disease control rate, and a favorable safety profile. These results support testing for *NTRK* gene fusions in patients of all ages with CNS tumors. Clinical trial information: NCT02637687, NCT02576431. Research Sponsor: Bayer Pharmaceuticals and Loxo Oncology, a subsidiary of Lilly.

2003 **Oral Abstract Session**

The 1994 National Cancer Institute's strategy to fund multi-institutional, multidisciplinary consortia to design and conduct early phase clinical trials in patients with high grade gliomas. *First Author: Stuart A. Grossman, Johns Hopkins Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: : In the early 1990's, the NCI suspended activities of the Brain Tumor Study Group seeking to shift clinical brain tumor research from phase III trials to innovative and correlative rich phase I/II studies. In 1994, NCI funded three early phase brain tumor consortia, later reduced to two consortia in 1999 and one in 2009. In 2020, the NCI announced it would discontinue funding the brain tumor consortium and emphasize pre-clinical glioblastoma drug development (RFA-CA-20-047). **Methods:** The activities of the New Approaches to Brain Tumor Therapy (NABTT: 1994-2009) and Adult Brain Tumor Consortium (ABTC: 2009-2021) were summarized using data from the Central Operations Office that served the consortia for 27 years. **Results:** From 1994-2020, 48 consortium meetings were held to discuss, develop, conduct, and evaluate early phase clinical trials. These involved multidisciplinary brain tumor experts (neuro-oncologists, neurosurgeons, radiation oncologists, neuropathologists, statisticians, pharmacologists, imaging experts, immunologists, etc) from 27 US academic centers and hospitals. 85 clinical trials were written, approved by NCI and the Brain Malignancy Steering Committee, and conducted. Most trials evaluated NCI-provided therapeutic agents. 34 trials were conducted in collaboration with 27 pharmaceutical companies eager to develop malignant brain tumor therapeutics; for 9 of these the consortia held the IND. 4870 patients were accrued: 3375 to therapeutic and 1495 to non-therapeutic studies. 49 grant proposals were submitted to fund consortium activities with a 46% approval rate. 91 peer reviewed manuscripts were published, with 174 presentations and abstracts. 18 pharmaceutical symposia were conducted to attract new agents toward early phase brain tumor research. Consortia sponsored 34 Guest Lectureships and multidisciplinary symposia to focus on relevant critical research areas. Additionally, the consortia provided unique opportunities for young faculty to lead multicenter NABTT/ABTC trials with appropriate support and mentorship. **Conclusions:** Therapeutic progress for high grade gliomas has been slow for many reasons (95% of systemically administered agents do not penetrate the blood-brain barrier, inherent treatment resistance, immunologically "cold" phenotype, etc). NABTT/ABTC focused multidisciplinary, multi-institutional experts on major challenges unique to brain tumor research. The consortia developed innovative early phase clinical studies rich in correlative endpoints, fostered research grants, hosted relevant topical symposia, and provided leadership roles for young investigators while bringing together the NCI, industry, and committed multidisciplinary academicians to explore novel therapeutic options for patients with primary brain tumors. Research Sponsor: NCI.

2004 **Oral Abstract Session**

EORTC 1709/CCTG CE.8: A phase III trial of marizomib in combination with temozolomide-based radiochemotherapy versus temozolomide-based radiochemotherapy alone in patients with newly diagnosed glioblastoma. *First Author: Patrick Roth, Department of Neurology, University Hospital Zürich, Zürich, Switzerland*

Background: Patients with newly diagnosed glioblastoma receive postoperative standard therapy with radiotherapy (RT), and concomitant and up to six cycles of maintenance temozolomide (TMZ) chemotherapy (TMZ/RT→TMZ). Marizomib is a novel, irreversible and brain-penetrant pan-proteasome inhibitor with encouraging findings in preclinical models and early-stage clinical trials for patients with newly diagnosed and recurrent glioblastoma. Therefore, a phase 3 trial was designed to explore the activity of marizomib in addition to TMZ/RT→TMZ. ClinicalTrials.gov Identifier: NCT03345095 **Methods:** EORTC 1709/CCTG CE.8 is a multicenter, randomized, controlled, open label phase 3 superiority trial. Eligibility criteria included histologically confirmed newly diagnosed glioblastoma and a Karnofsky performance status (KPS) > 70. Eligible patients were stratified for institution, age, KPS as well as extent of surgery, and centrally randomized in a 1:1 ratio. The primary objective of this study is to compare overall survival (OS) in patients receiving marizomib in addition to standard treatment with patients receiving standard treatment only. Secondary endpoints include progression-free survival (PFS), safety, neurocognitive function, and quality of life. **Results:** The study was opened at 49 EORTC sites in Europe, 23 CCTG sites in Canada, and 8 sites in the US. Patient enrolment started in June 2018 and was close to completion at the time of a planned interim analysis in September 2020. A total of 749 patients (of the planned 750) were randomized when the IDMC recommended to discontinue enrollment. Age, KPS and extent of resection were well balanced between the 2 study arms. No difference in median OS was observed between the standard arm (15.9 months) and the marizomib arm (15.7 months; HR = 0.99). Median PFS was 6.1 vs. 6.2 months (HR = 1.02). Patients in the marizomib group had more often grade 3/4 treatment-emergent adverse events (TEAE) compared to the standard therapy group (42.6% vs. 20.5%), including ataxia, hallucinations and headache. **Conclusions:** The addition of marizomib to standard radiochemotherapy did not improve OS or PFS in patients with newly diagnosed glioblastoma. Final survival analyses including determination of MGMT promoter methylation status and analyses of other secondary endpoints are ongoing. Clinical trial information: NCT03345095. Research Sponsor: Celgene / BMS.

2005 **Oral Abstract Session**

A Phase 0 'trigger' trial of CDK4/6 plus ERK1/2 inhibitors in recurrent glioblastoma. *First Author: Nader Sanai, Ivy Brain Tumor Center, Barrow Neurological Institute, Phoenix, AZ*

Background: The RB-CDK4/6 and MAPK signaling pathways are dysregulated in glioblastoma (GBM). Our recent phase 0 study of ribociclib in recurrent GBM patients suggested that CDK4/6 inhibitor monotherapy is not durable. In this ongoing, dual-drug phase 0 study (NCT04391595), we evaluate the tumor pharmacokinetics (PK) and tumor pharmacodynamics (PD) of abemaciclib, a selective CDK4/6-inhibitor, plus LY3214996, a selective ERK1/2 inhibitor, in recurrent GBM patients. **Methods:** Adult patients eligible for this open-label, multicenter phase 0 protocol had recurrent GBM with (1) intact RB expression, (2) >30% pERK expression, and (3) CDKN2A/B deletion or CDK4/6 amplification. Prior to a planned resection, patients received six days of abemaciclib (150mg BID) plus LY3214996 (200mg QD). In a Time-Escalation Arm, ten patients were assigned to 3-5 hour or 7-9 hour intervals from final drug dose to tumor removal. Tumor tissue (gadolinium [Gd]-enhancing and nonenhancing regions), cerebrospinal fluid (CSF), and plasma were collected. Total and unbound drug concentrations were measured using validated LC-MS/MS methods. Tumor PD effects, including RB and RSK phosphorylation, were compared to matched archival or pre-treatment biopsied tissue. A PK 'trigger' (*i.e.,* unbound concentration > 5x biochemical IC_{50}) was set for each drug. Gd-nonenhancing tumor tissue exhibiting abemaciclib and LY3214996 concentrations in excess of their trigger threshold qualified patients for postoperative dual-drug therapy. **Results:** In this interim analysis, no dose-limiting toxicities were observed. In Gd-nonenhancing tumor regions, median unbound concentrations of abemaciclib (including its equipotent M2 and M20 metabolites) were 31.2 nM (3-5 hour cohort) and 25.1 nM (7-9 hour cohort). In the same tissue, median unbound concentrations of LY3214996 were 52.0 nM (3-5 hour cohort) and 10.2 nM (7-9 hour cohort). Tumor RB and RSK phosphorylation decreased in 6/10 and 2/10 patients, respectively. Gd-enhancing tumor proliferation (MIB-1) was decreased in 8/10 patients. 5/10 patients exceeded PK thresholds for both abemaciclib (12 nM) and LY3214996 (25 nM), thereby entering the study's therapeutic expansion phase. **Conclusion:** Abemaciclib and LY3214996 achieve pharmacologically-relevant concentrations in Gd-non-enhancing GBM tissue and are associated with suppression of the RB pathway and tumor proliferation. Following 6 days of presurgical drug exposure, the Optimal Time Interval (OTI) for tissue sampling was 3-5 hours after the final drug dose. Based on this interim analysis, the trial will accrue an additional 25 patients at this OTI. Clinical trial information: NCT04391595. Research Sponsor: The Ben and Catherine Ivy Foundation, Other Foundation.

Evaluating the benefit of adaptive randomization in the CC-115 arm of the Individualized Screening Trial of Innovative Glioblastoma Therapy (INSIGhT): A phase II randomized Bayesian adaptive platform trial in newly diagnosed MGMT unmethylated glioblastoma. *First Author: Rifaquat Rahman, Dana-Farber/Brigham and Women's Cancer Center, Boston, MA*

Background: Adaptive randomization adjusts enrollment rates based upon early trial results, which can allow for decreased enrollment for therapies less likely to meet the primary endpoint of a trial. CC-115, a CNS-penetrant, oral inhibitor of mammalian target of rapamycin kinase (mTOR) and deoxyribonucleic acid-dependent protein kinase (DNA-PK), was evaluated in the Individualized Screening Trial of Innovative Glioblastoma Therapy (INSIGhT) trial. As CC-115 was discontinued due to concerns about toxicity and unfavorable risk-to-benefit ratio, we sought to investigate the impact of adaptive randomization in its testing. **Methods:** In INSIGhT, adults with newly diagnosed MGMT-unmethylated glioblastoma and available genomic data are adaptively randomized to an experimental arm or the control arm of standard radiotherapy with concurrent and adjuvant temozolomide. Patients randomized to CC-115 received it (10mg po BID) with radiotherapy and as adjuvant monotherapy, and a safety lead-in 3+3 design was used for this arm. By simulating the INSIGhT trial with standard uniform randomization, we estimated the reduction of enrollment rate and sample size of the CC-115 arm that was attributable to adaptive randomization. **Results:** Twelve patients were randomized to CC-115; 58% (n = 7) patients had possible treatment-related CTCAE grade > 3 toxicity. Compared to the control arm, there was no significant difference in progression-free survival (PFS, HR 0.66, 95% CI 0.32-1.36, p = 0.3) or overall survival (OS, HR 0.93, 95% CI 0.43-2.03, p = 0.8). Based on early PFS results, randomization probability to CC-115 decreased from 25% to 16%. At the time of the CC-115 arm closure, 14% of enrolled INSIGhT patients had been randomized to this arm. Compared to average expected enrollment by standard randomization, the use of adaptive randomization decreased the number of patients randomized to CC-115 by 50% (12 patients vs. 18 patients [95% CI 11-25 patients]). **Conclusions:** The INSIGhT trial, designed with adaptive randomization, facilitated more efficient testing of CC-115 and decreased the number of patients allocated to the CC-115 arm relative to a standard randomization design. Clinical trial information: NCT02977780. Research Sponsor: Puma Biotechnology, Inc.; Celgene Corp.; Eli Lilly and Company; Accelerated Brain Cancer Cure, Burroughs Wellcome Fund.

Olaparib in recurrent IDH-mutant high-grade glioma (OLAGLI). *First Author: Francois Ducray, Service de Neuro-oncologie, Hôpital Neurologique, Hospices Civils de Lyon, Lyon, France*

Background: There is a need to develop new treatments in IDH-mutant high-grade gliomas recurring after radiotherapy and chemotherapy. Based on preclinical studies showing that IDH-mutant tumors could be vulnerable to PARP inhibition we launched a phase II study to test the efficacy of olaparib (Lynparza) monotherapy in this population. **Methods:** Adults with recurrent high-grade IDH-mutant gliomas after radiotherapy and at least one line of alkylating chemotherapy (PCV or TMZ), KPS > 60, normal organ function were enrolled. The primary endpoint was 6 months PFS according to RANO criteria. Patients were treated with olaparib 300 mg twice daily. We used a single-stage Fleming design with p0 = 30%, p1 = 50%, a type I unilateral error rate of 5% and a power of 80%. **Results:** 35 patients with recurrent IDH-mutant gliomas (IDH1R132H-mutant n = 32, other IDH mutation n = 3, 1p/19 codeleted n = 16, 1p/19q non-codeleted n = 14) were enrolled (malignantly transformed low-grade gliomas n = 21, anaplastic gliomas n = 8, glioblastomas n = 6). Median time since diagnosis was 7.4 years (1-22 years), median time since radiotherapy was 2.8 years (0.6-18 years), median number of previous chemotherapy lines was 2 (1-5). With a median follow-up of 11 months, 30 patients had stopped treatment due to tumor progression and 2 patients were still on treatment 16 to 18 months after treatment start. At 6 months, 11/35 patients were progression-free (31 %). According to RANO criteria, based on local investigator analysis, 2 patients (5%) had a partial response and 14 patients a stable disease (37%) with a median duration of response of 9 months (4-18 months+). Median PFS and OS were 2.3 and 15.9 months and were similar in 1p/19q codeleted and non-codeleted patients. A grade 3 olaparib-related adverse event was observed in 5 patients (14%, lymphopenia n = 3, fatigue n = 2, diarrhea n = 1) and a grade 2 in 15 patients (43%), most frequently consisting in fatigue (23%), gastrointestinal disorders (20%) and lymphopenia (20%). No patient definitively stopped olaparib due to side effects. **Conclusions:** In this heavily pre-treated population of recurrent IDH-mutant gliomas, olaparib monotherapy was well tolerated and resulted in some activity supporting its evaluation in association with alkylating chemotherapy in recurrent IDH-mutant gliomas in future studies. Clinical trial information: NCT03561870. Research Sponsor: French Ministry of Health, Other Foundation, Pharmaceutical/Biotech Company.

2008 **Oral Abstract Session**

Impact of mutant IDH (mIDH) inhibition on DNA hydroxymethylation, tumor cell function, and tumor immune microenvironment (TIME) in resected m*IDH1* lower-grade glioma (LGG). *First Author: Min Lu, Agios Pharmaceuticals, Inc., Cambridge, MA*

Background: Somatic mutations in *IDH1* and *IDH2* occur in ~80% and ~4% of LGGs, respectively, promoting tumorigenesis via increased levels of the oncometabolite D-2-hydroxyglutarate (2-HG). Vorasidenib (VOR; AG-881) is an oral, brain-penetrant, dual inhibitor of mIDH1/2; ivosidenib (IVO; AG-120) is a first-in-class oral inhibitor of mIDH1. In this ongoing perioperative study, treatment with IVO/VOR reduced 2-HG levels in resected tumors vs untreated control tumors in patients (pts) with LGG (NCT03343197; Mellinghoff SNO 2019). We assessed the biological impact of 2-HG suppression on tumors and TIME. **Methods:** Pts (n = 49) with recurrent, non-enhancing, mIDH1-R132H LGG eligible for resection were randomized to IVO (500 mg QD/250 mg BID), VOR (10/50 mg QD), or no treatment, for 4 weeks preoperatively. Tumor tissue samples collected at surgery were assessed in genomic (n = 42), transcriptomic (n = 42), and immunohistochemistry (IHC; n = 43) analyses. Unpaired t-test was used for statistical comparisons. **Results:** Optimal 2-HG suppression (post-treatment 2-HG below the upper limit of 2-HG levels in a reference set of 15 wild-type [wt] IDH samples) was observed in 23 of 40 pts, including 9 (90%) pts receiving VOR 50 mg QD and 6 (50%) receiving IVO 500 mg QD. Of samples with valid biomarker data, those with optimal 2-HG suppression (n = 21) showed upregulation of neural differentiation-related gene expression, but downregulation of stemness-related gene expression, vs those with suboptimal 2-HG suppression (post-treatment 2-HG above upper limit of wt IDH 2-HG levels; n = 17; $p < 0.01$). IHC analysis of the proliferation marker Ki-67 showed a ~2-fold decrease in Ki-67–positive cells in samples with optimal 2-HG suppression (mean 2.7%; n = 22) vs those with suboptimal suppression (5.8%; n = 16; $p < 0.05$). Epigenetic analysis revealed a ~2-fold increase in mean 5-hydroxymethylcytosine (5hmC) levels in samples with optimal (0.36%; n = 17) vs suboptimal 2-HG suppression (0.2%; n = 15; $p < 0.05$), suggesting reversal of TET2 inhibition. IHC analysis of TIME revealed increases in mean CD3+ and CD8+ tumor-infiltrating lymphocyte levels in samples with optimal (1.05% [CD3]/0.22% [CD8]; n = 22) vs suboptimal 2-HG suppression (0.44% [CD3]/0.07% [CD8]; n = 16; $p < 0.05$). Optimal 2-HG suppression was associated with upregulation of gene expression related to type I interferon signaling and antigen presentation ($p < 0.01$). **Conclusions:** These data suggest that both tumor-intrinsic and -extrinsic mechanisms underlie 2-HG suppression by VOR and IVO. VOR, and IVO to a lesser extent, increased 5hmC, promoted cellular differentiation, and inhibited tumor cell proliferation; both also increased T-cell infiltration, activated interferon signaling, and increased antigen presentation capability. These data support development of VOR in combination with immunotherapy. Clinical trial information: NCT03343197. Research Sponsor: Agios Pharmaceuticals, Inc.

2009 **Clinical Science Symposium**

First-in-human CAN-3110 (ICP-34.5 expressing HSV-1 oncolytic virus) in patients with recurrent high-grade glioma. *First Author: E. Antonio Chiocca, Brigham and Women's Hospital, Boston, MA*

Background: Recurrent glioma patients have few therapeutic options and an expected survival of only 7 to 10 months. New treatments to improve the prognosis of this patient population are a dire medical need. Oncolytic viruses (OVs) are emerging as important new agents for cancer treatment. The first FDA approved OV was talimogene laherparepvec (Imlygic, T-Vec) for treatment of melanoma. T-Vec, as most other clinical HSV-1 based OVs, is deleted in the ICP34.5 gene, which is responsible for HSV-1 neurovirulence. However, deletion of ICP34.5 also impedes efficient viral replication. CAN-3110 (rQNestin34.5v2) maintains a copy of the HSV1 ICP34.5 gene under transcriptional control of the tumor-specific promoter for nestin to drive robust tumor-selective replication. CAN-3110 replicates in malignant glioma cells far above levels seen with ICP34.5 deleted viruses. This potency also created the hypothetical risk for increased neurovirulence, thus the regulatory advice to conduct a cautious nine-dose-level Phase-1 dose escalation study in patients with recurrent high-grade glioma (HGG). **Methods:** From September 2017 to February 2020, thirty patients with biopsy-confirmed recurrent high-grade glioma were treated in an open label clinical trial. Patients with multifocal, multicentric, tumors larger than 5 cm, and tumors that had recurred multiple times were eligible. All patients received best standard of care treatments as indicated by their physician. CAN-3110 was injected intratumorally starting at $1x10^6$ plaque forming units (pfu) and dose-escalating (3+3 design) by half log increments up to $1x10^{10}$ pfu. Tissue (when possible) and blood samples were obtained before and during treatment for experimental medicine analyses. **Results:** CAN-3110 was well tolerated with no dose limiting toxicity observed. The initial tissue diagnosis of the recurrent tumor for the 30 subjects was 26 glioblastoma, 3 anaplastic oligodendroglioma, and 1 anaplastic astrocytoma. The median overall survival (mOS) of the entire study group is 13.25 months. Post-treatment tissue is available for 18/30 subjects and revealed persistence of HSV antigen and CD8+ T cell infiltrates. Additional response, immunologic (including T cell receptor repertoire), transcriptomic and single cell RNA sequencing analyses are ongoing. **Conclusions:** Administration of CAN-3110 into recurrent glioma was well tolerated without evidence of ICP34.5-induced encephalitis/meningitis. Histological and molecular analyses showed evidence of biological activity and that CAN-3110 injection was associated with immune activation and viral antigen persistence. Although definitive clinical efficacy cannot be determined in this small phase 1 study, OS of CAN-3110 treated subjects compares favorably to historical reports and warrants further clinical studies. Clinical trial information: NCT03152318. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

2010 **Clinical Science Symposium**

Phase 1 dose-escalation trial using convection-enhanced delivery of radiolabeled monoclonal antibody for diffuse intrinsic pontine glioma following external radiation therapy. *First Author: Mark M. Souweidane, Weill Cornell Medical College, New York, NY*

Background: The prognosis of diffuse intrinsic pontine glioma (DIPG) is dire with a median overall survival less than one-year. ^{124}I-omburtamab is a radiolabeled monoclonal antibody that targets B7-H3 epitope. We evaluated the safety of administering escalating doses and volumes of ^{124}I-omburtamab via convection-enhanced delivery (CED) in children with DIPG. **Methods:** MSKCC 11-011 trial is a standard 3+3 phase 1, open-label, dose escalation study in patients with non-progressive DIPG. CED of ^{124}I-omburtamab was performed between 4-14 weeks post-external radiation therapy. Nine dose levels of a single injection of ^{124}I-omburtamab (Y-mAbs Therapeutics, USA) (range 0.25 to 8.0 mCi; and volume of infusion (V_i) from 250 to 8,000 µl) have been evaluated so far. Patients were assessed weekly for 30 days. **Results:** 46 children were evaluable for primary and secondary endpoints. The median age at enrolment was 6.5 years (range 2-17). Two patients have experienced AEs CTCAE grade 3 that were categorized as dose limiting toxicities (DLTs), which led to inclusion of three more patients at both the 4 and 6 mCi dose levels. Eight patients have reported transient AEs of grade 3 considered related to ^{124}I-omburtamab. The acute grade 3 AEs were generally indicative of nervous system effects due to volume intolerance or radiation injury, and included hemiparesis (n = 3), dysarthria (n = 3), ataxia (n = 3), dysphagia (n = 2), muscular weakness (n = 2) and gait disturbance (n = 1). There were no related AEs CTCAE grade 4 or 5. Estimations of distribution volumes based on T2-weighted imaging were linearly related to volume with a mean volume of distribution/volume of infusion ratio (V_d/V_i) between 3 and 3.5. The mean ratio of lesion-to-whole body absorbed dose was ~1000. Median overall survival from diagnosis across all cohorts was 14.8 months (n = 46, 95% CI 11.5, 16.8) and the survival rate estimates (with 95% confidence intervals) at 1, 2, 3 and 5 years were 0.63 (0.46;0.76); 0.13 (0.05;0.26); 0.08 (0.02;0.19); and 0.04 (0.00;0.16), respectively. Four patients have survived > 3 years; two remain alive at 46 and 96 months and two have died at 43 and 53 months, both with CNS disease outside of the treatment field and one with extra-CNS metastases. **Conclusions:** ^{124}I-omburtamab via CED into the brain stem of children with DIPG and previously irradiated provides a possibility for improved treatment of DIPG. A dose of 8mCi and an infusion volume of 8,000 µl is considered safe and may provide a distribution volume large enough to cover tumor volumes up to 20 cm^3. The median overall survival of all patients included in the trial appears to be increased with 3-4 months compared to historical control data from consortia trials. A phase 2 trial aiming at investigating the efficacy of radiolabeled omburtamab administered via CED is being planned. Clinical trial information: NCT01502917. Research Sponsor: YmAbs Therapeutics.

2011 **Clinical Science Symposium**

Cerebrospinal fluid circulating tumor cells as a predictive biomarker for proton craniospinal irradiation for leptomeningeal metastases. *First Author: N. Ari Wijetunga, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Leptomeningeal metastasis (LM) involves seeding of tumor cells to the cerebrospinal fluid (CSF) and the leptomeninges. Proton craniospinal irradiation (pCSI) has been shown to be potentially effective for patients with solid tumor LM. We evaluated whether CSF circulating tumor cells (CSF-CTC) and neuroimaging correlate with outcomes in patients with LM treated with pCSI. **Methods:** We reviewed a single-institution retrospective database of patients treated with pCSI for LM between 2018-2020 who had ≥ 3 months (mos.) follow-up and identified 58 patients. Pre-pCSI CSF-CTC using CellSearch and magnetic resonance imaging (MRI) data, and post-pCSI CSF-CTC nadir before initiation of new cancer-directed therapy were assessed. The optimal cutoff for pre-pCSI CSF-CTC was determined using maximally selected rank statistics. Kaplan Meier analysis was used to identify univariate correlates with CNS progression free survival (CNS PFS) and overall survival (OS), calculated from start of pCSI. Multivariate Cox proportional hazards modeling was used to test independence of univariate associations. **Results:** The median follow-up for patients who were censored (n = 15, 26%) was 15 mos. (interquartile range (IQR): 9 -21). Most patients were diagnosed with lung (n = 27, 47%) or breast cancer (n = 22, 38%). The median CNS PFS and OS were 6 mos. (IQR: 3 – 9) and 8 mos. (IQR: 5 – 18), respectively. Of the 49 patients with pre-pCSI CSF-CTCs analyzed, CSF-CTCs were identified in 43 (88%). Pre-pCSI CSF-CTC< 53/3mL was associated with improved CNS PFS (11.8 vs 6.0 mos., p = 0.01), and a trend toward improved OS (16.7 vs 7.7 mos., p = 0.08). On pre-pCSI MRI, patients with parenchymal brain metastases (n = 33, 57%) had worse OS (6.7 vs 12.7 mos., p = 0.01) but not CNS PFS. Patients with both brain and spine LM (n = 42, 72%) compared to those only one site or no visible disease (n = 16, 28%) showed worse CNS PFS (5.8 vs 7.5 mos., p = 0.03) and OS (7.7 vs 16.7 mos., p = 0.05). In a multivariate model, pre-pCSI CSF-CTC was significantly associated with CNS PFS (p = 0.03) while brain and spine LM on MRI was not (p = 0.20) No patient had an increase in CSF-CTC immediately post-pCSI, and in those with both detectable pre-pCSI CSF-CTCsand a post-pCSI. measurement(n = 29, 50%), the median decrease at nadir was 37/3mL (range: 0-200) occurring at a median of 1.6 mos. (range: 0.5 -5.2). A decrease in CSF-CTC > 37/3mL was associated with improved CNS PFS (7.1 vs 4.4 mos., p = 0.04) but not OS (12.5 vs.7.7 mos., p = 0.2). **Conclusions:** Proton CSI is an effective treatment for patients with solid tumor LM and can result in prolonged disease control in some patients. Lower CSF-CTC count prior to pCSI and larger changes after pCSI are predictive of survival outcomes, arguing for early pCSI intervention for solid tumor LMD. Early treatment escalation after pCSI can be considered for patients with high pre-pCSI CSF-CTC and a smaller nadir post-pCSI. Research Sponsor: U.S. National Institutes of Health.

Serial plasma and CSF cell-free tumor DNA (cf-tDNA) tracking in diffuse midline glioma patients undergoing treatment with ONC201. *First Author: Evan Cantor, University of Michigan, Ann Arbor, MI*

Background: Diffuse midline glioma (DMG) with the H3K27M mutation is a lethal childhood brain cancer, with patients rarely surviving 2 years from diagnosis. There are few available means of monitoring the disease beyond serial MRI scans, making clinical decision making slow, difficult, and often reactive. **Methods:** We conducted a multi-site phase 1 trial of the imipridone ONC201 for children with H3K27M-mutant glioma (NCT03416530). Patients enrolled on Arm D of the trial (n=24) underwent serial lumbar puncture (baseline, 2 and 6 months) for cell-free tumor DNA (cf-tDNA) analysis at time of MRI. Additionally, patients on all arms of the trial at the University of Michigan underwent serial plasma collection. CSF collection was feasible in this cohort, with no procedural complications. We collected a total of 96 plasma samples and 53 CSF samples from 29 patients, including those with H3F3A (H3.3) (n=13), HIST13HB (H3.1) (n= 4), and unknown H3 status/not biopsied (n=12) [range of 0-8 CSF samples and 0-10 plasma samples]. We performed digital droplet polymerase chain reaction (ddPCR) analysis and/or amplicon-based electronic sequencing (Oxford Nanopore) of cf-tDNA samples and compared variant allele fraction (VAF) to radiographic change (maximal 2D tumor area on MRI). **Results:** Preliminary analysis of samples (n=58) demonstrates a correlation between changes in tumor size and H3K27M cf-tDNA VAF, when removing samples with concurrent bevacizumab. Analysis of remaining CSF and plasma samples is ongoing, including analysis of novel biomarkers of response. In multiple cases, early reduction in CSF cf-tDNA predicts long-term clinical response ($>$1 year) to ONC201 and does not increase in cases of later-defined pseudo-progression (radiation necrosis). For example, a now 9-year old patient with thalamic H3K27M-mutant DMG underwent treatment with ONC201 after initial radiation and developed an increase in tumor size at 4 months post-radiation (124% baseline) of unclear etiology at the time. Meanwhile, her ddPCR declined from baseline 6.76% VAF to $<$1%, which has persisted, with now near complete response (85% tumor reduction) at 30 months on treatment from diagnosis. **Conclusions:** In summary, we present the feasibility and utility of serial CSF/plasma monitoring of a promising experimental therapy for DMG. Research Sponsor: Defeat DIPG.

Long-term results of the GEINO 1401 TRIAL: Randomizing patients to stop or to continue temozolomide until 12 cycles. *First Author: Marta Domenech, Institut Catala d'Oncologia Badalona. Applied Research Group in Oncology (B- ARGO Group), Institut Investigació Germans Trias i Pujol (IGTP), Badalona, Spain*

Background: We previously presented our results of the GEINO 1401 trial that randomized patients diagnosed with glioblastoma and treated with chemoradiotherapy and adjuvant temozolomide (TMZ) followed by six cycles of TMZ, to receive an extended use of TMZ up to 12 cycles or to control. We found no differences in 6-months neither progression free survival (PFS) nor overall survival (OS). In this report we actualize our results and analyse long-term survivor patients (LTSP). **Methods:** The trial NCT02209948 randomized (ratio 1:1) 159 patients diagnosed with glioblastoma who had been treated with standard therapy to stop treatment or to continue up to 12 cycles of TMZ. Patients were stratified based on their O6-methylguanine-DNA-methyltransferasa (MGMT) methylation status and presence or absence of measurable disease at inclusion. We update here OS outcomes and analyse the data of LTSP defined as an OS over 30 months from diagnosis. **Results:** At a median follow-up of 20 months, 82.4% of the patients had died and 89.9% had progressed. The median OS from randomization was 22.0 months for the control arm and 18.2 for the experimental arm: HR 0.957 (95%CI 0.806-1.136, p = 0.615). At 2 years from randomization there were a 61% of survivors in the TMZ group and 62% in the control group. There were a 49.7% of LTSP showing no differences between TMZ and control group. We found a higher prevalence of methylated MGMT in LTSP, but no differences were shown in patients with or without measurable disease at inclusion, status of IDH and the use of bevacizumab after progression. **Conclusions:** Adding 6 cycles of TMZ after the first 6 adjuvant cycles confers no additional benefit in OS. Nearly 50% of the patients included in GEINO 1401 who had been previously treated with TMZ 6 cycles without progressing were LTSP. Clinical trial information: NCT02209948. Research Sponsor: Spanish Institute Carlos III.

Preliminary results of the abemaciclib arm in the Individualized Screening Trial of Innovative Glioblastoma Therapy (INSIGhT): A phase II platform trial using Bayesian adaptive randomization. *First Author: Eudocia Quant Lee, Dana-Farber Cancer Institute, Boston, MA*

Background: The cyclin D-CDK4/6-Rb pathway is activated in most glioblastomas. Abemaciclib is a potent CDK4/6 inhibitor with good brain penetration approved for HR+/HER2- breast cancer. In order to efficiently evaluate the potential impact of abemaciclib on overall survival (OS) in newly diagnosed glioblastoma and to simultaneously develop information regarding potential genomic biomarker associations, abemaciclib was included as an arm on the Individualized Screening Trial of Innovative Glioblastoma Therapy (INSIGhT) trial. INSIGhT is a phase II platform trial using response adaptive randomization and deep genomic profiling to more efficiently test experimental agents in MGMT unmethylated glioblastoma and potentially accelerate identification of novel therapies for phase III testing. Initial randomization was equal between abemaciclib, control, and two other experimental arms but subsequent randomization was adapted based on efficacy as determined by progression-free survival (PFS). Ineffective arms were discontinued and new arms added by protocol amendment. We report preliminary results for the abemaciclib arm which has completed accrual. **Methods:** Patients with newly diagnosed MGMT-unmethylated glioblastoma were randomized to receive either radiotherapy with concomitant and adjuvant temozolomide at standard doses or standard radiochemotherapy followed by adjuvant abemaciclib (150-200 mg orally BID). Treatment continued until progression or development of unacceptable toxicities. The primary endpoint was OS which was assessed using the log-rank test estimated via the Kaplan Meier method using a type I error of 5%. The hazard ratio (HR) was estimated using a cox proportional hazards model. Association between abemaciclib efficacy and cyclin D-CDK4/6-Rb pathway genomic alterations was also investigated. **Results:** There were 142 patients (69 control; 73 treated with abemaciclib). Abemaciclib was generally well-tolerated with no new toxicity signals identified. PFS was significantly longer (HR 0.67; p = 0.03, logrank test) with abemaciclib (median 6.54 months) compared to the control arm (median 5.88 months). For patients with activation of the CDK4 pathway the PFS HR was 0.64 (p-value = 0.04). However, there was no significant improvement in overall survival (HR 0.9; p-value $>$ 0.05) between abemaciclib (median 15.5) compared to the control arm (median 15.5). **Conclusions:** Abemaciclib was well-tolerated and prolonged PFS but there is no evidence of an overall survival improvement compared to standard radiochemotherapy. Clinical trial information: NCT02977780. Research Sponsor: Dana-Farber Cancer Institute.

2015 **Poster Discussion Session**

Randomized phase 2 study of nivolumab (nivo) plus either standard or reduced dose bevacizumab (bev) in recurrent glioblastoma (rGBM). *First Author: Manmeet Singh Ahluwalia, Rose Ella Burkhardt Brain Tumor and Neuro-Oncology Center, Neurological Institute, Taussig Cancer Institute and Cleveland Clinic, Cleveland, OH*

Background: Trials with anti-PD1 in rGBM have shown limited efficacy. VEGF is highly up regulated proangiogenic growth factor in GBM contributing to tumor-associated immunosuppression. Preclinical data suggests a potential dose effect of anti-VEGF therapy on immunomodulation. Hence, a combination of anti-PD1 and anti-VEGF may be a promising approach in rGBM. **Methods:** 90 patients with first-recurrent GBM were randomized (1:1) to nivolumab (240 mg IV Q2 weeks) with bevacizumab at standard (10 mg/kg; Arm A) or at low dose (3 mg/kg; Arm B) IV Q2 weeks. Stratification included extent of resection, age, performance status and MGMT methylation status. Single cell RNA sequencing with CITE-seq was used to analyze blood samples from pre- and 8 weeks post-treatment among 8 responders and 8 non-responders. Progression-free survival (PFS) and overall survival (OS) were compared between two arms. **Results:** 90 patients (Median age 60.6 years ranged 27.4-86.4, 67.8% male, median KPS 80) were enrolled between May 2018 and Jan 2020. Patients were followed in median 7.7 months (Range 0.7, 28.2). 35 of 88 patients were MGMT methylated (2 indeterminate). Overall OS was not significantly different between arm A and arm B (1 year: 41.1 vs 37.7%, p = 0.14), while OS was better for arm A in age $>$ 60 (At 1-year: 46.2% vs 23.8%; Median: 10.6 vs 5.9 months; P = 0.046). OS was no different in the two arms for age $\leq$ 60 years (At 1-year: 35.6% vs 56.4; Median 8.0 vs 12.4 months; P = 0.90). Single cell RNA sequencing with CITE-seq was used to analyze blood samples from 16 patients, baseline and 8 weeks post treatment. Standard dose bevacizumab treated patients had decreased myeloid derived suppressor cells and an inflammatory response gene signature at 8 weeks. Most frequent toxicities ($>$ 20%) included fatigue (45.6%), proteinuria (34.4 %), diarrhea (28.9%), hypertension (23.3%) and lipase increase (21.1%). Toxicities in grade 3-4 were hypertension (7.8%), fatigue (5.6) and other non-neurological toxicities including DVT, PE, infection, and abnormal liver function. **Conclusions:** Overall PFS and OS rates appear similar for nivolumab with either standard or low-dose bevacizumab compared to historical benchmarks of bevacizumab monotherapy. Nivolumab with standard bevacizumab may benefit older but not younger patients. Ongoing response evaluation and immunocorrelative data will be presented. Clinical trial information: NCT03452579. Research Sponsor: Bristol Myers Squibb.

2016 **Poster Discussion Session**

Digital measurement of functional status of patients with glioblastoma. *First Author: Yasaman Demastani, Karyopharm Therapeutics Inc., Newton, MA*

Background: Among the primary aims of new therapies for glioblastoma (GBM) are the reduction of morbidity and restoration or preservation of quality of life (QoL). Selinexor (SEL) is a first-in class, oral, selective inhibitor of nuclear export which blocks exportin 1 (XPO1), forcing the nuclear retention and reactivation of tumor suppressor proteins, ultimately causing cell death in cancer cells. SEL is approved for the treatment of previously treated multiple myeloma and DLBCL. XPORT-GBM-029 (NCT04421378) is a phase 1 dose finding study followed by an open-label randomized phase 2, 3-arm trial to evaluate SEL in combination with standard therapies for newly diagnosed and recurrent GBM: Arm A (ndGBM, uMGMT) – radiation +/- SEL; Arm B (ndGBM, mMGMT) – radiation and temozolomide +/- SEL; Arm C (rGBM) – lomustine +/- SEL at first relapse. We look to identify sensitive, reliable, and clinically meaningful digital assessments of the functional status of ndGBM and rGBM patients via a patient-centric approach. **Methods:** XPORT-GBM-029 incorporates standard clinical and imaging evaluations of GBM progression with novel digital tools that objectively measure motor and cognitive function. The study is conducted at 50 sites globally with the aim of enrolling 350 patients with newly diagnosed and recurrent GBM. Following discussions with KOLs and patient advocacy partners at EndbrainCancer, we surveyed GBM patients and their caregivers to identify disease manifestations critical to patients' QoL. The survey revealed four key areas impacting patients' QoL that can be affected by GBM therapies and can be objectively monitored: cognitive function, lateralization, fatigue, and sleep. In this trial we use objective measurements to evaluate SEL's effects on GBM patients' QoL. Patients wear inertial sensors to measure their activity and sleep and complete a cognitive battery at baseline and before each MRI. **Results:** Associations between objective digital measures of activity, gait, fatigue, sleep, and cognition will be examined with respect to clinical assessments including physical examinations, modified Response Assessment in Neuro-Oncology (mRANO), Neurologic Assessment in Neuro-Oncology (NANO), Karnofsky Performance Score (KPS) and Patient Reported Outcome (PRO) QoL questionnaires. Descriptive summary statistics and plots are employed in exploratory data analysis, and other advanced data mining methods may also be considered. **Conclusions:** XPORT-GBM-029 trial is probably the first large, prospective, longitudinal study in GBM patients employing digital markers and may provide useful information regarding the utility of wearable and mobile devices for measuring functional outcomes in clinical trials. Clinical trial information: NCT04421378. Research Sponsor: Karyopharm Therapeutics Inc.

Superior overall survival (OS) and disease-free survival (DFS) predictions for patients with glioblastoma multiforme (GBM) using Cellworks Singula: myCare-022-03. *First Author: Patrick Y. Wen, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: The Cellworks Singula Therapeutic Response Index (TRI) has been developed to assist clinicians and GBM patients in choosing between competing therapeutic options. In contrast to approaches that consider single aberrations, which often yield limited benefit, Cellworks utilizes an individual patient's next generation sequencing results and a mechanistic multi-omics biology model, the Cellworks Omics Biology Model (CBM), to biosimulate downstream molecular effects of cell signaling, drugs, and radiation on patient-specific in silico diseased cells. For any individual patient and alternative therapy, Cellworks integrates this biologically modeled multi-omics information into a continuous Singula TRI Score, scaled from 0 (low therapeutic benefit) to 100 (high therapeutic benefit). We demonstrate that Singula is strongly associated with OS and DFS beyond standard clinical factors, including patient age, patient gender, and physician prescribed treatments (PPT). **Methods:** In this study, Singula's ability to predict response was evaluated in a retrospective cohort of 100 GBM patients with OS and DFS data from The Cancer Genome Atlas (TCGA) project, treated with PPT. As a primary analysis of the CBM and TRI Score, Cox Proportional Hazards (PH) regression and likelihood ratio (LR) tests were used to assess the hypothesis that Singula is predictive of OS and DFS above and beyond patient age, patient gender, and PPT. A p-value < 0.05 for the corresponding likelihood ratio statistic was required to be considered significant. **Results:** Multivariate analyses were performed to assess the performance of the Singula Therapy Response Index after adjusting for the contribution of standard clinical factors. The same Singula TRI algorithm and clinical cutoffs were used for all clinical outcome measures. These analyses, shown in the table, suggests that the proposed Singula TRI provides predictive value of OS and DFS above and beyond patient age, patient gender, and PPT. **Conclusions:** The Singula TRI Score provides a continuous measure scaled from 0 (low benefit) to 100 (high benefit) for alternative GBM therapeutic options. In this retrospective cohort, Singula was strongly predictive of OS and DFS and provided predictive value beyond PPT, patient age and gender. These results will be further validated in larger scale, prospectively designed clinical studies. Research Sponsor: None.

LR analysis for TRI.

	OS	OS	OS	DFS	DFS	DFS
Test	df	χ^2	p-value	df	χ^2	p-value
Likelihood Ratio	1	6.2326	0.0125	1	4.9160	0.0266

A multisite clinical trial of spectroscopic MRI-guided radiation dose escalation for newly-diagnosed glioblastomas. *First Author: Hui-Kuo George Shu, Department of Radiation Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Glioblastoma (GBM) is the most common adult primary malignant brain tumor. These pts have poor outcomes [median overall survival (OS) ~ 16 months] despite radiation therapy (RT) to 60 Gy and temozolomide (TMZ). Magnetic resonance spectroscopy (MRS) measures levels of specific metabolites in the brain including choline (Cho) and N-acetyl aspartate (NAA). Previously, we found that high Cho/NAA ratios can aid in localizing regions of brain at high risk for GBM recurrence that may not be appreciated on standard contrast-enhanced (CE) MRI. Based on this finding, we conducted a clinical trial to assess the feasibility and safety of using an advanced volumetric MRS technique termed spectroscopic MRI (sMRI) to guide RT dose escalation for newly-diagnosed GBMs. **Methods:** Our clinical trial (NCT03137888) funded by the NCI (RO1CA214557) enrolled pts at 3 institutions (Emory U, U Miami, Johns Hopkins U) from 5/2017 to 4/2019. This study was approved by the IRB at each respective institution. Eligibility criteria included newly-diagnosed GBM pts $\geq$ 18 years of age with a tumor site that could be adequately imaged by sMRI. Cho/NAA ratio was normalized to the contralateral normal appearing white matter (NAWM). For RT planning, standard gross tumor volumes (GTV1 & 2) were defined based on T2-FLAIR and T1 CE MRIs and 5 mm margins were added to generate clinical tumor volumes (CTV1 & 2). GTV3 (= CTV3, sMRI-defined) was generated by the union of residual CE tumor and Cho/NAA $\geq$ 2x NAWM. To remain eligible, CTV3 was required to be $\leq$ 65 cc. Planning target volumes (PTVs) were generated by applying a 3 mm margin around CTVs. 50.1, 60 and 75 Gy in 30 fractions were prescribed to PTV1, PTV2 and PTV3, respectively. All pts received standard concurrent/adjuvant TMZ. Survival curves were generated by the Kaplan-Meier method. Toxicities were assessed according to CTCAE v4.0. **Results:** 30 pts met eligibility and were treated on study. Mean/median ages were 56.4/58.9 years. 9 pts (30%) were MGMT methylated; 2 pts (6.7%) harbored an IDH1 mutation. With median followup of 21.4 months in censored pts, median OS was 23.0 months. 11 of 30 pts were documented to have experienced grade 3 or greater toxicities that were at least possibly due to their treatment. Of the 7 pts who experienced these by 9 months post-RT, most were attributable to TMZ (thrombocytopenia x 4, thrombocytopenia/neutropenia x 1, transaminitis x 1) and only one case (headaches/fatigue x 1) could potentially be ascribed to RT. Increased risk of pseudoprogression or radiation necrosis, especially beyond 3 months post-RT, was noted but these were clinically manageable and did not result in toxicity $\geq$ grade 3. **Conclusions:** Dose-escalated RT to 75 Gy guided by sMRI appears feasible and safe for pts with newly-diagnosed GBMs. OS outcome is also quite promising and warrants additional testing. Based on these results, a phase II randomized trial is planned at ECOG-ACRIN (EAF211). Clinical trial information: NCT03137888. Research Sponsor: U.S. National Institutes of Health.

2019 **Poster Discussion Session**

Gene expression signature to predict radiation response in lower-grade gliomas. *First Author: David C Qian, Department of Radiation Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Standard of care for lower-grade glioma (LGG) is maximal safe resection and risk-adaptive adjuvant therapy. While patients who benefit the most from adjuvant chemotherapy have been elucidated in prospective randomized studies, comparable insights for adjuvant radiotherapy (RT) are lacking. We sought to identify and validate patterns of gene expression that are associated with differential outcomes among LGG patients treated by RT from two large genomics databases. **Methods:** Patients from The Cancer Genome Atlas (TCGA) with LGG (WHO grade II–III gliomas) treated by surgery and adjuvant RT were randomized 1:1 to a training set or an internal validation set. Using patients in the training set, association between gene expression from resected tumor and progression-free survival (PFS) as well as overall survival (OS) was evaluated with adjustment for clinicopathologic covariates. A genomic risk score (GRS) was then constructed from the expression levels of top genes also screened for involvement in glioma carcinogenesis. The prognostic value of GRS was subsequently validated in the internal validation set of TCGA and a second distinct database, compiled by the Chinese Glioma Genome Association (CGGA). **Results:** From TCGA, 289 patients with LGG received adjuvant RT alone (38 grade II, 30 grade III) or chemoradiotherapy (CRT) (51 grade II, 170 grade III) between 2009 and 2015. From CGGA, 178 patients with LGG received adjuvant RT alone (40 grade II, 13 grade III) or CRT (41 grade II, 84 grade III) between 2004 and 2016. The genes comprising GRS are *MAP3K15*, *MAPK10*, *CCL3*, *CCL4*, and *ADAMTS1*, involved in MAP kinase activity, T cell chemotaxis, and cell cycle transition. High GRS, defined as having a GRS in the top third, was significantly associated with worse outcomes independent of age, sex, glioma histology, WHO grade, *IDH* mutation, 1p/19q co-deletion, and chemotherapy status in the training set (OS HR 2.74, $P < 0.001$; PFS HR 1.61, $P = 0.014$). These findings were further validated in the internal validation set (OS HR 1.84, $P = 0.015$; PFS HR 1.58, $P = 0.027$) and again in the CGGA external validation set (OS HR 1.72, $P = 0.001$). Association between GRS and outcomes was observed only among patients who received RT (RT alone or CRT), in both TCGA and CGGA. **Conclusions:** This study successfully identified an expression signature of five genes that stratified outcomes among LGG patients who received adjuvant RT, with two rounds of validation leveraging independent genomics databases. Expression levels of the highlighted genes were associated with survival only among patients whose treatments included RT, but not among those with omission of RT, suggesting that expression of these genes may be predictive of radiation treatment response. While additional prospective studies are warranted, interrogation of these genes to determine high/low GRS may be considered in the multidisciplinary management of LGGs. Research Sponsor: U.S. National Institutes of Health.

2020 **Poster Discussion Session**

Comparison of immune microenvironment between primary lung tumors and paired brain metastatic tumors. *First Author: Likun Chen, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Lung cancer is one of the most common causes of brain metastases (BMs) and is always associated with poor prognosis. To evaluate the characteristics of the tumor immune microenvironment in brain metastases of non-small-cell lung cancer (NSCLC), we investigated the immunophenotype of primary NSCLC and paired brain metastases. **Methods:** Forty-three Chinese patients with NSCLC who had BMs at presentation or during the course of their disease were admitted to the Sun Yat-Sen University Cancer Center (Guangzhou, China) from 2000 to 2019. RNA sequencing (RNA-seq) of eighty-six formalin-fixed, paraffin embedded (FFPE) samples from primary lung tumors and paired brain metastases of 43 patients was conducted to comprehensively analyze the tumor immune microenvironment. **Results:** Our data revealed that brain metastases compared with primary lung tumors exhibited reduced tumor infiltrating lymphocytes (TILs) (all 28 immune cell subtypes $P < 0.05$), lower fraction of activated CD8 T cell and effector memory CD8 T cell in total TILs ($P = 0.028$, $P < 0.001$, respectively); higher fraction of macrophage and neutrophil in total TILs ($P < 0.001$, $P < 0.01$, respectively). Comparing with the primary lung tumors, the scores of some immune related signatures, including MHC non-class signature, IFN gamma signature and T-cell-inflamed gene-expression profile (GEP) signature, were significantly lower in brain metastases ($P = 0.004$, $P = 0.009$, $P = 0.004$, respectively), while the score of MHC class-II signature was higher in brain metastases ($P = 0.045$). We found the distributions of tumor microenvironment immune types (TMIT) in brain metastases and primary lung tumors were different. Brain metastases contained significantly lower proportion of TMIT I (high PD-L1/ high CD8A) (23%) than primary lung tumors (47%) ($P < 0.05$). Besides, we found three immune inhibitory checkpoint molecules, namely C10orf54 (VISTA), CTLA4 and CD274 (PD-L1) were downregulated in brain metastases than in primary lung tumors ($P < 0.001$, $P < 0.001$, $P = 0.034$, respectively). Moreover, there was poor correlation of PD-L1 expression between paired brain metastases and primary lung tumors ($R = 0.28$, $P = 0.068$). Unsupervised hierarchic cluster analysis revealed the primary lung tumors had two distinct patterns of immune gene signatures, namely Cluster A and Cluster B, and the tumors in Cluster B were immune rich, but associated with poor prognosis (log-rank $P = 0.021$). **Conclusions:** Our work illustrates the immune landscape of brain metastases from NSCLC, and suggests that the tumor immune microenvironment in brain metastases compared with primary lung tumors is further immunosuppressed, that may help guide immunotherapeutic strategies for NSCLC brain metastases. Research Sponsor: National Natural Science Foundation of China (81572270).

2021 **Poster Discussion Session**

Profiling of immune checkpoint biomarkers by multiplex immunofluorescence in breast cancer brain metastases. *First Author: Gaia Griguolo, Department of Surgery, Oncology and Gastroenterology, University of Padua, and Division of Medical Oncology 2, Veneto Institute of Oncology IOV-IRCCS, Padova, Italy*

Background: Despite potential clinical implications, the complexity of immune microenvironment in breast cancer (BC) brain metastases (BM) is still poorly understood. Multiplex immunofluorescence (mIF) allows simultaneous visualization of several IF labeled proteins while maintaining spatial information. This novel technique can be used to comprehensively describe BCBM immune microenvironment, potentially providing useful information to guide novel therapeutic approaches. **Methods:** Clinical data and archival BM samples from 60 BC patients undergoing neurosurgery (2003-2018) at three institutions were collected. BCBMs were characterized using a custom mIF panel, including immune checkpoint and co-inhibitory molecules (CD3, PD1, PD-L1, TIM3, LAG3, CD163) and localization (keratin for tumor recognition) markers. Mean marker density was determined by digital image analysis (positive cells/mm2) and classified in tumor and stroma areas. Associations between immune marker densities, BC subtype and overall survival from BM diagnosis (OS) were studied. **Results:** Sixty BCBM samples were analyzed; 32% HR+/HER2-, 38% HER2+, 30% HR-/HER2-. At a median follow-up of 43 months, the only clinical variable associated with OS was BC subtype (shortest for HR-/HER2- and longest for HER2+, p=0.02). In the total sample area and tumor area, no significant difference in marker density was observed according to BC subtype. In the stroma area, a significant difference in TIM3+ cell density was observed according to BC subtype (highest density in HR+/HER2- and lowest density in HER2+ tumors, Kruskal-Wallis p=0.017). Higher CD163 density (a marker of M2 macrophage polarization), both in the tumor and in the stroma area, was significantly associated with worse OS, even after correction by BC subtype. In the subgroup of patients with HR+/HER2- BCBM, high TIM3+ cell density in the stroma area was significantly associated with longer OS (median OS 54.1 versus 23 months respectively for TIM3+ density above and below median value; p=0.01). **Conclusions:** In BCBM, stromal TIM3+ immune infiltrate differs according to BC subtype. M2 macrophage polarization is consistently associated with worse OS across all BC subtypes and might represent a potential therapeutic target for these patients. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

2022 **Poster Discussion Session**

Phase 1, 2 trial of concurrent anti-PD1 and stereotactic radiosurgery for melanoma and non-small cell lung cancer brain metastases (NCT02858869). *First Author: Mohammad Khurram Khan, Emory University, Atlanta, GA*

Background: The safety and efficacy of concurrent pembrolizumab (anti-PD1) and stereotactic radiosurgery (SRS) for brain metastases (BM) is unknown. **Methods:** Patients with melanoma or NSCLC, 1-10 brain metastases, ≥ 1 extra-cranial lesion, age ≥ 18, and ECOG 0-1 were treated with anti-PD1 every 3 weeks. SRS was administered 1-2 days after starting anti-PD1. SRS used three different radiation arms: Arm A used 6 Gray (Gy) in 5 fractions (fx), Arm B used 9 Gy in 3 fx, and Arm C used 18-21 Gy in single fx. Primary endpoint was grade 3 CNS toxicity at 3 months (CTCAE v 4.0). Secondary endpoints were overall survival (OS), local control (LC) within the SRS field, intracranial progression free survival (IC-PFS), extra-cranial progression free survival (EC-PFS), rate of extra-cranial clinical benefit, and immunological changes. OS, LC, IC-PFS, and EC-PFS were estimated using the Kaplan-Meier method, and covariates were compared using log-rank tests. 95% confidence intervals for 6-month and 12-month were estimated using Greenwood's formula. **Results:** 25 patients were treated from 2016 until 2020. The mean age was 61. The mean number of CNS lesions was 2.7. The mean number of extra-cranial lesions was 2.5. Six were enrolled on Arm A, 12 on Arm B, and 7 on Arm C. 21 had melanoma. 4 had NSCLC. Of the melanoma, 8 were BRAF-, 10 were BRAF+, and 3 had unknown mutation status. 12 patients (48%) had progressed on prior immunotherapy and/or other oncological therapies. The trial met its primary endpoint, with no grade 3 CNS toxicity at 3 months. Two patients (8%) experienced ≥ Grade 3 anti-PD1 related toxicity, and no grade 5 toxicity was noted. The median OS was 32.8 months. The 6 and 12 month OS were 79.1% (56.5-90.8%) and 67.8% (43.3-83.5%), respectively. The 1 year OS was similar between previously treated and treatment naïve patients (71.8% vs. 65.6%), suggesting some role for SRS in overcoming therapy resistance. However, with longer follow-up, the OS trended worse (p=0.07) for previously treated patients. LC was 95.7% (72.9-99.4%) at 6 and 12 months. IC-PFS at 6 months was 69.1% (45.8-83.9%), and at 12 months was 57.5% (33.7-75.5%). The EC-PFS at 6 and 12 month was 54.5% (32.1-72.4%) and 43.6% (22.3-63.2%), respectively. Clinical benefit, which was defined as a best overall response of stable disease or better according to RECIST 1.1, occurred in 12 patients (48%). No outcome differences were noted amongst the three different SRS arms. 70% of the patients demonstrating early activation (within 3 weeks of starting SRS/anti-PD1) of CD8+PD1+Ki67+ T cells demonstrated a clinical benefit. 100% of patients that failed to show early activation of CD8+PD1+Ki67+ T cells progressed. **Conclusions:** Concurrent pembrolizumab (Anti-PD-1) and SRS is safe and effective. Early activation of CD8+PD1+Ki67+ T cells correlates with improved outcome. Further trials testing pembrolizumab and SRS are justified. Clinical trial information: NCT02858869. Research Sponsor: Merck Pharmaceuticals.

2023 **Poster Discussion Session**

A phase II trial combining nivolumab and stereotactic brain radiosurgery for treatment of brain metastases in patients with NSCLC. *First Author: Philip Wong, Department of Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Previous studies suggested activity of anti-PD-1 in brain metastases from non-small cell lung cancer (NSCLC) and renal cell cancer (RCC). This investigator initiated phase 2 trial examined the safety and efficacy of combining nivolumab with radiosurgery (SRS) in the treatment of patients with brain metastases from NSCLC and RCC. **Methods:** This is a multicentre open-label trial (NCT02978404) in which patients diagnosed with NSCLC or RCC, having ≤ 10 cc of un-irradiated brain metastases, no whole brain radiotherapy and no prior immunotherapy were eligible. Study treatment commenced with a dose of nivolumab (240mg or 480mg IV), which was continued for up to 2 years at bi-weekly or monthly intervals until progression. SRS (15-21Gy) to all visible un-irradiated brain lesions was administered within 14 days after the first dose of nivolumab (cycle 1). Patients were followed by brain MRI, CT scan of the chest, abdomen and pelvis, neurocognitive and quality of life questionnaires (FACT-Br) every 3 months. The primary endpoint was intracranial progression free survival (icPFS), with death and disease progression within the brain as events. Results from NSCLC patients are presented here. **Results:** Of the 26 study patients, 22 NSCLC patients were enrolled between Aug 2017 and January 2020. Patients had a median of 2 (1-9) brain metastases. The median diagnosis-specific graded prognostic score was 2 (1-3). Median treatment and follow-up durations were 4.3 months (0-24.8 months) and 11 months (0-24.8 months), respectively. Forty-two percent of the patients had received prior cytotoxic chemotherapy, and 1 patient had received prior brain SRS. PD-L1 status was known for 21 of the 22 NSCLC (12 with ≥50% PD-L1 expression (DAKO 22C3). Median icPFS was 5.0 months (3 intracranial progression and 8 deaths without progression in the brain). Accounting for death as a competing risk, the 1-year cumulative incidence of intracranial relapse was 17.4%. Median extracranial PFS and overall survival were 2.9 months and 14 months, respectively. Four grade 3 adverse events in 2 patients were related to nivolumab or SRS. The rate of survival free of neurocognitive decline (Hopkins Verbal Learning Test total recall) was estimated to be 89% by 4 months. Mean FACT-Br total scores were 89.4 at baseline and improved ($p = 0.01$) to 139.3 within 2-4 months. **Conclusions:** Neurocognitive and quality of life assessments suggest that upfront SRS during nivolumab is well tolerated. High intracranial control was observed, but deaths from extracranial disease progression resulted in short icPFS. Studies evaluating the strategic addition of SRS combined with more efficacious systemic treatments are needed. Clinical trial information: 02978404. Research Sponsor: Bristol Myers Squib.

2024 **Poster Discussion Session**

Multi-center, single arm phase II study of the dual mTORC1/mTORC2 inhibitor vistusertib for patients with recurrent or progressive grade II-III meningiomas. *First Author: Scott Randall Plotkin, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Grade II/III meningiomas represent about 20% of tumors and have increased rates of recurrence with no approved medical therapies. Historically, the progression-free survival at 6 months (PFS-6) for these tumors is 25%. The Response Assessment in Neuro-Oncology (RANO) group identified a PFS-6 rate of > 35% to be of interest for trials of grade II/III meningioma. **Methods**: *NF2* gene inactivation occurs in the majority of meningiomas and is associated with mTORC1 activation. Human studies of everolimus for neurofibromatosis 2 patients documented growth arrest in only a minority of tumors. Based on our studies showing mTORC2/SGK1 pathway activation in *NF2*-deficient meningiomas and the known paradoxical activation of the mTORC2/AKT pathway in meningiomas, we hypothesized that dual inhibition of mTORC1/2 would be superior in meningiomas. Treatment of primary meningioma cells with vistusertib led to decreased cell proliferation and showed greater efficacy than rapamycin, regardless of *NF2* expression. We studied the effect of vistusertib in patients with progressive or recurrent grade II/III meningiomas (NCT03071874). Vistusertib was administered orally at 125mg twice daily on two consecutive days each week. MRIs were obtained every 2 cycles (1 cycle = 28 days). Tumor size was defined as the largest cross-sectional area. Progression was defined as ≥25% increase in the sum of products of all measurable lesions over smallest sum observed. The primary endpoint was PFS-6. Secondary endpoints included toxicity, radiographic response, and correlative studies including immunohistochemistry for mTORC1/2 pathway activation and genetic biomarkers. **Results**: Twenty-eight patients (13 female), with a median age of 58 years (range, 32 to 77 years), were enrolled in this multicenter study. The median Karnofsky performance status was 80. Twenty-five patients have been followed to six months or to tumor progression. The median duration of treatment was 6.5 month (range, 1-18 months). Four patients chose to discontinue treatment, 1 withdrew to intercurrent illness, and 1 was withdrawn due to non-compliance. PFS-6 is 51.5% (CI, 29.3% - 70.0%). Adverse events at least possibly related to vistusertib with frequency > 10% include nausea (54%); fatigue (36%); hypophosphatemia (29%); diarrhea, anorexia, dry mouth, and hypertriglyceridemia (all 14%); hypertension, vomiting, increased ALT, constipation, and weight loss (all 11%). **Conclusions**: Vistusertib treatment was associated with a PFS-6 rate that exceeds the RANO target of 35% for recurrent high-grade meningioma. The follow-up data continue to mature. Adverse events were tolerable in this patient population. Correlative studies to identify biological factors that correlate with response are under way. These data support the initiation of larger randomized studies of vistusertib in this setting. Clinical trial information: NCT03071874. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

2025 **Poster Session**

Radiosurgery dose reduction for brain metastases on immunotherapy (RADREMI): Early results from a multicenter phase I trial. *First Author: Shearwood McClelland, Indiana University School of Medicine, Indianapolis, IN*

Background: The rate of symptomatic radiation necrosis in patients treated with immune checkpoint inhibitor (ICI) therapy and concomitant single-fraction stereotactic radiosurgery (SRS) is as high as 20% (Martin et al., JAMA Oncology 2018). Here, we present the first results from the Radiosurgery Dose Reduction for Brain Metastases on Immunotherapy (RADREMI) trial, aimed to identify reduced-dose SRS that is safe and efficacious for this patient population. **Methods:** RADREMI is a prospective multicenter, single arm phase I pilot study. Patients age > 18 receiving ICI with SRS for 1-10 brain metastases on MRI from biopsy-confirmed primary malignancy with estimated median survival of at least 6 months (by disease-specific graded prognostic assessment) and no history of whole brain radiation therapy were eligible. The primary endpoint was six-month symptomatic radiation necrosis (defined as a six-month rate of clinical symptomatology requiring steroid administration and/or operative intervention concomitant with imaging findings consistent with radiation necrosis), based on a historical six-month symptomatic radiation necrosis rate of 16% and an expected rate of 5%. Secondary endpoints included six-month local control and six-month radiographic radiation necrosis. Local control was defined according to Response Assessment in Neuro-Oncology (RANO) criteria, and was compared to historical controls of 87-91% six-month local control with RTOG 90-05 SRS dosing. The Fisher's exact test was used for statistical analysis. This trial is registered at clinicaltrials.gov, NCT04047602. **Results:** Between December 18, 2019 and January 21, 2021, 39 lesions were treated in 17 patients receiving ICI delivered within 30 days before SRS from whom we recruited and obtained consent. All patients were treated with RADREMI dosing, which involved SRS doses of 18 Gy for lesions 0-2 cm, 14 Gy for lesions 2.1-3 cm, and 12 Gy for lesions 3.1-4 cm. The most common ICI used was single-agent pembrolizumab (49% of lesions, 59% of patients), followed by single-agent nivolumab (31% of lesions, 12% of patients). For the 11 lesions (six patients) meeting the primary endpoint (median follow-up = 259 days), the six-month symptomatic radiation necrosis rate was 0% per treated lesion, and 0% per treated patient, which was not significantly different from historical controls ($p = 0.478$). The six-month local control rate was 100% per treated lesion, and 100% per treated patient, comparable to historical controls ($p = 0.476$). **Conclusions:** In the first prospective trial to investigate dose-reduced SRS with concomitant ICI in treating metastatic brain disease, early results support the safety and efficacy of RADREMI dosing in this patient population. These findings warrant further multi-institutional collaborative trials of RADREMI dosing for this population. Clinical trial information: NCT04047602. Changes in the blood-brain barrier properties in vitro after treatment with sera from breast cancer patients with primary cancer and visceral, bone or cerebral metastases. *First Author: Carolin Julia Curtaz, University of Würzburg, Department of Gynecology and Obstetrics, Würzburg, Germany*

Background: The progression of brain metastases during breast cancer correlates with poor overall survival, but also with a reduced quality of life. During the metastatic progression of breast cancer, the key event for entry into the brain is the migration of cancer cells across the blood-brain barrier (BBB). To date, it is still controversial which serum factors play a role in cerebral expansion and what effects they have on the BBB. We hypothesize that sera from breast cancer patients with cerebral metastases contain unique factors that can affect BBB integrity. **Methods:** We used the $CD34^+$ cells-derived human in vitro BBB model (brain-like endothelial cells, BLECs) in co-culture with brain pericytes, which was validated in our previous studies, to analyse the BBB properties after patient sera treatment. We used paracellular permeability measurements for fluorescein (400 Da), immunofluorescence staining, Western blot and mRNA analysis to examine the effects of patient sera on the properties of BBB in vitro. We collected serum samples from five patient cohorts (30 patient per group planned/150 in total/ current recruited patients 130): 1) healthy donors (current recruited patients- 23), 2) breast cancer patients with primary cancer (recruited patients- 30), 3) breast cancer patients with bone metastases (recruited patients- 29), 4) visceral metastases (recruited patients- 30), or 5) cerebral metastases (current recruited patients-18). We then used 2% patient sera in cell culture medium to treat the cells for 24 hours. **Results**: Sera from breast cancer patients with cerebral and bone metastases led to a significant increase in the paracellular permeability for fluorescein. This could also be visualized by immunostaining cells with anti-claudin-5 antibody. Tight junction protein claudin-5 and occludin mRNA was reduced in BLECs, while mRNA of efflux pumps Breast cancer resistance protein (BCRP) and P-glycoprotein (P-GP) was induced in BLECs treated with serum from breast cancer patients with primary cancer, cerebral and visceral metastases. At the protein level, efflux pumps BCRP and P-GP were induced in cells treated with sera from breast cancer patients with cerebral metastases, while they were reduced in cells treated with sera from breast cancer patients with bone metastases. **Conclusions:** Sera from breast cancer patients with primary cancer and breast cancer metastases have an effect on the integrity of BBB in vitro. Reduced barrier properties of brain endothelial cells can contribute to the formation of cerebral metastases in advanced stages of breast cancer. Real-world outcomes of breast cancer patients with brain metastases treated with radiotherapy in Ontario: A population-based study. *First Author: Katarzyna Joanna Jerzak, University of Toronto, Toronto, ON, Canada*

Background: Brain Metastases (BrM) are a major cause of morbidity and mortality in patients with metastatic breast cancer (MBC). Real-word data regarding time to development of breast cancer BrM and survival outcomes is lacking. **Methods:** We conducted a retrospective, observational population-based cohort study to assess treatment patterns and outcomes of patients with de-novo MBC who received radiotherapy for intracranial metastatic disease between January 2009 and December 2018. We used population health administrative databases in Ontario held at ICES, an independent, non-profit research institute. Primary endpoints were i) cumulative incidence of radiotherapy for BrM accounting for the competing risk of death, and ii) time from MBC diagnosis to brain radiotherapy. Secondary endpoints included overall survival (OS) and radiation therapy toxicity. Data were censored if patients were alive on the same therapy at last available follow-up with the last cut-off date being March 31, 2019. Kaplan-Meier analyses were performed for the time to event endpoints and compared using the log-rank test. Cumulative incidence of radiotherapy for BrM from the diagnosis of MBC was calculated using the Cumulative Incidence Function (CIF), accounting for the competing risk of death using a competing risk analysis. Multivariable regression models were used to account for confounding variables. **Results:** 3,916 patients with de-novo MBC were identified, among whom 549 (14%) developed BrM requiring radiotherapy; cumulative incidence of BrM at 7-year follow-up was highest among patients with HER2+/HR- (34.7%) and HER2+/HR+ (28.1%) disease, followed by triple negative MBC (21.9%) and HR+/HER2- (12.1%) subtypes. The median time from diagnosis of MBC to first radiotherapy treatment for BrM was 7.5 months, 15.0 months, 16.8 months and 19.8 months, in TNBC, HER2+/HR-, HR+/HER2- and HER2+/HR+ subtypes, respectively. The median OS from radiotherapy among patients with breast cancer BrM was 5.1 months in the overall cohort. When analyzed by subtype, the median OS was 2.6 months, 4.8 months, 8.7 months, and 9.4 months in TNBC, HR+/HER2, HER2+/HR+ and HER2+/HR- subtypes, respectively. In a multivariable Cox regression model, a triple negative or HR+/HER2- breast cancer subtype, treatment with WBRT, age > 60 and a high-income quintile (4 or 5) were independently prognostic for shorter OS after adjustment for the index year at diagnosis. Patients treated with stereotactic radiosurgery (SRS) had lower 30-day mortality (6.4% vs. 18.9%, $p = 0.003$) and lower likelihood of hospitalization within 30 days of therapy (9.6% vs. 20.2%, $p = 0.015$) compared to patients treated with WBRT. **Conclusions:** Approximately 1 in 7 patients with MBC will require radiotherapy for BrM. Our data support the use of SRS when clinically indicated and provide insights regarding the time to development of BrM by breast cancer subtype. Research Sponsor: Eli Lilly.

2028 **Poster Session**

The efficacy and clinical survival outcome of different first-line treatments in EGFR-mutant non-small cell lung cancer with brain metastases. *First Author: Huijuan Wang, The Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou, China*

Background: Brain metastasis is one of the most important factors for poor prognosis of lung cancer, and the incidence of brain metastasis in EGFR-mutant(m+) advanced NSCLC is more common. The first-generation EGFR TKI is a standard first-line treatment. The purpose of this study is to explore the best method for EGFRm+ NSCLC with brain lesions, and to find out correlative factors influencing survival outcome. **Methods:** The clinical data of NSCLC with brain metastases was retrospectively analyzed. All patients had received 1st generation EGFR TKI, and patients were divided into 4 group, group A : EGFR TKI monotherapy, group B: EGFR TKI plus chemotheapy(CT),Group C:EGFR TKI plus bevacizumab, group D :EGFR TKI plus CT plus bevacizumab.The efficacy of intracranial and extracranial lesions and survival outcome were analyzed. **Results:** A total of 584 EGFRm+ advanced NSCLC patients from December 2017 to May 2020 were screened,and 228(39%) had brain metastasis at baseline in the treatment-naive. Among them, 194pts had complete medical record and follow-up data. At the follow-up date (January 1, 2021), 147pts had disease progressed and 78pts had died. Intracranial PFS of group A,B,C,D were 11.1m(n = 97), 11.3m(n = 59) , 21.2m(n = 19), and 18.9m(n = 19), respectively. No difference was found between A and B group (P = 0.745), so as C and D group (P = 0.684).But, the intracranial PFS of group C+D(with bevacizumab) was significantly longer than group A+B(11.3m (95%CI 12.2-14.8) vs 21.0m (95%CI 15.2-22.7), P = 0.007).The extracranial PFS of groups A, B, C, and D were 11.0m, 14.3m, 21.7m, and 18.9m, respectively,and the P value were 0.006, 0.002, and 0.011, respectively when compared with group A. The mOS of groups A ,B were 27.8m and 24.2m,respectively, but group C and D had not yet reached. The intracranial ORR of group A, B, C, and D were 17.9% (14/78), 37.3% (19/51), 60.0% (9/15), and 66.7% (10/15), respectively. The extracranial ORR were 48.5% (47/97), 81.1% (43/53), 73.7% (14/19), and 73.7% (14/19),respectively. **Conclusions:** For EGFR-mutant NSCLC with brain metastases, the first-generation EGFR-TKI plus bevacizumab can significantly improve the efficacy of intracranial lesions, delay the progression of intracranial lesions, and prolong suvival time, Although the first-generation EGFR-TKI plus CT could improve extracranial ORR when compared with ERGF-TKI monotherapy, it has limited efficacy on intracranial lesions and could not increase survival time. Research Sponsor: None.

Heterogeneity of HER2 expression in circulating tumor cells of patients with breast cancer brain metastases and impact on brain disease control. *First Author: Douglas Guedes Castro, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: The HER2 expression switching in circulating tumor cells (CTC) of breast cancer is dynamic and may have prognostic and predictive clinical implications. This study aims to analyse the association between expression of HER2 in CTC of patients with breast cancer brain metastases (BCBM) and brain disease control. **Methods:** Exploratory analysis of a prospective assessment (NCT02941536) of CTC before (CTC1) and 4–5 weeks after (CTC2) stereotactic radiotherapy/radiosurgery (SRT). CTC were isolated and quantified by a method of isolation by size of tumors and analyzed by immunocytochemistry to evaluate the expression of HER2. Distant brain failure-free survival (DBFFS), the primary endpoint, and overall survival (OS) were estimated by Kaplan-Meier estimator. Log-rank tests were applied in order to compare the survival curves. For multivariate analysis of prognostic factors that affected DBFFS and OS, the Cox proportional model was adjusted. **Results:** The median age at SRT was 54 (34-70), the diagnosis-specific graded prognostic assessment (DS-GPA) was 1–2 in 17.5% and 2.5–4 in 82.5% and the primary immunophenotype (PIP) was HER2-enriched in 51%, luminal B (LB) in 31% and triple negative (TN) in 18% of the total of 39 patients. CTC were detected in all 39 patients before SRT and the median CTC1 was 2 CTC/mL. After SRT, CTC were detected in 34 of 35 patients (4 deaths between CTC1 and CTC2) and the median CTC2 was 2.33 CTC/mL. HER2 was expressed in CTC1 and/or CTC2 in 9 patients, of which only 2 patients had PIP HER2-enriched. After a median follow-up of 16.6 months, there were 15 patients with distant brain failure and 16 deaths. The median DBFFS and OS were 15.3 and 19.5 months, respectively. Median DBFFS was 7 months in patients with PIP TN and was not reached in PIP LB and HER2-enriched (p = 0.036); 14 months in patients with DS-GPA 1-2 and 7 months with DS-GPA 2.5-4 (p = 0.017); 10 months in patients without HER2 expressed in CTC and not reached in patients with HER2 expressed in CTC (p = 0.012). Median OS was 4.8 months in patients with PIP TN and was not reached in PIP LB and HER2-enriched (p = 0.0026); 19.54 months in patients with DS-GPA 1-2 and 7.6 months with DS-GPA 2.5-4 (p = 0.00088); 17 months in patients without HER2 expressed in CTC and not reached in patients with HER2 expressed in CTC (p = 0.104). On multivariate analysis, DBFFS was superior in patients with PIP HER2-enriched (HR 0.128, 95% CI 0.025–0.534; p = 0.013) and OS was superior in patients with PIP HER2-enriched (HR 0.073, 95% CI 0.018-0.288; p < 0.0001) and LB (HR 0.224, 95% CI 0.062–0.816; p = 0.023). The status of expression of HER2 in CTC was not included in Cox model for DBFFS due to lack of events in patients with HER2 expressed in CTC. **Conclusions:** The expression of HER2 in CTC was associated with a longer DBFFS and the switching of HER2 expression between PIP and CTC may have impact on prognosis and treatment selection of BCBM. Research Sponsor: International Atomic Energy Agency.

2030 **Poster Session**

Outcomes of immunotherapy (ICI) alone vs tyrosine kinase inhibitors (TKI) alone versus ICI and TKI combined in renal cell carcinoma brain metastasis. *First Author: Patrick Joseph O'Shea, Cleveland Clinic, Cleveland, OH*

Background: Renal cancer is the fourth most common cause of metastatic tumors to the brain. Tyrosine kinase inhibitors (TKIs) targeting VEGFR and other receptors, such as sunitinib, pazopanib, etc., have been used as first line for renal cell carcinoma brain metastasis (RCCBM). Immune Checkpoint Inhibitors (ICIs) targeting PD-L1 and CTLA-4 interactions, such as nivolumab and ipilimumab respectively, have also been used as first line treatment for RCCBM. However, the efficacy of TKIs alone, ICIs alone, or TKIs and ICIs combined as first line treatment has emerged as a topic of interest. **Methods:** Patients with RCCBM treated with either TKIs, ICIs, or both at our tertiary care center from 2010-2019 were evaluated. Overall Survival (OS) was measured from initiation of either TKI or ICI therapy to date of death or last follow up. The Cox proportional hazard model was used to determine differences in OS. **Results:** 218 patients with RCCBM were included. Of these, 32 were treated with ICIs alone, 112 were treated with TKIs alone, and 76 were treated with a combination of ICIs and TKIs. For ICI treatment alone the median age at diagnosis was 61 years (Interquartile range (IQR) 38-82), 72% of the patients were male, and 97% were white. For TKI treatment alone the median age at diagnosis was 58 years (IQR 37-82), 70% of the patients were male, and 92% were white. For the combination cohort the median age at diagnosis was 63 years (IQR 45-79), 69% of the patients were male, and 97% were white. OS for patients receiving ICI, TKI, and combination treatment had a median of 69.1, 42.7, and 126.0 months and a 2-year rate of 77%, 69%, and 93%, respectively. With ICI treatment as a reference, TKI treated patients had an OS hazard ratio of 1.32 (95% CI = 0.78 - 2.21, p = 0.30) and ICI/TKI combination had an OS hazard ratio of 0.52 (95% CI = 0.30 - 0.92, p = 0.024). **Conclusions:** A combination treatment of ICIs and TKIs was associated with an increase in OS when compared to treatment with either TKIs or ICIs alone in patients with RCCBM. These results should be interpreted cautiously due to treatment selection bias. Further studies need to be done to control for other patient variables such as performance status, number of intracranial lesions, and extra-cranial metastasis. Research Sponsor: None.

Overall survival outcomes for RCCBM patients.

Outcome	Treatment	No Obs	Estimated Median (months)	2-year rate	Hazard Ratio (95%CI)	P
OS	ICI	30	69.1	77% (57%, 88 %)	Ref	
	Both ICI and TKI	76	126.0	93% (85 %, 97 %)	0.52 (0.30, 0.92)	0.024
	TKI	112	42.7	69% (60 %, 77 %)	1.32 (0.78, 2.21)	0.30

Outcomes of first-generation versus third-generation epidermal growth factor receptor (EGFR) inhibitors in non-small cell lung cancer with brain metastases (NSCLCBM). *First Author: Vineeth Tatineni, Burkhardt Brain Tumor and Neuro-Oncology Center, Cleveland Clinic, Cleveland, OH*

Background: Non-small cell lung cancer (NSCLC) is the most common cause of brain metastases, with 10-30% of patients developing brain metastases. EGFR is a transmembrane glycoprotein that is mutated in up to 50% of NSCLCs. First-generation EGFR tyrosine kinase inhibitors (TKI), such as erlotinib and gefitinib, are limited by blood-brain barrier (BBB) penetration and exon 20 (T790M) tumor mutations. Third-generation EGFR TKIs, such as osimertinib, have shown better BBB penetration and efficacy against T790M mutations. In this retrospective study, we evaluated the overall survival (OS) and progression-free survival (PFS) in NSCLCBM patients treated with first and third-generation EGFR TKIs. **Methods:** NSCLCBM patients diagnosed between 2010 and 2019 at our tertiary care center were investigated. Information regarding molecular marker status, systemic therapies, and date of progression were collected. OS was defined as the start date of systemic therapy to the date of last follow-up or death. OS and PFS were estimated by the Cox proportional model. **Results:** A total of 193 NSCLCBM patients with an EGFR mutation were identified. 33 EGFR mutant patients received first-generation EGFR TKIs, of which 56.7% were females, 82.1% were white, and had a median age of 63.2 years. 22 patients received third-generation EGFR TKIs, 64.1% being female, 76.9% being white, and with a median age of 71.5 years. The median OS (mOS) in patients who received first and third-generation EGFR TKIs was 59.8 months and 65.9 months respectively (p-value (p) = 0.06). The median PFS (mPFS) between the first and third-generation EGFR TKI cohorts was 44.3 months and 66.9 months respectively (p= 0.048, hazard ratio (HR) = 0.50 (95% confidence interval (CI) = 0.25, 0.99). **Conclusions:** Newer generation of targeted therapies in NSCLCBM have focused on overcoming previous efficacy hurdles, including BBB penetration and resistant mutations. We determined that there was a significant mPFS benefit in osimertinib compared to erlotinib or gefitinib, and a trend towards significant mOS benefit in osimertinib compared to erlotinib or gefitinib in patients with NSCLCBM. However, these results should be interpreted cautiously due to treatment selection bias, and further studies need to be conducted on brain metastases lesion size and response rates. Research Sponsor: None.

Outcomes of first-generation and third-generation EGFR TKIs.

Systemic Therapy	Patients (N)	mOS (months)	Hazard Ratio (95% CI)	P-value	mPFS (months)	Hazard Ratio (95% CI)	P-value
Erlotinib or Gefitinib	33	59.8	Reference	Reference	44.3	Reference	Reference
Osimertinib	22	65.9	0.51 (0.26, 1.03)	0.06	66.9	0.50 (0.25, 0.99)	0.048

2032 **Poster Session**

Clinical and genomic predictors of brain metastases (BM) in non-small cell lung cancer (NSCLC): An AACR Project GENIE analysis. *First Author: Protiva Rahman, Vanderbilt University Medical Center, Nashville, TN*

Background: 30-50% of patients with non-early NSCLC will eventually develop BM, with a median survival of less than one year from BM diagnosis. There are no widely accepted clinical risk models for development of BM in patients without them at baseline. We predicted the binary risk of BM using clinical and genetic factors from a large multi-institutional cohort. **Methods:** Stage II-IV NSCLC patients from the AACR Project GENIE Biopharma Consortium dataset were eligible. This consisted of 4 academic institutions who curated clinical data of patients who had somatic next-generation tumor sequencing (NGS) between 2015-2017. We excluded patients who had BM at baseline, died within 30 days of NSCLC diagnosis, or did not undergo brain imaging. Covariates included demographics, anticancer therapies (received up to 90 days prior to BM development and within 5 years from NSCLC diagnosis), and NGS data; radiotherapy (RT) data were not available. NGS features included mutations and copy number alterations. These features were restricted to those classified as oncogenic by OncoKB. Univariate feature selection with Fisher's test ($p<.1$) was performed on medication and genetic features. We compared 5 different machine learning models for prediction: random forest (RF), support vector machine (SVM), lasso regression, ridge regression, and an ensemble classifier. We split our data into training and test sets. 10-fold cross-validation was done on the training set for parameter tuning. The area under the receiver-operating curve (AUC) is reported on the test set. **Results:** 956 patients were included, 192 (20%) in the test set. Univariate features associated with BM were treatment with etoposide, Asian race, presence of bone metastases at NSCLC diagnosis, mutations in *TP53* and *EGFR,* amplifications of *ERBB2* and *EGFR,* and deletions of *RB1, CDKN2A* and *CDKN2B.* Univariate features inversely associated with BM were older age, treatment with nivolumab, vinorelbine, alectinib, pembrolizumab, atezolizumab, and gemcitabine, as well as mutations in *NOTCH1* and *KRAS.* Ridge regression had the best AUC, 0.73 (Table). **Conclusions:** We achieved reasonable prediction performance using commonly obtained clinical and genomic information in non-early NSCLC. The biologic role of the associated alterations deserves further scrutiny; this study replicates similar findings for *EGFR* and *KRAS* in a much smaller cohort. Certain subsets of NSCLC patients may benefit from increased surveillance for BM and transition to drug therapies known to effectively cross the blood-brain barrier, e.g., nivolumab and alectinib. Inclusion of additional covariates, e.g., brain RT, may further improve model performance. Research Sponsor: American Association for Cancer Research GENIE BioPharma Collaborative.

Presentation and management of patients with brain metastases of primary melanoma, non-small cell lung cancer, and breast cancer origin. *First Author: Yuki Kawahara, University of South Florida Morsani College of Medicine, Tampa, FL*

Background: As systemic therapy improves; the prevalence of brain metastases is increasing. Screening brain MRIs are currently recommended for all stage ≥ II non-small cell lung cancer (NSCLC) and stage IIIB–IV melanoma patients, but only when neurologic symptoms arise in stage IV or recurrent breast cancer (BC) patients. This study assessed the presentation and institutional outcomes treating brain metastases (BM) of BC, NSCLC, and melanoma origin. **Methods:** Patients with BM treated between 2014 and 2019 with primary melanoma, NSCLC, and BC were identified. Characteristics of initial BM diagnoses were retrieved from clinical chart review. Kruskal-Wallis and Pearson's chi-square tests were used to test differences between groups. Overall survival (OS) was calculated from dates of initial BM diagnosis using the Kaplan–Meier method. **Results:** A total of 959 patients were identified (BC 18%, NSCLC 51%, melanoma 31%). BC patients were younger at initial presentation (BC median age: 57, NSCLC 65, melanoma 62, $p< 0.0001$). At BM diagnosis, BC patients were more likely to have concurrent systemic metastasis (BC 77%, NSCLC 42%, melanoma 69%, $p< 0.0001$), at least 5 BM (BC 27%, NSCLC 14%, melanoma 13%, $p= 0.0004$), and leptomeningeal disease (BC 23%, NSCLC 6%, melanoma 6%, $p< 0.0001$). Patients with BC were significantly more likely to receive whole brain radiation therapy (WBRT) (BC 58%, NSCLC 37%, melanoma 22%, $p< 0.0001$) and less likely to receive stereotactic radiation (BC 26%, NSCLC 48%, melanoma 58%, $p< 0.0001$) following initial BM diagnosis. There were no significant differences in surgical resection between cancer types (BC 24%, NSCLC 24%, melanoma 29%, $p =0.166$). Median OS was shorter for BC (BC 9.9 months, NSCLC 10.3 months, melanoma 13.7 months, $p= 0.0006$) following BM diagnosis. **Conclusions:** Our institutional analysis found BC patients were more likely to be younger, present with more advanced brain disease, require WBRT, and have poorer OS than NSCLC and melanoma patients following initial brain metastasis diagnosis. This may be due in part to a lack of brain MRI screening recommendations in BC. Further investigation is needed to determine which BC patients are at sufficient risk to warrant brain MRI screening. Research Sponsor: None.

Outcomes of first, second, and third-generation anaplastic lymphoma kinase (ALK) inhibitors in non-small cell lung cancer brain metastases (NSCLCBM). *First Author: Vineeth Tatineni, Burkhardt Brain Tumor and Neuro-Oncology Center, Cleveland Clinic, Cleveland, OH*

Background: Non-small cell lung cancer (NSCLC) is the most common cause of brain metastases. ALK, which codes for tyrosine kinase receptors, is rearranged in 4-7% of NSCLC. First-generation ALK inhibitors have restricted efficacy due to poor blood-brain barrier (BBB) penetration and ALK-resistant tumor mutations. Second-generation ALK inhibitors have shown better BBB penetration, while third-generation ALK inhibitors were efficacious even against ALK-resistant mutations. In this retrospective study, we investigated the overall survival (OS) and progression-free survival (PFS) in NSCLCBM patients treated with first, second, and third-generation ALK inhibitors. **Methods:** NSCLCBM patients between 2010 and 2019 were evaluated. We analyzed data regarding molecular marker status, systemic therapies, and date of progression. OS was defined as the start date of systemic therapy to the date of last follow-up or death. The Cox proportional model was used to estimate OS and PFS. **Results:** A total of 90 patients had ALK gene rearrangement. 16 ALK positive patients received first-generation ALK inhibitor (crizotinib), with a median age of 59.2 years, 50% of the cohort being female and 83.3% being white. Another 17 patients received second-generation (alectinib, ceritinib, brigatinib) and third-generation ALK inhibitors (lorlatinib), with a combined median age of 52.2 years and a cohort of 52.6% females and 72.2% white patients. The 5-year OS rate was 49% (95% confidence interval (CI) = 24%, 71%) for first-generation ALK inhibitors and 76% (95% CI = 40%, 92%) for second and third-generation ALK inhibitors (p-value (p) = 0.019). The median PFS (mPFS) for patients who received first-generation ALK inhibitors was 45.3 months and for those who received second or third-generation ALK inhibitors was 180.1 months. The respective 5-year PFS rate was 43% (95% CI = 19%, 65%) and 72% (95% CI = 42%, 89%). **Conclusions:** Newer generations of targeted therapies in NSCLCBM have improved BBB penetration and effectiveness against resistant mutations. We determined that there was a significant 5-year OS benefit in patients who received second and third-generation ALK inhibitors compared to first-generation ALK inhibitors, and a respective trend towards significant PFS benefit in newer-generation ALK inhibitors when compared to first-generation. These results are encouraging, but the effect on intracranial lesion size and response rates should be examined in the future. Research Sponsor: None.

Outcomes of first-generation vs. second and third-generation ALK inhibitors.

Systemic Therapy	Patients (N)	mOS (months)	5-Year OS Rate (95% CI)	P-value	mPFS (months)	5-Year PFS Rate (95% CI)	P-value
Crizotinib	16	51.6	49% (24%, 71%)	Reference	45.3	43% (19%, 65%)	Reference
Alectinib, Ceritinib, Brigatinib, or Lorlatinib	17	NA	76% (40%, 92%)	0.019	180.1	72% (42%, 89%)	0.061

2035 **Poster Session**

An investigation into the impact of next generation sequencing on the use of targeted treatments in glioblastoma. *First Author: Jordan John, Northwestern Feinberg School of Medicine, Chicago, IL*

Background: Next-generation sequencing (NGS) provides clinicians immense amounts of information about a patient's cancer. NGS allows the detection of a wide range of gene alterations undetectable by older techniques. This has the promise to help guide clinicians in their decision-making as genetic alterations can be both prognostic and predictive. NGS may reveal new treatment options for patients with glioblastoma. The goal of this project was to evaluate how often NGS results influence the use of targeted treatment agents in glioblastoma. This study did not investigate the impact of NGS on reclassification of cancers, prognosis, or treatment decisions outside of the use of targeted therapy. **Methods:** We conducted a retrospective chart review to see if adult glioblastoma patients received treatments for potentially actionable gene alterations and for fusion variants because of NGS. Here we looked at alterations labeled as actionable from the Tempus company's NGS results. We collected diagnosis and treatment information from the Electronic Medical Record and from the Electronic Data Warehouse. We examined if patients after receiving NGS would receive targeted treatment, as that likely indicated these treatments were given due to NGS indication. We excluded cytotoxic chemotherapy agents and bevacizumab as these therapies are utilized regardless of a targeted gene indication. This analysis excluded treatments received in clinical trials in which enrollment was independent of NGS. This analysis looked at the proportion of patients with actionable alterations that were treated with targeted agents. **Results:** 261 glioblastoma patients were found on NGS to have mutations which were potentially actionable. Thirty-three of these patients (12.6%) received a respective targeted therapy, and the other 228 patients (87.4%) did not receive an NGS guided targeted therapy. 97 patients had EGFR copy number gains or EGFR gain of function mutations of which 21 were treated with depatuxizumab mafodotin, and one additional patient who was treated with ABBV 321. Of the NGS treatment guided therapies, depatuxizumab mafodotin was the most used targeted agent in our sample set. Additionally, there were 30 patients with fusion variants and 11 of them were FGFR3-TACC3 fusions. Of these 11, 4 received targeted regimens (36.4%) with either TAS-120, pemigatinib, erdafitinib, or erdafitinib with ponatinib. The other fusion variants were not acted upon. **Conclusions:** These preliminary results suggest that NGS data currently does not frequently impact treatment decisions for glioblastoma . Although this study is limited by being a single institution study, future efforts include expanding this analysis to multiple institutions. With improvements in therapeutics as well as with wider availability of NGS testing, sequencing data may impact a larger percentage of glioblastoma patients. Research Sponsor: None.

2036 **Poster Session**

Palliative care service utilization and advance care planning issues for adult glioblastoma patients: A systematic review. *First Author: Adela Wu, Stanford University Medical Center, Stanford, CA*

Background: Glioblastoma (GBM) is a devastating disease with a median survival under 2 years and a 10-year survival rate of 0.71%. As patients with GBM suffer simultaneously from both a terminal cancer and a neurodegenerative disease, proactive provision of advance care planning (ACP) and palliative care (PC) seem appropriate. We conducted a systematic review exploring the published literature on the prevalence of ACP, healthcare services utilization at the end of life (EOL, including PC services), and location of death among adults with GBM, and the experiences of their caregivers. **Methods:** We systematically searched PubMed, Embase, Scopus, and Cochrane Library from database inception until 12/20/2020, using search terms including 'glioblastoma', 'end of life', 'advance care planning', and 'advance directive'. Preferred reporting items for systematic reviews and meta-analyses (PRISMA) guidelines were followed. Inclusion criteria were quantitative and qualitative studies written in English of adults with GBM and their caregivers, with at least 20 subjects. Included studies were assessed for quality using the Newcastle-Ottawa Scale. **Results:** We screened 344 article abstracts and 39 full text articles to yield a final cohort of 16 articles that fit inclusion criteria. These studies reported the experiences of 10,706 GBM patients and 123 caregivers. All were nonrandomized studies conducted in six countries with all but two published in 2014 or later. Across studies, ACP documentation varied from 4-55%, PC referral was pursued in 39-40% of cases, and hospice referrals were made for 66-76% of adult GBM patients. Hospitalizations frequently occurred at the EOL, 20-56% of patients spent over 25% of their overall survival time hospitalized, and 39-64 % of deaths occurred in the home setting. Caregivers commonly reported restrictions on their ability to work (60%), financial barriers to care (29%), and feeling unprepared (29%). **Conclusions:** Despite having both a terminal disease and neurocognitive decline, a majority of adults with GBM do not pursue ACP or have access to PC. There is a dearth of focused and high-quality studies on ACP, PC, and hospice use among adults with GBM. Prospective studies that address these and additional aspects related to end-of-life care in this population, such as healthcare costs and inpatient supportive care needs, are needed. Research Sponsor: None.

Phase 1 dose-escalation study of ACT001 in patients with recurrent glioblastoma and other advanced solid tumors. *First Author: Jason D. Lickliter, Nucleus Network Limited, Melbourne, Australia*

Background: ACT001, an orally-available parthenolide derivative targeting NF-κB and STAT3 signaling pathways, has immunomodulatory effects and showed promising activity in preclinical models of glioblastoma (GBM). The updated data in this report summarizes clinical findings from this first-in-human clinical trial of ACT001 in patients with advanced solid tumors, including GBM. **Methods:** Eligible patients were adults with ECOG PS 0-1 and satisfactory hematologic, renal and hepatic function. Additionally, GBM patients had progressive disease despite initial radiation and temozolomide, measurable tumor and no radiation treatment within 3 months prior to enrollment. ACT001 was given orally BID until intolerance or disease progression. Dose escalation followed a standard 3+3 design. Gliomas were imaged with MRI every 8 weeks and responses assessed using RANO criteria. **Results:** A total of 24 patients were enrolled as of this report: 14 with primary GBM, 2 with secondary GBM, 2 with anaplastic astrocytoma, 2 with colorectal cancer and 1 with each of anaplastic oligioastrocytoma, diffuse intrinsic pontine glioma, non-small cell lung cancer and pleural epithelioid mesothelioma. Median age was 49 years old (range 32-72). ACT001 dose levels were 100 mg BID, 200 mg BID, 400 mg BID, 600 mg BID, 900 mg BID and 1200 mg BID. Study drug treatment was well tolerated with no dose-limiting toxicity or ACT001-related SAE observed. The originally-planned maximum dose of 600 mg BID and the 1200 mg BID dose were expanded to 7 and 5 patients, respectively. The plasma half life of ACT001 was approximately 3-4 hours and no accumulation was observed after multiple dosing. Cmax and $AUC_{0\text{-last}}$ were approximately dose linear across the evaluated dose range. Of the 19 patients with recurrent malignant gliomas, a complete remission was observed in 1 patient with GBM (ongoing 27 months from starting ACT001) and stable disease lasting $\geq$ 6 months was seen in 3 patients. Preliminary biomarker analysis of PBMC samples revealed a post-treatment reduction in CD4+ Treg cells at some dose levels. **Conclusions:** In this first-in-human phase 1 study, ACT001 was well tolerated and showed satisfactory bioavailability and preliminary evidence of anti-tumor activity in malignant glioma patients dosed at 400 mg BID or lower. A phase 1b trial in recurrent GBM patients of ACT001 at 200-400 mg BID in combination with anti-PD-1 therapy is planned. Clinical trial information: ACTRN12616000228482. Research Sponsor: Accendatech AU Pty Ltd.

2038 **Poster Session**

Efficacy finding cohort of a cancer peptide vaccine, TAS0313, in treating recurrent glioblastoma. *First Author: Yoshiki Arakawa, Department of Neurosurgery, Kyoto University Graduate School of Medicine, Kyoto, Japan*

Background: TAS0313 is a cancer vaccine cocktail comprising three long peptides with a total of 12 cytotoxic T lymphocyte (CTL) epitope peptides. These peptides were derived from eight cancer-associated antigens (EGFR, KUA, LCK, MRP3, PTHRP, SART2, SART3, and WHSC2) that are overexpressed in various cancer types including glioblastoma (GBM). We performed a single-arm, multicenter efficacy confirmatory cohort study as part of the TAS0313 Phase I/II study in patients with recurrent GBM. **Methods:** The enrolled patients with histologically or cytologically confirmed grade IV GBM (including gliosarcoma, giant cell glioblastoma, and epithelioid glioblastoma) had at least one of the following HLA types: HLA-A*02:01, -A*02:06, -A*02:07, -A*11:01, -A*24:02, -A*31:01, or -A*33:03. Eligible patients were those who received standard radiotherapy and temozolomide, had a confirmed first or second recurrence, or progression with measurable disease outcomes with good performance status (Karnofsky Performance Status score $>$ 70). TAS0313 (27mg) was subcutaneously administered on days 1, 8, and 15 of cycles 1 and 2 and day 1 of cycle 3 or later in 21-day cycles until disease progression or unacceptable toxicity occurred. Tumor response was evaluated using The Response Assessment in Neuro-Oncology criteria. The antigen-specific CTL and immunoglobulin G (IgG) were analyzed by ELISPOT assay and Luminex assay, respectively, before and after treatment. The primary objective was to evaluate the efficacy of TAS0313. Secondary and exploratory methods were used to evaluate the safety and immune response of TAS0313. **Results:** As of 10th September 2020, 10 patients have been treated with TAS0313 (eight with GBM and two with gliosarcoma). The median age of participants was 56.5 [range, 33–69 years], and methylation status of the MGMT promoter was methylated in four patients, unmethylated in four, and unknown in two. The best overall response was partial response 1/10 (10.0%) and stable disease 4/10 (40.0%). One case showed 69.1% tumor shrinkage. The treatment of two patients was ongoing for over 7 months. The 6-month progression-free survival (PFS) rate was 25.0%, and the median PFS was 2.3 months. The most common adverse drug reactions (ADRs) were grade 1–2 injection site reactions and pyrexia. There were no grade 4 or 5 ADRs. In some patients, TAS0313 treatment was confirmed to increase CTL and IgG levels compared with pre-treatment samples. **Conclusions:** TAS0313 showed promising efficacy with expected immune responses and favorable safety and tolerability in patients with recurrent GBM. Further investigation of TAS0313 is warranted to validate our findings. Clinical trial information: JapicCTI-183824. Research Sponsor: TAIHO PHARMACEUTICAL Co., Ltd.

2039 **Poster Session**

A phase II study of anlotinib combined with STUPP regimen in the treatment of patients with newly diagnosed glioblastoma (GBM). *First Author: Peijing Li, Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Hangzhou, China*

Background: STUPP regimen is now the standard treatment for newly diagnosed GBM, while the effectiveness is limited. This study assessed the efficacy and safety of anlotinib, a multitarget tyrosine kinase inhibitor, combined with the STUPP regimen in treating these patients. **Methods:** This is a phase II, multicenter, open-label, single-arm trial (NCT04119674). Thirty-three patients (17 males and 16 females) were enrolled from 8 hospitals in China between January 2019 and February 2021. Inclusion criterion included 1) newly diagnosed histologically confirmed glioblastoma (WHO grade IV), 2) 2-6 weeks (wks) after surgery with healed incision, 3) 18-70 years old, 4) KPS$\geq$60, 5) at least one measurable lesion according to RANO criteria, 6) radiotherapy (RT), chemotherapy, immunotherapy or biotherapy naïve. All patients received 54-60 Gy radiation (1.8-2.0 Gy per fraction, five days per week) concurrently with temozolomide (TMZ, 75mg/m^2, orally, QD) and anlotinib (8mg, orally, QD, d1-14/3wks). Adjuvant therapy started four weeks after RT completion, including six cycles of TMZ (150-200mg/m^2, orally, d1-5/4wks) and eight cycles of anlotinib (8mg, orally, QD, d1-14/3wks). Patients who completed adjuvant therapy were administrated anlotinib continuously until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS). Safety assessment was done in patients who received at least one dose of study agent. **Results:** The median age is 52 (range 32-69) years. Analyses included data collected through February 6, 2021. The median treatment duration was 6.5 months. The median PFS was not reached, and the median overall survival (OS) was 17.4 months [95%CI 11.6-23.2]. The 1-year PFS and OS rate was 84.0% and 100.0%, respectively. Tumor response occurred in 21 patients, 63.6% (21/33) objective response (CR/PR), and 24.2% (8/33) patients had stable disease (SD).The clinical benefit rate (CBR), defined as the proportion of patients who achieved durable disease control (CR/PR/SD) more than six months, was 57.6% (19/33). Hypertension (6.1%) was the most common $\geq$grade 3 adverse event. No treatment related death occurred in this study through the last follow-up. Overall, toxicities are mild and manageable. **Conclusions:** Anlotinib combined with the STUPP regimen is efficacious and well-tolerated in newly diagnosed GBM patients. Clinical trial information: NCT04119674. Research Sponsor: None.

2040 **Poster Session**

A phase I/II study to evaluate the safety and efficacy of a novel long-acting interleukin-7, NT-I7, for patients with newly diagnosed high-grade gliomas after chemoradiotherapy: The interim result of the phase I data. *First Author: Jian Li Campian, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: High-grade gliomas (HGG) patients can develop prolonged lymphopenia after standard radiation therapy (RT) and temozolomide (TMZ), which has been shown to correlate with worse survival. Interleukin-7 (IL-7) level, a cytokine that stimulates T-cell homeostasis and proliferation, is disproportionally low in HGG patients with lymphopenia. NT-I7 (efineptakin alfa) is the first-in-class long-acting recombinant human IL-7 that supports proliferation and survival of CD4+ and CD8+ T-cells in humans and mice. Our previous study demonstrated that NT-I7 could correct lymphopenia and improve the survival of orthotopic murine glioma models. The current study aims to examine the safety of administering NT-17 after chemoradiotherapy to HGG patients and its effect on systemic absolute lymphocyte count (ALC). **Methods:** All patients with newly diagnosed HGG who have completed concurrent RT/TMZ were considered eligible, regardless of ALC. NT-I7 was initially administered intramuscularly within 1 week after completion of RT/TMZ and then every 12 weeks for up to 4 doses. Patients also received adjuvant TMZ 4 weeks after RT/TMZ. The phase I study tested 6 dose levels of NT-I7, including 60, 120, 240, 540, 720, and 960 mcg/kg, adopting an accelerated phase for the first two doses followed by the standard 3+3 design. The primary endpoint was the safety of NT-I7 in HGG. The Phase II study is a double-blinded randomized study with 10 patients per arm to evaluate the effect of NT-I7 on ALC compared to placebo controls. Blood samples at baseline and during the NT-I7 administrations will be collected for immune profiling by CyTOF, single-cell RNA-sequencing, and cytokine analysis. **Results:** Phase I was completed with 19 patients (2 anaplastic oligodendrogliomas and 17 glioblastomas), with a median age of 58 years (range: 25-78). Median baseline ALC was 1000 cells/mm3 before NT-I7 administration, and the median baseline dexamethasone use was 0 mg/day (range 0-12). The median number of NT-I7 doses given was 2 (range: 2-4). Treatment-related adverse events (TRAEs) were dose-dependent. The most common TRAEs were grade 1/2 injection site reactions (50%), flu-like symptoms (26%), rash (21%), and fatigue (21%). Two patients had dose-limiting toxicities at 960 mcg/kg (a grade 3 elevated alanine aminotransferase and a grade 3 muscle pain). ALC was increased in a dose-dependent manner with a range of 1.3 – 4.1 fold at week 4 after NT-I7 injection and lasted up to 12 weeks. Thus, 720 mcg/kg was identified as the recommended phase II dose (RP2D). **Conclusions:** NT-I7 is well tolerated for HGG patients after chemoradiotherapy and has a RP2D of 720 mcg/kg. Immune profiling and cytokine analysis are ongoing and will be updated. The Phase II randomized study to evaluate the effect of NT-I7 vs placebo on ALC and survival is ongoing. Clinical trial information: NCT03687957. Research Sponsor: NeoImmuneTech, Other Foundation.

2041 **Poster Session**

PD-L1-R: A MR based surrogate for PD-L1 expression in Glioblastoma multiforme. *First Author: Francesco Sforazzini, CCU Translational Radiation Oncology, German Cancer Research Center (DKFZ), Medical Faculty, Heidelberg (HD) University Hospital (UKHD), National Center for Tumor Diseases, UKHD, HD Ion-Beam Therapy Center (HIT), German Cancer Consortium (DKTK) center HD, Heidelberg, Germany*

Background: Efficacy of PD-L1 immune checkpoint inhibitor therapy in Glioblastoma multiforme (GBM) is limited and the prognostic value of PD-L1 in GBM is an active field of research. We therefore sought to identify a MR based surrogate for PD-L1 expression in GBM. **Methods:** T1 post contrast images (T1ce) acquired immediately before surgery of 121 subjects with primary GBM (RTK I, II and mesenchymal subtype, as determined from Illumina Human Methylation array data) were analyzed. Following standard pre-processing (bias filed correction, brain extraction), 1150 radiomics features were calculated from gross tumor volumes (GTV). The cohort was then divided into training/validation (70%/30%). Cross-validation and model-selection were applied to identify features associated with PD-L1-M expression (estimated from methylation data and highly correlated with PD-L1 RNA-sequencing based measure, as recently reported). Features were used to identify two groups of tumors differing in PD-L1-M expression (PD-L1-R high and low), for which a logistic regression model was trained. Overall survival was assessed between PD-L1-R high/low. **Results:** PD-L1-R high and low groups showed significant differences in PD-L1-M values (training: p=0.002, validation: p=0.04, full cohort: $p<0.001$). The same model was used to split tumors into 2 groups, using features from non-T1ce sequences. All of the tested MR modalities showed at least a trend in PD-L1-M values in the two groups (T2w: p=0.037, T1w: p=0.089, FLAIR: p=0.091). Further investigations on the whole cohort (121 subjects) showed that PD-L1-R low group was enriched for RTK II sub-type (48%), while PD-L1-R high for mesenchymal sub-type (48%). Refer to Table 1 for more information. In addition, evaluation of survival data showed a difference in overall survival (likelihood ratio test p value 0.048, OR 0.52, 95% CI [0.27; 0.98]), with the PD-L1-R high group having a better prognosis. **Conclusions:** We presented a radiomics model PD-L1-R which allowed to identify GBM with low and high PD-L1-M expression from T1 post contrast agent images. Future work should validate these findings in independent cohorts. Research Sponsor: Marie SkÅ‚odowska-Curie grant agreement No. 766276.

GBM tumor sub-types in the two groups identified using the proposed radiomics signature.

	# Subjects	Mean PD-L1-M	# RTK I	# RTK II	# Mesenchymal
PD-L1-R High	60	-3.08	8	23	29
PD-L1-R Low	61	-5.35	17	29	15

The p value between the tumor sub-types in the two groups was 0.015 (calculated using Fisher's test). The results refer to the whole cohort, using features extracted from T1ce images.

Gene fusions in glioblastoma: Results of Gliocat project. *First Author: Ainhoa Hernandez Gonzalez, Institut Catala d'Oncologia Badalona. Applied Research Group in Oncology (B- ARGO Group), Institut Investigació Germans Trias i Pujol (IGTP), Badalona Barcelona, Spain*

Background: Malignant gliomas are heterogeneous diseases in genetic basis. The development of sequencing techniques, such as RNA-Sequencing, has identified many gene rearrangements encoding novel oncogenic fusions. Gene fusion discovery can potentially lead to the development of novel treatments, however studies of gene fusions in glioma remain limited. **Methods:** The GLIOCAT project studied 139 patient samples of newly diagnosed glioblastoma who had received the standard first-line treatment from 2004 to 2015, to identify gene fusion events from glioblastoma transcriptome data (RNA-Seq). The molecular subtype could be studied in 124 cases. RNA-Seq reads were mapped against the reference human genome with STAR-fusion version 0.7.0, specifically, with FusionInspector validate (http://star-fusion.github.io). Two other platforms, FusionHub (https://fusionhub.persistent.co.in) and Oncofuse (www.unav.es/genetica/oncofuse.html), were applied to eliminate false positives or previously described in healthy tissue and to predict of the oncogenic potential each fusion. **Results:** A total of61 patients showed 103 different fusions, a median of two fusions by sample. The majority of gene fusions were intrachromosomal and most frequently implied chromosome was 12 followed by 7. In addition, fusions were more common in patients with MGMT promoter methylation, TCGA classical subtype and 18 IGS subtype. There were no differences in age, sex, type of surgery or long survivors ($>$ 30 months). Ten fusions were already described in cancer, including three in gliomas (FRS2-KIF5A, EGFR-SEPT14 and FGFR3-TACC3). From the detected fusions, 22 of them included an oncogene or protooncogene. **Conclusions:** In our study, we report the landscape of gene fusions from a large data set of glioblastomas analyzed by RNA-seq. The majority of the fusions were private fusions. A minority of these recur in a low frequency but as many as a quarter of them included an oncogene or protooncogene. RNA-seq of GBM patient samples it is an important tool for the identification of patient-specific fusions that could drive personalized therapy. Furtherless, we will plan to validate this gene fusions. Research Sponsor: Carlos III Health Institute, La Fundació La Marató.

Improved risk stratification via integration of radiomics and dosiomics features in patients with recurrent high-grade glioma undergoing carbon ion radiotherapy (CIRT). *First Author: Patrick Salome, CCU Translational Radiation Oncology, German Cancer Research Center (DKFZ), Medical Faculty, Heidelberg (HD) University Hospital (UKHD), National Center for Tumor Diseases, UKHD, HD Ion-Beam Therapy Center (HIT), German Cancer Consortium (DKTK) center HD, Heidelberg, Germany*

Background: Unique radiobiological and physical properties of carbon ion radiotherapy (CIRT) may be favorably utilized to improve outcome in recurrent High-Grade Glioma (rHGG). There are currently no standardized criteria for stratification of rHGG patients for re-irradiation (re-RT). This study evaluated the impact of morphological data (radiomics) and physical information (dosiomics) in stratifying rHGG patients for CIRT. **Methods:** Quantitative radiomics and dosiomics features were extracted from CIRT planning CTs with dose distribution (DD) and multiparametric MRIs (mpMRI, pre re-RT) of 141 patients (recurrent grade III: n=56 40%, grade IV: n=85 60%) treated with a median dose of 42 Gy (RBE) and a median fraction of 13. The MR sequences considered are T1 weighted pre-and post-contrast agent, fluid-attenuated inversion recovery (FLAIR) and apparent diffusion coefficient (ADC). Benefit of a re-RT risk score (RRRS), comprising the initial tumour grade, age and the Karnofsky Performance Score was shown to correlate with superior outcome in CIRT and conventional re-RT and was also studied here in parallel. Feature sets - a) RRRS, b) radiomics, c) dosiomics features - were evaluated both separately and combined. Multiple feature selection methods were used independently on the CT, DD and the MR sequences, followed by a stepwise Cox's Proportional Hazard model selection per modality or combination thereof. Multivariable models were ranked by 10-fold cross-validated concordance index (C-I). **Results:** Compared to the RRRS model (OS/PFS, C-I: 0.68/0.61), the multimodality model considering radiomics and dosiomics features (RD) allowed improved prognostic separation (OS/PFS, C-I: 0.77/0.70). The RD signature consisted of 12 and 10 textural features for the OS and PFS models. Combining the RD model with RRRS yielded the best performance (OS/PFS, C-I: 0.78/0.73). No significant correlation between the textural features and the prescribed dose, tumor grade and volume was found, with the Spearman's correlation coefficient ranging between -0.06 to 0.17. **Conclusions:** Integrating multimodal information outperforms unimodal prognostic separation of rHGG following CIRT, highlighting the importance to consider biological, physical and morphological data for patient stratification. Prospective validation studies of this multimodal stratifier is warranted. Research Sponsor: Funding by the H2020 MSCA-ITN PREDICT project.

A phase I dose-escalation study to evaluate pharmacokinetics, safety and tolerability of ACT001 in patients with advanced glioma. *First Author: Yehui Shi, Tianjin Medical University Cancer Hospital, Tianjin, China*

Background: Management of advanced gliomas including glioblastoma multiforme (GBM) remains as an unmet medical need. Here we report our clinical experience with ACT001, or dimethylamino micheliolide, a synthesized derivative from parthenolide (a natural product of sesquiterpene lactone class), in Han Chinese patients with advanced glioma. **Methods:** Adult patients were enrolled in a 3+3 dose escalation phase 1 study with the following pre-defined ACT001 cohorts: 100mg, 200mg, 400mg, 600mg and 900mg, twice a day (BID). Pharmacokinetics and adverse events were evaluated during the study. Imaging studies were performed using RANO criteria to assess the therapeutic afficacy. **Results:** 16 patients with advanced glioma were enrolled in this single agent dose escalation study including 8 primary GBM, 4 astrocytoma (grade 2-3) and 4 other advanced glioma. The median age was 49 years (range: 31-70). Safety evaluation was performed in five cohorts and 13 of the 16 subjecst were evaluable for drug tolerability analysis. ACT001 was tolerated very well and no DLT or MTD was identified. Other than grade 1 adverse reactions (AE) in most cases and grade 2 AEs in other clinical findings, no drug-related grade 3 AE was noted. Pharmacokinetic analysis indicates that there was approximately linear correlate between the drug exposure (C_{max}, $AUC_{0\text{-}t}$ and $AUC_{0\text{-}inf}$) and study drug dosages evaluated. $T_{1/2}$ is 4 hours with mean Cmax increased from approximate 300ng/ml to 5000ng/ml in a dose dependent manner with no significant dose accumulation during repeated dosing challenge. Post baseline MRI scans were performed in 11 out of 16 subjects. Among these 11 subjects, 1 GBM patient had a partial response (PR) at end of cycle 2 but had disease progressed at end of cycle 4; two non-GBM patients had a stable disease (SD) lasting for 5 or 6 cycles respectively before being taken off study due to disease pregression (PD) and other 8 patients had a PD. Of note, 9 out of these 11 subjects had stable or even improved clinical performance by the time they were taken off study due to PD. Five other subjects withdrew their consents or were taken off study due to clinical disease progression. Of note, subject S12 with diffusive astrocytoma was taken off study due to PD while still with a stable clinilcal performance and stereotactic biopsies targeting the progressed lesion didn't reveal viable tumor tissues other than presence of macrophage/microglia. This subject was still alive 666 days after being taken off study. The mode of ACT001 actions is proposed to be at least partially related to its effects on tumor immune microenvironment. **Conclusions:** ACT001 was safe and tolerated well in patients. Clinical response was observed including a pathologic response in a subset of patients dosed at lower dose cohorts. iRANO criteria will be used in future studies based on its impacts on tumor immune microenvitonment. Clinical trial information: ChiCTR-OIC-17013604. Research Sponsor: Accendatech Co., Ltd.

Pilot trial treating recurrent GBM patients with precision medicine regimens. *First Author: Jennifer Leigh Clarke, University of California, San Francisco, San Francisco, CA*

Background: Recurrence of GBM after initial treatment with surgery, radiation, and chemotherapy is nearly universal. Salvage therapies have limited efficacy with median overall survival (OS) of approximately 9 months and 6-month-progression-free survival (PFS-6) of 10-25% for both targeted and traditional therapies. Given GBM's molecular heterogeneity, targeting a single molecular abnormality in isolation has consistently failed as a strategy, and precision combination approaches are needed. **Methods:** The primary objective was to demonstrate the feasibility of implementing a personalized drug regimen for patients (pts) with surgically resectable recurrent GBM within 35 days of surgery. Secondary objectives included safety and efficacy. Eligible pts signed consent before surgery, and tumor tissue was analyzed using the CLIA-approved "UCSF500" next-generation sequencing panel with paired tumor/germline sequencing. A specialized genomic tumor board made individualized treatment recommendations incorporating sequencing results of the recurrent tumor and clinical history for each pt, using up to 4 FDA-approved drugs in combination (all drugs provided by study). Correlative studies will be reported separately. **Results:** 19 pts signed consent and 16 pts had surgery on trial, 1 with pathology showing treatment effect only. The remaining 15 pts were all genetically profiled and successfully started their individualized treatment within 35 days of surgery, meeting the primary feasibility endpoint. **Conclusions:** Implementation of an individualized treatment regimen was feasible in a timely fashion in surgically resectable recurrent GBM pts, with encouraging preliminary efficacy results. Further investigation is warranted, both to validate efficacy and to streamline this approach in larger pt populations. Clinical trial information: NCT03681028. Research Sponsor: Glioma Precision Medicine Program.

Drug Used	(Epi)Genetic alteration	# of pts treated
Afatinib	EGFR amplification +/- mutation or rearrangement	10
Abemaciclib	CDKN2A/B deletion or CDK4 amplification	8
Olaparib	ATRX loss or MGMT hypermethylation	5
Everolimus	PTEN loss +/- PIK3CA mutation	5
Trametinib	NF1 loss	2
Propranolol	TP53 mutation	1

$ATRX^{Loss}$ to impair glioma stem cell viability and self-renewal via proton radiotherapy induced necrosis. *First Author: Angel Garces, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Glioblastoma Multiforme (GBM-Grade IV) is the most aggressive form of glioma in the USA carrying only a 15 month median survival time. Although $IDH1^{R132H}$ is traditionally associated with improved glioma patient survival and clinical response to chemotherapy, astrocytoma (LGG) patients also harbor $ATRX^{Loss}$, an inactivation of the ATRX chromatin remodeling protein shown to impair DNA damage repair via non-homologous end joining. The recent discovery of glioma stem cells (GSCs), a subpopulation of chemoradioresistant, self-renewable, tumor initiating cells known to promote tumor recurrence, presents a new target for therapeutic intervention. However, the mechanisms by which $ATRX^{Loss}$ contributes to GSC proton radiotherapy (PRT) sensitivity, a more tumor specific and cytotoxic form of radiation therapy than conventional X-rays (XRT), are not well understood. *We hypothesize that $ATRX^{Loss}$ impairs GSC post-radiation viability and self-renewal capacity by promoting necrosis to a higher extent after PRT than XRT.* **Methods:** Isogenic TS543-$ATRX^{WT}$ and TS543-$ATRX^{Loss}$ patient derived glioma cells were cultured as neurospheres and treated with 2-8 Gy XRT or PRT. GSC viability was quantified using the CellTiterGlo 3D assay 12 days after irradiation. The Annexin V apoptosis and necrosis assay was conducted every 8 hours up to 72 hours after irradiation. GSC self-renewal, based on neurosphere formation frequency, was quantified using extreme limiting dilution analysis (ELDA). **Results:** $ATRX^{Loss}$ significantly decreased TS543 GSC viability after 2-8 Gy radiation therapy compared to $ATRX^{WT}$ (Unpaired t-test with Welsh's correction and Holm-Sidak's Multiple Comparisons Test $p<0.0001$). TS543-$ATRX^{Loss}$ also significantly inhibited GSC self-renewal over TS543-$ATRX^{WT}$ when subject to either 6 Gy PRT or XRT (Pairwise $Pr(>\chi^2)<0.01$). Interestingly, PRT significantly reduced GSC viability to a higher extent than XRT in both TS543-$ATRX^{WT}$ and TS543-$ATRX^{Loss}$, which demonstrates the effectiveness of PRT to treat $ATRX^{Loss}$ gliomas. Follow up studies confirmed that $ATRX^{Loss}$ sensitizes TS543 GSCs more extensively to the cytotoxic effects of PRT compared to XRT via the upregulation of necrosis at 72 hours post-irradiation (Two-way ANOVA with Tukey's post-hoc Multiple Comparisons Test $p<0.0001$). **Conclusions:** We conclude that $ATRX^{Loss}$ substantially contributes to PRT sensitivity in GSCs, thereby supporting the benefits of PRT for astrocytoma patients. Our future experiments will further elucidate the biological mechanisms by which $ATRX^{Loss}$ confers PRT sensitivity, especially via dsDNA damage. Research Sponsor: U.S. National Institutes of Health.

Evaluation of GM-CSF and $AS01_B$ adjuvants in a phase I/IIa trial of a therapeutic CMV vaccine (VBI-1901) against recurrent glioblastoma (GBM). *First Author: Patrick Y. Wen, Dana-Farber Cancer Institute, Boston, MA*

Background: Cytomegalovirus (CMV) antigens have been reported in over 90% of GBMs. $CD4^+$ and $CD8^+$ T cells are most frequently directed against the gB and pp65 antigens, respectively, and are immunogenic targets in a CMV-based GBM vaccine. **Methods:** We enrolled a total of 20 patients with KPS at least 70 and first recurrence of GBM into 2 arms of the Phase IIa extension of gB/pp65 enveloped virus-like particles (eVLPs) adjuvanted with either GM-CSF given intradermally or with $AS01_B$ given intramuscularly (NCT03382977). Patients were vaccinated with VBI-1901 every 4 weeks, with serologic immune-monitoring 2 weeks after each vaccination and surveillance brain MRI scans every 6 weeks. **Results:** 10 patients (6 women, 4 men) with a median age of 58 (33-67 yrs) were enrolled into the GM-CSF arm and 10 patients (3 women, 7 men) with a median age of 65 (40-67) enrolled into the $AS01_B$ arm. Disease control rates of 40% and 50% were observed in the GM-CSF and $AS01_B$ arms, respectively, with 2 sustained PRs in the GM-CSF arm. The 6-month OS rate for the GM-CSF arm is 80% and is estimated to be comparable for the $AS01_B$ arm. CMV-specific CD4+ effector memory T cells may correlate with tumor responses in both arms of the study, with $AS01_B$ boosting higher frequencies of these cells regardless of baseline CD4/CD8 ratio. **Conclusions:** These encouraging results from both arms of the trial justify further clinical evaluation in a randomized, controlled trial expected to begin later in 2021. Clinical trial information: NCT03382977. Research Sponsor: VBI Vaccines Inc, Pharmaceutical/Biotech Company, U.S. National Institutes of Health, William Rhodes and Louise Tilzer-Rhodes Center for Glioblastoma at NewYork-Presbyterian Hospital.

Targeted agents recommended by the CNS TAP tool compared to those selected by a tumor board in a molecularly-driven clinical trial in children and young adults with DIPG. *First Author: Holly Roberts, University of Michigan Medical School, Ann Arbor, MI*

Background: Genetic sequencing of diffuse intrinsic pontine glioma (DIPG) and diffuse midline glioma (DMG) biopsy specimens has revealed genomic heterogeneity, fueling an interest in individualized, targeted treatment options. The Pacific Pediatric Neuro-Oncology Consortium recently completed a feasibility study PNOC003: Molecular Profiling for Individualized Treatment Plan for DIPG (NCT02274987), in which a multidisciplinary tumor board recommended targeted agents based on the molecular and genetic profiling of each patient's tumor. Separately, our group developed a numeric scoring tool of targeted anticancer agents, the Central Nervous System Targeted Agent Prediction (CNS TAP) tool, which combines pre-clinical, clinical, and CNS penetration data with patient-specific genomic information to generate a numeric score for each agent to objectively evaluate these targeted therapies for use in patients with CNS tumors. We hypothesized that highly-scored agents within the CNS-TAP tool would overlap, at least in part, with the agents recommended by the molecular tumor board in PNOC003. **Methods:** For each study participant (n=28), a retrospective analysis was completed, utilizing the genomic report to identify actionable genetic alterations and to input patient-specific data into CNS TAP to identify the highest scoring agents. We compared high-scoring agents within the CNS TAP tool with recommendations from the PNOC003 tumor board for each of the enrolled 28 patients. **Results:** Overall, 93% (26/28) of patients had at least one agent recommended by both the tumor board and CNS TAP. Additionally, 39% (37/95) of all agents recommended by the tumor board were also selected by CNS TAP, with additional analysis ongoing. **Conclusions:** There was significant overlap between the highest-scoring and selected agents via CNS TAP compared with those chose by the molecular tumor board. Through this work, we also identified factors that likely contributed to the discordance in choice of targeted therapies. Without clinician input, the CNS TAP tool is unable to account for drug-drug interactions, includes only designated anticancer agents, and cannot easily be updated in real time, requiring extensive manual literature review for each included agent. However, CNS TAP provides an objective evaluation of targeted therapies, in contrast to inherently subjective recommendations of a tumor board. Given the discordance identified between these methods and the strengths of each, a prospective study incorporating both CNS TAP and a molecular tumor board for targeted therapy selection in patients with high grade glioma is warranted. Research Sponsor: None.

2049 **Poster Session**

A phase I/IIa study to evaluate the safety and efficacy of blood-brain barrier (BBB) opening with the SonoCloud-9 implantable ultrasound device in recurrent glioblastoma patients receiving IV carboplatin. *First Author: Ahmed Idbaih, Inserm U 1127, Cnrs Umr 7225, Sorbonne Universités, UPMC Univ Paris 06 Umr S 1127, Institut Du Cerveau Et De La Moelle Épinière, ICM, Paris, France*

Background: Low intensity pulsed ultrasound (LIPU) in conjunction with intravenous microbubbles can transiently and reversibly disrupt the blood-brain barrier (BBB), allowing for an increase in the tissue concentration of chemotherapy agents in the brain. Mass spectrometry data from preclinical models (mouse, swine) showed a $>$ 5x enhancement in carboplatin brain concentrations, which correlated well with the spatial distribution of a Gadolinium (Gd) contrast agent used for magnetic resonance imaging (MRI). **Methods:** The primary objective of this phase I/IIa study (NCT03744026) was to demonstrate the safety of BBB disruption using LIPU in patients with recurrent glioblastoma. This study was a 3+3 design using escalating numbers (3, 6, 9) of activated 1 MHz ultrasound emitters. Nine patients were treated in the escalation phase and another 12 patients were treated with 9 emitters in the expansion phase. Eligibility included recurrent GBM (any recurrence) with a maximum tumor size of $<$ 70 mm. The SonoCloud-9 device (CarThera, Paris, France) was implanted during tumor debulking/resection surgery and replaced the bone flap, with the device targeting the tumor and surrounding peritumoral brain. The device was activated every four weeks for a duration of 270 seconds, concomitantly with IV DEFINITY microbubbles (10 ml/kg), to disrupt the BBB prior to administration of carboplatin (AUC 4-6). MRI was performed to verify safety and evaluate efficacy of BBB disruption with Gd enhancement. **Results:** No DLTs were observed. The overall tolerance of the SonoCloud-9 implant was good, with two transient, manageable grade 3 wound infections and one grade 1 acquired meningocele event considered as probably related to the overall procedure. The most frequent neurologic adverse events were grade 1 blurred vision (5%) and dizziness (5%). **Conclusions:** Significant Gd enhancement was observed after more than 90% of sonication sessions, suggesting effective BBB disruption and carboplatin enhancement. Clinical trial information: NCT03744026. Research Sponsor: CarThera.

2051 **Poster Session**

Malignant glioma subset from Actuate 1801: A phase 1/2 study of 9-ING-41, a glycogen synthase kinase 3 beta (GSK-3β) inhibitor, as a single agent and combined with chemotherapy, in patients with refractory hematologic malignancies or solid tumors. *First Author: Yazmin Odia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: GSK-3β, a serine/threonine kinase, is a key regulator of metabolism and glycogen biosynthesis. GSK-3β aberrant overexpression promotes tumor progression and chemotherapy resistance through NF-κB and p53-mediated apoptotic pathways. GSK-3β inhibition impacts immunomodulation through downregulation of checkpoints, such as PD-L1 and LAG-3, and increasing NK and T-cell mediated killing of tumor cells. 9-ING-41 is a small-molecule potent selective GSK-3β inhibitor with preclinical antitumor activity against several tumor types. In chemoresistant PDX models of glioblastoma (GBM), 9-ING-41 enhanced the antitumor effect of CCNU and CPT-11. **Methods:** In the first-in-human study (NCT03678883), patients (pts) with refractory malignancies received 9-ING-41 monotherapy (n = 65) or in combination with one of 8 cytotoxic regimens after prior treatment with the same chemotherapy (n = 162). We report the subset of pts with recurrent gliomas treated with 9-ING-41 monotherapy IV twice a week in 21-day cycles at different dose levels (3.3, 5, 9.3, 15mg/kg), or in combination with lomustine 30 mg/m^2 orally once weekly in 84-day cycles. Primary objective was safety and tolerability. **Results:** An RP2D of 15mg/kg IV was confirmed across all 9 regimens, no accentuation of chemotherapy-related toxicity noted. Of 18 glioma patients enrolled, 13 were GBM, 2 anaplastic astrocytomas, 1 diffuse astrocytoma, and 1 anaplastic oligodendroglioma. Four patients received single agent 9-ING-41, 14 treated concurrently with lomustine. Demographics: 6 female, 12 male; median age 52 (30-69) years; median ECOG was 1 (0-2). All received first-line radiation and temozolomide (18/18), prior therapies for recurrences included nitrosoureas (15/18), bevacizumab (8/18), TTFields (6/18), immune checkpoint inhibitor (4/18). Median recurrences 3 (1-6). Genomic alterations from available NGS reports included: IDH WT (11), IDH mutation (3), MGMT promoter unmethylated (11), MGMT promoter methylated (1), 1p19q co-deletion (10), EGFR amplification (6), EGFR v3 mutation (3), TERT promoter mutation (6), PTEN loss (3), NF1 rearrangement (2), ATRX loss (2), TP53 mutated (4), CDKN2A deletion (2), RB1 loss (1), PALB-2 mutation (10). No SAEs or grade 3/4 AEs attributed to 9-ING-41 were noted; AEs included G1/2 transient vision changes (9/18, 50%), infusion reactions (4/18, 22%). Side effects from lomustine included: G3/4 thrombocytopenia (3/14, 21%), and G1/2 fatigue (4/14, 28%). Best overall response: 1 minimal response (-43%) after 2 cycles of 9-ING-41 and lomustine. Median days on therapy was 55 (4-305), 4/18 (22%) were stable for 20 weeks or longer. **Conclusions:** These results show 9-ING-41 alone or in combination is safe and warrants further study in glioma patients. Clinical trial information: NCT03678883. Research Sponsor: Actuate Therapeutics.

2053 **Poster Session**

The clinical significance of telomerase reverse transcriptase (*TERT*) promoter mutations, telomere length and O6-methylguanine DNA methyltransferase (*MGMT*) promoter methylation status in newly diagnosed and recurrent *IDH*-wildtype glioblastoma (GBM) patients (PTS): A large mono-institutional study. *First Author: Giuseppe Lombardi, Department of Oncology, Oncology 1, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: the clinical significance of *TERT* promoter mutations, telomere length and their interactions with *MGMT* promoter methylation status in patients with *IDH*-wildtype GBM patients remain unclear. We performed a large mono-institutional study to better investigate their impact and their interaction on clinical outcomes **Methods:** *TERT* promoter mutations (C228T and C250T), relative telomere length (RTL) and *MGMT* methylation status were assessed in 278 newly diagnosed and in 65 recurrent *IDH*-wildtype GBM PTS which were treated at Veneto Institute of Oncology (Padua, Italy) from Dec 2016 to Jan 2020. We have retrospectively explored association between gene characteristics and neuroradiological response (RANO criteria), progression-free survival (PFS), overall survival (OS). Telomere length was measured by monochrome multiplex PCR and RTL values were calculated as a telomere/single-copy gene ratio **Results:** characteristics of newly diagnosed GBM PTS were: median age 63 ys, ECOG PS 0-1 in 71% of PTS, radical surgery in 38%, 78% received radiation therapy plus TMZ, *MGMT* was methylated in 53%, *TERT* promoter was mutated in 80% (75% C228T, 25% C250T), median RTL was 1.57 (range 0.4-11.37). Objective response rate was reported in 15% of PTS, median OS was 15ms (95% CI 13-18ms), median PFS was 8ms (95% CI 7-9ms). At multivariable analysis, *TERT* promoter mutations and RTL were not associated with clinical outcomes; about OS, *TERT* promoter mutations and RTL reported a HR of 1.05 (95% CI 0.64-1.64) and 0.99 (95% CI 0.89-1.10), respectively; *MGMT* methylated tumors showed significant improved PFS and OS with a HR of 0.54 (95% CI 0.40-0.71) and 0.47 (95% CI 0.34-0.64), respectively. All interactions among *MGMT* status, *TERT* mutation status and RTL were not statistically significant. Characteristics of recurrent GBM PTS were: median age 55 ys, ECOG PS 0-1 in 60% of PTS, *MGMT*met in 37%, TERT promoter mutations in 75% (75% C228T, 25% C250T), RTL was 1.67 (range 0.68-8.87). At multivariable analysis, only *MGMT* methylated tumors resulted significantly associated to prolonged OS (HR 0.16; 95% CI 0.07-0.40). No gene interaction was significant. **Conclusions:** for the first time worldwide, we analyzed the impact of *TERT* promoter mutations, RTL and *MGMT* methylation status in both newly diagnosed and recurrent *IDH*-wildtype GBM PTS. *TERT* promoter status and RTL were not associated with clinical outcomes at both diagnosis and relapse. *MGMT* promoter methylation status was the only prognostic factor in both cases. No significant interaction was demonstrated between *TERT* promoter mutations, RTL and *MGMT* methylation status. Research Sponsor: None.

2054 **Poster Session**

Resection and surgically targeted radiation therapy for locally recurrent GBM. *First Author: David Brachman, GT Medical Technologies, Tempe, AZ*

Background: Recurrent GBM (rGBM) is a diffuse disease, and resection (R) alone does not provide durable local control (LC) or prolong overall survival (OS). Hypothesizing R plus immediate radiation (RT) may achieve durable LC and secondarily improve OS by permitting time for subsequent potentially effective but biologically slower treatments to have an impact, we prospectively evaluated R combined with a novel surgically targeted radiation therapy (STaRT) device utilizing Cs-131 embedded in bioresorbable collagen tiles. **Methods:** From 2/13-2/18 patients (pts) with locally recurrent GBM were treated on a prospective single arm trial (ClinicalTrials.gov, NCT#03088579) of maximum safe resection and immediate RT (GammaTile, GT Medical Technologies, Tempe AZ). Upon resection the at-risk areas of the surgical bed were lined with the GammaTile (GT) device, delivering 60-80 Gy at 5 mm. Follow up treatments were not specified but captured; no pt. underwent additional local therapy without progression, and no pt. was lost to follow up. We present study specified endpoints of local control (LC), overall survival (OS), and adverse events (AE), and a post hoc, hypothesis-generating analysis of outcomes by receipt of systemic (Sys) therapy. **Results:** 28 locally recurrent GBM were treated, 20 at first progression (range 1-3). Median age was 58 years (yrs.) (range 21-80), KPS 80 (60-100), female: male ratio 10:18 (36/64%). MGMT was methylated in 11%, unmethylated in 18%, and unknown in 71%. For all pts., median OS was 10.7 months (mo.) (range .1-42.3), and radiographic LC was 8.8 mo. (range .01-34.5). LC (defined as $<$ 15 mm from surgical bed) was maintained in 50% of pts., and no first failure was local. 12 mo. OS was 75% for pts. $<$ 50 yrs. vs. 43% for $>$ 50 yrs. (HR .46, p = .009). MGMT, KPS, and sex were non-predictive. After R+GT, 17 pts. received $>$ 1 cycle of systemic therapy (Sys), either as adjuvant or salvage, alone or in combination. Sys was bevacizumab (BEV) in 15 pts., temozolomide (TMZ) in 12, and lomustine (CCNU) in 8 (N $>$ 17 as some pts. received $>$ 1 Sys). Post hoc analysis disclosed a 15.1 mo. OS for pts. receiving $>$ 1 cycle of Sys (Sys+, N = 17) vs. 6.5 mo. for no Sys (Sys-, N = 11) (hazard ratio (HR) .38, p = .017)). LC was 11.4 mo. for Sys+ and 2.1 mo. for Sys- (HR .44; p = .16)). Median OS (mo.) for BEV+ vs. BEV- was 16.7/4.5 (HR .38, p = .017), for TMZ+ vs. TMZ- 17.5/6.7 (HR .40, p = .025) and for CCNU+ vs. CCNU- 17.5/7.9 (HR .61, p = .25), respectively. Three attributed AE occurred, 1 dehiscence requiring surgery and 2 radiation brain effects, medically treated. 4 unrelated deaths occurred $<$ 60 days post-op, all in the Sys- cohort, impacting their opportunity for subsequent treatment. **Conclusions:** In this study local treatment alone was insufficient to achieve prolonged OS. Post hoc analysis suggests R+GT coupled with Sys may have potential to impact OS in rGBM patients. GT was FDA cleared in 2020 for use in newly diagnosed malignant and all recurrent intracranial neoplasms. Clinical trial information: NCT#03088579. Health-related quality of life for glioblastoma short and long-term survivors receiving treatment with TTfields. *First Author: Joshua David Palmer, The James Cancer Hospital at The Ohio State University, Columbus, OH*

Background: The aim of this study was to administer the first large-scale, international survey eliciting real-world patient-reported quality-of-life (QoL) for patients with newly diagnosed and long-term glioblastoma (GBM) currently receiving treatment with TTFields. **Methods:** A survey was designed and mailed to 2,815 patients actively using TTFields for treatment of GBM in the United States (US, n = 2,182) and Europe (EU, n = 633). The survey included 1) demographic information, 2) patient-reported clinical information and 3) EuroQol's EQ-5D-5L and EQ visual analogue scale (EQ-VAS) surveys. Univariate and multivariate analyses were performed on five dimensions (mobility, self-care, usual activity, pain/discomfort, anxiety/depression) of the EQ-5D-5L and EQ-VAS to understand the impact of patient demographics and clinical characteristics on QOL. **Results:** A total of 1,106 patients were included (39.3% response rate) with 782 and 324 responses in the US and EU, respectively. The median time from diagnosis was 14 mos (range, 0-301 mos) and ≥24 mos in 28.4% of patients. Patients were mostly male (62.3%) with a mean age of 58.5 (SD = 12.5) and 69.3% had stable disease. Mean EQ-VAS was 68.2 for all patients and was significantly higher for those with $>$ 15 months since diagnosis compared to $<$ 15 months since diagnosis (p = 0.008). There were significantly fewer problems reported on self-care (p = 0.04) and usual activity (p = 0.007) in patients with a longer time since diagnosis in the univariate analysis. In the multivariate analysis, patients with a longer time since diagnosis reported significantly better EQ-VAS (p = 0.04). The effect size in the multivariate analysis for time since diagnosis on EQ-VAS was higher in the progressed subgroup (p = 0.17) compared to the broader sample (0.08). The EQ-VAS and all five dimensions including mobility, self-care, usual activity, pain/discomfort, and anxiety/depression were improved for stable patients compared to progressed patients in the univariate and multivariate analyses. However, when stratified by progression status, progressed patients with longer time from diagnosis had significantly fewer reported problems with mobility (p = 0.04), self-care (p = 0.004) and usual activity (p = 0.008), and significantly better self-rated health status (p = 0.02). **Conclusions:** GBM survivors receiving TTFields reported significantly improved health status over time since diagnosis. Long-term survival with TTFields does not have a detriment in patient reported quality of life, in fact with longer time from diagnosis QOL significantly improves. This is true for patients with stable and progressed disease. Future prospective clinical trials are needed to further study the impact of our treatment and tumor progression on patient QOL. 2056 **Poster Session**

Scalp-sparing radiation with concurrent temozolomide and tumor treating fields (SPARE) for patients with newly diagnosed glioblastoma. *First Author: Ryan C Miller, Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA*

Background: Standard of care for patients with newly diagnosed glioblastoma includes concurrent chemoradiation and maintenance temozolomide with Tumor Treating Fields (TTFields). Preclinical studies suggest TTFields and radiation treatment have synergistic effects. We report our clinical trial evaluating safety and tolerability of scalp-sparing radiation with concurrent temozolomide and TTFields. **Methods:** This is a single arm pilot study. Adult patients (age ≥ 18 years) with newly diagnosed glioblastoma and a KPS of ≥ 60 were eligible. All patients received concurrent scalp-sparing radiation (60 Gy in 30 fractions) with temozolomide (75 mg/m2 daily) and TTFields (200 kHz). Maintenance therapy included temozolomide and continuation of TTFields. Radiation treatment was delivered through TTFields arrays. The primary endpoint was safety and toxicity of TTFields concurrent with chemoradiation in patients with newly diagnosed glioblastoma. **Results:** A total of 30 patients were enrolled in the trial. Twenty were male and ten were female, with a median age of 58 years (range 19 to 77 years). Median KPS was 90 (range 70 to 100). Median follow-up was 8.9 months (range 1.6 to 21.4 months). Twenty (66.7%) patients had unmethylated MGMT promotor status and ten (33.3%) patients had methylated promoter status. Median time from surgery to radiation was 34 days (26 to 49 days). Scalp dose constraints were achieved for all patients, with the mean dose having a median value of 8.3 Gy (range 4.3 to 14.8 Gy), the D20cc median was 26.1 Gy (range 17.7 to 42.8 Gy), and the D30cc median was 23.5 Gy (range 14.8 to 35.4 Gy). Skin adverse events (AEs; erythema, dermatitis, irritation, folliculitis) were noted in 83.3% of patients, however, these were limited to Grade 1 or 2 events, which resolved spontaneously or with topical medications. No patient had radiation treatment interruption due to skin AEs. Other Grade 1 events included pruritus (33.3%), fatigue (30%), nausea (13.3%), headache (10%), dizziness (6.7%), and cognitive impairment (3.3%). Other Grade 2 events included headache (3.3%). Nineteen patients (63.3%) had progression, with a median PFS of 7.6 months (range 1.6 to 12.7 months). Overall survival was not reached. **Conclusions:** Concurrent TTFields (200 kHz) with scalp-sparing chemoradiation is a safe and feasible treatment option with limited toxicity. Future randomized prospective trials are warranted to define therapeutic advantages of concurrent TTFields with chemoradiation. Clinical trial information: NCT03477110. Research Sponsor: None.

2057 **Poster Session**

Phase 1 trial of drug resistant immunotherapy: A first-in-class combination of MGMT-modified $\gamma\delta$ t cells and temozolomide chemotherapy in newly diagnosed glioblastoma. *First Author: Louis B. Nabors, University of Alabama at Birmingham, Birmingham, AL*

Background: Temozolomide (TMZ) transiently upregulates NKG2D ligands targeted by innate immune effector cells. Lymphodepletion impairs this immune response, however, genetic modification of *ex vivo* expanded $\gamma\delta$ T cells with an MGMT-expressing lentivector confers resistance to TMZ, allowing concurrent chemotherapy and $\gamma\delta$ T cell infusion, thereby targeting the tumor when NKG2DL are maximally expressed. This Drug Resistant Immunotherapy (DRI) is currently being evaluated in a Phase 1 first in human study (NCT04165941) and interim safety and biologic correlative analysis are detailed here for the first dosing cohort. **Methods:** Adults with newly diagnosed, untreated glioblastoma (GBM), adequate organ function, and a KPS≥70% will be enrolled. Subjects undergo subtotal resection and placement of a Rickham reservoir followed 3-4 weeks by apheresis from which $\gamma\delta$ T cells are expanded, transduced with an MGMT-expressing lentivector, harvested, and cryopreserved. Standard of care induction TMZ/radiation therapy is initiated followed by 6 cycles of maintenance TMZ. Intravenous TMZ (150mg/m^2) and intracranial dosing of 1 x 10^7 $\gamma\delta$ T cells occur on day 1 of each maintenance cycle. Daily oral TMZ 150mg/m^2 follows for Days 2-5. Dose level 1 (DL1) subjects receive 1 fixed dose of $\gamma\delta$ T cells and DL2 receive 3 doses administered on Day 1 of each of first 3 cycles of TMZ dependent on absence of dose limiting toxicity. Primary endpoint is safety; secondary endpoints include progression free and overall survival. Immunologic and genomic correlative analyses are being conducted at specific time points from peripheral blood and cerebral spinal fluid collected from the Rickham. **Results:** Six subjects (4 females, 2 males) have been enrolled in DL1. All subjects were IDH1-WT with 5 subjects MGMT unmethylated and 1 methylated. Of these, 1 generated inadequate gd T cells and 2 withdrew consent prior to DRI treatment. For the 3 that received DRI, treatment-related adverse events with maximum CTCAE Grade 3 occurred in 1 subject; UTI, dehydration, and thrombocytopenia. The most common Grade 1/2 events included: fever, leukopenia, nausea, and vomiting which were attributable to TMZ or radiotherapy. Circulating T cells remained below normal range throughout maintenance phase in 2/3 subjects. NK and gd T cell numbers remained within low normal range for 3/3 and 2/3 subjects, respectively. Serum Th1 (IFNg, IL-2, TNFa) and Th2 (IL4, IL5, IL-10) cytokines were within clinical range although TNFa remained elevated from the gdT cell infusion through day +30 in 2 subjects. **Conclusions:** Administration of MGMT-gene modified gdT cells and TMZ as DRI is feasible in lymphodepleted subjects during TMZ maintenance phase and sufficiently safe to warrant further investigation at additional doses. Clinical trial information: NCT04165941. Research Sponsor: In8-bio Inc.

Cost-effectiveness of concomitant and adjuvant temozolomide for glioblastoma patients with unmethylated O^6-methylguanine-DNA methyltransferase promoter regions in the United States. *First Author: Manav Dev Midha, Department of Economics, Case Western Reserve University, Cleveland, OH*

Background: Promoter region methylation of the O^6-methylguanine-DNA methyltransferase (MGMT) gene has emerged as a predictive factor for longer overall (OS) and progression-free (PFS) survival response to concomitant and adjuvant temozolomide (TMZ) chemotherapy in glioblastoma. Recently, several investigators have suggested the small survival benefit of TMZ for unmethylated patients is insufficient to warrant the increased risk of adverse events and that these patients should instead be enrolled in clinical trials. This study informs the debate by estimating the incremental costs and benefits associated with TMZ use in methylated and unmethylated patients based on available published evidence. **Methods:** Published OS and PFS Kaplan-Meier curves were digitized, parameterized, and extrapolated to ten years. Partitioned Survival Analysis trees were constructed in TreeAge Pro 2020. Costs of TMZ, RT, and inpatient hospitalization were included, among others. It was assumed that all patients receive surgery prior to beginning radiation, and that RT and TMZ (six adjuvant cycles) dosing was standard. Published utilities associated with the progression-free and post-progression health states, subject to each treatment, were used. A 3% annual discount rate and a willingness-to-pay of $150,000/quality-adjusted life year (QALY) were assumed. Probabilistic sensitivity analysis (PSA) was conducted. **Results:** In methylated patients, RT + TMZ versus RT is associated with $67,622 in additional costs and 10.91 additional quality-adjusted life months (QALMs). In unmethylated patients, RT + TMZ versus RT is associated with $9,203 in additional costs and 2.24 additional QALMs. The implied incremental cost effectiveness ratios (ICERs) support TMZ use in both populations and suggest it is more favorable for unmethylated patients ($74,378/QALY and $49,302/QALY for methylated and unmethylated patients, respectively). However, the incremental net monetary benefit (INMB) associated with TMZ use is substantially smaller for unmethylated patients ($18,797 versus $68,753) due to the smaller survival gains for this population. PSA results indicate that TMZ is more likely to be cost-effective for methylated (89.3%) than unmethylated (77.4%) patients. **Conclusions:** Post-radiation clinical trial enrollment should be considered instead of TMZ for unmethylated glioblastoma patients. While the estimated ICER justifies the use of TMZ for unmethylated patients – in fact, does so more strongly than for methylated patients – the relatively small incremental health benefit is plausibly outweighed by the opportunity cost of not enrolling these patients in clinical trials that offer the possibility of more substantive gains to current and future glioblastoma patients. Comprehensive molecular pharmacodynamic assessment identifies response markers of intermediary metabolism associated with BPM 31510-IV treatment in advanced glioblastoma multiforme patients. *First Author: Seema Nagpal, Stanford University, Stanford, CA*

Background: BPM 31510-IV is a drug-lipid conjugate nanodispersion containing oxidized Coenzyme Q10 (CoQ10) in clinical development for glioblastoma multiforme (GBM). In a recently concluded Phase 1 study of BPM 31510-IV (NCT03020602), in addition to safety and tolerability, longitudinal pharmacodynamic samples (20 samples/cycle of 28 days) were collected at various times in patient's refractory to radiation, temozolomide, and bevacizumab. **Methods:** Comprehensive multi-omic (proteomic, lipidomic, metabolomic) profiles were generated from buffy coat (proteomics only), plasma, and urine matrices. These data were further analyzed using bAIcis, a Bayesian statistics based artificial intelligence (AI) software, creating causal networks linking clinical information and endpoints to molecular composition of diverse biomatrices of patients prior to, as well as during, treatment with BPM 31510-IV. Twelve subjects comprised the intent to treat population (ITT) which were stratified across days of treatment (DR1; $\leq$28 days; DLT period; n=6) and (DR2, OS; $>$28 days; n=6). Bayesian networks and regression analysis were performed on the outputs of the analysis. Molecular analyte panels (combination of proteins, lipids, and metabolites) descriptive of progression free survival (PFS), adverse events (possibly/probably related to BPM 31510-IV), and of overall survival (OS) were generated. **Results:** Significant alteration ($p<0.05$) of metabolically associated protein and critical metabolite drivers of intermediary metabolism were identified as causally related to PFS. Significant quantitative changes in levels of several proteins (buffy coat) and metabolites (urine) were identified with probable or possible associations to adverse events in BPM 31510-IV treated subjects. **Conclusions:** Overall, alterations in proteins and metabolites influencing mitochondrial function and intermediary metabolism that differentiated responders versus non-responders and identified potential markers of adverse events associated with BPM 31510-IV exposure were identified and will be further explored for complementary diagnostic utility. Research Sponsor: BERG LLC.

2060 **Poster Session**

Phase I study of ruxolitinib with radiation and temozolomide in patients with newly diagnosed grade III gliomas and glioblastoma. *First Author: Yasmeen Rauf, Cleveland Clinic, Cleveland, OH*

Background: Ruxolitinib is a novel, potent, and selective inhibitor of JAK1 (Janus kinase 1) and JAK2 with modest to marked selectivity against TYK2 (tyrosine kinase 2) and JAK3, respectively. Ruxolitinib interferes with the signaling of a number of cytokines and growth factors that are important for hematopoiesis and immune function. JAK signaling involves recruitment of signal transducers and activators of transcription (STATs) to cytokine receptors, activation, and subsequent localization of STATs to the nucleus leading to modulation of gene expression. Dysregulation of the JAK/STAT pathway has been associated with several types of cancer and increased proliferation and survival of malignant cells. **Methods:** Newly diagnosed patients with unmethylated MGMT Glioblastoma or grade III glioma were recruited to Arm 1. Every patient received ruxolitinib and 60 Gy radiation for 6 weeks over 6 weeks (2Gy x 30). The dose of Ruxolitinib was administered given the 3+3 design. Level 1 or starting dose was 10 mg twice daily, level 2 was 15 mg twice daily, level 3 was 20 mg twice daily and level -1 was 5 mg twice daily. Arm 2 was started once safe dose was established for Arm 1 for each dose level. Patients with methylated MGMT glioblastoma or grade III glioma were eligible for Arm 2. Every patient received ruxolitinib + radiation x 60 Gy + daily temozolomide at 75 mg/m2 for 6 weeks over 6 weeks. Overall survival (OS) and progression-free survival (PFS) were estimate by Kaplan-Meier method and compared using log rank test. **Results:** 45 patients had survival data, 25 patients were Arm I and 20 arm II. The median OS and PFS were 18.2 (95% CI: 3.6-NA) months for Arm 1 and were not reached for Arm 2. OS and PFS Rate at 1 year was 61% (95% CI: 43-85%) and 51% (35-76%) for Arm 1, and 95% (85-100%) for Arm 2 ($p = 0.01$ and $p = 0.002$), respectively. **Conclusions:** Patients that received ruxolitinib + radiation x 60 Gy + daily temozolomide at 75 mg/m2 for 6 weeks over 6 weeks (Arm 2) had significantly better PFS and OS than those that received ruxolitinib + radiation x 60 Gy alone. Clinical trial information: NCT03514069. Research Sponsor: Case Comprehensive Cancer Center.

Safety and feasibility of rhenium-186 nanoliposome (^{186}RNL) in recurrent glioma: The ReSPECT phase 1 trial. *First Author: Andrew J. Brenner, University of Texas Health San Antonio Cancer Center, San Antonio, TX*

Background: While external beam radiation therapy (EBRT) remains a central component of the management of primary brain tumors, it is limited by tolerance of the surrounding normal brain tissue. Rhenium-186 NanoLiposome (^{186}RNL) permits the delivery of beta-emitting radiation of high specific activity with excellent retention in the tumor. We report the results of the phase 1 study in recurrent glioma. **Methods:** A Phase 1 dose-escalation study of ^{186}RNL in recurrent glioma utilizing a standard 3+3 design was undertaken to determine the maximum tolerated dose of ^{186}RNL. ^{186}RNL is administered by convection enhanced delivery (CED). Infusion is followed under whole body planar imaging and SPECT/CT. Repeat SPECT/CT imaging is performed immediately following, and at 1, 3, 5, and 8 days after ^{186}RNL infusion to obtain dosimetry and distribution. Subjects were followed until disease progression by RANO criteria. **Results:** Eighteen subjects were treated across 6 cohorts. The mean tumor volume was 9.4 mL (range 1.1 – 23.4). The infused dose ranged from 1.0 mCi to 22.3 mCi and the volume of infusate ranged from 0.66 mL to 8.80 mL. From 1 – 4 CED catheters were used. The maximum catheter flow rate was 15 μl/min. The mean absorbed dose to the tumor volume was 239 Gy (CI 141 – 337; range 9 - 593), to normal brain was 0.72 Gy (CI 0.34 – 1.09; range 0.005 – 2.73), and to total body was 0.07 Gy (CI 0.04 – 0.10; range 0.001 – 0.23). The mean absorbed dose to the tumor volume when the percent tumor volume in the treatment volume was 75% or greater (n = 10) was 392 Gy (CI 306 – 478; range 143 – 593). Scalp discomfort and tenderness related to the surgical procedure did occur in 3 subjects. The therapy has been well tolerated, no dose-limiting toxicity has been observed, and no treatment-related serious adverse events have occurred despite markedly higher absorbed doses typically delivered by EBRT in patients with prior treatment. Responses have been observed supporting the clinical activity. Final results from the dose escalation will be presented. **Conclusions:** ^{186}RNL administered by CED to patients with recurrent glioma results in a much higher absorbed dose of radiation to the tumor compared to EBRT without significant toxicity. The recommended Phase 2 dose is 22.3 mCi in 8.8 mL of infusate. Clinical trial information: NCT01906385. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Cohort	Activity (mCi)	Infusate Volume(mL)	Concentration (mCi/mL)	Subjects
1	1.0	0.66	1.5	3
2	2.0	1.32	1.5	3
3	4.0	2.64	1.5	3
4	8.0	5.28	1.5	3
5	13.4	5.28	2.5	3
6	22.3	8.80	2.5	3

Autologous stem cell transplantation (ASCT) versus whole brain radiation (WBRT) as a consolidation therapy in primary CNS lymphoma (PCNSL): A nationwide analysis. *First Author: Yazan Samhouri, Division of Medical Oncology, Allegheny Health Network, Pittsburgh, PA*

Background: High dose methotrexate-based regimens remain the most effective treatment against PCNSL but optimal consolidative strategy has yet to be determined. There is lack of high scale clinical trials comparing WBRT versus ASCT as consolidation therapy. Only two phase II randomized clinical trials (PRECIS and IELSG 32) have addressed this question. In this comprehensive national cancer database (NCDB) analysis, we examine the effect of WBRT versus ASCT on survival in PCNSL, we also sought to investigate clinical and socioeconomic predictors of treatment selection **Methods:** We conducted a retrospective cohort analysis using de-identified data accessed from the NCDB. The NCDB provided records of 16579 patients diagnosed with PCNSL between 2004 and 2016. We excluded patients who tested positive for HIV, and those who started chemotherapy > 120 days or started radiation > 365 days since diagnosis, to account for immortal time bias. Patients were divided into two treatment groups based on consolidation therapy: ASCT and WBRT. Multivariable regression models were used to analyze predictors of treatment selection. To account for variable baseline characteristics, we used propensity score weighting methodology. Survival estimates were calculated using the Kaplan-Meier and Cox proportional hazard regression methods **Results:** We identified 1620 patients with PCNSL who fulfilled the inclusion criteria. ASCT and WBRT were received by 197 patients and 1423 patients, respectively (Table). On multivariable analysis, increased age decreased the odds of receiving ASCT (OR 0.997, CI: 0.996-0.999, P <.001). Patients live in rural areas (OR 1.174, CI: 1.051-1.312, P= .005), those with higher education (OR 1.089, CI: 1.020-1.163, P=.01), and those who live further from the treating facility (OR 1.001, CI: 1.001-1.001, P<.001) received more ASCT. With a median follow up duration of 27.8 months, adjusted-median OS was 91.4 months and not reached for WBRT and ASCT groups, respectively (log-rank P<.001). Adjusted 3-year OS was 82% and 67% in ASCT and WBRT, respectively (HR: 0.43, CI: 0.29-0.64, P<.001) **Conclusions:** Consolidation with ASCT had improved OS compared with WBRT. There is a trend toward increased ASCT use and decreased WBRT use over the study period. We found clinical and socioeconomic factors that affected treatment selection. Research Sponsor: None.

Predictive value of lymphocyte immunophenotyping (LIP) in primary central nervous system lymphoma (PCNSL). *First Author: Axel Berthelot, APHM, Marseille, France*

Background: Immunity plays an important role in PCNSL development. PCNSL predictive factors need to be improved. Objective: to evaluate the characteristics and predictive value of blood LIP in PCNSL patients. **Methods:** we prospectively analyzed blood LIP in all newly PCNSL referred to our institution between December 2013 and January 2020. LIP analysis was performed before rituximab and chemotherapy administration. The clinical, radiological, histological, biological and treatment data were retrospectively collected. **Results:** fifty-three patients were included with a median age of 69.7 (range 21.7-87.5). Median KPS was 60 (range 30-100). All patients presented with cerebral involvement, 13 (25%) with cerebrospinal fluid extension and 8 (15%) with ocular extension. Thirty-four patients (62%) benefited of steroid treatment at the time of LIP. Patients characteristics did not differ depending on steroid intake. Forty-eight patients (95%) benefited of polychemotherapy with high-dose methotrexate as first line treatment. We observed three (6%) lymphoproliferative syndromes on the LIP and 33 patients (64%) presented with one or several lymphopenias: 21 (40%), 24 (46%) and 9 (17%) NK, T and B lymphopenias respectively. Only 11 patients (21%) had normal LIP. Median CD4/CD8 ratio was 2.11 (range 0.54-9.11). This ratio was normal, low or high in 27%, 28% and 44% of patients respectively. The presence of steroids did not impact LIP results, including CD4 (p = 0.475) or CD8 (p = 0.726) rates and CD4/CD8 ratio (p = 0.727). Complete or partial responses, stable and progressive disease (PD) were observed in 24 (50%), 10 (21%), 4 (8%), and 10 (21%) patients respectively. CD4/CD8 ratio tended to be different between refractory (PD patients) and non-refractory patients (p = 0.077). A ROC curve analysis was performed with an AUC of 0.684 allowing the selection of a CD4/CD8 ratio cutoff of 1.97 with a sensibility, specificity, positive predictive value, and negative predictive value to identify refractory patients of 90%, 55%, 35% and 95% respectively. Median progression-free survival (PFS) and overall survival (OS) were 14.7 (95%CI: 6.5-22.9) and 43.2 (95%CI: 21.6-64.9) months, respectively. In multivariate analyses, adjusted by KPS, a CD4/CD8 ratio > 1.97 was associated with poor PFS (p = 0.043, HR = 3.32 [1.02-4.88]) and tended to be associated with worse OS (p = 0.064). **Conclusions:** LIP at baseline may predict refractory disease and exhibits a prognostic value in PCNSL patients. Research Sponsor: None.

2064 **Poster Session**

A phase II, open-label, single-arm trial of pembrolizumab for refractory atypical and anaplastic meningioma and hemangiopericytoma. *First Author: Shlomit Yust-Katz, Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel*

Background: Grade II and III meningiomas are invasive tumors which tend to recur following initial treatment and are associated with shorter survival (relative to grade I). Hemangiopericytoma (HPC) is a dural based tumor that originates in the pericytes in the walls of capillaries. Treatment options for these tumors include surgical resection and radiation. There are no defined standard treatments after failure of these modalities, and efficient systemic treatments are lacking. This trial concept was formed following previous reports of high PD-L1 levels in anaplastic meningioma. We currently report our initial experience with pembrolizumab for refractory atypical/anaplastic meningioma (RAM) and HPC patients. **Methods:** This is a single arm, single institute, phase 2 trial. Inclusion criteria included patients with RAM or HPC whose all previous lines of treatment were exhausted. All patients were treated with pembrolizumab (200mg every 3 weeks) until disease progression. Primary endpoint was 6- and 12-months progression free survival (PFS). The study was planned for 25 patients and we report here preliminary results. **Results:** Through February 2021, 12 patients were enrolled to this study (two with HPC, 10 with RAM). After a median follow up of 18.5 months, the 6 and 12 months PFS were 25% and 16.7% respectively, with a median PFS of 2.75 months. Two patients had a partial response while all others progressed, making the overall response rate 16.7%. One of the responders had HPC and has been stable for 30 months, while the second had atypical meningioma and was stable for 13 months. Median survival has not been yet reached; 1 year survival rate was 82.5%. Grade 3 toxicities included hyperglycemia, elevated liver enzymes and fatigue (that did not cause treatment discontinuation), with no grade 4 or 5 toxicities. PD-L1, mutation burden, MSI and other genomic analyses are still pending. **Conclusions:** Pembrolizumab induced a low response rate for RAM and HPC. However, a subset of patients might benefit from this treatment with a prolonged response period. To define this subpopulation further molecular studies are needed. Clinical trial information: NCT03016091. Research Sponsor: MSD.

TPS2065 **Poster Session**

LUMINOS-101: Phase 2 study of PVSRIPO with pembrolizumab in recurrent glioblastoma. *First Author: Andrew E. Sloan, University Hospitals Cleveland Medical Center & Seidman Cancer Center, Cleveland, OH*

Background: The prognosis for patients (pts) with recurrent (r) glioblastoma (GBM) is poor, with no highly effective approved therapies. Treatment failure may result from poor penetration of drugs through the blood-brain barrier and the immunosuppressive nature of the tumor microenvironment (TME). PVSRIPO, a recombinant poliovirus (PV):rhinovirus chimera, is a novel, non-neurovirulent, intratumoral immunotherapy. Trial results in rGBM pts show greater long-term survival with PVSRIPO monotherapy (21%, 36-60 months [mos]) vs criteria-matched external controls (4%, 36 mos; 2%, 60 mos; Desjardins 2018 *NEJM*). PVSRIPO targets CD155 (PV receptor), expressed on solid tumors and on APC. PVSRIPO infection results in inflammatory-mediated destruction of tumor cells but non-lethal lingering infection in TME APC. This leads to type I/III interferon-dominant inflammation and, ultimately, tumor antigen-specific T cell activation and recruitment (Brown 2017 *Sci Transl Med*), which is potentiated by immunologic recall to intratumoral replicating virus via prior vaccination. Induction of type 1 IFN dominant inflammation and compensatory activation of the PD-1:PD-L1 immune checkpoint (IC) pathway support investigation of PVSRIPO in combination with PD-1/L1 IC inhibitors. Immunologically cold mouse glioma models show PVSRIPO+anti-PD-1 therapy resulted in greater anti-tumor response than either agent. **Methods:** LUMINOS-101 is a phase 2, multicenter, open-label, single-arm study of intratumoral infusion of PVSRIPO (Day 1: $5x10^7$ $TCID_{50}$) followed by the anti-PD-1 monoclonal antibody pembrolizumab (200mg IV q3w) in adult pts with rGBM. The trial objective is to evaluate anti-tumor activity and safety and tolerability of the combination. Eligibility criteria include pts ≥18 years who had prior PV and boost IPOL® immunizations, histologically confirmed supratentorial rGBM, infusible 1 to ≤5.5cm enhancing disease, confirmed disease progression following prior therapies, and KPS ≥70. Key exclusion criteria include multifocal disease; discontinuation of prior anti-PD-1/L1 agent for toxicity; prior intratumoral therapy, immunotherapy, or radiotherapy within 12 weeks; high-dose systemic corticosteroids; chemotherapy, anti-VEGF, or TTF therapy ≤1-6 weeks depending on the therapy; serious cerebral herniation syndrome; extensive leptomeningeal, subependymal, or ≥1cm enhancing disease crossing the midline; and severe active comorbidities. Primary endpoints are objective response rate, duration of response, and safety. Secondary endpoints include overall and progression-free survival and disease control rate and duration. Exploratory endpoints include assessment of tumor and blood for biomarkers of response. The initially planned safety lead-in period is now fully enrolled. Recruitment is ongoing in the US, and results will inform the design of a randomized phase 3 trial. Clinical trial information: NCT04479241. Research Sponsor: Istari Oncology.

TPS2066 **Poster Session**

BrainStorm: A brain metastases research platform to tackle the challenge of central nervous system (CNS) metastases in solid tumors (Oncodistinct 006). *First Author: Nuria Kotecki, Institut Jules Bordet, Bruxelles, Belgium*

Background: Better knowledge on the evolving epidemiology and biology of CNS metastases are key elements for the development of new treatment strategies and identification of promising therapeutic targets. A multidisciplinary Brain Metastases Clinical Research Platform called BrainStorm was launched by the Jules Bordet Institute and the Oncodistinct network. The BrainStorm program includes mainly patients with non-CNS metastatic solid tumors with high risk of developing CNS metastases allowing to build a large database focusing on three time periods: before the diagnosis of CNS metastases (Part A), at diagnosis (Part B) and after the diagnosis of CNS metastases (Part C). **Methods:** Subjects with newly diagnosed non-CNS metastases or up to 24 months from diagnosis of non-CNS metastases from triple-negative and HER2-positive breast cancer, lung cancer and melanoma are eligible for part A of the program. Subjects presenting with a 1st CNS event and not yet enrolled (previously mentioned cohorts and a cohort of other tumor types) can enter directly in parts B and subsequently part C of the study. Eligible subjects are followed for 48 months for relevant clinical data, neurological examinations, quality of life, survival status, and undergo examinations and samplings (Table 1). A total of 280 subjects (40 per cohort) with a 1st CNS event will be enrolled. The main objectives of the program are to collect clinical and biological data with the aim to identify risk factors for CNS metastases development (Part A) and to better understand the biology of CNS metastases (brain and leptomeningeal –Parts B and C) aiming to discover new targets for therapy and intensify the multidisciplinary approach for the management of CNS metastases from solid tumors. The translational part of the program will evaluate among others the use of cerebrospinal fluid circulating tumor DNA (CSF-ctDNA) as a surrogate for CNS metastases in order to characterize its molecular landscape. Currently, the study is recruiting in several sites within the Oncodistinct network. The data collected will help to develop innovative multidisciplinary research projects that could be implemented in all parts of the BrainStorm program. Clinical trial information: NCT04109131. Research Sponsor: Fondation Cancer Luxembourg, Other Foundation, Les amis de l'Institut Bordet.

Main study procedures in the BrainStorm program.

TPS2067 **Poster Session**

A phase III multicenter randomized controlled trial of postsurgical stereotactic radiotherapy versus surgically targeted radiation therapy (STaRT) for the treatment of large (>2.5cm) newly diagnosed brain metastases: Trial in progress. *First Author: Jeffrey S. Weinberg, MD Anderson Cancer Center, Houston, TX*

Background: Resection (R) followed by single or multi-fraction stereotactic radiosurgery (SRT) of brain metastases lowers resection bed recurrence compared to R alone. Nevertheless, for larger (>2.5cm) brain metastasis, 12-month recurrence rates after R+SRT can exceed 20–30%. Aiming to improve outcomes, a permanently implanted collagen tile brachytherapy device (GammaTile or GT, GT Medical Technologies, Tempe, AZ) utilizing Cs-131 seeds embedded within a bioresorbable collagen tile was developed and is described as Surgically Targeted Radiation Therapy (STaRT) to distinguish it from external beam radiation therapy. It is hypothesized that immediate adjuvant radiotherapy (RT) and/or RT dose intensification could improve outcomes. The device is FDA-cleared for this indication and early commercial use is demonstrating favorable safety and efficacy outcomes. STaRT allows rapid dose delivery of radiation therapy directly to the tumor bed with predictable dosimetry immediately at the time of resection, and an intense but localized radiation treatment, which may confer a reduced risk for radiation necrosis compared to other therapies. The device is easily placed with minimal additional operative time and limited staff radiation exposure. It is hypothesized that R+ STaRT will increase the surgical bed recurrence-free survival, while reducing the impact on functional and neurocognitive status compared to R+SRT. **Methods:** Multicenter, randomized, comparison trial of patients with resectable, previously untreated "index" brain metastases measuring ≥2.5–5 cm, and 0–3 other tumors, will be preoperatively randomized 1:1 to undergo either R+ SRT or R+STaRT to the index lesion; unresected tumors in both groups will receive SRT. Planned sample size is 180 from 13 sites . Enrollment will open in Q1. Primary endpoint is surgical bed-recurrence free survival. Secondary endpoints include overall survival, quality of life (Functional Assessment of Cancer Therapy-Brain, Linear Analog Self-Assessment), neurocognition (Hopkins Verbal Learning Test, Trail Making Tests, Controlled Oral Word Association), functional status (Karnofsky Performance Scale, Barthel-ADL), and adverse events. Follow-up will be at 1,3,6,9, and 12 months, then every 6 months through 24 months. This will be the first randomized trial comparing R+SRT versus R+STaRT delivered by Cs-131 sources in permanently implanted resorbable collagen tile carriers. Primary and secondary outcome measures will be captured to elucidate the potential risks and benefits of these two differing post-operative RT delivery methods in the setting of newly diagnosed metastatic brain tumors. Clinical trial information: NCT04365374. Research Sponsor: GT Medical Technologies.

TPS2068 **Poster Session**

The potential utility of end-binding protein 1 (EB1) as response-predictive biomarker for lisavanbulin: A phase 2 study of lisavanbulin (BAL101553) in adult patients with recurrent glioblastoma. *First Author: Crescens Tiu, The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Lisavanbulin (BAL101553, prodrug of BAL27862) is a novel tumor checkpoint controller that promotes tumor cell death by modulating the spindle assembly checkpoint. BAL27862 is a lipophilic, small molecule (MW 387) shown in rodents to penetrate the brain (1:1 plasma ratio) with promising antitumor activity in orthotopic models of glioblastoma (GB) as monotherapy or in combination with radiotherapy (RT) ± chemotherapy. In a completed phase 1 study (Lopez et al. ESMO 2020, NCT02490800) with daily oral lisavanbulin in patients with recurrent GB or high-grade glioma, the RP2D was determined at 25 mg/day. In this phase 1 study, two patients (out of 20 patients) with GB show a long-lasting (> 2 years) clinical benefit with improvement in clinical symptoms and in target and/or non-target GB lesions as per RANO criteria. Both patients show strong end-binding protein 1 (EB1) expression in their GB tissues as assessed by immunohistochemistry staining. EB1, a protein located on the plus-ends of microtubules, is involved in microtubule (MT) function and has been associated with stemness of glioma cells and a more aggressive disease. Data from GB mouse models suggest that EB1 is a predictive marker for response to lisavanbulin. The prevalence of EB1-positivity in GB is estimated at ~5%. This ongoing phase 2 study is an extension of the completed Phase 1 study and is conducted to confirm prospectively whether EB1 is a response-predictive biomarker for lisavanbulin in GB. **Methods:** This is an ongoing multicenter, open-label, phase 2 study using a Simon Two-Stage design to assess the efficacy of lisavanbulin in patients with recurrent GB. The study is being performed in the UK, Switzerland and Germany. Patients with histologically-confirmed GB and recurrent disease after prior RT with alkylating chemotherapy (de-novo/primary GB) or after prior chemotherapy or RT (secondary GB), are eligible for enrollment if their GB archival tumor tissue is EB1-positive. EB1-positivity is defined as moderate to strong EB1-staining in at least 70% of GB tumor cells using a CE-marked immunohistochemistry Clinical Trial Assay (Targos Molecular Pathology GmbH). The primary study objective is the overall response rate by RANO, with MRI scans being performed every 8 weeks. Secondary endpoints include progression-free survival and overall survival. Adverse events are assessed using CTCAEv5. To develop a potential RNA-based response signature, molecular profiling of tumor tissue is performed using whole transcriptome sequencing (RNAseq) in each patient enrolled in the study to define the genomic expression profiles in patients with EB1-positive GB. Nine evaluable patients are to be enrolled in Stage 1, and an additional 10 patients will be enrolled in stage 2 if at least 2 objective responses per RANO criteria are observed in stage 1. Clinical trial information: 02490800. Research Sponsor: Basilea Pharmaceutica International Ltd.

TPS2069 **Poster Session**

Phase 2 trial of newly diagnosed high-grade glioma treated with concurrent radiation therapy, temozolomide, and BMX-001. *First Author: Katherine B. Peters, Duke University, Durham, NC*

Background: High-grade gliomas (WHO grade III-IV) patients experience marked morbidity and mortality. While the standard of care for newly diagnosed high-grade glioma patients is surgery followed by concurrent chemotherapy and radiation therapy (RT), the outcomes remain poor. BMX-001 ($MnTnBuOE\text{-}2\text{-}PyP^{5+}$) is a metalloporphyrin with differential action in response to radiation therapy and chemotherapy-induced oxidative stress. As shown in preclinical evaluations, BMX-001, when used with radiation, can protect normal, healthy tissues and augment cell kill in malignant cancer cells, notably, human glioblastoma xenografts. We evaluated the safety of BMX-001 in combination with concurrent RT and temozolomide (TMZ) in a phase 1 study of newly diagnosed high-grade glioma patients and we found that BMX-001 is safe and well-tolerated in this population. The maximum tolerated dose of BMX-001 during concurrent RT and TMZ was determined to be 28 mg delivered subcutaneously (SC) followed by 16 biweekly SC doses at 14 mg (Peters et al., Neuro-Oncology 2018). **Methods:** For this multi-site, open-label, phase 2 study (NCT02655601), we will randomize approximately 160 patients 1:1 to concurrent RT and TMZ with BMX-001 versus concurrent RT and TMZ alone. Key eligibility criteria include newly diagnosed histologically confirmed high-grade glioma (WHO III-IV), 18 ≥ years, and Karnofsky performance status ≥ 70%. The primary endpoint is overall survival. Secondary endpoints are objective cognitive performance, bone marrow protection, safety and tolerability, progression-free survival, overall tumor response rate, and plasma pharmacokinetics. Exploratory endpoints are patient-reported outcomes of health-related quality of life (as assessed by Functional Assessment of Cancer Therapy–Brain, Functional Assessment of Cancer Therapy-Cognition, and Functional Assessment of Chronic Illness Therapy-Fatigue), qualitative hair loss, and white matter integrity (as measured by MRI diffusion tensor/susceptibility imaging). Since November 2018, this phase 2 study has enrolled 147 of 160 high-grade glioma patients at nine sites in US. Clinical trial information: NCT02655601. Research Sponsor: BMX through an STTR grant, as above.

TPS2070 **Poster Session**

Safety and efficacy study of retifanlimab and epacadostat in combination with radiation and bevacizumab in patients with recurrent glioblastoma. *First Author: Jian Li Campian, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Recurrent glioblastoma (rGBM) after chemoradiotherapy has a dismal outcome with very limited treatment options. Addition of reirradiation to bevacizumab appears to improve progression-free survival (PFS) but does not improve overall survival (OS). Immune checkpoint inhibitors of programmed cell death-1 (PD-1) pathway appear to have limited single-agent activity for rGBM due to its immunesuppressive microenvironment. Indoleamine 2,3 dioxygenase 1 (IDO1) is an inducible and rate-limiting enzyme that catabolizes tryptophan (Trp) into kynurenine (Kyn). IDO1 is over-expressed in 50~90% of GBM patients, and high IDO1 levels correlate with reduced OS. Epacadostat is a highly potent and selective oral inhibitor of IDO1 and may increase tumor sensitivity to anti-PD-1 blockade. Retifanlimab is a humanized anti-PD-1 monoclonal antibody directed against PD-1. The purpose of this study is to evaluate the safety and efficacy of combining retifanlimab plus or minus epacadostat with reirradiation and bevacizumab for rGBM patients. **Methods:** This is an open-label nonrandomized phase II study of two sequential cohorts for bevacizumab-naïve adults with rGBM: retifanlimab + bevacizumab+ radiation (cohort A), and retifanlimab + epacadostat + bevacizumab + radiation (cohort B). Each cohort will enroll 24 evaluable patients. Key eligibility criteria include candidates for reirradiation and bevacizumab, age $\geq$ 18 years, Karnofsky performance status $\geq$ 60%, and dexamethasone dose $\leq$ 4 mg/day. The primary endpoint is OS. Secondary endpoints include PFS, neurologic functions, and toxicity. The correlative endpoints include studies assess the anti-glioma immune response, serum Kyn/Trp ratio, and RNA expression of IDO1 and PD-L1 from available tissue. The trial is actively enrolling. At the time of abstract submission, 16 of the planned 24 patients in Cohort A have been enrolled. Clinical trial information: NCT03532295. Research Sponsor: Incyte Corporation.

Treatment regimen.

	Dose			
Treatment	**Retifanlimab**	**Epacadostat**	**Bevacizumab**	**Radiation**
Cohort A	500 mg IV Q4W	–	10 mg/kg IV Q2W	3.5 Gy x 10 QD
Cohort B	500 mg IV Q4W	600 mg PO Twice daily	10 mg/kg IV Q2W	3.5 Gy x 10 QD

TPS2071 **Poster Session**

A phase 1/2 study of selinexor in combination with standard of care therapy for newly diagnosed or recurrent glioblastoma. *First Author: Yazmin Odia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Glioblastoma multiforme (GBM) is the most common and aggressive primary brain tumor with a median overall survival (OS) of 15 months for patients with newly diagnosed GBM (ndGBM) and 5-7 months for patients with recurrent GBM (rGBM). To improve the prognosis of patients with GBM, novel therapies are urgently needed. Selinexor is a first-in class, oral, selective inhibitor of nuclear export that blocks exportin 1 (XPO1), forcing the nuclear retention and reactivation of tumor suppressor proteins, ultimately causing death of cancer cells. Selinexor is an FDA-approved treatment for patients with heavily pretreated multiple myeloma, for patients who received at least one prior therapy, and for patients with relapsed/refractory diffuse large B-cell lymphoma. Increased XPO1 expression in gliomas was associated with higher pathological stage and poorer prognosis. In a phase 2 study in rGBM (NCT01986348), selinexor demonstrated encouraging intratumoral penetration and single-agent efficacy at 80 mg once weekly with durable response and disease stabilization in heavily pretreated patients. In preclinical studies, selinexor showed synergy with radiation, temozolomide, or lomustine. The current trial tests the hypothesis that the addition of selinexor to standard therapy will improve clinical outcomes for patient with ndGBM or rGBM. **Methods:** This phase 1 dose finding study is followed by a 1:1 randomized phase 2 (n= 350) efficacy exploration trial to independently evaluate 3 regimens: Arm A – radiation +/- selinexor in unmethylated O^6-methylguanine-DNA-methyltransferase (uMGMT) ndGBM; Arm B – radiation and temozolomide +/- selinexor in mMGMT ndGBM; Arm C – lomustine +/- selinexor in first relapsed rGBM following frontline radiation and temozolomide. The phase 1 primary endpoint is maximum tolerated dose/recommended phase 2 dose, with secondary endpoints of overall response rate (ORR) per modified Response Assessment in Neuro-Oncology (mRANO), duration of response (DOR), progression free survival (PFS), and OS. The phase 2 primary endpoint for Arms A and B in ndGBM is PFS, with key secondary endpoints being OS, PFS at 6 months, ORR, and DOR. For Arm C, the phase 2 primary endpoint is OS, while key secondary endpoints are PFS, PFS at 6 months, ORR, and DOR. The study has 70% power to detect a hazard ratio of 0.67 between selinexor and control for primary efficacy in Arms A and B, and 80% power to detect a hazard ratio of 0.70 for Arm C. We are currently enrolling patients nationwide. Clinical trial information: NCT04421378. Research Sponsor: Karyopharm Therapeutics Inc.

TPS2072 **Poster Session**

First-in-human dose escalation and food effect study of oral ONC206 in adults with recurrent primary CNS neoplasms. *First Author: Brett Theeler, Neuro-Oncology Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: The majority of recurrent CNS tumors lack effective systemic therapy options following surgical resection and adjuvant radiotherapy. ONC201, the founding member of the imipridone class of small molecules, has induced durable tumor regressions in patients with diffuse midline glioma, H3 K27M-mutant (DMG H3K27M). ONC206, the second imipridone to enter clinical development, is a DRD2 antagonist and ClpP agonist that exhibits differentiated receptor pharmacology and gene expression profiles in tumors relative to ONC201. The compound is orally bioavailable, penetrates the blood-brain barrier, and exhibits anti-cancer efficacy without toxicity in several preclinical cancer models with pronounced efficacy in myc-overexpressing CNS tumors. **Methods:** A first-in-human, open label, dose escalation, and food effect Phase I study of oral ONC206 (NCT04541082) is currently enrolling. Patients must be 18 years or older and diagnosed with a recurrent, primary CNS neoplasm. Eligible diseases include recurrent glioblastoma, WHO Grade 2 and 3 infiltrating glial neoplasms, DMG H3K27M, ependymoma, medulloblastoma, malignant meningiomas, and other rare primary CNS neoplasms. Dose escalation, initially with weekly dosing, will follow a standard 3+3 design. After the MTD is established, a food effect cohort will enroll with a balanced, single-dose, two-arm, two-period, crossover design. The primary endpoint is to determine DLT during the first 28-day cycle. Secondary endpoints will include objective response rate by RANO criteria, overall and progression-free survival, and disease control rate. Exploratory biomarker analyses based on preclinical correlations with efficacy will include DRD2, DRD2 dimer, ClpP, DRD5, c-myc, and n-myc expression. Clinical trial information: NCT04541082. Research Sponsor: U.S. National Institutes of Health.

TPS2073 **Poster Session**

A multicenter observational study of cs-131 seeds embedded in a collagen carrier tile in intracranial brain neoplasms: Trial in progress. *First Author: K. Stuart Lee, Vidant Health, Greenville, NC*

Background: Brachytherapy is an efficacious means for radiation delivery in the treatment of a spectrum of central nervous system tumors. Traditional brachytherapy methods have been limited by uneven dose distribution, complicated workflow, extended procedural times, the cost of dedicated equipment, and frequent adverse events. To address these issues, a permanently implanted device with Cs-131 radiation seeds embedded in a bioresorbable collagen carrier tile (GammaTile [GT], GT Medical Technologies, Tempe, AZ USA) was developed. Described as surgically targeted radiation therapy (STaRT) to distinguish it from external beam radiation therapy, the device is FDA-cleared for use in newly diagnosed malignant intracranial neoplasms and recurrent intracranial tumors, and has demonstrated excellent safety and local control outcomes in early commercial use. **Methods:** The overarching primary objectives of this multicenter, prospective, observational (phase IV) registry study are to evaluate "real-world" clinical outcomes and patient reported outcomes that measure the safety and efficacy of STaRT using the GT device. The registry is planned for 600 prospectively enrolled subjects at up to 50 enrolling sites. All adult patients undergoing surgical resection of brain tumors of any pathology with intra-operative GT placement are eligible for enrollment, upon consent. Information on patient demographics, tumor pathology, overall survival, adverse events related to radiation or surgery, and quality of life (FACT-Br and LASA) will be collected. Serial MRIs will be collected, and timing of surgical bed recurrence and/or distant recurrence will be collected. Data will be collected at 1-, 3-, 6-, 9-, 12-, 18-, and 24-months, then every 6 months through 5 years. Results will be used to benchmark clinical outcomes of GT therapy, allow for comparisons to other existing treatments, and facilitate the design of future clinical trials. Enrollment opened on November 15, 2020, and seven subjects have been enrolled to date at three centers. This study will be the first observational study of resection plus STaRT, delivered by Cs-131 sources in permanently implanted bioresorbable collagen tile carriers, and will allow for evaluation of this treatment approach in a real world setting, as well as provide an information platform for cross-comparison of results obtained from ongoing GT clinical trials. Clinical trial information: NCT04427384. Research Sponsor: GT Medical Technologies.

TPS2074 **Poster Session**

GBM AGILE: A global, phase 2/3 adaptive platform trial to evaluate multiple regimens in newly diagnosed and recurrent glioblastoma. *First Author: Patrick Y. Wen, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: GBM AGILE, Glioblastoma Adaptive, Global, Innovative Learning Environment, is an international, multi-arm, seamless phase 2/3 response adaptive randomization platform trial designed to evaluate multiple therapies in newly diagnosed (ND) and recurrent glioblastoma (GBM) with the goal of identifying effective therapies matching them accurately to different patient subtypes in an accelerated manner. It is a collaboration between academic investigators, patient organizations and industry to support new drug applications for newly diagnosed and recurrent GBM. **Methods:** The primary objective of GBM AGILE is to identify therapies that effectively improve overall survival in patients with ND or recurrent GBM. Bayesian response adaptive randomization is used within subtypes of the disease to assign participants to investigational arms based on their performance. Operating under a Master Protocol, GBM AGILE allows multiple drugs from different pharmaceutical companies to be evaluated simultaneously and/or over time against a common standard of care control. Based on performance, a drug may graduate and move to a rapid stage 2 (phase 3) within the trial, and the totality of the data can be used for a new drug application. An active pipeline is critical to the ongoing success of GBM AGILE. With the leadership of the trial's Arm Selection Committee, uniform processes for including new drugs have been established to ensure a consistent review of drugs/drug combinations over the course of the trial. Factors considered include relevant pre-clinical data, preliminary evidence for antitumor activity. pharmacokinetic data to support proposed drug dosing and administration, and potential biomarkers helpful for the development of a drug. GBM AGILE provides an efficient mechanism to screen and develop robust information regarding the efficacy of proposed novel therapeutics and associated biomarkers for GBM and to quickly move therapies and biomarkers into clinic. GBM AGILE received IND approval from the FDA in April 2019, screening its first patient in June 2019. Site activation is ongoing in the US, with over 35 active sites and over 425 patients screened (as of February 2021). Expansion to Canada, Europe and China are under progress. Clinical trial information: NCT03970447. Research Sponsor: Bayer, Kazia Therapeutics Limited, Kintara Therapeutics Inc, Other Foundation.

2500 **Oral Abstract Session**

Clinical activity of systemic VSV-IFNβ-NIS oncolytic virotherapy in patients with relapsed refractory T-cell lymphoma. *First Author: Joselle Cook, Mayo Clinic, Rochester, MN*

Background: Oncolytic virotherapy is a novel immunomodulatory therapeutic approach for relapsed refractory hematologic malignancies. The Indiana strain of Vesicular Stomatitis Virus was engineered to encode interferon beta (IFNβ) and sodium iodine symporter (NIS) to produce VSV-IFNβ-NIS. Virally encoded IFNβ serves as an index of viral proliferation and enhances host anti-tumor immunity. NIS was inserted to noninvasively assess viral biodistribution using SPECT/PET imaging. We present the results of the phase 1 clinical trial NCT03017820 of systemic administration of VSV-IFNβ-NIS among patients (pts) with relapsed refractory Multiple Myeloma (MM), T cell Lymphoma (TCL) and Acute myeloid Leukemia (AML). **Methods:** VSV-IFNβ-NIS was administered at $5x10^9$ $TCID_{50}$ (50% tissue culture infectious dose) dose level 1 to dose level 4, $1.7x10^{11}$ $TCID_{50}$. The primary objective was to determine the maximum tolerated dose of VSV-IFNβ-NIS as a single agent. Secondary objectives were determination of safety profile and preliminary efficacy of VSV-IFNβ-NIS. Correlative objectives included monitoring viremia and virus shedding. Adverse events (AEs) are reported based on CTCAE V4; cytokine release syndrome (CRS) grading was based on Lee (Blood 2014) criteria. **Results:** 15 pts received VSV-IFNβ-NIS: MM (7), TCL(7) and AML(1); 3 pts were treated at each dose level (DL) 1 through 3 (respectively 0.05, 0.17, and 0.5×10^{11} $TCID_{50}$), & 6 pts were treated at dose level 4 ($1.7x10^{11}$ $TCID_{50}$). There were no dose limiting toxicities. The most frequent grades 3 & 4 AEs were hematologic: lymphopenia (46.6 & 26.6%), neutropenia (13.3% & 6.7%). CRS grades 1 (6.7%) and 2 (46.6%) were the non-hematologic AEs of note; mostly at DL 4. Only 1 pt required transient pressor support. Responses were seen in pts with T cell lymphoma. At DL2, there was a partial response (PR) lasting 3 months in a pt, post 12 prior lines of therapy. At DL4 there was a 6 month PR in a pt with PTCL and another pt with cutaneous relapse of PTCL who enjoys an ongoing CR, more than 1 year post VSV infusion; both pts received 5 prior lines of therapy. Viremia was detected in all pts at the end of infusion only up to 72 hrs post infusion; no infectious virus was recovered in buccal swabs or urine. Neutralizing anti-VSV antibodies were present by day 29. IFN levels were detectable within 30 mins of infusion, peaking between 4 & 48 hrs. TCL pts mounted higher hIFNβ levels within 48 hrs; the pt with CR mounted peak hIFNβ response of 18213.3pg/ml at 48 hrs post infusion, 15-fold higher than any other pt. **Conclusions:** VSV-IFNβ-NIS can be safely administered by IV infusion among heavily pretreated pts with hematologic malignancies. VSV-IFNβ-NIS as a single agent appears to be most effective at DL4 among patients with TCL, with an ongoing CR in a patient at DL4 more than 1 year post administration. Future trials of combination strategies with immunemodulatory drugs are currently being planned. Clinical trial information: NCT03017820. Research Sponsor: Mayo Myeloma SPORE.

2501 **Oral Abstract Session**

Phase II evaluation of the triple combination of PDS0101, M9241, and bintrafusp alfa in patients with HPV 16 positive malignancies. *First Author: Julius Strauss, Laboratory of Tumor Immunology and Biology, NCI, NIH, Bethesda, MD*

Background: There are more than 630,000 cases of HPV associated malignancies including cervical, oropharyngeal and anal cancer worldwide annually. HPV 16 is responsible for the majority of these cases. About 15-20% of HPV associated malignancies respond to PD-(L)1 inhibitors, but for the overwhelming majority of patients who progress on these immunotherapies there is no effective standard of care therapy. Preclinical studies have shown that the triple combination of PDS0101 (Versamune-HPV), a liposomal multipeptide therapeutic vaccine targeting HPV 16 E6/E7, M9241, a tumor-targeting immunocytokine composed of IL-12 heterodimers fused to a monoclonal antibody targeting free DNA in necrotic tumor regions, and bintrafusp alfa, a bifunctional fusion protein targeting TGF-β and PD-L1, resulted in maximum HPV-specific T cell responses, T cell tumor infiltration and tumor reduction as compared to any one or two of these agents alone. **Methods:** Fourteen pts with HPV 16+ relapsed or refractory advanced cancer were enrolled to the triple combination of PDS0101, M9241 and bintrafusp alfa (NCT04287868). Pts received bintrafusp alfa at 1200 mg flat dose i.v. every 2 weeks, M9241 at 16.8 mcg/kg s.c. every 4 weeks and PDS0101 given as two separate 0.5 ml s.c. injections every 4 weeks. Dose reductions of M9241 to 8 mcg/kg were allowed as well as skipped doses of any agent for ongoing toxicities. **Results:** Fourteen pts with advanced HPV 16+ cancers (5 cervical, 2 vaginal/vulvar, 4 anal, 3 oropharyngeal) were treated. 4/14 (28.6%) pts had a grade 3 treatment related toxicity including grade 3 hematuria in 2 pts with cervical ca and prior pelvic radiation and grade 3 AST/ALT elevation in 2 pts, one with anal ca and one with vaginal ca. For one patient with grade 3 AST/ALT elevation dose reduction of M9241 from 16.8 to 8 mcg/kg allowed for continued treatment with AST/ALT remaining at grade 1 or less. One additional patient had transient asymptomatic grade 4 neutropenia. No other treatment related grade 3 or greater toxicities were noted. 10/14 (71%) pts have had objective responses: 1 CR (anal ca) and 9 PRs (3 cervical, 2 vulvar/vaginal, 2 anal, 2 oropharyngeal) with 9/10 of these responses ongoing after a median 5 month of follow up. Of the 14 pts, 6 pts have checkpoint naïve disease and 8 pts have checkpoint refractory disease. 5/6 (83%) pts with checkpoint naïve disease and 5/8 (63%) pts with checkpoint refractory disease have had objective responses. Analyses of immune responses and other immune correlates are ongoing. **Conclusions:** Triple combination of PDS0101, M9241 and bintrafusp alfa appears to have a manageable safety profile along with early evidence of notable clinical activity for pts with both checkpoint naïve as well as checkpoint refractory HPV 16+ advanced malignancies. Clinical trial information: NCT04287868. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

2502 **Oral Abstract Session**

First report of the safety/tolerability and preliminary antitumor activity of HB-201 and HB-202, an arenavirus-based cancer immunotherapy, in patients with HPV16+ cancers. *First Author: Alan Loh Ho, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human papillomavirus 16 (HPV16) is linked to several cancer types. Treatment options are limited for patients with HPV16 positive (HPV16+) recurrent or metastatic cancers. Generation and maintenance of HPV16+ malignant state require stable expression of HPV16-specific E7 and E6 oncoproteins, also a source of immunogenic neoantigens. HB-201 and HB-202 are replicating live-attenuated vectors based on lymphocytic choriomeningitis virus and Pichinde virus, respectively, which express the same non-oncogenic HPV16 E7E6 fusion protein to induce tumor-specific T-cell responses. This is a first-in-human phase 1/2 study of HB-201 monotherapy and HB-201 & HB-202 alternating 2-vector therapy. Dose escalation is ongoing with a 3+3 design. **Methods:** Phase 1 is assessing different regimens and dose levels of HB-201 monotherapy and HB-201 & HB-202 alternating 2-vector therapy given intravenously (IV) with or without an initial intratumoral administration. The patient population includes HPV16+ head and neck squamous cell carcinoma (HNSCC) and other HPV16+ cancers. Safety, tolerability, and preliminary antitumor activity by Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 or immune RECIST are assessed. **Results:** As of Jan 2021, 25 patients with a median of 3 prior anticancer treatments have been enrolled. All had HPV16+ confirmed genotype; the most common primary site was oropharynx (72%). No dose-limiting toxicities were reported. Treatment-emergent adverse events (TEAEs) occurred in 21 patients (84%), were generally mild or moderate, with events related to study drug reported in 14 patients (56%). TEAEs reported in >10% of patients regardless of causality included fatigue, pyrexia, nausea, decreased appetite, anemia, arthralgia, chills, constipation, diarrhea, hypertension, influenza-like illness, pneumonia, and vomiting. Serious TEAEs developed in 6 patients (24%), including 1 with grade 5 hemorrhagic shock deemed unrelated to study drug. Grade 3 fatigue was the only serious or grade ≥3 TEAE assessed as related to study drug. TEAEs caused no treatment discontinuation. There were 18 patients evaluable for efficacy. For the 16 patients on HB-201 monotherapy, assessment of target lesions showed 2 partial responses (including 1 patient with an unconfirmed immune CR) and 6 patients had stable disease (SD). For the 2 patients on HB-201 & HB-202 alternating therapy, both had SD. So far, the longest duration of response was 4.8 months (144 days) and the maximum decrease in tumor diameter was 60%, both seen in HNSCC patients receiving HB-201 IV. **Conclusions:** HB-201 monotherapy and HB-201 & HB-202 2-vector alternating therapy were generally well-tolerated and showed preliminary antitumor activity as monotherapy in heavily pre-treated patients with HPV16+ HNSCC and other solid tumors. Clinical trial information: NCT04180215. Research Sponsor: Hookipa Biotech Gmbh.

2503 **Oral Abstract Session**

Phase 1 study of SHR-1701, a bifunctional fusion protein targeting PD-L1 and TGF-β, in patients with advanced solid tumors. *First Author: Dan Liu, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Early Drug Development Center, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Dual inhibition of PD-1/PD-L1 and TGF-β pathways is a promising therapeutic strategy for multiple tumor types. SHR-1701 is a novel bifunctional anti-PD-L1/TGF-βRII agent. This dose escalation and expansion phase 1 study aimed to evaluated the safety and preliminary anti-tumor acitivity of SHR-1701 in refractory solid tumors. **Methods:** The dose escalation period was initiated by accelerated titration (1 mg/kg Q3W) and then switched to 3+3 scheme (3, 10, 20, and 30 mg/kg Q3W and 30 mg/kg Q2W). The dose expanded at doses of 10, 20, and 30 mg/kg Q3W and 30 mg/kg Q2W. The primary objectives were to determine the safety profile, MTD, and RP2D of SHR-1701. **Results:** 17 pts (1 mg/kg Q3W [n = 1]; 3, 10, 20 and 30 mg/kg Q3W [n = 3 each]; 30 mg/kg Q2W [n = 4]) were enrolled in dose escalation part. No DLT was observed and MTD was not reached. Another 32 pts (10 mg/kg Q3W [n = 8]; 20 and 30 mg/kg Q3W [n = 9 each]; 30 mg/kg Q2W [n = 6]) were enrolled in dose expansion part. Of 49 enrolled pts, 33 pts (67.3%) had received ≥2 lines of prior systemic therapy. As of data cutoff on Oct 30, 2020, the median duration of SHR-1701 exposure was 6.0 weeks (range, 2.0-78.6). The most common reported TRAEs were increased ALT/AST, anemia, hypothyroidism, and increased bilirubin/conjugated bilirubin, with incidence > 15%. The incidence of irAEs reported by the investigator was 46.9% and 4 pts received systemic corticosteroids. Hypothyroidism and rash were the most common irAEs with incidence > 10%. The incidence of Grade ≥3 TRAEs was 18.4%. The incidence of Grade ≥3 irAEs was 10.2%. 1 pt suffered early death for liver failure more likely caused by tumor progression. PK analysis showed a linear dose-exposure relationship with SHR-1701 dosing from 1 to 30 mg/kg. The peripheral PD-L1 target occupancy rate exceeded 90%, and nearly complete TGF-β1 trapping was detected in all dose groups. Of 49 enrolled pts, 45 pts completed at least once efficacy evaluation. The ORR was 17.8% (95% CI, 8.0%-32.1%), with 8 pts achieving PR (2 lung adenocarcinoma, 1 HCC, 1 ESCC, 1 dMMR-CRC, 1 renal cancer, 1 epiglottis cancer, and 1 pancreatic acinar cell carcinoma). The DCR was 40.0% (18/45; 95% CI, 25.7%-55.7%). Majority of responses (7/8) were still ongoing, and the median DoR had not been reached yet. Based on data of saftety, PK, PD, and efficacy, we recommended 30 mg/kg Q3W as the RP2D. **Conclusions:** SHR-1701 showed acceptable safety profile and encouraging antitumor activity in refractory solid tumors, establishing the foundation for further exploration. Clinical trial information: NCT03710265. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

2504 **Oral Abstract Session**

COM701 with or without nivolumab: Results of an ongoing phase 1 study of safety, tolerability and preliminary antitumor activity in patients with advanced solid malignancies (NCT03667716). *First Author: Daniel A. Vaena, West Cancer Center and Research Institute., Memphis, TN*

Background: COM701 is a novel first in class humanized IgG4 monoclonal antibody that binds with high affinity to poliovirus receptor related immunoglobulin domain containing (PVRIG), blocking its interaction with its ligand, PVRL2. Blocking of PVRIG leads to enhanced activation of T/NK cells and in mouse models inhibits tumor growth. We report new and updated results on safety/tolerability/pharmacokinetics and antitumor activity from this ongoing study including final results in dose escalation combination cohort, monotherapy expansion cohort (MEC). **Methods:** We enrolled a total of 51 DLT-evaluable pts: Arm A (COM701 mono dose escalation), 16 pts in 8 cohorts (0.01 – 20 mg/kg IV Q3/4 wks); Arm B (COM701 0.3 – 20 mg/kg + nivolumab (NIVO) 360 mg/480 mg IV Q3/Q4 wks), 15 pts in 5 cohorts; 20 pts in MEC (NSCLC, OVCA, breast, endometrial and CRC) at the recommended dose for expansion(RDFE), 20 mg/kg IV Q4 wks. Key inclusion criteria: Age ≥18 yrs, histologically confirmed metastatic solid malignancy, has exhausted available standard tx, ECOG 0-1, prior ICI permissible (except prior tx with a PVRIG inhibitor). Key exclusion criteria: active autoimmune disease requiring systemic tx, hx inflammatory lung disease. Primary objectives – safety/tolerability of COM701 ± NIVO (AEs, CTCAE v4.03), PK, RDFE. Key secondary/exploratory objectives - antitumor activity of COM701 ± NIVO (RECIST v1.1), evaluation of PVRL2 expression in tumor biopsy, blood cytokines and immunophenotyping. **Results:** No DLTs were reported in Arms A or B. COM701 PK profile similar in Arm A, 20 mg/kg IV Q4 wks (cohort 8) and Arm B cohort 5 (COM701 20 mg/kg + NIVO 480 mg; all IV Q4 wks). Frequency of TEAEs in safety population (N=54 pts): pts on COM701 mono (N=38)- No AE (4), Grade≤2 (21), G3 (11), G4 (1), G5 (1, PD), pts on combo (N=16) - Grade≤2 (8), G3 (7), G5 (1, PD). Serious TEAE: pts on COM701 mono 11/38, pts on combo 6/16. Most frequent AEs in Arm A: Grade ≤2 fatigue 12/38 pts (31%), nausea 9/38 (23%); Arm B: fatigue 7/16 pts (44%) and AST increased 4/16 pts (25%). Antitumor activity - in Arm A (cohort 8), a pt with platinum resistant primary peritoneal cancer had confirmed PR ongoing 14 months. In Arm B (COM701 10 mg/kg + NIVO 480 mg, all IV Q4 wks), a pt with anal SCCA; confirmed CR, ongoing 18 months, last tx with prior PD on NIVO. In addition, a pt with renal cell CA had confirmed SD [ongoing 13 months, COM701 0.3 mg/kg + NIVO 360mg; IV Q3 wks],] In MEC, 30% (6/20 pts) had best response of SD [1-endometrial, 3 NSCLC, 2 OVCA], 2 pts [NSCLC, OVCA] ongoing at 6/4 months. Overall 16pts had prior tx-refractory disease, 9(56%) had best response of ≥SD. Of 18 pts with prior tx with ICI, 13 (72%) had best response of ≥SD. Datacut 14Dec2020. **Conclusions:** COM701 ± NIVO well tolerated with no new safety signals. Encouraging signal of antitumor activity including in pts with prior tx with ICI or prior tx-refractory disease. Clinical trial information: NCT03667716.. Research Sponsor: Compugen Ltd.

2505 **Oral Abstract Session**

Preliminary clinical and biologic results of GB1275, a first-in-class oral CD11b modulator, alone and with pembrolizumab, in advanced solid tumors (KEYNOTE A36). *First Author: Haeseong Park, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: GB1275 is a first-in-class, oral CD11b modulator that reduced myeloid-derived suppressor cells (MDSCs) and tumor associated macrophages (TAMs), repolarized M2 immunosuppressive TAMs to an M1 phenotype, resulting in increased tumor infiltration of activated CD8+ T cells and antitumor efficacy in preclinical models. Here, we report preliminary results from an ongoing, first-in-human dose-escalation study in specific advanced tumors using GB1275 alone or with pembrolizumab. (NCT04060342) **Methods:** Phase 1 comprises dose escalation and expansion. During dose escalation, cohorts of 3 to 6 subjects were sequentially assigned to ascending dose levels of GB1275 from 100 mg to 1200 mg BID in one of two dosing regimens: Regimen A [GB1275 monotherapy orally (PO) twice a day (BID)] and Regimen B [GB1275 PO BID plus pembrolizumab 200 mg IV every 3 weeks (q3wks)]. Dose escalation was based on safety including dose-limiting toxicities (DLTs). Following dose escalation, up to 40 subjects with specific tumor types are to be treated in expansion with the selected GB1275 dose plus pembrolizumab to assess safety, pharmacokinetics, and preliminary clinical and biomarker activity. **Results:** As of January 8, 2021**,** 45 subjects were treated [44 in dose escalation: 23, Regimen A; 21, Regimen B. 1 in expansion, Regimen B], with median (range) GB1275 exposure of 42.0 days (4-263). No DLTs were reported. GB1275-related adverse events occurred in 24/45 (53.3%) subjects; photosensitivity reaction (20.0%), dysesthesia (13.3%) and pruritus (13.3%) were most frequent (≥10%). Stable disease was reported in 6/19 (31.6%) response-evaluable subjects in Regimen A and 9/16 (56.3%) in Regimen B. In Regimen B (800 mg), one partial response was reported in a subject with MSS-CRC treated for 263 days, and one prolonged stable disease (227 days) was reported in a gastric cancer (GC) subject previously treated with pembrolizumab plus bavituximab for less than 3 months due to progression; both subjects are continuing study treatment. A dose-dependent increase in GB1275 systemic exposure was observed up to 800 mg BID. Down-regulation of peripheral MDSCs was seen with both regimens. Regimen-dependent gene clusters in whole blood were noted. An increase in tumor infiltrating lymphocyte (TIL) counts was noted in both Regimens A and B. **Conclusions:** Dose escalation of GB1275, up to 1200 mg in Regimens A and B, demonstrated tolerability as monotherapy and combined with pembrolizumab in subjects with advanced cancers. Encouraging antitumor activity in Regimen B (800 mg) was observed in subjects with MSS-CRC and GC. Biological activity reflected by MDSC modulations in blood and TIL Increases in tumor biopsies with GB1275 alone and with pembrolizumab supports the mechanism of GB1275. GB1275 800 mg BID plus pembrolizumab 200 mg IV q3wks was selected for evaluation in the expansion phase. Clinical trial information: NCT04060342. Research Sponsor: Gossamer Bio, Inc.

2506 **Oral Abstract Session**

Preliminary results of a phase II study of alrizomadlin (APG-115), a novel, small-molecule MDM2 inhibitor, in combination with pembrolizumab in patients (pts) with unresectable or metastatic melanoma or advanced solid tumors that have failed immuno-oncologic (I-O) drugs. *First Author: Anthony W. Tolcher, Texas Oncology-San Antonio Babcock, San Antonio, TX*

Background: Alrizomadlin (APG-115) restores *TP53* function, activating p53-mediated apoptosis in tumor cells with wild-type *TP53* and/or MDM2 amplification. Alrizomadlin also functions as a host immunomodulator and hence may restore antitumor activity in pts with cancers failing PD-1/PD-L1 blockade. **Methods:** This US multicenter trial assessed alrizomadlin combined with pembrolizumab in pts with unresectable/metastatic melanoma or advanced solid tumors that had failed I-O drugs; or pts with malignant peripheral nerve sheath tumor (MPNST), liposarcoma, or ATM mutant solid tumors that had failed any standard therapy. Eligible pts had ECOG performance status of 0-2 and no CNS metastases. The phase II study cohorts included pts with melanoma, NSCLC, solid tumor with ATM mutation, well-differentiated/dedifferentiated liposarcoma, urothelial carcinoma, and MPNST. Alrizomadlin was administered orally at 150 mg once every other day for 2 consecutive weeks with 1 week off and pembrolizumab at 200 mg via IV infusion for 30 minutes on Day 1 of a 21-day cycle. **Results:** As of December 25, 2020, 84 pts had been treated in 6 cohorts: melanoma (n = 26), NSCLC (n = 23), ATM mutation (n = 9), liposarcoma (n = 14), urothelial (n = 9), and MPNST (n = 3). In the PD-1/PD-L1 inhibitor-failed melanoma cohort, there was 1 confirmed partial response (PR) out of 5 pts with uveal melanoma, 2 PR (1 confirmed and 1 unconfirmed) of 5 pts with mucosal melanoma, and 1 confirmed PR of 11 pts with cutaneous melanoma. ORR in the melanoma cohort was 17.4% (4/23 evaluable pts), and the disease control rate was 60.9% (14/23). In the MPNST cohort, 1 of 3 pts had an unconfirmed ongoing PR. In I-O drug-failed NSCLC (n = 14 evaluable) and urothelial (n = 5 evaluable) cohorts, each reported 1 confirmed PR. Common treatment (alrizomadlin or pembrolizumab)-related adverse events (TRAEs) (≥ 10%) were nausea (63.1%), thrombocytopenia (36.9%), vomiting (33.3%), fatigue (31.0%), decreased appetite (27.4%), diarrhea (21.4%), neutropenia (15.4%), and anemia (11.9%). Grade ≥ 3 TRAEs (≥ 5%) included thrombocytopenia (20.2%), neutropenia (14.2%), and anemia (8.3%). Eleven pts discontinued treatment due to AEs: 5 were treatment related, including 2 grade 4 thrombocytopenia, and 1 each of grade 2 vomiting, grade 2 fatigue, and grade 2 posterior reversible encephalopathy syndrome (PRES). Three treatment-related SAEs were PRES, pyrexia, and asthenia. **Conclusions:** Alrizomadlin combined with pembrolizumab is well tolerated and may restore antitumor effects in pts with cancer resistant to or intolerant of I-O drugs, as suggested by preliminary antitumor activities in multiple tumor types. Internal study identifiers: APG-115-US-002; Keynote MK-3475-B66. Clinical trial information: NCT03611868. Research Sponsor: Ascentage Pharma Group Corp Ltd (Hong Kong).

2507 **Oral Abstract Session**

Safety and efficacy of a novel anti-CD20/CD19 bi-specific CAR T-cell therapy (C-CAR039) in relapsed or refractory (r/r) B-cell non-Hodgkin lymphoma (B-NHL). *First Author: Aibin Liang, Tongji Hospital of Tongji University, Shanghai, China*

Background: C-CAR039 has been developed as a novel 2nd generation 4-1BB bi-specific CAR-T targeting both CD19 and CD20 antigens with an optimized bi-specific antigen binding domain. C-CAR039 can eradicate CD19/CD20 single or double positive tumor cells *in vitro* and *invivo*. The tissue cross reactivity and whole genome membrane proteome array studies further confirmed the specificity of C-CAR039. **Methods:** GMP manufacturing of C-CAR039 was carried out in a serum free and fully closed semi-automatic system. Dose escalation and expansion studies were conducted to evaluate the safety and efficacy of C-CAR039 in r/r B-NHL patients. C-CAR039 was administered as a single intravenous dose after a 3-day cyclophosphamide plus fludarabine conditioning regimen. **Results:** As of 1/31/2021, 28 patients were infused and 25 (DLBCL, n = 22; PMBCL, n = 1; tFL, n = 1; FL, n = 1) were evaluable for safety and efficacy at dose ranges of 1.0×10^6 to 5.0×10^6 CAR-T cells/kg. The median age was 54 (range, 28-71) years, median number of prior lines of therapy was 3 (range, 1–5), 76% (19/25) of patients were in Ann Arbor Stage III/IV, and 80% (20/25) were refractory to their last treatment. 5 patients (20%) received bridging therapy. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded according to ASTCT 2019 criteria. Of the 25 patients, 24 (96%) experienced CRS, 23 (92%) were grade 1 or 2, 1 patient was grade 3. Median time to onset of CRS was 3 days (range, 0-10), with median duration of 4 days (range, 1-25). 2 patients had a grade 1 ICANS. Grade≥3 neutropenia, anemia, thrombocytopenia and infection were reported in 88%, 40%, 16% and 0% of patients, respectively. The best overall response rate was 92%, complete response (CR) rate was 84% and median time to response was 1.0 month (range, 0.9-1.2). With a median follow-up of 5.3 months, 76% remained in CR. Kaplan Meyer estimation of PFS at 6 months was 87.3% (95% CI, 71.2 to 100.0). Median duration of response has not been reached. Furthermore, C-CAR039 showed an encouraging cellular kinetic profile. In 25 evaluable patients, the median T_{max} was 11 day, the median C_{max} was 139,497 copies/mg gDNA, and the median $AUC_{0-28DAY}$ of 1,673,844 day*copies/μg gDNA. **Conclusions:** C-CAR039 demonstrated a favorable safety profile and promising efficacy in this early clinical trial in patients with r/r B-NHL that might allow it to differentiate from existing therapies. The early clinical efficacy signal is encouraging and compares favorably to anti-CD19 CAR-T and peer therapies. These findings will be evaluated in more patients with longer follow-up to confirm safety, efficacy and duration of response. Clinical trial information: NCT04317885, NCT04655677, NCT04696432, NCT04693676. Research Sponsor: Cellular Biomedicine Group Inc.

2508 **Oral Abstract Session**

Safety and efficacy of a novel anti-CD20 chimeric antigen receptor (CAR)-T cell therapy in relapsed/refractory (r/r) B-cell non-Hodgkin lymphoma (B-NHL) patients after failing CD19 CAR-T therapy. *First Author: Aibin Liang, Tongji Hospital of Tongji University, Shanghai, China*

Background: Relapse due to loss of the CD19 targeted epitope presents a therapeutic challenge of CD19 CAR-T therapy. These patients universally have a poor outcome and the unmet medical need is high. CD20 is a proven therapeutic target for B-NHL, supported by approved and widely used monoclonal antibody therapy. C-CAR066 is a novel 2nd generation chimeric antigen receptor T (CAR-T) therapy targeting CD20 antigen. Preclinical studies suggest that C-CAR066 has superior anti-tumor activity compared to CAR-Ts derived from scFVs of Leu16, Rituximab and Obinutuzumab and anti-CD19 BBZ CAR with FMC63. **Methods:** A phase I clinical trial (NCT04036019) was conducted to evaluate the safety and efficacy of C-CAR066 in subjects with r/r B-NHL who were previously treated with anti-CD19 CAR-T therapy. Patients ($\geq$ 18 years) with r/r DLBCL, r/r FL or r/r MCL, ECOG $<$ 2 were eligible. GMP manufacture of C-CAR066 was in a serum free and fully closed semi-automatic system. A 3-day cyclophosphamide plus fludarabine regimen was followed by a single infusion of C-CAR066. Bridging therapy was allowed. **Results:** As of Jan 31, 2021, 7 patients (6 DLBCL, 1 tFL) were enrolled and infused with C-CAR066 at dose ranges of 2.0 x 10^6 to 4.8x10^6 CAR-T cells/kg. The manufacturing success rate was 100%. The median age was 51 (range, 41-62) years, and 42.9% (3/7) patients were male. The median number of prior lines of therapy was 5 (range, 2-6). One patient (14.3%) underwent autologous stem cell transplant (ASCT) and one patient received bridging therapy. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded according to ASTCT 2019 criteria. All 7 patients experienced CRS and most (85.7%) were grade 1 or 2. One patient had grade 4 CRS and recovered after treatment with tocilizumab and corticosteroids. Median time to onset of CRS was 5 days (range, 1-9), with median duration of 4 days (range, 2-17). There were no episodes of ICANS. Grade $\geq$3 neutropenia, anemia, thrombocytopenia, and infections were reported in 57.1%, 42.9%, 28.6%, and 14.3% of patients, respectively. At a median follow-up of 7.8 months, the best overall response rate was 100%, with 71.4% (5/7) achieving complete response (CR). Median time to response was 1.0 month (range, 0.9-2.7). Median time to CR was 2.7 months (range, 0.9-2.8). By the cutoff date, 3 patients (2 PR, 1 CR) had disease progression. Median duration of response was not reached. **Conclusions:** C-CAR066 has shown a favorable safety profile and promising efficacy in patients with r/r B-NHL following failure of CD19 CAR-T therapy. These results show that C-CAR066 has a different mechanism of action compared to anti-CD-19 CAR-T therapy and could provide a solution to address the unmet medical need in B-NHL patients that have failed anti-CD19 CAR-T therapy. Clinical trial information: NCT04036019. Research Sponsor: Cellular Biomedicine Group Inc.

2509 **Poster Discussion Session**

Phase Ib study of the anti-TGF-β monoclonal antibody (mAb) NIS793 combined with spartalizumab (PDR001), a PD-1 inhibitor, in patients (pts) with advanced solid tumors. *First Author: Todd Michael Bauer, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: TGF-β plays a key role in regulating the tumor microenvironment. Emerging evidence suggests TGF-β is a key activator of cancer-associated fibroblasts, leading to fibrotic network development and immune exclusion. Preclinical data in murine models showed that TGF-β blockade alleviates intratumoral fibrosis, augmenting the efficacy of PD-1 immunotherapy. NIS793 is a human IgG2 mAb that binds to TGF-β. This study investigates NIS793 + spartalizumab in pts with advanced solid tumors. **Methods:** Pts initially received NIS793 (0.3–1 mg/kg Q3W) monotherapy; following evaluation of two dose levels, dose escalation continued with NIS793 + spartalizumab (NIS793 0.3–30 mg/kg Q3W + spartalizumab 300 mg Q3W; or NIS793 20–30 mg/kg Q2W + spartalizumab 400 mg Q4W) in pts with/without prior anti-PD-(L)1 therapy. In dose expansion, pts with non-small cell lung cancer (NSCLC) resistant to prior anti-PD-(L)1 or pts with microsatellite stable colorectal cancer (MSS-CRC) were treated at the recommended dose for expansion (RDE). Paired tumor biopsies were required from all pts. The primary objectives were to characterize safety and tolerability of the combination and determine the RDE. **Results:** By December 1, 2020, 60 pts were treated in the dose-escalation phase, mainly with NIS793 + spartalizumab (n = 49), and 60 pts were treated in dose expansion (MSS-CRC: n = 40; NSCLC: n = 20). Two pts were still receiving treatment. No dose-limiting toxicities were observed, and the RDE was established as 30 mg/kg (2100 mg) NIS793 + 300 mg spartalizumab Q3W. Overall 50% pts experienced $\geq$1 treatment-related AE (TRAE). The most common were rash (n = 15/120), pruritus (n = 10/120), fatigue (n = 9/120), and nausea (n = 8/120). Grade 3/4 TRAEs occurred in 11% pts, with rash (3%) being the most common. Treatment-related serious AEs were reported in 8 pts; 6 were grade 3/4 in severity. No deaths occurred due to AEs; 3 (2.5%) pts discontinued due to AEs. PK for NIS793 was linearly dose proportional with no obvious correlation between exposure and response. Two pts achieved a partial response (PR; one confirmed in clear cell renal cell carcinoma and one unconfirmed in NSCLC) during dose escalation of the combination. Two confirmed PRs were achieved in the MSS-CRC dose-expansion group. Biomarker data showed evidence of target engagement through increased TGF-β/NIS793 complexes and depleted active TGF-β in peripheral blood. Gene expression and protein analyses in tumor biopsies displayed decreased TGF-β target genes, decreased TGF-β signatures and increased immune signatures suggesting modulation of the TGF-β pathway and preliminary evidence of biological activity. **Conclusions:** Data showing target engagement and TGF-β pathway inhibition supported the proof of mechanism of NIS793. The RDE of the combination was established and well tolerated in pts with advanced solid tumors. Clinical trial information: NCT02947165. Research Sponsor: Novartis.

2510 **Poster Discussion Session**

Safety, pharmacokinetic and pharmacodynamic results from dose escalation of SAR439459, a TGFβ inhibitor, as monotherapy or in combination with cemiplimab in a phase 1/1b study. *First Author: Stephen K. Williamson, University of Kansas Medical Center, Westwood, KS*

Background: SAR439459 is a human anti-TGFβ monoclonal antibody that neutralizes all isoforms of TGFβ. In preclinical models, combining SAR439459 with an anti-PD-1 showed improved anti-tumor activity compared to single agent. Here we report preliminary results of SAR439459 ± cemiplimab in a first in human study. **Methods:** This is an open-label study (dose escalation and expansion) of SAR439459 ± cemiplimab administered intravenously in adult patients with advanced solid tumors to determine safety and tolerability, the maximum tolerated dose (MTD) and/or maximum administered dose (MAD) of SAR439459 ± cemiplimab, pharmacokinetics (PK); pharmacodynamic (PD) and preliminary clinical benefit. In Part 1A, SAR439459 (0.05-15 mg/kg) was administered as monotherapy Q2W in an adaptive Bayesian design with overdose control. In Part 1B, SAR439459 doses cleared from monotherapy were administered in combination with fixed dose of cemiplimab (3 mg/kg Q2W or 350 mg Q3W) in a 3+3 design. **Results:** As of 31 January 2020, 28 (1A) and 24 (1B) patients with ECOG performance status of 0-1 with a median age of 60.5 and 63 years respectively were enrolled. In Part 1A, 25 patients (89.3%) had at least one treatment emergent adverse event (TEAE) and 15 (53.5%) experienced grade (G)$\geq$ 3 events. In Part 1B, 22 patients (91.7%) had at least one TEAE and 14 (58.3%) experienced G $\geq$ 3 events. Dose-limiting toxicities (DLTs) were evaluable in 24 and 21 patients respectively. In 1A, 2 DLTs were reported in 2 of 8 evaluable patients in dose level (DL) 4: G5 brain stem hemorrhage in a patient on concomitant low molecular weight heparin treatment and G3 myocardial infarction in a patient with diabetes, chronic kidney disease, chronic obstructive pulmonary disease, and hypertension. In 1B, 1 of 6 evaluable patients in DL5 had DLTs (G3 ALT and AST increase). MTD was not reached in either part. Ten patients had best overall response of stable disease: 6 in 1A and 4 in 1B. The PK of SAR439459 was dose proportional over the dose range tested with no evidence of cemiplimab effect on SAR439459 PK, when given in combination. Treatment with SAR439459 ± cemiplimab led to rapid reduction in total plasma TGFβ level in all dose levels tested and induced CD8 & NK cells expansion and Th1 cytokines production, suggesting peripheral T cell activation. Preliminary results from paired tumor biopsies collected from patients treated with SAR439459 ± cemiplimab in expansion showed trend of TGFβ signaling pathway inhibition and conversion from excluded to inflamed tumor-immune phenotype. **Conclusions:** SAR439459 ± cemiplimab showed an acceptable tolerability profile overall. MTD was not reached. Peripheral and tumor target engagement and modulation of key immune cells was observed in treated patients. Dose expansion cohorts are currently enrolling selected solid tumor patients. Funding: Sanofi. Clinical trial information: NCT03192345. Research Sponsor: Sanofi.

2511 **Poster Discussion Session**

Preliminary safety, pharmacokinetics (PK), pharmacodynamics (PD) and clinical efficacy of ulildlimab (TJ004309), a differentiated CD73 antibody, in combination with atezolizumab in patients with advanced cancer. *First Author: Francisco Robert, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

Background: CD73 is implicated in tumor resistance to checkpoint immunotherapy (CPI) and plays a critical role in adenosine-mediated immune suppression. Ulildlimab, a differentiated CD73 antibody, inhibits the adenosine pathway in a non-competitive and unique intra-dimer binding mode. Ulildlimab suppresses tumor growth when combined with a PD-(L)1 inhibitor in multiple pre-clinical models. **Methods:** This 3+3 dose-escalation phase 1 study (NCT03835949) evaluated safety, tolerability, PK, PD and preliminary efficacy in cancer patients. Ulildlimab was administered intravenously at doses of 5, 10 or 15 mg/kg weekly (QW) or 15 or 20 mg/kg every 3 weeks (Q3W) alone in the first cycle and in combination with atezolizumab (1,200 mg Q3W) starting on week 4. Soluble CD73 in serum and CD73 receptor occupancy (RO) in circulating $CD19^+$ B cells were measured. Expression of PD-L1, CD73 and A2A receptor was analyzed in baseline tumor specimens (n = 14). Tumor responses were assessed by RECIST/iRECIST. **Results:** As of 17 January 2021, 20 patients with advanced solid tumors were enrolled (M:F 8:12; mean age = 64; median prior regimens = 3 (range 1-9)). Ulildlimab was well-tolerated with no dose limiting toxicity. The most common treatment-related adverse events were first dose infusion related reactions (65%, n = 13) most commonly comprising chills/rigors, nausea, and vomiting (Grade 1 or 2) that resolved in subsequent infusions. PK appears linear at doses $\geq$ 10 mg/kg and modelling indicated a mean derived effective half-life of ~19 days. Soluble CD73 was undetectable and complete RO was achieved in all patients after the first dose at $\geq$ 10 mg/kg. Anti-drug antibody was detected in 3/20 patients (15%). Among 13 efficacy-evaluable patients dosed at $\geq$ 10 mg/kg, complete response (CR = 1) and partial response (PR = 2) were observed in 3 patients (ORR = 23%) together with 3 stable disease (SD) patients (DCR = 46%). One PD-(L)1 inhibitor naïve patient with clear cell ovarian cancer achieved CR at 10 mg/kg QW and remains on study after 12 months. Two patients with NSCLC dosed at 15 mg/kg QW and 20 mg/kg Q3W, respectively, achieved PR. One patient failed nivolumab and the other received no prior PD-(L)1 inhibitor treatment. CD73 was expressed on 78% (mean) of malignant cells from archival tumor specimens in responders compared to 23% in non-responders. **Conclusions:** Ulildlimab is safe and well tolerated up to 20 mg/kg Q3W and 15 mg/kg QW. Full saturation of circulating and cell-bound CD73 was achieved at doses $\geq$ 10 mg/kg. Ulildlimab exhibited evidence of clinical activity in both PD-(L)1 treatment naïve and refractory cancer patients with high archival tumor expression of CD73. The results of this phase 1 study encourage further clinical investigation to evaluate the efficacy of ulildlimab in the treatment of solid tumors. Clinical trial information: NCT03835949. Research Sponsor: TRACON Pharmaceuticals Inc.

2512 **Poster Discussion Session**

BDB001, an intravenously administered toll-like receptor 7 and 8 (TLR7/8) agonist, in combination with pembrolizumab in advanced solid tumors: Phase 1 safety and efficacy results.

First Author: Manish R. Patel, Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, FL

Background: BDB001 is an intravenously administered TLR 7/8 dual agonist immune modulator capable of reprogramming dendritic cells to produce antitumor activities. BDB001 monotherapy has demonstrated favorable tolerability and robust systemic immune activation leading to durable clinical responses in a phase I dose escalation trial. Here, we report on the safety and efficacy of BDB001 in combination with pembrolizumab in a phase I dose escalation trial in advanced solid tumors (NCT03486301). **Methods:** BDB001-101 is a phase 1, open label, dose escalation/expansion trial of BDB001 (IV, Q1W) in combination with pembrolizumab (IV, Q3W) in patients with advanced solid tumors. The primary endpoint was safety and tolerability. Secondary endpoints included efficacy, pharmacokinetics and pharmacodynamic profiling of immune activation. **Results:** Twenty-three subjects with 13 different tumor types were enrolled across 4 dose levels. Sixty one percent were female, median age was 63 years (range, 33-86), median number of prior therapies was 3 (range, 1-8), and 48% of tumors had progressed on prior anti-PD-(L)1 therapy. Overall, BDB001 in combination with pembrolizumab was well tolerated and dose-limiting toxicities were not observed. The most common treatment related adverse events (TRAEs) were fever (39.1%), fatigue (39.1%), chills/rigor (34.8%), pruritus/rash (21.7%), and nausea (13.0%). Most of these TRAEs were grade 1 or 2 and transient. Only 3 (13.0%) subjects experienced grade 3 TRAEs of fatigue, rash, stomatitis, and alkaline phosphatase elevation. There were no grade 4 or 5 TRAEs. Pharmacodynamic evaluation of plasma cytokine levels showed robust increases in interferon gamma and interferon inducible protein-10 (IP-10) at BDB001 Dose Level 3 and 4. Preliminary efficacy evaluation of the 14 subjects treated at Dose Level 3 and 4 showed durable and deep clinical responses in 4 (29%) subjects with anti-PD-(L)1 mAb refractory melanoma, hepatocellular carcinoma, cholangiocarcinoma, and platinum-resistant ovarian carcinoma. The responses were observed by the initial efficacy assessment at 9-weeks, with some seen as early as 4-weeks. In addition, 4 (29%) subjects had stable disease for a disease control rate of 57%. To date, median time on treatment is 14.4 weeks (range, 6.0 – 42.1+) with 3 subjects still active on treatment. **Conclusions:** Intravenously administered BDB001 in combination with pembrolizumab is well tolerated. Rapid and deep clinical responses were observed, supported by robust systemic immune activation. BDB001 in combination with pembrolizumab is a promising novel therapeutic option for patients with advanced solid tumors and is being evaluated in an ongoing dose expansion trial. Clinical trial information: NCT03486301. Research Sponsor: Seven and Eight Biopharmaceuticals Inc.

2513 **Poster Discussion Session**

ARTISTRY-1: Nemvaleukin alfa monotherapy and in combination with pembrolizumab in patients (pts) with advanced solid tumors.

First Author: Valentina Boni, START Madrid CIOCC Madrid, Madrid, Spain

Background: Nemvaleukin alfa (nemvaleukin, ALKS 4230) is a novel, engineered cytokine that selectively binds the intermediate-affinity interleukin-2 (IL-2) receptor complex to preferentially activate $CD8^+$ T cells and natural killer cells with minimal expansion of regulatory T cells, designed to leverage antitumor effects of the IL-2 pathwaywhile mitigating potential toxicity that would limit use. **Methods:** ARTISTRY-1 (NCT02799095) is a phase 1/2 study. Parts A (dose escalation 0.1-10 μg/kg) and B (6 μg/kg [recommended phase 2 dose]) are monotherapy; pts receive intravenous nemvaleukin for 5 days every 14 or 21 days. In Part C, pts receive nemvaleukin (3 or 6 μg/kg) every 21 days in combination with pembrolizumab (200 mg on day 1). We present safety and antitumor activity (RECIST v1.1, iRECIST) data as of 12/02/2020. **Results:** In Part A, 39 pts received nemvaleukin. No dose-limiting toxicities were observed; maximum tolerated dose was not reached. Part B enrolled immune checkpoint inhibitor–pretreated pts into melanoma or renal cell carcinoma (RCC) cohorts. 18 pts with melanoma enrolled; 10 were evaluable, 2 (both with metastatic mucosal melanoma) achieved a partial response (PR; 1 unconfirmed). 24 pts with RCC enrolled; 1 of 16 evaluable pts achieved a PR (awaiting confirmation). 12 pts in each cohort continue on study. In Parts A and B, treatment-related adverse events in ≥40% included chills (74.4% and 52.4%, respectively) and pyrexia (74.4% and 47.6%, respectively). In Part C (83 evaluable pts), 12 objective responses (OR) were observed; an additional 5 pts had stable disease (SD) >6 months (1 pt with breast cancer, 2 with ovarian cancer, and 2 with non-small-cell lung cancer). Nemvaleukin did not demonstrate any additive toxicity to that already established with pembrolizumab alone. OR data are summarized in the table. **Conclusions:** Nemvaleukin was generally well tolerated and demonstrated antitumor activity as monotherapy and in combination with pembrolizumab. Pharmacodynamic studies to identify biomarkers are ongoing. Future research of monotherapy and combination therapy with nemvaleukin is warranted. Clinical trial information: NCT02799095. Research Sponsor: Alkermes, Inc.

2514 **Poster Discussion Session**

Preliminary results of a phase 1b study of fruquintinib plus sintilimab in advanced colorectal cancer.

First Author: Ye Guo, Shanghai East Hospital, Shanghai, China

Background: To explore the safety and synergistic anti-tumor effect of fruquintinib (a VEGFR inhibitor) in combination with sintilimab (an anti-PD-1 Ab) in patients (pts) with advanced colorectal cancer (CRC) and other solid tumors. **Methods:** This is an ongoing phase Ib/II, multicenter, two-stage study. Pts with variety cancer types, including CRC, were enrolled and is continuously enrolling in the study. For this interim analysis, all pts were analyzed for safety whereas only CRC pts were analyzed for efficacy. MMR status were analyzed for all enrolled CRC pts. Stage 1 was classical "3+3" dose escalation with pts assigned to one of the following 4 cohorts, fruquintinib taken orally at 3mg (Cohort A, 3 weeks on/ 1 week off), 4mg (Cohort B, 3 weeks on/ 1 week off), 5mg-intermittent (Cohort C, 2 weeks on/ 1 week off) or 3mg-continuous (Cohort E, once daily), while sintilimab was given at 200mg intravenously with Q4W in Cohort A and Cohort B whereas Q3W in Cohort C and Cohort E. DLT was observed for 28 days. Stage 2 was dose expansion with pts receiving 5mg-intermittent or 3mg-continuous fruquintinib plus sintilimab (200mg, Q3W). The primary endpoints were safety and tolerability and secondary endpoint was objective response rate (ORR). **Results:** As of Jan 5, 2021, 44 CRC pts which failed to at least 2 previous lines of therapy containing fluoropyrimidine, oxaliplatin or irinotecan were enrolled. They received either 5mg-intermittent or 3mg-continous dosage (n = 22, each), the ORR was 22.7% (10/44, 95% CI: 11.5-37.8%) with 27.3% (6/22, 95% CI: 10.7-50.2%) in 5mg-intermittent group and 18.2% (4/22, 95% CI: 5.2-40.3%) in 3mg-continuous group. With a median follow-up time of 8.3 (range: 0-9.6) months, the K-M estimated median PFS was 6.8 (95% CI:5.6-NA) months and 4.3 (95% CI:3.5-NA) months for 5mg-intermittent group and 3mg-continuous group, respectively. Overall, 60 pts were enrolled for safety analysis, including 23 in stage1 and 37 (only CRC) in stage 2. In stage 1, all pts experienced TEAEs, 52.2% of which were ≥ grade 3. The most frequently reported TEAEs were TSH increasing (73.9%), fecal occult blood positive (56.5%), and Palmar-plantar erythrodysaesthesia syndrome (PPES) (56.5%). SAEs occurred in 8 (34.8%) pts and no treatment-related death was reported. One patient in Cohort B reported manageable DLT. In stage 2, all pts experienced TEAEs, 18 (48.6%) pts experienced ≥ grade 3 TEAEs with 6 (31.6%) in 5mg-intermittent group and 12 (66.7%) in 3mg-continuous group. The most common TEAEs were proteinuria (45.9%) and TSH increasing (37.8%). TEAEs leading to either fruquintinib or sintilimab discontinuation occurred in 3 (5%) pts each. **Conclusions:** Fruquintinib plus sintilimab showed promising efficacy and favorable safety profile in advanced CRC. Clinical trial information: NCT03903705. Research Sponsor: Hutchison MediPharma Limited, Pharmaceutical/Biotech Company.

2515 **Poster Discussion Session**

Safety and efficacy of AK112, an anti-PD-1/VEGF-A bispecific antibody, in patients with advanced solid tumors in a phase I dose escalation study.

First Author: Jermaine Coward, ICON Cancer Care, South Brisbane, QLD, Australia

Background: AK112 is a tetrameric bispecific antibody targeting PD-1 and VEGF-A. Published data suggests that the combination of anti-VEGF-A with immune checkpoint inhibitor (ICI) therapy produces complementary and synergistic antitumor effects. Given the strong correlation between VEGF-A and PD-1 expression in the tumor microenvironment, it is postulated that the simultaneous blockade of these 2 targets by AK112 as a single agent might achieve higher target binding specificity and produce enhanced antitumor activity, with an improved safety profile, compared to the co-administration of anti-PD-(L)1 and anti-VEGF therapies. Here, we present preliminary safety and efficacy data from a dose escalation study of AK112. **Methods:** A multicenter, phase I, open-label dose escalation and expansion study in advanced solid tumors that are resistant/refractory to standard therapies, began in December 2019 to determine the safety and efficacy of AK112 (0.3 mg/kg to 30 mg/kg) administered IV every 2 weeks (Q2W) using an accelerated titration followed by 3+3+3 dose escalation design. Selected dose escalation cohorts were expanded to a maximum of 18 subjects with selected solid tumor types for further evaluation of safety, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity, and anti-tumor activity. Pts with prior exposure to ICI were eligible. PD studies examined serum VEGF levels and PD-1 receptor occupancy (RO) on circulating T-cells as an indication of target engagement. **Results:** As of 13 Jan 2021, 29 pts, median age 60 years [30-76], have received AK112 at doses of 0.3 mg/kg (n = 1), 1.0 mg/kg (n = 3), 3.0 mg/kg (n = 3), 10.0 mg/kg (n = 13), 20.0 mg/kg (n = 8), and 30.0 mg/kg (n = 1) Q2W. Treatment-related adverse events (TRAEs) occurred in 55.2% of pts. G3 TRAEs occurred in 10.3% [3/29] and treatment-related SAEs occurred in 3.4% [1/29] of pts. There was no G4 TRAE. No DLT occurred. TRAEs leading to treatment discontinuation occurred in 6.9% of pts [2/29]. Most frequent TRAEs were arthralgia (17%), diarrhea (14%), rash (10%), and fatigue (10.3%). Of the 17 evaluable pts treated at doses ≥ 3 mg/kg Q2W, the ORR was 23.5% (4/17) and disease control rate (DCR) was 64.7% (11/17). Among the 4 responders, a responder (endometrial ca) had not received prior ICI or bevacizumab, 2 responders (ovarian ca, mesothelioma) had received prior ICI therapy; and a responder (microsatellite stable colorectal ca) was previously treated with bevacizumab. **Conclusions:** AK112, up to 20 mg/kg Q2W (inclusive), can be given safely to pts and demonstrated encouraging anti-tumor activity with an ORR of 23.5% when dosed ≥ 3 mg/kg Q2W in a pt population with various solid tumors resistant/relapsed to standard therapies. Enrolment is currently ongoing at 30.0 mg/kg Q2W and in dose escalation cohorts selected for expansion. Updated data, including PK, serum VEGF, and RO will be presented. Clinical trial information: NCT04047290. Research Sponsor: Akeso Biopharma, Inc.

2516 **Poster Discussion Session**

A first-in-human study of AO-176, a highly differentiated anti-CD47 antibody, in patients with advanced solid tumors. *First Author: Howard A. Burris III, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: AO-176 is a humanized IgG2 antibody that specifically targets CD47. Expressed by multiple tumor types, CD47 binds to signal regulatory protein a (SIRPa) on phagocytes, including macrophages and dendritic cells. The CD47-SIRPa complex results in a "don't eat me" signal that allows the tumor to escape removal by the innate immune system, disabling the generation of an adaptive immune response. The differentiated mechanisms of action of AO-176 include promotion of phagocytosis, direct tumor cell killing through programmed cell death type III and induction of damage associated molecular patterns/immunogenic cell death, preferentially binding to tumor cells vs. normal cells, and enhanced binding at an acidic pH as found in tumor microenvironments. AO-176 has negligible binding to RBCs. **Methods:** In a phase 1/2 first-in-human study (NCT03834948) of AO-176, pts with advanced solid tumors associated with high CD47 expression and an ECOG PS of 0-1 were enrolled into escalating dose cohorts of AO-176 given IV every 7 days. Objectives included evaluation of safety, dose-limiting toxicity (DLT) and recommended phase 2 dose (RP2D), antitumor activity, pharmacokinetic (PK) parameters and exploratory biomarkers. **Results:** As of 4 Jan 2021, 27 pts were enrolled (median age 64 years; 67% female; 67% ECOG PS 1; median [range] of 4 [1-7] prior therapies for metastatic disease). Dose levels of 1, 3, 10, 20 and 20 (using step-up dosing) mg/kg were evaluated in >250 infusions. Most common (>10%) treatment-related adverse events (TRAEs) of any grade were thrombocytopenia and infusion-related reaction (IRR) (33% each), anemia (22%) with no evidence of hemolysis, nausea (19%), and fatigue (15%). The only G3+ TRAE occurring in >10% of pts was asymptomatic, brief thrombocytopenia (22%). No platelet transfusions were given. DLTs included IRRs in 2 pts dosed at 20 mg/kg, and asymptomatic thrombocytopenia and a cerebrovascular accident in 1 pt each in the 20 mg/kg step-up cohort. The RP2D was 10 mg/kg. Implementation of additional pre-medication and a 6-hr infusion duration in cycle 1 eliminated subsequent IRRs. Dexamethasone tapering and shortening of the infusion duration to 2 hrs was successful in all pts after cycle 1. Interim PK analysis of AO-176 demonstrated consistent exposure with linear PK. The $T_{1/2}$ was ~5 days. One pt with endometrial carcinoma who had not responded to any of 4 prior systemic regimens had a confirmed PR and remains on study for >1 year. 7 pts had SD as a best response, with 2 pts (endometrial carcinoma, gastric cancer) on study for >6 mos. **Conclusions:** AO-176 is a well-tolerated, differentiated anti-CD47 therapeutic. Durable anti-tumor activity was observed. Evaluations of AO-176 in combination with paclitaxel in pts with select solid tumors (NCT03834948) and as a single-agent in pts with multiple myeloma (NCT04445701) are ongoing. Clinical trial information: NCT03834948. Research Sponsor: Arch Oncology.

2517 **Poster Discussion Session**

First-in-human phase 1 dose escalation study of HX009, a novel recombinant humanized anti-PD-1 and CD47 bispecific antibody, in patients with advanced malignancies. *First Author: Aflah Roohullah, South Western Sydney LHD, Liverpool, Australia*

Background: HX009 is a novel humanized antibody fusion protein which binds to CD47 and PD-1 concurrently. HX009 significantly inhibited tumor growth in mouse xenograft models. In Cynomolgus monkeys, the highest non-severely toxic dose in repeat dose testing was 15mg/kg. HX009-I-01 (ClinicalTrials.gov: NCT04097769) is a first-in-human study evaluating the safety and efficacy of HX009 in subjects with advanced malignancies. Here we report the preliminary results from this study. **Methods:** The study is being conducted in Australia at 3 sites. The study design follows a 3+3 dose-escalation scheme, enrolling cohorts of at least 3 subjects (except the first dose level) sequentially until MTD or the maximum dose is reached. HX009 is administered as single agent every 2 weeks via intravenous infusion. The 7 dose levels planned are: 0.1mg/kg (1 subject), 0.3mg/kg, 1mg/kg, 2mg/kg, 3mg/kg, 5mg/kg, 7.5mg/kg. All AEs are graded using NCI CTCAE v5.0. Efficacy assessments are per RECIST 1.1. Blood samples are obtained for pharmacokinetics (PK) and for immunogenicity assessments by the development of Antidrug Antibodies. **Results:** As of the January 22 2021 cutoff date, 21 patients (12M/9F) with a median age of 69.0 years (range 38-86) have received dose levels of 0.1-7.5 mg/kg. Patients with the following tumor types have been enrolled: colorectal cancer (7), squamous cell carcinoma (3), endometrial cancer (2), breast cancer (3), malignant epithelioid mesothelioma (1), gallbladder cancer (1), pancreatic cancer (1), glioblastoma(1), ovarian cancer (1), gastro-esophageal junction adenocarcinoma (1). Patients had received a median of 3 (range 1-9) prior anti-cancer regimens. Treatment-related AEs have been reported in 10 (47.6%) patients to date. Most AEs are grade 1 or 2. The most frequent treatment-related AEs include nausea (n = 2, G1), rash (n = 2, G1), vomiting (n = 2, G1), and decreased appetite (n = 2, G1). Only 1 treatment-related SAE of pneumonitis. One treatment-related anemia (G2), and no thrombocytopenia. No DLT was observed in all 7 dose levels. Among 18 patients who have had at least one post-baseline tumor assessments, partial responses (PR) have been achieved in 3 patients with the following tumor types (dose level): gallbladder adenocarcinoma (1mg/kg), triple negative breast cancer (5mg/kg), metastatic squamous cell carcinoma of head and neck (5mg/kg). In addition, there are 6 patients with best overall response of stable disease. As of the data cutoff date, 6 patients are still receiving treatment. Updated clinical and PK results will be presented at the meeting. **Conclusions:** HX009, on an every 2 weeks dosing schedule, up to 7.5 mg/kg, is well-tolerated, without any DLT to date. Antitumor activity was seen at 1 mg/kg and 5 mg/kg cohorts with objective responses in multiple tumor types; Further investigation in phase Ib/II studies is warranted. Clinical trial information: NCT04097769. Research Sponsor: HanX Biopharmaceutical Inc, Hangzhou, China.

2518 **Poster Discussion Session**

Phase I INSIGHT platform trial: Advanced safety and efficacy data from stratum D evaluating feasibility and safety of eftilagimod alpha (soluble LAG-3 protein) combined with avelumab in advanced solid tumors. *First Author: Thorsten Oliver Goetze, Krankenhaus Nordwest, University Cancer Center Frankfurt and Institut für Klinische Krebsforschung IKF GmbH am Krankenhaus Nordwest, Frankfurt Am Main, Germany*

Background: Stratum D of the INSIGHT platform trial evaluates s.c. eftilagimod alpha (efti, IMP321) combined with avelumab in advanced solid tumors. Efti is an MHC class II agonist which activates antigen-presenting cells followed by CD8 T-cell activation. Combination with PD-1/PD-L1 blockade aims at enhanced efficacy. **Methods:** This IIT platform trial consists of 5 strata: intratumoral (A) or intraperitoneal efti (B); s.c. efti with SOC (C) or with PD-L1 inhibition (D). Strat E is currently under development and starts soon with a new efti combination. This abstract focuses on preliminary data of Strat D. Patients (pts) received 800mg avelumab i.v. q2w along with s.c. efti: 6mg in cohort 1 (coh 1, 6 pts), 30mg in cohort 2 (coh 2, 6 pts). Primary endpoint: safety. **Results:** Recruitment has been completed with 12 pts (coh 1: gastric, gallbladder, colon cancer, pleural mesothelioma; coh 2: gastric, gastroesophageal, anal, rectum, cervix uteri). No dose limiting toxicities (DLTs) occurred. 10 serious adverse events (SAEs) were reported, none of them considered causally related (4 in 3 pts of coh 1 [1 acute renal insufficiency grade 5 in 1 pt, 2 preileus grade 3 in 1 pt, hearing impaired grade 4 in 1 pt] and 6 in 4 pts of coh 2 [1 anal hemorrhage and 1 gallbladder obstruction in 1 pt, 1 eye pain and 1 surgery to replace the feeding tube in 1 pt, each grade 3, 1 skin infection grade 2, 1 diffuse myocardial fibrosis grade 5]. 1 AE of special interest (AESI) possibly related with avelumab (sarcoidosis grade 1) occurred in coh 1. 2 pts completed max treatment duration with 24 cycles. In coh 1, 47 adverse events (AEs; grade 1-2, 29; grade 3, 14; grade 4, 3; grade 5, 1) occurred in 5 pts. Most common grade 1-2 AEs were nausea, pain in 33%, 33% of the pts. Most common grade 3 AEs were ileus, vomiting in 33%, 33% of the pts. 2 AEs grade 4 (hearing impaired, sepsis) and 1 AE grade 5 (acute renal insufficiency) were reported. All AEs grade 3-5 were considered causally unrelated. In coh 2, 51 adverse events (AEs; grade 1-2, 29; grade 3, 19; grade 4, 2; grade 5, 1) occurred in 5 pts. The most common grade 1-2 AE was hypothyroidism in 33% of the pts. 1 AE grade 5 (diffuse myocardial fibrosis) was reported. Only 1 AE grade 3-5 was considered causally related (urinary tract infection grade 3 related with avelumab). 5 pts showed partial response as best response (2 coh 1: colon, pleural mesothelioma; 3 coh 2: gastric, anal, cervical), 1 stable disease with clinical progression (coh 2) (all but one of these pts still alive), 5 disease progressions acc. to RECIST 1.1 (3 coh 1, 2 coh 2), 1 clinical progression (coh 1). Signals of activity were also observed in pre-treated *MSS/PD-L1$_{low}$* pts. **Conclusions:** Combined treatment with avelumab 800mg and efti 6mg (coh 1) or 30 mg efti (coh 2) seems feasible and safe. No unexpected AEs occurred. Signals of efficacy with CPI combination were seen (DCR 50%). Clinical trial information: NCT03252938. Research Sponsor: IMMUTEP.

2519 **Poster Discussion Session**

Pan cancer analysis of the intra-tumoral microbiome's correlation with racial disparities. *First Author: Wei Tse Li, University of California San Diego, San Diego, CA*

Background: Microbiome composition can influence cancer development and is moderated by diet, hygiene, sanitation, and other environmental variables. For example, a Mediterranean diet could increase breast *Lactobacillus* abundance, while the gut microbiome changes dramatically with fructose intake. Recent studies have revealed correlations between microbial abundance and racial disparities in cancer. Given these reports, it is critical to examine whether environmental influences on the microbiome contribute to racial disparities in cancer incidence and prognosis. **Methods:** We examined the intra-tumoral microbiome in the lungs, breasts, bladder, colon, rectum, cervix, head and neck, prostate, and pancreas (n = 4,169). Raw tumor RNA sequencing data were downloaded from The Cancer Genome Atlas (TCGA) and aligned to bacterial genomes. Microbial abundance was correlated to race, ethnicity, and prognostic variables (Kruskal-Wallis test or Cox regression, $p < 0.05$). **Results:** We identified several microbes correlated with racial disparities for breast and bladder cancer, two microbes for lung squamous cell carcinoma, and one microbe for colon cancer. For breast cancer, African Americans have the highest mortality rate, followed by white Americans and Asian Americans. We found that four microbes, all under the order Burkholderiales, were positively correlated with poor prognosis and were most abundant in African Americans and least abundant in Asian Americans. Therefore, increased abundance of these microbes may contribute to the observed mortality differences between races. For bladder cancer, Asian Americans have the lowest incidence and mortality rates. Seven microbes, including two *Geobacillus*, two *Pseudomonas*, and two Burkholderiales, positively correlate with good prognosis and are upregulated in Asian Americans. High *Pseudomonasfluorescens* abundance is positively correlated with decreased risk of death (HR: 0.57, 95% CI: 0.38-0.85). High abundance of the Burkholderiales *R. pickettii* (HR: 0.62, 95% CI: 0.42-0.92) and *V. paradoxus* (HR: 0.59, 95% CI: 0.36-0.98) also exhibit the same trend. *Geobacillus* and *Pseudomonas* are both present in food, while Burkholderiales can cause nosocomial infections and are altered by diet. **Conclusions:** Our study is the most comprehensive to date investigating racial differences in the intra-tumoral microbiome. Our data serve as a starting point for exploring whether environmental influence of microbial abundance contributes to racial disparities in cancer. Research Sponsor: None.

2520 **Poster Discussion Session**

Safety and efficacy of neoadjuvant pembrolizumab in mismatch repair deficient localized/locally advanced solid tumors. *First Author: Kaysia Ludford, The University of Texas MD Anderson, Houston, TX*

Background: Pembrolizumab (Pembro), anti-PD1 therapy, is FDA approved for refractory microsatellite instability high (MSI-H)/deficient mismatch repair (dMMR) advanced/metastatic solid tumors. The robust activity of anti-PD1 therapy in these tumors argues for a neoadjuvant organsparing approach. However, the role of anti-PD1 monotherapy in the neoadjuvant setting is unknown. **Methods:** This is a phase 2 open-label, single center trial (NCT04082572) of MSI-H/dMMR non-metastatic solid tumors with localized unresectable or high risk resectable (defined as ≥ 20% recurrence) with measurable disease per RECISTv1.1 and ECOG PS 0/1. Treatment is Pembro 200mg every 3 wks for 8 cycles (6 months) followed by surgical resection with option to continue therapy for 18 cycles (12 months) followed by observation. First restaging is at 6 wks and includes baseline and 3-week 70-gene ctDNA assessment. To continue on study, patients are required to have PR/CR, SD with tumor shrinkage or SD with decline in ctDNA [highest variant allele frequency (VAF) baseline mutation]. The co-primary endpoints are safety and pathological complete response (pCR). Key secondary endpoints are response rate and organsparing at one year for patients who declined surgery. **Results:** Between 12/2019 and 2/2021, 32 pts were enrolled and treated. Enrolment goal of 35 anticipated to be met by 4/2021. Baseline characteristics included 13 females, median age of 63 yrs (range 26 - 91), Lynch syndrome in 12 pts, BRAF V600E mutation in 11 pts. Tumor type included 24 CRC and 8 non-CRC (1 endometrial, 1 gastric, 1 meningeal, 2 duodenal, 1 ampullary, 2 pancreatic). At baseline disease was resectable in 23 (72%). Among 30 evaluable pts, best overall response rate was 77%: 30% CR (n = 9), 47% PR (n = 14), 20% SD (n = 6), 3% PD (n = 1). Only one pt progressed after initial SD of -18%. Median follow-up is 6.1 months (range 0.1 - 14). Among the 6 (20%) pts who underwent surgery, pCR was seen in 3 (50%). A non-operative approach (pembro for 12 months) has been chosen in 15 pts and 1-year organ-sparing was seen in 2/2 evaluable pts. Treatment-related grade 3/4 immune adverse events (TRAE) were seen in 3 (9%) pts: grade 3 immune hepatitis (2) and grade 3 type 1 diabetes (1). Baseline ctDNA was positive in 17 (53%) pts with a median of 4 mutations per pt (1 - 35) and median highest VAF of 0.9% (range 0.3% to 38.2%). Among 26 pts with successful tumor tissue testing, median tumor mutations were 10.5, range 1 to 21 (Oncomine 134 gene panel). ctDNA decline at 3 weeks was seen in 14/17 (82%) patients. Luminal disease was present in 24 pts with endoscopic response of: CR in 13 (54%), major response 1, pending follow-up evaluation 6, not evaluated 3, and no response in 1. **Conclusions:** Neoadjuvant pembrolizumab is safe with encouraging clinical activity and this data suggests that a non-operative management for dMMR/MSI-H localized solid tumors should receive further investigation. Clinical trial information: NCT04082572. Research Sponsor: Merck and Co.

2521 **Poster Session**

Early safety and efficacy from a phase I open-label clinical trial of CD137(4-1BB) agonistic antibody LVGN6051 as monotherapy and in combination with pembrolizumab. *First Author: Siqing Fu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: LVGN6051, a monoclonal antibody against CD137 (also known as 4-1BB or TNFRSF9) with an engineered Fc capable of selectively binding to the Fcγ receptor IIB, acts as a conditional CD137 agonist, resulting in immune activation optimally in tumor microenvironment (Qi, Nat. Commun. 2019). In preclinical models, LVGN6051 demonstrated robust anti--tumor efficacy and safety as a single agent and in combination with anti-PD-1 antibodies. Therefore, we have initiated this first-in-human study of LVGN6051 alone or in combination with pembrolizumab for the treatment of advanced or metastatic malignancy. **Methods:** This study includes accelerated dose escalation monotherapy up to 2 mg/kg of LVGN6051, and traditional 3 + 3 design for higher doses of LVGN6051 alone or in combination with pembrolizumab. Then, this study will enroll patients with specific types of malignancies following Simon's two-stage design. Both agents are administered once every 3 weeks. Primary objectives of this study were to define the safety profile and to establish the recommended phase 2 dose (RP2D) of LVGN6051 alone or in combination with pembrolizumab. Pharmacokinetics, immunogenicity, pharmacodynamics and clinical efficacy will be also evaluated. **Results:** At the cut-off date on January 18, 2021, 16 subjects have been enrolled into the monotherapy cohorts (n=12, no DLT observed up to 7 mg/kg), and the combination cohort (n=4, ongoing at LVGN6051 2 mg/kg and pembrolizumab 200 mg, one DLT observed). No treatment-related adverse event (TRAE) was observed in monotherapy. Treatment-emergent adverse events (TEAE) in combination included increased ALT/AST, thrombocytopenia, and fatigue. In the combination cohort, one patient with predominant hepatic metastases and history of intermittent grade 2 hepatic impairment experienced grade 3 increased ALT/AST (DLT) on cycle 1 day 15 that were resolved to her baseline without corticosteroids on cycle 1 day 18. TRAE included increased ALT/AST, thrombocytopenia, neutropenia, nausea and fatigue. Seven of 10 evaluable patients in the monotherapy cohorts demonstrated stable disease with the longest treatment being 8+ months. Tumor reductions by >10% were observed in melanoma and neuroendocrine tumor on monotherapy. One patient with metastatic head and neck squamous cell carcinoma who had progressed on an anti-PD-L1 based therapy showed an immune partial response (iPR) for 6+ months to the combination therapy. **Conclusions:** Preliminary evidence showed that LVGN6051 was well tolerated and tumor shrinkages were observed. While we continue assessing its safety profile, antitumor activity was observed in the LVGN6051 and pembrolizumab cohort. The favorable safety profile and preliminary antitumor activity warrant further evaluation in patients with advanced malignancies. Clinical trial information: NCT04130542. Research Sponsor: Lyvgen Biopharma Holdings Limited.

2522 **Poster Session**

Activity results of the GATTO study, a phase Ib study combining the anti-TA-MUC1 antibody gatipotuzumab with the anti-EGFR tomuzotuximab or panitumumab in patients with refractory solid tumors. *First Author: Elena Garralda, Early Drug Development Unit (UITM), Vall d'Hebron University Hospital and Institute of Oncology (VHIO) and Medical Oncology, Vall d'Hebron University Hospital (HUVH), Barcelona, Spain*

Background: The phase I GATTO study explored the feasibility, tolerability and preliminary activity of combining Gatipotuzumab (GAT), a novel humanized monoclonal antibody binding to the tumor-associated epitope of mucin-1 (TA-MUC1), and an anti-EGFR antibody. Preclinical evidence suggests a complex interaction between TA-MUC1 and EGFR on the cell surface of epithelial tumors and synergistic antibody dependent cell cytotoxicity activity with the double targeting. **Methods:** Initially 20 patients with refractory metastatic disease were treated with GAT administered at 1400 mg Q2W in combination with the glyco-optimized anti-EGFR antibody Tomuzotuximab (TOM) at 1200 mg Q2W. Due to the risk of infusion related reactions, three cycles of TOM were given before start of combined treatment with GAT. After this regimen was proven safe and no DLT was observed, 30 additional patients including colorectal cancer (CRC) already treated with anti-EGFR antibodies, non-small cell lung cancer (NSCLC), head and neck and breast cancers received TOM and GAT administered at the same doses, with GAT treatment starting already one week after the first dose of the anti-EGFR antibody. As allowed in the study expansion, Panitumumab (PAN) was used in place of TOM in 9 CRC patients at investigator's choice. **Results:** By the time of the final analysis in January 2021, 52 patients were enrolled, and 50 received at least one dose of both GAT and anti-EGFR antibodies. Safety was overall good and results are reported in a separate abstract. Because of the difference in treatment schedule, activity results of the two parts of the study are summarized separately. There were 2 and 4 RECIST partial responses in the first and second part of the study, all in CRC patients. In the expansion phase, the median Progression Free Survival (PFS) of CRC patients who received TOM (10) and PAN (9) was 1.9 and 5.5 months, respectively. There were 2 responses in each subgroup and the duration of response was 3.8 and 7.2 months in patients receiving TOM and PAN, respectively. The PFS for NSCLC was 5.3 months and 2 heavily pretreated patients achieved a prolonged control of disease of 10.6 and 9.4 months. The trial was accompanied by a comprehensive translational research program for identification of biomarkers, including soluble TA-MUC1 in serum. In the extension phase patients with baseline values above median appeared to have improved PFS and overall survival; this was not the case for patients of the first part of the study who received GAT only after 3 doses of TOM. **Conclusions:** Combination of TA-MUC1 and EGFR targeting antibody is safe and feasible. Interesting anti-tumor activity was observed in heavily pretreated CRC and NSCLC patients. Levels of soluble TA-MUC1 may have predictive value and potentially be a companion biomarker for further development of the combination Clinical trial information: NCT03360734. Research Sponsor: Glycotope GmbH.

Phase I study of LBL-007, a novel anti-human lymphocyte activation gene 3 (LAG-3) antibody in patients with advanced solid tumors. *First Author: Yuankai Shi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: LAG-3 is an immune checkpoint receptor expressed on activated T cells to negatively regulate these cells, resulted in tumor immune escape. LBL-007, a novel anti-LAG-3 antibody, was developed by screening of a human antibody phage display library and demonstrated specific binding to human LAG-3, stimulation of IL-2 release and blockage of LAG-3 binding to its ligands including MHC II. It has shown that LBL-007 significantly inhibited tumor growth in a mouse MC38 tumor model in hLAG-3 knock-in mice with more pronounced tumor inhibition when combined with an anti-PD-1 antibody. **Methods:** A phase I, multicenter, open-label and first-in-human study was conducted to evaluate the safety, tolerability, and PK in patients with advanced solid tumors. The dose escalation phase was designed with 6 dose cohorts of LBL-007 at 0.05, 0.25, 1, 3, 6 and 10 mg/kg (iv every 2 weeks), using a modified 3+3 design. Key inclusion criteria included: age≥18 years, histologically/cytologically confirmed advanced solid tumors, failed ≥2 lines of prior standard therapies, ECOG of 0-1, and adequate hematologic, renal, hepatic, and cardiac function. Patients who received anticancer or immunotherapy 4 weeks from first dose of LBL-007 were excluded. The primary endpoints were tolerability and safety. Adverse events (AEs) were graded by National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE) v5.0. Any potential efficacy was assessed by objective response rate (ORR) evaluated by CT/MRI per RECIST 1.1. **Results:** From March 12th, 2020 to Feb 9th, 2021, 17 patients were evaluated in this study. There were no dose limiting toxicities (DLTs) at any dose cohorts, and patients were tolerated very well. Overall, there were 129 adverse events (AEs), and 8 events were serious adverse event (SAE), of which 5 were defined as suspected unexpected serious adverse reaction (SUSAR), but most unlikely treatment related AEs (TRAEs). All AEs regardless of attribution included anemia, hypocalcemia, and flu related respiratory infection, etc. The most common AEs were anemia (14, 10.9%), hypocalcemia (6, 4.7%) and thrombocytopenia (4, 3.1%). Totally, there were 8 patients without disease progression, defined as SD at the first evaluation and sustained for 3.5-9 months. The target lesions in 2 of these 8 patients were reduced by 18.9% and 23.2% (both in esophagus cancer). The progression-free survival of these 2 patients was 4.4 and 9.0 months, respectively. Patients are also being enrolled into the indication exploratory phase (3 and 6 mg/kg), testing the combination therapy with an anti-PD-1 antibody in patients with melanoma and other solid tumors. **Conclusions:** The dose escalation part of the study revealed tolerability of LBL-007 with an impressive safety profile, and potentially some encouraging signs of anti-tumor activities. Clinical trial: Chinaclinicaltrials.org.cn (1900025904). Clinical trial information: CTR20210196. Research Sponsor: Leads Biolabs.

2524 **Poster Session**

Safety and tolerability results of the GATTO study, a phase Ib study combining the anti-TA-MUC1 antibody gatipotuzumab with the anti-EGFR tomuzotuximab or panitumumab in patients with refractory solid tumors. *First Author: Sebastian Ochsenreither, Charité Comprehensive Cancer Center, Berlin, Germany*

Background: The phase I GATTO study explored the feasibility, tolerability and preliminary activity of combining gatipotuzumab (GAT), a novel humanized monoclonal antibody binding to the tumor-associated epitope of mucin-1 (TA-MUC1) and an anti-EGFR antibody. Preclinical evidence suggests a complex interaction between TA-MUC1 and EGFR on the cell surface of epithelial tumors driving carcinogenesis processes and synergistic antibody dependent cell cytotoxicity activity with the dual targeting. **Methods:** Initially the study enrolled in a primary phase (PP) 20 patients with EGFR positive metastatic solid tumors, for whom no standard treatment was available. The first 6 patients were enrolled into a safety run-in phase and the number of dose-limiting toxicities (DLTs) was evaluated, in order to de-escalate the doses if needed. Patients received GAT administered at 1400 mg Q2W in combination with the glyco-optimized anti-EGFR antibody tomuzotuximab (TOM) at 1200 mg Q2W. Due to the risk of infusion related reactions (IRR), the first dose of TOM was reduced to 720 mg split over 2 consecutive days and three cycles of TOM monotherapy were given before start of treatment with GAT. As this regimen was proven safe, no DLT was observed and the initial dose remained unchanged, the study was amended to enroll in an expansion phase (EP) 30 additional patients with refractory colorectal cancer (CRC), non-small cell lung cancer (NSCLC), head and neck and breast cancers. TOM and GAT were given at the same doses and GAT treatment started already one week after the first dose of the anti-EGFR antibody. Additionally investigator had the choice to use a commercial anti-EGFR antibody in place of TOM. **Results:** By the time of the final analysis in January 2021, 52 refractory patients were enrolled and 50 received at least one dose of both GAT and anti-EGFR antibodies. Panitumumab (PAN) was used in 9 CRC patients. Because of the difference in treatment schedule, results are summarized separately for the 20 and 30 patients in PP and EP. Overall, the combined treatment was well tolerated and no DLT was observed in the whole study, nor related SAE or death. There were no treatment emergent adverse events (TEAEs) leading to dose interruptions or reductions in the PP and 2/30 (6.7%) patients in EP stopped both TOM and GAT. 16 IRRs were reported in 8/20 (40%) PP patients, and 40 IRRs in 10 (33.3%) EP patients. Only one event of chills was severe and only 6 events were related to GAT in the EP, all others to TOM. Other frequent TEAEs were those commonly observed with anti-EGFR treatment such as skin toxicity in 17 (85%) PP and 26 (86.7%) EP patients and hypomagnesemia in 10 (50%) PP and 7 (23.3%) EP patients. **Conclusions:** Combination of TA-MUC1 and EGFR targeting antibody is safe and feasible. Future studies should test this combination together with chemotherapy Clinical trial information: NCT03360734. Research Sponsor: Glycotope GmbH.

2525 **Poster Session**

Changes in T lymphocyte subsets in different tumors before and after radiotherapy: A meta-analysis. *First Author: Xiaoxia Zhu, Radiation Oncology Department, Zhujiang Hospital, Southern Medical University, Guangzhou, China*

Background: Radiation therapy (RT) induces an immune response, but the relationship of this response with tumor type is not fully understood. **Methods:** We searched English-language electronic databases including PubMed, EMBASE, and the Cochrane Library to collect studies about the changes in CD3+ T lymphocytes, CD4+ T lymphocytes, and CD8+ T lymphocytes before and after radiotherapy in tumor patients from January 2015 to December 2019. The quality of the included literature was evaluated using the NOS scale provided by the Cochrane Collaboration, and statistical software RevMan 5.4 was used to analyze the included literature. $p < 0.05$ was considered to indicate statistical significance. **Results:** A total of 17 studies in 15 articles involving 1735 tumor patients were included. All data were collected within 1 month before or after radiotherapy. Meta-analysis showed that numbers of $CD3^+$ T lymphocytes were significantly reduced after radiotherapy compared with before treatment (standard mean difference [SMD]: -0.76; 95% CI [-1.46, -0.06]; p = 0.03), as were those of $CD4^+$ T lymphocytes (SMD: -0.50; 95% CI: [-0.88, -0.12]; p = 0.01), but there was no statistically significant difference for CD8+ T lymphocytes (SMD: 0.19; 95% CI: [-0.23, 0.62]; p = 0.38). Subgroup analysis showed significant decreases in CD3+ T lymphocytes in liver cancer,esophageal cancer, head and neck cancer , pancreatic cancer and breast cancer after radiotherapy**.** Numbers of CD4+T lymphocytes increased after radiotherapy in breast cancer,and a decrease was observed in liver cancer, esophageal cancer, colorectal cancer , and head and neck cancer. CD8+ T lymphocyte numbers also increased compared with before radiotherapy in esophageal cancer, lung cancer , and colorectal cancer . But a decrease in liver cancer and head and neck cancer. **Conclusions:** Numbers of CD3+ and CD4+ T lymphocytes decreased after radiotherapy, whereas CD8+ T lymphocytes showed no significant change. Within 1 month of radiotherapy, the tumor microenvironment showed an immunosuppressive state. The degree of immune response induced by radiotherapy differed between tumor types. 2526 **Poster Session**

A phase 1, open-label, dose escalation study of the safety and tolerability of T3011 in advanced cutaneous or subcutaneous malignancies. *First Author: Andrew Mark Haydon, Alfred Health, Melbourne, VIC, Australia*

Background: T3011 is a genetically modified, next-generation oncolytic HSV-1 with 2 exogenous genes encoding the active heterodimer human interleukin 12 (IL-12) and the Fab fragment of an anti-human PD-1 antibody. Locally produced IL-12 induces the synthesis of interferon-gamma (IFN-γ) production, enhancing cytolytic activity of natural killer cells and cytotoxic T lymphocytes. The anti PD-1 antibody blocks checkpoint inhibition of T effector cells. Extensive preclinical studies demonstrate that T3011 (and murine equivalent T3855) has potent antitumor activities. **Methods:** This phase 1 multicenter, open-label, dose escalation study evaluates the safety of intratumoral (IT) T3011 given once every other week (Q2W) in patients (pts) with advanced cutaneous or subcutaneous malignancies. The primary objective is to determine the Recommended Phase 2 Dose of T3011 based on the overall safety, pharmacokinetic and pharmacodynamic profile. Eligible pts are ≥ 18 years, have cutaneous or subcutaneous advanced cancer that has progressed on standard treatment and at least 1 measurable tumor lesion (≥ 10 mm) suitable for T3011 IT injection. Part 1 of the study uses a 3+3 design to evaluate the safety and tolerability of T3011 monotherapy in 4 escalating doses (1×10^6, 1×10^7, 5×10^7, and 1×10^8 PFU/mL). Up to 4 mL of T3011 may be injected based on tumor size. Total enrollment will be determined by toxicities observed. **Results:** As of Feb. 14, 8 pts have received IT T3011 (Q2W): 3 in Cohort 1 (1×10^6), 3 in Cohort 2 (1×10^7), and 2 in Cohort 3 (5.0×10^7 PFU/ml). Maximum doses per pt was 11. Enrollment continues in Cohort 3. T3011 was well tolerated with no ≥ Grade 3 treatment-related adverse events (AEs), no DLTs or treatment-related SAEs reported to date. Common AEs were pain at injection site, leukopenia, anemia, hypocalcemia, nausea, fever, headache, dermatitis, and diaphoresis. Viral shedding was analyzed in blood, urine and saliva at various times during the study. No Viral DNA was detected in blood or urine samples (first 3 pts analyzed) to date. Biopsy samples taken from injected tumors from 2 melanoma pts (Cohort 1) revealed significant reduction of viable tumor cells after 4 injections (Week 9) compared with baseline. In particular, one post-treatment biopsy contained 45% tumor necrosis area with dramatic increases of CD8 + and NKT cells. CD3+ and CD4+ cells as well as PD-1 expression were increased in post-treatment biopsies of both pts. **Conclusions:** T3011 IT injection was well tolerated at the first 2 dose levels. Post treatment biopsies from 2 pts (Cohort 1) demonstrated significantly reduced tumor cell viability as well as increased lymphocyte infiltration indicating on-target anti-tumor activities of T3011. To date, 5 out of 6 evaluable pts had SD as best response and 6 enrolled pts remain on study. Dose escalation is continuing. Clinical trial information: NCT04370587. Research Sponsor: None.

2527 **Poster Session**

Safety and PK/PD of ALLO-647, an anti-CD52 antibody, with fludarabine (Flu)/cyclophosphamide (Cy) for lymphodepletion in the setting of allogeneic CAR-T cell therapy. *First Author: Michael Timothy Tees, Moffitt Cancer Ctr and Rsrch Inst, Tampa, FL*

Background: Allogeneic chimeric antigen receptor (CAR) T cell therapy holds promise in addressing logistical/manufacturing challenges of autologous CAR T cell therapy. ALLO-501 (anti-CD19; uses Cellectis technologies) and ALLO-715 (anti-BCMA) are allogeneic CAR T cell products whose a) disrupted TCRα constant gene may reduce GvHD risk, and b) edited CD52 gene may permit use of ALLO-647 (a humanized anti-CD52 mAb) to selectively deplete host T cells. **Methods:** The ongoing ALPHA (ALLO-501) and UNIVERSAL (ALLO-715) trials include patients (pts) with relapsed/refractory large B-cell or follicular lymphoma and multiple myeloma, respectively. The lymphodepletion regimen included ALLO-647 (39 mg [low dose, LD; n = 33], 60 mg [n = 12], or 90 mg [high dose, HD; n = 27]) with Flu 30 mg/m^2/d x 3d +/- Cy 300 mg/m^2/d x 3d (Flu+Cy, n = 66; Cy, n = 6) (ALLO-647/Flu +/- Cy) before CAR T infusion. A mixed-effects population pharmacokinetic (PK) model was fit to ALLO-647 concentration *vs.* time data. Pharmacodynamic (PD) effects on host T cells, IL15, and CAR T cell expansion were also studied. **Results:** As of the data cut, 72 pts were treated. Common Grade ≥3 AEs were neutropenia (71%), thrombocytopenia (42%), anemia (39%), and lymphopenia (28%). Neutrophil, hemoglobin, and platelet counts did not differ by ALLO-647 dose, suggesting these dim-$CD52^+$ cells were unaffected. Gr ≥3 infections were seen in 21% pts; 33 had infusion-related reactions (IRR; Gr 1: 13%; Gr 2: 32%; Gr 3: 1.4%). IRR incidence and severity were higher with HD ALLO-647. The optimal PK model included a saturable (concentration-dependent) elimination pathway; clearance varied as a function of baseline lymphocyte count (LC). Serum ALLO-647 levels increased with dose; median modelled Cmax was 4,224 and 14,139 ng/mL for LD and HD, respectively. With ALLO-647/Flu +/- Cy, all but 2 pts reached a LC nadir < 0.05×10^9 cells/L, typically by D-3. Duration of lymphodepletion was typically longer with HD ALLO-647. Median duration of T-cell suppression (< 10 cells/μl) was ~ 8.5 and 13.6 days from CAR T infusion, respectively, for LD and HD ALLO-647. With HD, T cell counts were < 10 through D+28 in 17 pts and > 10 in 2. In 68 evaluable pts, compared to LD, HD ALLO-647 was associated with higher D0 serum IL15 levels, which have been linked to improved clinical response (eg, Kochenderfer *JCO* 2017). Higher CAR T expansion was also observed post D+14 with HD ALLO-647 compared to LD, creating an opportunity for clinical response. **Conclusions:** ALLO-647/Flu +/- Cy had a tolerable safety profile and produced a deep and durable window of lymphocyte depletion. ALLO-647 exhibited target-mediated drug disposition; clearance increased with higher baseline LC. HD was associated with higher IL15 levels and better CAR T expansion, suggesting dose responses. Enrollment in both studies is ongoing; updated safety and PK/PD data will be presented. Clinical trial information: NCT04093596. Research Sponsor: Allogene Therapeutics.

Novel CoupledCAR technology for treating colorectal cancer. *First Author: Lei Xiao, Innovative Cellular Therapeutics Co., Ltd, Shanghai, China*

Background: Chimeric antigen receptor (CAR) T cell therapy has made significant progress in the treatment of blood cancers such as leukemia, lymphoma, and myeloma. However, the therapy faces many challenges in treating solid tumors. These challenges include physical barriers, tumor microenvironment immunosuppression, tumor heterogeneity, target specificity, and limited expansion in vivo. **Methods:** We designed a CAR lentivirus vector that consisted of a humanized CD19-specific single-chain variable fragment (scFv), a 4-1BB costimulatory domain, and a CD3ζ signaling domain.The lentivirus was produced by transfecting HEK-293T cells with CAR lentiviral vectors and viral packaging plasmids. Patient's CD3 T cells was cultured in X-VIVO medium containing 125U/mL 1interleukin-2 (IL-2), and transduced with CAR lentivirus at certain MOI 24h after stimulated by anti-CD3/CD28 magnetic beads. Transduction efficiency was evaluated at 7 to 9 days after CAR lentivirus transduction, and quality controls for fungi, bacteria, mycoplasma, chlamydia, and endotoxin were performed. After infusion, serial peripheral blood samples were collected, and the expansion and the cytokine release of CART cells were detected by FACS and QPCR,respectively. The evaluation of response level for patients were performed at month 1,month 3,and month 6 by PET/CT. **Results:** We engineered CoupledCAR T cells with lentiviral vectors encoding an anti-GCC (guanylate cyclase 2C) CAR molecule. To verify the safety and efficacy of CoupledCAR-T cells for treating solid tumors, we conducted several clinical trials for different solid tumors, including seven patients with colorectal cancer. These seven patients failed multiple rounds of chemotherapy and radiotherapy. In the clinical trial, the metastatic colorectal cancer patients were infused with autologous anti-GCC CoupledCAR-T cells range from 4.9×10^5/kg to 2.9×10^6/kg. We observed that CoupledCAR-T cells expanded significantly in the patients and infiltrated tumor tissue sites, demonstrating enhanced anti-tumor activities. PET/CT showed significant tumor shrinkage and SUV max declined, and the ongoing responses were monitored. Patient 3 achieved complete response and the best overall response rate (ORR, include complete remission, complete metabolic response, and partial response.) was 57.1% (4/7), complete remission (CR) rate was 14.3% (1/7). **Conclusions:** In conclusion, the clinical data demonstrated that CoupledCAR-T cells effectively expanded, infiltrated tumor tissue sites, and kill tumor cells in patients with colorectal cancer. We used immunotherapy to achieve complete remission in patients with advanced colorectal cancer for the first time. We are recruiting more colorectal cancer patients to further test the safety and efficacy of anti-GCC CoupledCAR T cells. Since our CoupledCAR technology is a platform technology, we are expanding it to treat other solid tumors using different target tumor markers. Research Sponsor: N/A.

2529 **Poster Session**

First-in-human data of ALLO-501A, an allogeneic chimeric antigen receptor (CAR) T-cell therapy and ALLO-647 in relapsed/refractory large B-cell lymphoma (R/R LBCL): ALPHA2 study. *First Author: Frederick Lundry Locke, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Allogeneic CAR T cell therapy addresses logistical/manufacturing challenges inherent in autologous (auto) CAR T therapy. ALLO-501A, which uses Cellectis technologies, is an allogeneic anti-CD19 CAR T cell product whose a) disrupted TCRα gene may reduce GvHD risk, and b) edited CD52 gene may permit use of ALLO-647 (a humanized anti-CD52 mAb) to selectively deplete host T cells. **Methods:** The ongoing ALPHA2 study is a single-arm, open-label, 2 phase study of ALLO-501A in non-HLA matched patients (pts) with R/R LBCL and ≥2 prior lines of therapy. Prior auto CD19 CAR T therapy is allowed if tumors remain $CD19^+$. Following lymphodepletion (LD) with ALLO-647 (60 mg or 90 mg), fludarabine 30 mg/m^2/d x 3d (Flu), and cyclophosphamide 300 mg/m^2/d x 3d (Cy), escalating doses of ALLO-501A (40 [DL1] or 120 [DL2] x 10^6 viable CAR T cells) were administered. Retreatment was allowed for PD or SD with suboptimal CAR T expansion. Pts who had ≥SD at D28 could receive a second dose in a consolidation cohort. Phase 1 assessed safety/tolerability and cell kinetics of escalating doses of ALLO-501A following LD. **Results:** By 1/15/21, 11/11 enrolled pts received ALLO-647 (60 mg: n=6; 90 mg: n=5). Mean duration from enrollment to start of therapy was 6 days. After LD, 1 and 9 pt(s) were treated with ALLO-501A at DL1 and DL2, respectively; 1 pt developed CNS lymphoma and was not treated. Of 10 pts treated, 1 pt received retreatment and 4 pts were enrolled in the consolidation cohort. Pts had a median age of 60 years; 8 were ≥ stage III at diagnosis, 5 had IPI scores ≥3, and 3 had baseline LDH > 2x ULN. Median number of prior therapies was 3 (range 2 – 7); 3 pts had received auto CD19 CAR T cell therapy. 4/8 evaluable pts had rapidly PD at study entry. Median FU was 1.7 months. No dose modifications were required and no pt experienced DLTs. The most common AEs were anemia, leukopenia, neutropenia and thrombocytopenia (73%); and lymphopenia (64%). No GvHD or ICANS were reported. CRS was seen in 2 (18%) pts, both Grade < 3. Infusion-related reactions, all grade <3, were observed in 4 (36%) pts. D28 response data are available for 8 pts: 1 died of PD before D28; 4 additional pts had PD, including 2 who progressed 2 and 3 mos. after auto CAR T; 1 had SD; and 2 (both DL2) had CR. Of those in CR, 1 had peak ALLO-501A expansion at D14, persistence until D42, and ongoing CR at 4 mo; 1, with a 4-mo response to prior auto CAR T, had peak expansion at D28 and remains in ongoing CR at D56 after ALLO-501A with pending persistence. **Conclusions:** This dose escalation cohort contained heavily pretreated, actively progressing pts, some of whom had failed auto CAR T. Preliminary data suggest an acceptable safety profile following ALLO-501A and ALLO-647 and early signs of efficacy in LBCL. Enrollment into the consolidation cohort is ongoing; updated clinical/biomarker data of resistance and clinical activity will be presented. Clinical trial information: NCT04416984. Research Sponsor: Allogene Therapeutics.

2530 **Poster Session**

CAR-T cells to deliver engineered peptide antigens and reprogram antigen specific T cell responses against solid tumors. *First Author: Daniel Y Lee, University of Pennsylvania, Philadelphia, PA*

Background: Neoantigen depleted malignancies such as colorectal cancer demonstrate primary resistance to immune checkpoint blockade, and solid tumors in general have shown resistance to chimeric antigen receptor (CAR) T cell therapy. However, CAR-T cells have been shown to be capable of delivering various therapeutic molecules in a targeted fashion to the tumor microenvironment, in some cases through extracellular vesicles (EVs). In vivo studies have shown that the presentation of foreign viral peptides by solid tumors can reprogram bystander virus-specific cytotoxic T cells (CTLs) against tumor cells. In this study, we demonstrate that CAR-T cells can deliver engineered peptide antigens to solid tumors, leading to presentation on tumor cells and anti-tumor response. **Methods:** Second generation CAR-T cells (41BB endodomain) targeting human CD19 (19BBz) or human mesothelin (M5BBz) were generated via retroviral and lentiviral transduction respectively. CAR-T cells were engineered to co-express peptides such as SIINFEKL of ovalbumin and NLVPMVATV of CMV pp65 among others. Peptides were isolated from EVs via ultracentrifugation. For in vivo studies, C57BL/6 or NSG mice were injected on the flank with relevant tumors and treated with peptide-CAR-T cells. In vitro studies utilized flow cytometry and xCELLigence killing assays. **Results:** Murine 19BBz CAR-T cells expressing the SIINFEKL peptide of ovalbumin (ova-19BBz) were found to transfer SIINFEKL peptide to tumor cells via EVs *in vitro* and *in vivo*, leading to peptide presentation on MHC-I of tumor cells. This resulted in significantly delayed tumor growth in tumor bearing mice transfused with OT-I T cells to mimic an existing antigen specific T cell pool. We expanded on these findings by isolating EVs from human M5BBz CAR-T cells expressing CMV viral peptides. Peptide-CAR-T EVs were co-cultured with human ovarian cancer cells to assess presentation to Jurkat T cells. Finally, we utilized primary human T cells from CMV+ healthy donors to assess the clinical feasibility of our peptide delivery approach. **Conclusions:** CAR-T cells can be engineered to deliver peptides to tumor cells for presentation and subsequent targeting by antigen specific CTLs. This represents a novel strategy for the treatment of non-immunogenic tumors. Research Sponsor: Mark Foundation for Cancer Research, Other Foundation, U.S. National Institutes of Health.

2531 **Poster Session**

A single-arm phase Ib study of autologous cytokine-induced killer (CIK) cell immunotherapy in combination with sintilimab plus chemotherapy in patients with advanced non-small cell lung cancer (NSCLC)-CCICC-002. *First Author: Xiubao Ren, Department of Biological Therapy, Tianjin Cancer Institute & Hospital, Tianjin, China*

Background: Immune checkpoint inhibitors plus chemotherapy had showed benefits for advanced non–small-cell lung cancer (NSCLC) patients without targetable mutations. Autologous cytokine-induced killer (CIK) cells can restore the antitumor immunity to improve patient outcome. Combining CIK cells with anti-PD-1 mAb plus chemotherapy may strengthen the results in patients with advanced NSCLC. **Methods:** This is a single-center, open-label, phase 1b trial of combination CIK cells with sintilimab (anti-PD-1 mAb) plus chemotherapy in stage IIIB-IV NSCLC patients. Systemic therapy naïve patients received platinum-based doublet chemotherapy, sintilimab, and CIK cells every 3 weeks for 4 cycles，then sintilimab, and CIK cells for maintenance therapy until disease progression or unacceptable toxicity. **Results:** From May 2019 to Jan 2021, 34 patients (19 squamous，15 non-squamous NCSLC)aged 46-73 years (median age 64 years) were enrolled. Among 32 evaluable patients, the ORR was 81.3% (73.7% in squamous and 92.3% in non-squamous NSCLC)and DCR was 100%. Among the 25 PR assessed by RECIST, CMR was demonstrated in 5 (23.1%) by PET-CT. Among 3 patients with brain metastases, 2 patients achieve intracranial CR, and 1 was PR. With a median follow-up of 7.5 months, the median DOR was not reached (range 0.5m-NA), and the median PFS and OS were not mature. Grade 3 or more TRAEs included pneumonia (n = 3); thrombocytopenia, leukopenia (n = 2 each); anemia, dysphagia, cardiomyopathy, rash (n = 1 each). Biomarkers and subgroups which correlated with efficacy and AEs are being analyzed included TMB, PDL1 expression, distribution of TILs, cytokines and so on. **Conclusions:** CIK cells therapy in combination with sintilimab plus chemotherapy were well tolerated and showed encouraging efficacy. Further studies are warranted to confirm these preliminary results. Research Sponsor: Tianjin Medical University Cancer Institute and Hospital. Clinical trial information: NCT03987867. Research Sponsor: National Key Technologies R&D Program of China grant Awards No. 2015BAI12B12 and 2018YFC1313400.

A phase I-IIa study of genetically modified Tie-2 expressing monocytes in patients with glioblastoma multiforme (TEM-GBM Study). *First Author: Gaetano Finocchiaro, Neuro-Oncology Unit-IRCCS San Raffaele Scientific Institute, Milan, Italy*

Background: Genetically modified cell-based therapies are relevant in immuno-oncology due to their potential for tumor specificity & potential durability. We developed a cell-based treatment, Temferon, relying on ex-vivo transduction of autologous HSPCs to express therapeutic payloads within the tumor microenvironment. Temferon targets IFNa to Tie-2 expressing macrophages (TEMs). **Methods:** TEM-GBM is an open-label, Phase I/IIa dose-escalation study evaluating safety & efficacy of Temferon in up to 21 newly diagnosed patients with glioblastoma & unmethylated MGMT promoter. Autologous HSPCs are transduced ex-vivo with a lentiviral vector encoding for IFNa. The transgene expression is confined to TEMs due to the Tie2 promoter & the post-transcriptional regulation by miRNA-126. **Results:** As of January 17 2021, 15 patients have been enrolled; 9 received Temferon (D+0) with follow-up of 61 – 559 days. There was rapid engraftment & hematological recovery after the conditioning regimen. Median neutrophil & platelet engraftment occurred at D+13 & D+12, respectively. Temferon-derived differentiated cells, as determined by the presence of vector genomes in the DNA of peripheral blood & bone marrow cells, were found within 14 days post treatment & persisted subsequently, albeit at lower levels (up to 18 months). We also detected very low concentrations of IFNa in the plasma (median 5pg/ml at D+30; baseline $<$ LLOQ) & in the cerebrospinal fluid, suggesting tight regulation of transgene expression. Three deaths occurred: two at D+343 & +402 after Temferon administration due to disease progression, & one at D+60 due to complications following the conditioning regimen. Seven patients had progressive disease (PD; range D+27-239) as expected for this tumor type. SAEs include infections, venous thromboembolism, brain abscess, hemiparesis, GGT elevation & poor performance status compatible with autologous stem cell transplantation, concomitant medications & PD. Four patients underwent second surgery. These recurrent tumors had gene-marked cells present & increased expression of IFN-responsive gene signatures compared to diagnosis, indicative of local IFNa release by TEMs. In one patient a stable lesion (as defined by MRI) had a higher proportion of T cells & TEMs within the myeloid infiltrate & an increased IFN-response signature than in a progressing lesion. The T-cell immune repertoire changed with evidence for expansion of tumor-associated clones. Tumor microenvironment characterization by scRNA & TCR sequencing is ongoing. **Conclusions:** Our interim results show that Temferon is well tolerated by patients, with no dose limiting toxicities identified to date. The results provide initial evidence of Temferon potential to modulate the TME of GBM patients, as predicted by preclinical studies. Clinical trial information: NCT03866109. Research Sponsor: Genenta Science.

In-depth immune and molecular profiling of melanoma patients receiving adoptive T-cell therapy reveals biomarkers of efficacy in ATATIL study. *First Author: Angela Orcurto, Department of Oncology, Ludwig Institute for Cancer Research Lausanne, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland*

Background: Adoptive cell therapy (ACT) using tumor-infiltrating lymphocytes (TIL) has demonstrated a curative potential for patients with metastatic melanoma (MM). Nevertheless, activity remains unsatisfactory in many patients, requiring development of biomarkers that predict therapeutic efficacy. We report results of a single-center phase I study to assess feasibility, safety and efficacy of TIL-ACT in MM patients (NCT03475134). **Methods:** Patients with MM refractory to at least one prior line of therapy received TIL therapy with lymphodepleting chemotherapy before T-cell infusion, followed by high-dose interleukin-2. RDG- and FDG-PET imaging was performed before and after TIL infusion. Multispectral immuno-fluorescence (mIF) imaging and bulk-RNA sequencing (Seq) were performed on tumor samples pre-ACT and post-ACT (day+30 and upon progression). Single-cell RNA-Seq and TCR-Seq were performed on pre-ACT tumor and ACT product, as well as on tumor-reactive and neoantigen-specific TILs and on longitudinal blood samples. **Results:** As of 02/02/2021, thirteen patients (enrolled between March 2018 and December 2020) have successfully completed TIL-ACT therapy, with a median follow-up of 9.5 months (IQR 3.0 -24.6). Median age was 53 years (range 20-69) and all were previously treated with PD-1 based blockade. Median number of TILs infused was 55.0 x10^9 cells (range 12.8-84.7). The best overall response rate by RECIST 1.1 and disease control rate in evaluable patients was 41.7% (5/12) and 50% (6/12) respectively at 3 months. Two patients have an ongoing near-complete response at 3 years. Up to data cut-off, 10 patients have progressed by RECIST v1.1, with median PFS of 4.8 months (95% CI 1.5 - 9.6), while median OS is not reached. mIF revealed biomarkers of response, which may allow proper identification of patients in subsequent studies. In addition, deep sequencing of bulk and neoepitope-specific TIL clonotypes highlighted transcriptomic signatures revealing cell programs regulating *in vitro* expansion, *in vivo* blood persistence as well as tumor infiltration post-ACT. RGD-PET data will also be presented. **Conclusions:** We demonstrate reproducibility of TIL-ACT in our center, consistently with previous reports. Comprehensive translational studies reveal immune correlates of clinical responses that contribute to the understanding of mechanisms of TIL potency and will guide the development of next-generation cell products. Clinical trial information: NCT03475134. Research Sponsor: Ludwig Institute for Cancer Research, Canton de Vaud, and BMS.

2534 **Poster Session**

PSMA targeted armored chimeric antigen receptor (CAR) T-cells in patients with advanced mCRPC: A phase I experience. *First Author: Matthew H. Carabasi, Thomas Jefferson University, Philadelphia, PA*

Background: CART-PSMA-TGFβRDN cells are autologous T cells engineered via lentiviral transduction to express a dominant negative form of TGFβRII (TGFβRDN) and a chimeric antigen receptor (CAR) with specificity to prostate specific membrane antigen (PSMA). The TGFβRDN renders CAR T cells resistant to TGFβ-mediated immunosuppression. CART-PSMA-02 is a multi-center, open-label, Phase 1 study evaluating the safety and feasibility of dosing patients with metastatic castration resistant prostate cancer (mCRPC) with CART-PSMA-TGFβRDN (NCT04227275). **Methods:** This is a 3+3 dose escalation study to determine the recommended phase 2 dose and schedule of CART-PSMA-TGFβRDN cells following lymphodepleting chemotherapy with cyclophosphamide and fludarabine. Single and fractionated doses are being evaluated. A cohort expansion will enroll patients to further explore the safety of the selected dose and schedule. **Results:** As of January 2021, 6 patients (pts) have been treated. Two pts were treated in the first dose level (1-3 x10^7 transduced T cells (TDN)). Four pts were treated in the second dose level (1-3 x 10^8 TDN with fractionated dosing). AEs occurring in $\geq$50 % of pts included cytokine release syndrome (CRS), anemia, thrombocytopenia, increased creatinine, nausea, fatigue, pyrexia and dehydration. No DLTs occurred in the 1st dose level. Four pts in the 2nd dose level developed CRS (3 Gr 1 and 1 Gr 2). One pt developed rapid G2 CRS that progressed to Gr 5 encephalopathy and Gr 5 multi-organ failure. Ferritin levels peaked at 56,974 ng/ml (baseline 2,903 ng/mL) despite aggressive immunosuppressive therapy including tocilizumab, dexamtheasone and anakinra. The post infusion cytokine profile indicated elevations in IL-1RA, TNF-alpha, VEGF, IL-10, MIP-1b, IFN-gamma, GM-CSF and notably lower levels of IL6 compared to published reports of CD19 CART-mediated CRS. Autopsy findings were consistent with HLH/MAS, confirming overactivity of the monocyte/macrophage compartment. Based on these observations, a modified immune toxicity management strategy that includes prophylactic anakinra (an IL1R antagonist) was instituted. Preliminary evidence of clinical activity of CART-PSMA-TGFβRDN was noted in the 2nd dose level. Two of 3 pts with 1 month follow-up demonstrated PSA decreases from baseline (1 with $>$95% decrease, 1 with $>$50% decrease). Both pts had stable disease per RECIST v1.1. A third pt with only 1 week follow-up had a 40% PSA decrease. Additional data analyses from all infused patients are ongoing and data from pts managed with modified immune toxicity management will be presented. **Conclusions:** Initial data indicates a unique immune toxicity profile and the potential for anti-tumor activity in mCRPC pts treated with CART-PSMA-TGFβRDN. Modified immune toxicity management could lead to identification of a manageable safety profile and therapeutically active dose. Clinical trial information: NCT04227275. Research Sponsor: Tmunity Therapeutics, Inc.

2535 **Poster Session**

A single-arm phase Ib study of multiple target cytotoxic T-lymphocyte (MCTL) in combination with toripalimab as second-line therapy in advanced non-small cell lung cancer (NSCLC). *First Author: Xiubao Ren, Department of Biological Therapy, Tianjin Cancer Institute & Hospital, Tianjin, China*

Background: Anti-PD-1/ PD-L1 (programmed cell-death 1) mAb treatment has been approved in the US and in Europe as second-line treatment for advanced NSCLC because of the good tolerance and efficacy in comparison with docetaxel. Unfortunately, The objective response rate is only around 20%. Multiple Target Cytotoxic T-lymphocyte (MCTL) cells can restore the antitumor immunity to improve patient outcome. Combining MCTL cells with anti-PD-1 mAb may strengthen the results as second-line treatment in patients with advanced NSCLC. (NCT04193098). **Methods:** This is a single-center, open-label, phase 1b trial of combination MCTL cells with toripalimab (anti-PD-1 mAb)as second-line treatment for advanced NSCLC. Systemic therapy patients received toripalimab every 3 weeks for 12 cycles and received MCTL cells every 3 weeks for 9 cycles, then toripalimab and MCTL cells for maintenance therapy until disease progression or unacceptable toxicity. **Results:** From June 2019 to October 2020, 14 pts aged 43-70 years (median age 59 years) were enrolled. The squamous/non-squamous ratio was 50%/50%. 8 (57.1%) were men, 13(92.8%) were ECOG PS=0-1, 5 (35.7%) had pleural effusion, and 3 (21.4%) had bone metastases. Among 13 evaluable pts, the ORR and DCR were 38.4% and 71.4%, At the time of data cutoff, the median DOR was not reached (range 8.25m-NA), the median PFS was 399 days (range 192d-NA), and the median OS were not mature. Adverse events (AEs) occurred in 5 (38.4%), No grade$\geq$3 AEs events occurred. Immune-related AEs were thyroid hypofunction (3, 23%) and weak (2, 15.4%). Biomarkers which correlated with efficacy and AEs are being analyzed. **Conclusions:** Multiple Target Cytotoxic T-lymphocyte (MCTL) in combination with toripalimab as second-line treatment for advanced NSCLC because of the well tolerated and encouraging efficacy. Further studies are warranted to confirm these results. Research Sponsor: Tianjin Medical University Cancer Institute and Hospital. Clinical trial information: NCT04193098. Research Sponsor: National Natural Science Foundation of China grants Awards No. U20A20375.

Initial results of a first-in-human, dose escalation study of a cell-based vaccine in HLA A*02+ patients (pts) with recurrent, locally advanced or metastatic HPV16+ solid tumors: SQZ-PBMC-HPV-101. *First Author: Antonio Jimeno, University of Colorado Comprehensive Cancer Center, Aurora, CO*

Background: Ineffective MHC-I presentation of tumor antigens to CD8+ T cells limits T cell activation and the efficacy of cancer vaccines. The Cell Squeeze technology drives peripheral blood mononuclear cells (PBMCs) through a microfluidic chip leading to temporary cell membrane disruption and delivery of HPV16 E6 and E7 antigens cytosolically. These antigen presenting cells (APC) were matured with CpG7909 and were not genetically modified. Preclinically, this approach showed improvement in MHC-I presentation for human and murine cells. In murine tumor studies, m-SQZ-PBMC-HPV elicited robust CD8+ T cell responses and improved anti-tumor effects when compared to other vaccine modalities. **Methods:** SQZ-PBMC-HPV-101 included pts with incurable HPV16+ cancers progressing after unlimited prior therapy, ECOG 0-1, adequate organ function and a biopsiable lesion. After leukapheresis at the study site, manufacturing of the cryopreserved product took $<$ 24 hours with a vein-to-vein time of approx. 1 week. Out-patient SQZ-PBMC-HPV was given IV q 3 weeks without a conditioning regimen. Double antigen priming (DP) was introduced with Cohort 3 and occurred on Cycle 1 Days 1 and 2. Maximum treatment duration for each patient was determined by the cell batch size. Response was assessed via RECIST 1.1 and iRECIST. Investigational biomarkers were measured pre- and post-treatment. **Results:** 12 pts [anal (7), head and neck (3), and cervical (2)] were dosed in 3 cohorts (3 pts in 0.5 x10e6/kg, 5 pts in 2.5 x10e6/kg, and 4 pts in 2.5x 10e6/kg [DP]). Median lines of prior Tx were 4 (range 1 - 7) and all but one pt were pretreated with checkpoint inhibitors (CPI); 10 pts had liver or lung metastases. All batches of SQZ-PBMC-HPV demonstrated CD8 activation in vitro after thawing, and batch size did not limit therapy duration at dose levels tested to date. Median number of doses were 3 (3 - 10), 3 (2 - 4), and 3 (3 – 4) in the 3 cohorts, respectively. One pt (10 doses) remained on study for 42 weeks. Tx was well-tolerated and there were no DLTs, Grade (G) $>$3 related SAEs or related G $>$3 AEs. One pt in cohort 1 experienced both a G2 infusion-related reaction and cytokine release syndrome. One pt in cohort 2 was not evaluable for DLT. Four out of 10 evaluable pts had stable disease per RECIST 1.1 as the best response. Preliminary tumor analyses pre- and post-therapy indicated increased immune activity in some patients after SQZ infusion. **Conclusions:** SQZ-PBMC-HPV-101 demonstrated clinical feasibility of the Cell Squeeze technology and favorable tolerability of engineered APCs. The study allows for the characterization of the immunogenicity of engineered APCs in humans. Preliminary results warrant the testing in combination with CPI. Efficacy, safety, and correlative biomarker data will be presented, from pre- and post-therapy biopsies and blood samples. Clinical trial information: NCT04084951. Research Sponsor: SQZ Biotechnologies.

2537 **Poster Session**

Anakinra (AKR) prophylaxis (ppx) in patients (pts) with relapsed/refractory multiple myeloma (RRMM) receiving orvacabtagene autoleucel (orva-cel). *First Author: Luciano J. Costa, University of Alabama at Birmingham, Birmingham, AL*

Background: Orva-cel is a B-cell maturation antigen–targeted chimeric antigen receptor (CAR) T cell therapy being evaluated in the phase 1/2 EVOLVE study (NCT03430011) in pts with RRMM who had at least 3 prior lines of therapy (Tx). We previously reported safety and efficacy in the phase 1 study and established the recommended dose (RD) of orva-cel as 600 $\times$ 10^6 CAR^+ T cells (Mailankody et al, ASCO 2020). Cytokine release syndrome (CRS), a dominant toxicity of CAR T cell therapy, is mediated in part by IL-1. We explore the role of ppx with AKR, an IL-1 signaling inhibitor, on reducing the incidence of grade (G) $\geq$2 CRS after orva-cel treatment at the RD. **Methods:** Fourteen pts were enrolled sequentially for AKR ppx and treated with orva-cel at the RD. The non-AKR ppx control group comprised the remainder of the phase 1 pts receiving orva-cel at the RD (n = 19). The median follow-up (range) was 3.0 mo (1.8–6.2) for the AKR ppx group and 8.8 mo (5.3–12.2) for the non-AKR ppx group. AKR was administered as 100 mg SC the night before orva-cel infusion, 3 h before the infusion (Day 1), and q24 h on Days 2–5. Dosing was increased to q12 h if CRS developed. CRS was graded by Lee (2014) criteria. Tocilizumab (T) and steroids (S) were used per protocol-specified treatment management guidelines. **Results:** Disease characteristics and outcomes are shown in the table. In AKR ppx and non-AKR ppx groups, median number of prior regimens was 6 and 5, and bridging Tx was used in 57% and 68% of pts, respectively. The total frequency of CRS was similar in the 2 groups, but with less G 2 in the AKR ppx pts; relative risk (95% CI) = 0.54 (0.21, 1.38). No G $\geq$3 CRS was seen in either group. The incidence of neurological events (NE), G $\geq$3 infection, and macrophage activation syndrome/hemophagocytic lymphohistiocytosis (MAS/HLH) was similar. T and S use was numerically lower with AKR ppx. Orva-cel expansion kinetics were similar in the 2 groups. All pts had a 2-month efficacy assessment, with ORR in 100% of AKR ppx and 95% of non–AKR ppx pts. **Conclusions:** In this nonrandomized evaluation of AKR ppx with orva-cel treatment, the incidence of G $\geq$2 CRS was lower in pts receiving AKR ppx. The use of AKR ppx produced no adverse effect on the incidence of NE, infection, or MAS/HLH, nor on orva-cel expansion or disease response. These results warrant further study of AKR ppx in CAR T cell therapy. Clinical trial information: NCT03430011. Research Sponsor: Bristol-Myers Squibb Company.

Preliminary analysis of a phase 1/2 study of NEXI-001 donor-derived multi-antigen-specific $CD8^+$ T-cells for the treatment of relapsed acute myeloid leukemia (AML) after allogeneic hematopoietic cell transplantation (HCT). *First Author: Monzr Al Malki, City of Hope Medical Center, Duarte, CA*

Background: Allogeneic HCT is a potentially curative therapy for many patients with AML that relies on a graft-versus-leukemia (GvL) effect. Patients who relapse after allogeneic HCT have a poor prognosis and few treatment options. Donor lymphocyte infusion (DLI) can achieve a GvL effect in some patients, however, efficacy is frequently associated with the development graft-versus-host disease (GVHD). There is a substantial need for treatment approaches that enhance the benefit of GVL while decoupling toxicities associated with GVHD. **Methods:** We report ongoing results from a first-in-human study (NCT04284228) of a non-genetically engineered, donor-derived adoptive cellular therapy product, NEXI-001, which contains multiple populations of $CD8^+$ T cells that recognize different HLA 02.01-restricted peptides from the WT1, PRAME, and Cyclin A1 antigens. NEXI-001 contains T cell memory subtypes that combine anti-tumor potency with long-term persistence. **Results:** At the time of this analysis, 7 patients with relapsed AML after allogeneic HCT were enrolled. Five Patients were treated with single infusions of NEXI-001 at three different dose levels: 50, 100 and 200 million. Currently, the median follow-up is 5 months. Significantly, GVHD, cytokine release syndrome, neurotoxicity, or NEXI-001-related adverse events were not observed. NEXI-001 treatment resulted in reductions in red blood cell and platelet transfusions and increased donor chimerism. Decreases in myeloblasts in bone marrow and peripheral blood and reduction in the size of an extramedullary myeloid sarcoma were suggestive of an anti-leukemia effect (Table). Correlative studies indicate that NEXI-001 $CD8^+$ cells undergo a rapid proliferation after infusion and are also associated with a robust hostlymphocyte recovery that occurs as quickly Day 3 after infusion. NEXI-001 infused $CD8^+$T cells are detectable by multimer staining in peripheral blood of patients and proliferate over time. TCR sequencing analyses determined that infused NEXI-001 cells contain T cell clones that were undetectable in the peripheral blood of patients at baseline but were detected in blood and bone marrow and persist over time. **Conclusions:** NEXI-001 has the potential to enhance GvL effect without the associated toxicities of GVHD, cytokine release syndrome, and neurotoxicity. Due to these encouraging results, the trial will proceed with an evaluation of repeated NEXI-001 dosing Clinical trial information: NCT04284228. Research Sponsor: NexImmune Inc.

Pt	NEXI-001 Dose	SAE	Initial Clinical Response
1	50m	No	Stable BM blasts Decreased need for transfusions Increased ANC Improved donor chimerism
2	100m	No	Stable BM blasts 18% reduction in size of myeloid sarcoma
3	100m	No	No response
4	100m	No	Stable BM blasts Decrease in PB blasts Decreased need for transfusions Increased ANC
5	200m	No	Stable BM blasts

Progression prediction model for solid tumors with clinical and immunological parameters. *First Author: Aleksei Viktorovich Novik, N.N. Petrov National Medical Research Center of Oncology, Saint-Petersburg, Russian Federation*

Background: The immune system has well-known relation to tumor progression. Numerous immune-related parameters exist, but only a minor part could be used as biomarkers, especially dynamic ones. We trained a progression prediction model based on clinical features and peripheral immune system assessments. **Methods:** Patients with immunogenic (melanoma, 295, kidney cancer, 81), non-immunogenic (soft tissue sarcoma, 47, colorectal cancer, 26) and multiple primary tumors (29) with immunologic assessments before treatment (23.5%), on therapy (58.3), and in follow-up after the treatment (18.2%) were randomly divided in 7:3 ratio to the training and test groups. Counts of lymphocytes, T-, B, NK cells, cytotoxic lymphocytes, T-helpers were used as immunologic parameters. Age, sex, disease, stage, therapy, mutational status, last response on treatment, disease and therapy duration, previous treatments were used as clinical ones. The model was trained to predict disease progression in the next three months using "Catboost" gradient boosting. We used ROC AUC to test model performance and Yoden's index for optimal cutoff calculation. We also studied the influence of model prediction on overall survival (OS) and time to progression (TTP) on the test dataset using the Kaplan-Meyer method and Cox regression. **Results:** We used 1682 assessments of immune parameters (immune status, IS) done in 354 patients (average 5 per patient) to train the model and 616 IS in 124 patients for validation. All IS of one patient were in the same group. The ROC AUC value of the model was 0.801. The model prediction of progression increased the probability of progressive disease from 37.5 to 62% and decreased the response rate from 37,5% to 8.4% (p = 0.016). The model prediction did not add information over known prognostic factors for OS in the multifactorial model but was an independent prognostic factor for TTP (HR 2.204, p = 0.011). False-positive results separate the group of patients with poor prognosis (OS 16 months, TTP 6 months) among patients with clinical benefit from patients with favorable prognosis (OS 61 months, TTP 18 months, $p < 0.001$), who had a truly negative model prediction. The possibility of prognosis improvement with therapy change was an essential factor for OS and TTP prediction ($p < 0.001$). The model was useful in predicting higher OS in patients with disease progression (p = 0.033) and shorter response duration in patients with clinical benefit (p = 0.03). **Conclusions:** Our progression prediction model provides clinically useful information and can be used for decision making in several clinical situations. Its utility should be tested in a prospective trial. Research Sponsor: None.

Concordance of blood and tissue TMB from NGS testing in real-world settings and their ability to predict response to immunotherapy. *First Author: Emma Sturgill, Sarah Cannon Research Institute, Nashville, TN*

Background: Tumor mutational burden (TMB) detected by tissue-based Next Generation Sequencing (NGS) is a biomarker for immunotherapy (IO) response. Plasma-based NGS vendors have developed methods for quantifying TMB from circulating tumor DNA; however, the concordance of blood-TMB (bTMB) and tissue-TMB (tTMB) in real-world settings has not been examined. In this study, we analyzed paired bTMB-tTMB values from cancer patients in community oncology clinics who underwent both plasma- and tissue-based NGS testing to determine whether bTMB predicts response to IO equal to tTMB. **Methods:** We analyzed 112 patient-matched bTMB-tTMB pairs from 102 unique patients in community oncology settings who received both plasma- and tissue-based NGS profiling at any point in care. NGS results were reported by Foundation Medicine (n = 28 plasma, n = 66 tissue), Guardant Health (n = 78 plasma), and Caris Life Sciences (n = 42 tissue). NGS results were linked with electronic medical records in Genospace, Sarah Cannon's precision medicine platform. Pearson's correlation (r) and Lin's concordance (ρ) coefficients were used for statistical analysis. **Results:** bTMB exceeded the patient-matched tTMB by an average 2.4-fold; therefore, while the two values showed a positive linear correlation (r^2= 0.62, p = 0.01e-27) their concordance was only moderate (ρ = 0.58, n = 112). Gastrointestinal cancers exhibited the lowest correlation (r^2= 0.01, p = 0.5) and concordance (ρ = 0.03, n = 35). The discordance between bTMB and tTMB was not an outcome of the specimens being collected on different dates, as the bTMB/tTMB ratio did not correlate with the time between plasma and tissue specimen collection (r^2= 0.003, p = 0.84, n = 112). While a majority of bTMB-tTMB pairs had agreement in high *vs.* low status (High ≥ 10 mut/Mb; Low < 10 mut/Mb), a considerable portion were bTMB-High/tTMB-Low (see table). Strikingly, the bTMB-High/tTMB-Low patients who received IO had an average time to treatment failure (TTF) that surpassed that of the bTMB-High/tTMB-High cohort (see table). Considering bTMB alone, patients with a high status outperformed those with a low status on IO (bTMB-High: TTF = 200 days, n = 21; bTMB-Low: TTF = 125 days, n = 12). **Conclusions:** In real-world settings where tissue- and plasma-based NGS panels are ordered as standard of care, bTMB values are consistently higher than tTMB values. This discrepancy leads to plasma-based tests resulting a TMB-High designation more frequently than tissue-based NGS tests. Patients who are TMB-High by plasma perform relatively well on IO, indicating that bTMB may be a particularly effective biomarker of IO sensitivity. Research Sponsor: None.

	tTMB-High	tTMB-Low
bTMB-High	n = 19 (17%) TTF = 183 days (n = 13)	n = 34 (30%) TTF = 227 days (n = 8)
bTMB-Low	n = 5 (5%) TTF = N/A	n = 54 (48%) TTF = 125 days (n = 12)

Genomic immunotherapy (IO) biomarkers detected on comprehensive genomic profiling (CGP) of tissue and circulating tumor DNA (ctDNA). *First Author: Takayuki Yoshino, National Cancer Center Hospital East, Kashiwa, Japan*

Background: The dramatic impact of IO on treatment outcomes has heightened interest in predictive biomarkers, including genomic markers such as tumor mutational burden (TMB) and microsatellite instability (MSI). The recent FDA approval of pembrolizumab for previously treated advanced solid tumors with elevated TMB (≥10 mut/Mb on FoundationOne CDx, F1CDx) now requires a better understanding of the prevalence of this and other IO biomarkers detected on CGP, including differences between TMB detected in tissue and mutational burden detected in blood (bTMB). **Methods:** Tissue and plasma biopsies were profiled with two CGP panels of 324 genes with 0.8 Mb genome coverage (F1CDx and FoundationOne LiquidCDx). Mutational burden was calculated by counting somatic variants (single nucleotide and indels, including synonymous variants, excluding germline and driver mutations) with variant allele frequency (VAF) ≥5% in tissue (TMB) or ≥0.5% in ctDNA (bTMB). MSI score was assessed using 95 repetitive loci and principal component analysis (tissue) or >1,800 repetitive loci (plasma). ctDNA levels were estimated using composite tumor fraction (cTF), a metric based on aneuploidy and VAF. **Results:** Pan-cancer, TMB ≥10 was detected in 19% of tissue cases (29,238/156,294) and was common in melanoma (53%), small cell (41%), NSCLC (40%), bladder (39%), and endometrial (24%). bTMB ≥10 was detected in 13% of liquid biopsies (806/6,295); prevalence by cancer type was correlated with prevalence of elevated TMB (r = 0.81). Samples with bTMB ≥10 had an elevated cTF (median 13%, IQR 5 - 31%) as compared to samples with bTMB <10 (median 1.8%, IQR 0.6 - 7%, p < 0.001). Among 353 cases with both tissue and liquid CGP results (median 11 months apart), the relative prevalence of TMB ≥10 (12%) and bTMB ≥10 (13%) were similar, with concordant detection in 303 cases (86%). MSI-high (MSI-H) was seen in 2.2% of tissue CGP (3,461/156,294), most often in endometrial (19%), stomach (6.0%), and colorectal (5.3%) cancers, while MSI-H was detected in 0.68% of ctDNA specimens (43/6,295), which were also those with elevated cTF (median 11%, IQR 7 - 23%). Of 3,504 cases with MSI-H signature on tissue or liquid CGP, 1,619 (46%) had a pathogenic mutation detected in *MLH1/MSH2/MSH6/PMS2* (15% predicted germline). *CD274* amplification was detected in 1,207 cases (0.77%) of tissue CGP and 11 cases (0.17%) in ctDNA. **Conclusions:** Elevated bTMB is overall less prevalent than elevated tissue TMB, though these biomarkers are detected in similar cancer types. Detection of bTMB ≥10 and MSI-H in liquid biopsy was associated with elevated ctDNA levels, suggesting a limit of detection, and potentially indicating a more aggressive biology in samples positive for these biomarkers. Further investigation is needed to understand the utility of bTMB for identifying high TMB tumors that may benefit from IO. Research Sponsor: Foundation Medicine.

Impact of circulating tumor DNA (ctDNA) detection on survival outcomes of patients (pts) treated with immune-checkpoint inhibitors (ICIs) in early clinical trials. *First Author: Vladimir Galvao, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Detection of ctDNA is a promising tool for managing pts in oncology. Most methods require whole-genome sequencing of tumor samples followed by the design of personalized panels for tracking purposes. In this work, we evaluated the prognostic and predictive value of total ctDNA quantification, using shallow whole-genome sequencing (shWGS) exclusively from plasma samples, in a prospective cohort of pts treated with ICIs in early clinical trials. **Methods:** IchorCNA pipeline was used to quantify ctDNA of shWGS from plasma ctDNA samples of pts treated with ICIs in phase 1 trials, collected at baseline and prior to cycle 2 (prec2). We investigated the association and correlation of ctDNA levels with surrogate markers for tumor burden (LDH levels, summatory of target lesions (TL), liver metastasis) using Spearman and Kruskal-Wallis tests. Kaplan-Meier estimates of overall survival (OS) of pts with baseline detectable ctDNA levels versus undetectable ctDNA were calculated. A multivariate Cox proportional hazards model, including continuous classical prognostic factors (LDH, albumin, hemoglobin, derived Neutrophil-to-Lymphocyte ratio (dNLR), platelets, number of metastases sites, ECOG PS) and ctDNA was performed. An estimate of progression free survival (PFS) of pts with ctDNA increase levels in preC2 versus a non-increase group was evaluated. **Results:** Since January 2018, 113 pts with no standard-treatment options were included. Median (m) follow up was 14.8 months (mo). Baseline ctDNA levels correlated significantly with baseline TL (R = 0.4, p < 0.001) and LDH levels (R = 0.61, p < 0.001). Pts with liver metastasis had higher levels of ctDNA (11,68 ng/ml) versus pts with no liver disease (2,31 ng/ml) (p < 0,001). In the survival analysis pts with detectable baseline ctDNA (74 pts) had significantly shorter OS compared with pts with undetectable ctDNA (39 pts); median 9.6 m (8.4 – 16.4) and NA m (13.6-NA), respectively (HR = 2.25 [1.18-4.29] p < 0.01). In the multivariate analysis, only ctDNA and albumin levels maintained the impact in OS (HR = 1.03, p < 0.05 and HR = 0.22, p < 0.05, respectively). Pts with early increases in ctDNA had a shorter PFS compared with those with a stabilization or decrease, median 1.9 m (1.6 – 4.0) and 3.0 m (2.6 – 3.8), respectively (HR = 2.19 [1.31-3.67], p < 0.01). **Conclusions:** Quantification of baseline ctDNA using shWGS is a strong independent prognostic factor. Early dynamic changes of ctDNA could be a useful tool to predict PFS outcomes. Research Sponsor: Swiss Bridge Award and BBVA Foundation.

Analysis of immune checkpoint blockade biomarkers in elderly patients using large-scale cancer genomics data. *First Author: Rossin Erbe, Johns Hopkins School of Medicine, Baltimore, MD*

Background: Immune checkpoint blockade (ICB) immunotherapy in some cases elicits striking patient responses, but its efficacy appears to be dependent on several incompletely understood factors. Most studies of ICB therapies in elderly patients have concluded that they received no reduced benefit or even increased benefit compared to the younger patients analyzed, despite the systemic age-related immune changes that might be expected to produce a less effective immune response, such as loss of the capacity to generate new naive T cells. To understand and apply these results, it is necessary to investigate the relationship of age and the immune tumor microenvironment. **Methods:** We apply bioinformatics methods to genomic, transcriptomic, and clinical data from 9,523 patients across 31 cancer types from TCGA, 15,557 patients with breast, colon, or head and neck cancers from Caris Life Sciences, and 37,961 patients across 8 cancer types collected by GENIE. From these data we apply multivariate linear models across and within individual tumor types to estimate age-related associations to tumor mutational burden (TMB), T cell receptor diversity (miTCR), differential gene expression (edgeR), pathway enrichment (mSigDB and fgsea), and immune cell type infiltration (Quantiseq and MIXTURE). **Results:** Our analysis of large-scale molecular and clinical databases associates patient age with changes in several major biomarkers of ICB response. Notably, a robust correlation between increased tumor mutational burden and age was found across three different large cohorts (TCGA, Caris Life Sciences, and GENIE) in most ICB-approved cancer types. In the TCGA data, TMB increased with age pan-cancer ($p < 1x10^{-16}$) and in 7 of 9 ICB-approved cancer types. These associations were validated in the larger cohort of patient samples in GENIE, which demonstrated correlations between increased TMB levels and patient age in all eight ICB-approved cancer types assayed (Table), as well as in the Caris colorectal (q < 0.001) and breast (q < 0.001) cancer cohorts. Significant associations of age to other biomarkers of ICB response (checkpoint gene expression, immune infiltration, and immune related pathway signaling) will be presented. **Conclusions:** These results provide context for the efficacy of ICB in elderly patients, highlight potential biomarkers for the treatment of elderly patients with immunotherapies, and strongly suggest the value of large-scale prospective study of elderly cancer patients treated with ICB. Research Sponsor: U.S. National Institutes of Health.

SER-ONCOVID: Seroconversion in solid-tumor cancer patients after COVID-19 diagnosis.

First Author: Anna Pous, ICO Badalona, Barcelona, Spain

Background: Cancer patients (pts) represent a high-risk population for severe COVID-19. Cancer-associated immunosuppression may hinder in the development of anti-SARS-CoV-2 antibodies. **Methods:** Data regarding baseline characteristics, COVID-19 and anti-SARS-Cov2 IgG were collected from cancer pts (solid tumors) who tested positive for COVID-19 (PCR+) between March and April 2020 at Catalan Institute of Oncology. We prospectively assessed anti-SARS-Cov2 IgG seroprevalence at 3 and 9 months post infection and explored clinico-pathologic factors associated with IgG positivity. We explored the impact of potential factors influencing antibody production at >9 months. **Results:** Of 49 pts registered between 10th March-26th April 2020, 21 died <3 months after the infection and 5 pts refused to participate, leaving 23 eligible pts for IgG testing. With respect to those not tested, IgG tested cohort was younger (median age: 64.0 vs 72.9 years, p = 0.001) and presented oncologic remission in 68.2% of cases (vs 34.6%, p = 0.043) at COVID-19 diagnosis. Median time from PCR+ to first and second IgG determination was 3.2 months (Interquartile range [IQR]: 2.9-4.1) and 9.5 months (IQR: 8.8-9.8), respectively. Out of 23 pts, 15 had both determinations and 8 had only one (3 in the first time point, 5 in the second one). We identified 16/18 pts IgG+ (88.9%) at 3 months and 17/20 pts IgG+ (85%) at 9 months. One IgG+ pt became IgG- at the second determination, one was IgG- at both timepoints, and one had an inconclusive result at the first but negative at the second timepoint. Key characteristics of patients by IgG result 9 months after COVID-19 diagnosis are shown in the table. **Conclusions:** We describe a high seroprevalence of anti-SARS-CoV-2 IgG at 3 and 9 months after COVID-19 diagnosis in solid tumour patients, irrespective of anti-cancer therapy exposure. Pts who were IgG+ at 9 months were older, and more likely to have required oxygen during prior COVID-19 in comparison to IgG- pts suggesting that infection severity may promote durable immunity. Frequency of early stage cancers was higher among IgG+ pts, suggesting less cancer-related immunosupression. Older (>70 years) and advanced cancer pts were under-represented in this series, warranting confirmation of these preliminary results in a larger cohort. Research Sponsor: None.

Characteristics of patients by IgG result determined at 9 months after COVID-19 diagnosis.

Characteristics assessed at COVID infection	IgG- (n=3)	IgG+ (n=17)
Median Age (years)	49.0 [49.0; 50.0]	66.0 [62.0; 70.0]

Using the tumor microenvironment to identify predictors of immunotoxicity to checkpoint inhibitors.

First Author: William Alexander, University at Buffalo, Buffalo, NY

Background: While Immune checkpoint inhibitors (ICI) have revolutionized the field of oncology, the benefits have come at the cost of serious side effects known as immune-related adverse events (irAEs). Approaches that can predict patients' susceptibility to irAEs are key to their early detection and management. In the present study, we investigate the association between irAEs reported during ICI therapy across multiple cancer types and markers of tumor immune response. Our primary objective is to explore potential biomarkers for assessing patients' risk of irAEs. **Methods:** 472 patients were evaluated who had tumor immune profiling performed paraffin embedded formalin fixed archival tumor biopsy samples using Omniseq Immune Report Card (IRC) and subsequently underwent ICI therapy. The IRC consisted of enumeration of tumor infiltrating lymphocytes (TILs) by immunohistochemistry (IHC) and TIL-associated genes by RNA-Seq, PD-L1 expression by IHC, and tumor mutational burden (TMB) by DNA-Seq. irAE type and grade were determined based on retrospective chart review. Fisher's exact test was used to determined statistically significant associations between immune markers and irAE development. **Results:** Patients with lung (55%), ovarian (9%), and melanoma (5%) cancers constituted the majority of the cases. The median age of patients was 61, with 56% being female and 44% male. Most patients underwent treatment with (94%). irAEs developed in 36% of patients, with 2% of patients developing high-grade irAEs (Grade 3 or 4). Skin (11%), thyroid (10%), and GI (9%), were the most commonly affected organ systems. Increased TILs were associated with increased risk for any irAE (p = 0.04). A stronger association was noted in patients who underwent anti-PD-1/L1 monotherapy (p = 0.01) and/or in cases of lung cancer (p = 0.01). Interestingly, subanalyses by gender showed a statistically significant correlation between increased TILs and risk for any irAE in males (p = 0.006) but not in females (p = 0.63). High PD-L1 (defined as > 70% by IHC) was also significantly associated with increased risk for any irAE (p = 0.03). Subanalyses by gender and age again showed a similar association in females (p = 0.0002) and/or patients < 65 years (p = 0.04). high TMB and any irAE in female patients (p = 0.01) and in breast cancer cases (p = 0.03). On multivariate analysis, TILs by IHC appeared to be the strongest predictor of irAEs (p = 0.03). **Conclusions:** The tumor immune microenvironment (TME) has been shown to influence response to ICI, yet its association with irAEs has not been well studied. Our analysis sheds light on potential TME predictors for irAE in patients receiving ICI therapy. Further studies are needed to deepen our understanding of immune toxicity and to develop tools for identifying patients who are at risk. Research Sponsor: U.S. National Institutes of Health.

A 4-chemokine signature to predict intermediate immunogenicity in homologous recombination repair deficient tumors.

First Author: Joan Miguel Romero, Research Institute of the McGill University Health Centre, Montreal, QC, Canada

Background: Treatment responses to immune checkpoint blockade (ICB) associate with T cell tumor inflammation. Tumors with mismatch repair deficiency display an inflammatory tumor phenotype and respond to ICB. Similarly, tumors with homologous recombination repair deficiency (HR-d) may be primed for ICB treatment. We have previously shown that a panel of 4 chemokines identifies a subclass of pancreatic cancer with markers of T cell-inflammation. Here, we evaluated this 4-chemokine signature in cancer types with HR-d molecular subclasses. **Methods:** We combined paired transcriptomes and genomic data of breast (n = 699), ovarian (n = 174) and prostate (n = 457) cancers from the Cancer Genome Atlas and tumor-enriched pancreas cancers (n = 121) to evaluate the 4-chemokine signature in HR-d vs. HR-proficient tumors across these 4 cancers. Metrics of antitumor immunity were also compared. **Results:** Across tumor types, elevated expression of the 4-chemokine signature (chemokine-hi) associated with transcriptional hallmarks of a T cell-mediated antitumor response, including antigen presenting cell stimulation, antigen presentation, and T cell activity. In tumors with a predominant COSMIC signature 3, which associates with HR-d, the 4-chemokine signature predicted intermediate levels of T cell-inflammation. **Conclusions:** These data suggest that 1) the 4-chemokine signature may be a clinically relevant biomarker in identifying subclasses of tumours responsive to immunotherapies, and that 2) HR-d tumors harbor intermediate immunogenicity. Correlation of treatment responses to immunotherapies with the 4-chemokine signature is needed validate its predictive value as a biomarker for treatment stratification with immunotherapies. First-in-human dose escalation of ALPN-202, a conditional CD28 costimulator and dual checkpoint inhibitor, in advanced malignancies.

First Author: Justin C Moser, HonorHealth Research and Innovation Institute, Scottsdale, AZ

Background: Strong preclinical rationale has emerged for combining checkpoint inhibition (CPI) with T cell costimulatory agonists, particularly CD28, a critical T cell costimulatory molecule recently recognized as a key target of checkpoint inhibition. ALPN-202 is a variant CD80 vIgD-Fc fusion that mediates PD-L1-dependent CD28 costimulation and inhibits the PD-L1 and CTLA-4 checkpoints. It has demonstrated superiority to CPI-only therapies intumor models, while demonstrating favorable safety in preclinical toxicology studies. **Methods:** This is a cohort-based, open-label dose escalation and expansion study of ALPN-202 in adults with advanced solid tumors or lymphoma (NCT04186637). Subjects with cancers refractory to standard therapies (including approved CPIs), or cancers without available standard or curative therapy are eligible. After two planned single-subject cohorts, a standard 3+3 dose escalation has been implemented with two dose schedules in parallel, Q1W and Q3W. Objectives include evaluation of safety and tolerability, PK, PD and preliminary anticancer activity of ALPN-202. Disease assessments are evaluated by RECIST v1.1 for solid tumors or by Lugano Classification for lymphoma. **Results:** As of January 2021, 20 subjects with advanced malignancies have received ALPN-202. Dose-dependent PK and target saturation have been preliminarily observed. So far, ALPN-202 has been well tolerated at dose levels ranging from 0.001 to 1 mg/kg weekly, with no DLTs. Low-grade skin toxicities (grade 1-2 rash) have been observed in 4 subjects (20%). Among 11 evaluable subjects, an unconfirmed partial response has been observed in one subject with colorectal carcinoma, while stable disease has been observed in 5 subjects with colorectal carcinoma, mesothelioma (2), cholangiocarcinoma, and renal cell carcinoma – for a preliminary clinical benefit (PR+SD) rate of 100% (4/4) at dose levels of 0.3 mg/kg and higher, or 54% (5/11) overall (table). The meeting presentation will update this data, which is expected to include the conclusion of Q1W dose escalation, as well as immune correlates. **Conclusions:** First-in-human dose escalation with ALPN-202 has been well tolerated at doses capable of engaging CD28 costimulation *in vivo* in association with dual PD-L1/CTLA-4 checkpoint inhibition, with early signs of anti-tumor activity. These findings suggest that CD28 agonism can be safely achieved in humans, and further suggest that dose expansion with ALPN-202 is warranted to assess the relevance of controlled CD28 costimulation as a novel approach to cancer immunotherapy. Clinical trial information: NCT04186637. Research Sponsor: Alpine Immune Sciences.

Phase 1A clinical trial of the first-in-class fascin inhibitor NP-G2-044 evaluating safety and anti-tumor activity in patients with advanced and metastatic solid tumors. *First Author: Vincent Chung, City of Hope, Duarte, CA*

Background: Fascin inhibitors block tumor metastasis and increase antigen uptake in intra-tumoral dendritic cells. Filopodia, finger-like protrusions on cell surfaces, are necessary for migration of metastatic tumor cells and intra-tumoral dendritic cells. Fascin is the primary actin cross-linker in filopodia and elevated levels correlate with increased risk of metastasis, disease progression and mortality. NP-G2-044 is a novel small molecule that inhibits function of fascin. Pre-clinical data demonstrate drug-associated reductions in tumor growth and metastasis, enhanced immune response and survival in treated animals, and drug-drug synergism when combined with anti-PD-1 antibodies. **Methods:** This multicenter phase 1A clinical trial was designed to evaluate safety and tolerability of NP-G2-044 and to identify the drug's recommended phase 2 dose (RP2D) using a 3+3 dose escalation design. NP-G2-044 was administered to patients (pts.) with treatment-refractory solid tumor malignancies as a single oral daily dose for 6-week cycles that included 4 weeks on (daily dosing) and 2 weeks off (rest). **Results:** A total of 23 pts. were enrolled in 7 dose cohorts ranging from 200-2100 mg. QD. Overall, NP-G2-044 appeared well-absorbed and distributed with Tmax of ~4 hrs and T1/2 of 20-24 hrs. Across all cohorts, no DLTs, drug-related SAEs or patient deaths were observed. Based on PK and safety findings, 1600 mg. daily was selected as the provisional RP2D. While no formal RECIST-based objective responses were observed, consistent with the drug's non-cytotoxic mechanism of action, preliminary signals of anti-tumor and anti-metastatic activity were observed. These include dose proportional increases in duration of treatment, progression-free-survival, and metastasis-free interval, in particular for 4/4 late-stage ovarian cancer patients (table). Comparison of time on treatment (TOT) for ovarian cancer patients. **Conclusions:** In this first-in-human clinical trial, the novel fascin inhibitor, NP-G2-044, appeared safe and well tolerated. Signals of single-drug anti-tumor and anti-metastatic activity were observed. A phase 2A clinical trial with a particular focus on Ovarian Cancer will seek to elucidate signals of RP2D activity in both monotherapy and the combination of NP-G2-044 with anti-PD-(L)1 immune checkpoint inhibitors. Clinical trial information: NCT03199586. Research Sponsor: Novita.

Preliminary results from a phase 1/2 study of BDC-1001, a novel HER2 targeting TLR7/8 immune-stimulating antibody conjugate (ISAC), in patients (pts) with advanced HER2-expressing solid tumors. *First Author: Manish Sharma, START-Midwest, Grand Rapids, MI*

Background: BDC-1001 is a novel ISAC consisting of an investigational trastuzumab biosimilar chemically conjugated to a TLR 7/8 agonist with a non-cleavable linker. BDC-1001 was designed to activate the innate immune system, eliciting antibody-mediated effector functions (eg, antibody-dependent cellular phagocytosis) and a durable adaptive immune response. In preclinical tumor models resistant to anti-HER2 treatments, BDC-1001 demonstrated potent and durable immune-mediated antitumor efficacy. **Methods:** A 4-part, phase 1/2 dose-escalation/expansion study was initiated to evaluate BDC-1001 ± PD1 inhibitor pembrolizumab in pts with HER2-expressing solid tumors who had progressive disease on standard of care (NCT04278144). Preliminary results of the monotherapy dose escalation (Part 1) are reported. Pts with advanced metastatic HER2-expressing (IHC2/3+) or amplified solid tumors received BDC-1001 IV q3w in a 3+3 design w/ 12 pts/cohort backfill allowed. Primary objectives were to evaluate safety, tolerability, dose-limiting toxicities (DLTs) and determine a phase 2 dose; secondary objectives were to assess pharmacokinetics (PK), pharmacodynamics and preliminary anti-tumor activity. **Results:** As of Jan 29, 2021, 20 pts w/ a median age of 65 (46-85) have enrolled in 4 dose levels (0.15mg/kg to 5 mg/kg). Cancer types include breast, biliary, cervical, colorectal (CRC), lung, gastroesophageal, salivary, urinary tract and endometrial. Pts had received a median of 4 (1-7) prior therapies; 65% received >1 prior anti-HER2 therapy. All pts completed the 21-day DLT period; no DLTs or drug-related serious adverse events (AEs) have been observed. AEs deemed related to BDC-1001 have been mild to moderate including infusion-related reactions. The MTD has not been reached (treatment duration 5-17+wk); enrollment is ongoing. PK evaluations showed Cmax levels consistent with predicted modeling based on non-human primates (NHP). One pt with microsatellite stable (MSS) HER2+ CRC with lung metastases had a confirmed partial response after 4 cycles and remains on study; 2 additional pts with metastatic MSS HER2+ CRC had stable disease (SD) and a pt with heavily pretreated MSS endometrial cancer with lung metastases had confirmed SD and remains on treatment 17+ wk; 3 of these pts had received 2 prior anti-HER2 therapies. **Conclusions:** In this first-in-human study, BDC-1001 appears to be well-tolerated up to the dose tested to date (5 mg/kg), with Cmax levels achieved as predicted by NHP modeling. Evidence of clinical activity have been observed, including in pts previously treated with anti-HER2 therapy. Dose escalation is ongoing and will be followed by combination dosing with CPI and the phase 2 component in selected tumors. Clinical trial information: NCT04278144. Research Sponsor: Bolt Biotherapeutics.

2550 **Poster Session**

Preliminary results of a first-in-human phase I dtudy of IMM01, SIRPα Fc protein in patients with relapsed or refractory lymphoma. *First Author: Mingyuan Sun, State Key Laboratory of Experimental Hematology, National Clinical Research Center for Hematological Disorders, Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College., Tianjin, China*

Background: IMM01 is a recombinant human signal regulatory protein α (SIRPα) IgG 1 fusion protein that exerts dual-mechanism antitumor activity via engagement of activating tumor cell phagocytosis and stimulating T-cell anti-tumor responses by binding CD47 on tumor cell membrane. IMM01 displays promising preclinical characteristics regarding its receptor occupancy/tumor exposure/efficacy relationship. Unlike anti-CD47 monoclonal antibodies, IMM01 shows unique property of weak human erythrocyte conjugation so as avoiding severe hemolysis. **Methods:** Monotherapy of IMM01 was conducted in 14 enrolled subjects with relapsed or refractory lymphoma who had failed standard therapies. Dose escalation was performed in routine design of accelerated single-patient followed by standard 3+3 to establish the preliminary data of safety as well as determination of a recommended expansion dosage. Each cycle contains 4 dosing weekly followed by a week rest. The tumor responses were evaluated based on Lugano Classification 2014. IMM01 pharmacokinetics (PK) and pharmacodynamics (PD) analyses were performed. **Results:** As of February 08, 2021, a total of 14 patients (median age 49 y; median prior therapy 3) were enrolled in 6 escalated dose cohorts (0.003 mg/kg, 0.01 mg/kg, 0.05 mg/kg, 0.15 mg/kg, 0.5 mg/kg and 1.0 mg/kg). The common tumor types were follicular lymphoma, Hodgkin lymphoma, diffuse large B-cell lymphoma. No DLTs were observed up to 1.0 mg/kg. One SAE (grade 2 increased amylase and grade 3 increased lipase) was reported, which induced by disease progression on pancreas. The most common treatment related adverse events were thrombocytopenia (54%), neutrophil count decreased (36%), Pyrexia (36%) and Anaemia (27%). There were grade 1 or 2 except for one patient experienced a grade 3 platelet count decreased (lower baseline at 70×10^9/L). Transient platelet count decrease after 2 hours and return to baseline at 24 to 48 hours post first infusion. In 12 evaluated patients, one patient with FL had a CR and maintained a 26-week response at the dose of 0.01 mg/kg. One patient with HL who had failed PD-1 inhibitor was confirmed PR at 27 weeks and continues the therapy, and one patient with MZL maintained SD for 12 weeks at the dose of 0.15 mg/kg. One patient with HL failed PD-1 inhibitor and one patient with FL maintained a shrunk SD for 12 weeks at the dose of 0.5 mg/kg. One patient with AITL was evaluated as a shrunk SD after 5 doses treatment at the dose of 1.0 mg/kg. Terminal half-life of IMM01 range from 53.8 hours to 73.3 hours. The AUC and C_{max} of IMM01 show nonlinear increases in the dose range of 0.05 mg/kg to 0.5 mg/kg. **Conclusions:** Preliminary data from the present phase 1 study of IMM01, a SIRPα IgG 1 fusion protein, demonstrate that IMM01 has an excellent preliminary safety, tolerability and promising anti-tumor activity up to doses of 1.0 mg/kg. Clinical trial information: ChiCTR1900024904. Research Sponsor: ImmuneOnco Biopharmaceuticals (Shanghai) Co.,Ltd.

2551 **Poster Session**

Results of a phase 1 study of SRF388, a first-in-human, first-in-class, high-affinity anti-IL-27 antibody in advanced solid tumors. *First Author: Amita Patnaik, START, San Antonio, TX*

Background: IL-27 is an immunosuppressive cytokine, consisting of two subunits p28 and EBI3, that upregulates immune checkpoint receptors (eg, PD-L1, TIGIT) and downregulates proinflammatory cytokines such as IFNγ, TNFα, and IL-17. SRF388 is a first-in-class, fully human IgG1 antibody to IL-27 that blocks the interaction between IL-27 and its receptor, thereby promoting immune activation in the tumor microenvironment. The IL-27 pathway is activated in hepatocellular carcinoma (HCC) and renal cell carcinoma (RCC), and high circulating levels of EBI3 are associated with inferior outcomes in both. Circulating EBI3 levels may serve as a predictive biomarker of SRF388 activity. **Methods:** Patients with advanced solid tumors refractory to standard therapy were enrolled in a phase 1 dose-escalation study (accelerated single patient followed by standard 3+3) to establish the preliminary safety of SRF388 as a monotherapy and to identify a dose suitable for expansion (NCT04374877). SRF388 was administered intravenously every 4 weeks. Tumor response was assessed by RECIST v1.1. SRF388 pharmacokinetic (PK) and pharmacodynamic (PD) [phospho-STAT (pSTAT) inhibition] analyses were performed. **Results:** As of January 26, 2021, 12 patients have received SRF388 at doses ranging from 0.003 to 10 mg/kg with 2 patients undergoing intra-patient dose escalation. Median age was 68 years, 67% were female, and ECOG PS was 0/1 (42%/58%). Median number of prior therapies was 2 (range 1–9), and 75% were anti-PD-(L)1 experienced (n = 9). The only treatment-related adverse events observed across dose levels were low-grade fatigue (n = 1, 8%), nausea (n = 1, 8%) and excess salivation (n = 1, 8%). No dose-limiting toxicities (DLTs) or $\geq$ Grade 3 related toxicity have occurred. Mean time on study is 12.5 weeks (range 4–40). One patient with RCC who received prior anti-PD-1 has prolonged stable disease for $>$ 9 months. SRF388 PK are linear with estimated $T_{1/2}$ ranging from 6–19 days. There is evidence of accumulation and no anti-drug antibody development to date. Maximal inhibition of the IL-27 signaling pathway as measured by $>$ 90% pSTAT inhibition in whole blood was achieved starting at 0.3 mg/kg. Given combined evidence of near-complete pathway inhibition and preclinical human equivalent dose modeling projecting biologically active doses, additional slots were opened for RCC and HCC starting at 1 mg/kg. **Conclusions:** Preliminary results of IL-27 pathway blockade with a first-in-class therapeutic demonstrates that SRF388 is well tolerated at doses that achieve maximal inhibition of downstream pSTAT signaling through the dosing period. Expansions are planned in HCC and RCC. Updated data including the recommended phase 2 dose, clinical outcomes, PK/PD and correlative analyses will be presented. Clinical trial information: NCT04374877. Research Sponsor: Surface Oncology.

2552 **Poster Session**

Selection of the recommended phase 2 dose (RP2D) for subcutaneous nemvaleukin alfa: ARTISTRY-2. *First Author: Omid Hamid, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: Nemvaleukin alfa (nemvaleukin, ALKS 4230) is a novel engineered cytokine that selectively binds the intermediate-affinity interleukin-2 receptor to preferentially activate CD8$^+$ T and natural killer (NK) cells with minimal expansion of regulatory T cells (T_{regs}),designed for use as a cancer immunotherapy. ARTISTRY-2 (NCT03861793) is an ongoing phase 1/2 study evaluating the safety, efficacy, and pharmacokinetic and pharmacodynamic (PD) responses of subcutaneous (SC) nemvaleukin in combination with pembrolizumab in patients (pts) with advanced solid tumors. **Methods:** In phase 1, cohort-specific doses of SC nemvaleukin are administered on an every-7-day (q7d) or every-21-day (q21d) schedule during a 6-week monotherapy lead-in period, followed by combination with pembrolizumab 200 mg q21d. We present safety, PD effects, and preliminary clinical activity outcomes as of 12/02/2020. **Results:** 57 pts received nemvaleukin doses ranging from 0.3 mg to 6 mg q7d or 1 mg to 10 mg q21d. The most frequent tumor types (> 5 pts) were colorectal, pancreatic, ovarian, and lung; median number of prior therapies was 4. Treatment-related adverse events (TRAEs) in > 30% pts overall were pyrexia (43.9%), chills (38.6%), injection site erythema (33.3%), injection site reaction (33.3%), and fatigue (31.6%). 3 mg q7d (n = 7) had no drug-related dose reductions, discontinuations, or deaths during the monotherapy or combination periods. 6 mg was declared the maximum tolerated dose (MTD) for q7d dosing as 2 of 8 pts experienced dose-limiting toxicities (DLTs). For 6 mg q21d (n = 7), no drug-related dose reductions, discontinuations, or deaths have occurred during the monotherapy period; combination period data are not mature. 10 mg was declared the MTD for q21d dosing as 1 of 9 pts experienced DLTs and 3 had TRAEs leading to dose reductions. Systemic exposure to nemvaleukin increased with increasing dose. Increases in NK cells and CD8$^+$ T cells of approximately 16-fold and 3-fold, respectively, at 3 mg q7d, and approximately 8-fold and 3-fold, respectively, at 6 mg q21d were observed, with minimal change in T_{regs}. 46 pts had at least 1 on-treatment scan as of the data cutoff date, and 30 (65%) had stable disease (SD) on the first scan. Of the 30 pts with ≥2 scans, 13 (43%) had 2+ consecutive scans of SD. 16 of 57 pts remain on therapy. Antitumor activity data for more recent cohorts are still maturing. Based on the totality of the safety, PD effects, and antitumor activity data, 3 mg q7d was selected as the RP2D for SC nemvaleukin. **Conclusions:** SC nemvaleukin 3 mg q7d was generally well tolerated as monotherapy and in combination with pembrolizumab, and demonstrated robust PD effects on NK cells and CD8$^+$ T cells with minimal expansion of T_{regs}. These PD effects are similar to or greater than those observed with intravenous nemvaleukin. Thus, 3 mg q7d was selected as RP2D; phase 2 expansion cohorts for combination with pembrolizumab are enrolling. Clinical trial information: NCT03861793. Research Sponsor: Alkermes, Inc.

2553 **Poster Session**

Initial results from a phase 1b study of ORIC-101, a glucocorticoid receptor antagonist, in combination with nab-paclitaxel in patients with advanced solid tumors. *First Author: Raghad Karim, NEXT Oncology, San Antonio, TX*

Background: ORIC-101 is a potent and selective, orally bioavailable, small molecule antagonist of the glucocorticoid receptor (GR). Preclinical studies have demonstrated that activation of GR signaling leads to decreased responsiveness to chemotherapeutics (eg, taxanes) and antiandrogens across multiple tumor types. Mechanistically, ORIC-101 inhibits GR transcriptional activity and blocks the prosurvival signals mediated by the activated nuclear hormone receptor. **Methods:** A 3+3 dose escalation design was used to assess safety, pharmacokinetics (PK), pharmacodynamics (PD), and select the Recommended Phase 2 Dose (RP2D) of ORIC-101 in combination with nab-paclitaxel (nab-pac; NCT03928314). ORIC-101 doses ranging from 80 to 240 mg once daily, given either intermittently or in a continuous dosing regimen, were evaluated in combination with weekly nab-pac at 75 or 100 mg/m^2. Plasma PK and PD biomarkers were assessed on day 1 and after repeat dosing. PD modulation in blood-derived peripheral blood mononuclear cells (PBMCs) was assessed by RT-qPCR for GR target genes. Antitumor activity was assessed by RECIST v1.1. **Results:** 21 patients with 10 different solid tumors, with and without a prior taxane, were treated in 5 cohorts. ORIC-101 exposure increased with dose, with no evidence for drug-drug interaction with nab-pac. In the initial cohort at 240 mg ORIC-101 and 100 mg/m^2 nab-pac, 2 patients experienced dose limiting toxicities (DLTs) of Grade 3 fatigue and Grade 4 neutropenia/thrombocytopenia, respectively. No further DLTs were observed in subsequent cohorts and the RP2D was established as 160 mg ORIC-101 dosed once daily continuously for 21 days with nab-pac 75 mg/m^2 given on days 1, 8, and 15 of each 28-day cycle, without requirement for prophylactic granulocyte colony-stimulating factor (G-CSF). The most common (> 15%), all grade treatment-related adverse events (AEs) were nausea (38%), diarrhea (33%), fatigue (29%), leukopenia (29%), neutropenia (29%), anemia (24%), and 19% of patients had increased liver function tests and alopecia. Biomarker data demonstrated ORIC-101-induced reduction in GR target gene expression in PBMCs, indicating PD modulation at all dose levels of ORIC-101. Preliminary antitumor activity was observed in 3 taxane-refractory patients with breast, endometrial, and pancreatic cancers. **Conclusions:** The combination of ORIC-101 and nab-paclitaxel demonstrated an acceptable tolerability profile and does not require prophylactic G-CSF. PK and PD showed no evidence of drug-drug-interaction and demonstrated GR target inhibition. Preliminary antitumor activity was observed in patients with solid tumors that previously progressed on a taxane-containing regimen. Dose expansion is ongoing at the RP2D in dedicated pancreatic, ovarian, triple negative breast cancers, and tissue-agnostic cohorts. Clinical trial information: NCT03928314. Research Sponsor: ORIC Pharmaceuticals.

2555 **Poster Session**

Results of a phase 1 dose-escalation study of AMV564, a novel T-cell engager, alone and in combination with pembrolizumab in patients with relapsed/refractory solid tumors. *First Author: Niharika B. Mettu, Duke University Medical Center, Durham, NC*

Background: Myeloid-derived suppressor cells (MDSC) contribute to an immunosuppressive tumor environment and are a barrier to immune therapy. CD33 signaling in immature myeloid cells promotes expansion of MDSC and production of immunosuppressive factors. AMV564 is a potent T cell engager that selectively depletes MDSC while promoting T cell activation and proliferation, via preferential binding to areas of high CD33 density. **Methods:** In this 3+3 dose escalation study, patients with relapsed/refractory solid tumors for whom no recognized standard therapy exists received AMV564 once daily via subcutaneous (SC) injection on Days 1-5 and 8-12 of a 21-day cycle, either alone or in combination with pembrolizumab (200 mg IV q3w). Study endpoints included incidence and severity of adverse events (AEs), pharmacokinetics (PK), and preliminary anti-tumor activity (using RECISTv1.1 criteria). **Results:** As of January 29, 2021, 20 patients were dosed in 3 monotherapy dose cohorts (15, 50, and 75 mcg/day), and 10 patients were dosed in 3 combination therapy cohorts (5, 15, and 50 mcg/day). Enrolled patients were: median age 64 years, 47% female, had received median 3.5 prior lines of therapy; 7 patients (35%) had received prior checkpoint inhibitor therapy (6 monotherapy patients, 1 combination therapy patient). No dose-limiting toxicity was observed and a maximum-tolerated dose was not reached in either the monotherapy or combination therapy cohorts. The most common treatment-related AEs (occurring in > 10% of patients, in order of decreasing frequency) in the monotherapy cohort were pyrexia, injection site reactions, fatigue, anemia, hypotension, pruritis, chills, and nausea. There were 2 cases of grade 2 cytokine release syndrome (CRS) at 75 mcg/day, both of which resolved after anti-IL6 therapy and study treatment was resumed. The most common treatment-related AEs in the combination cohorts (> 10% frequency) were injection site reaction, pyrexia, fatigue, pruritis, and anemia. No cases of CRS were noted in the combination cohorts. In preliminary PK analysis, estimated median plasma half-life for AMV564 after SC injection was > 48 hours, with dose-related increases in peak plasma concentration. Clinical responses were seen with monotherapy and combination therapy, including a complete response (CR) in a monotherapy-treated patient with ovarian cancer refractory to all standard therapies and anti-PD-1 therapy. **Conclusions:** AMV564 was well tolerated across multiple dose levels as monotherapy and in combination with pembrolizumab. Subcutaneous injection resulted in clinically relevant plasma exposures. Single-agent and combination therapy anti-tumor activity was observed. Further exploration of AMV564 clinical efficacy in expansion cohorts is ongoing. Clinical trial information: NCT04128423. Research Sponsor: Amphivena Therapeutics.

A phase 1b, open-label, dose-escalation study to evaluate camidanlumab tesirine (Cami) as monotherapy in patients (pts) with advanced solid tumors. *First Author: Igor Puzanov, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Depletion of tumor-infiltrating CD25+ regulatory T cells (T_{regs}), which inhibit tumor-specific immune responses, could contribute to tumor eradication. Cami (ADCT-301), an anti-CD25, pyrrolobenzodiazepine-based antibody-drug conjugate, targets CD25+ T_{regs}. A mouse surrogate has shown potent antitumor activity in solid tumor models. Here we report preliminary data from the monotherapy arm of a phase 1b trial of Cami in pts with selected advanced solid tumors. **Methods:** The monotherapy dose-escalation part of this open-label study enrolled pts (aged ≥18 years) with selected advanced solid tumors and no suitable existing therapy. The primary objective was to characterize safety and tolerability, and to identify the recommended phase 2 dose of Cami monotherapy. Secondary and exploratory objectives included evaluation of preliminary antitumor activity, pharmacokinetics (PK), pharmacodynamics (PD), and immunogenicity. Pts received Cami every 3 weeks (1 cycle) with dose escalation per a 3+3 design. Disease control rate (DCR) was assessed (complete and partial responses [CR, PR] and stable disease). **Results:** At data cut-off (Dec 17, 2020), 44 pts were enrolled, with primary tumor types (stage IVA/B: 27 pts; 61.4%) of colorectal (15 pts; 34.1%), pancreatic (14 pts; 31.8%), head and neck, ovarian/fallopian tube, and renal cell carcinoma (all 3 pts; 6.8%), non-small cell lung cancer (2 pts; 4.5%), gastric, esophageal/GEJ, melanoma, and triple-negative breast cancer (each 1 pt; 2.3%). Median (range) age was 60.5 (33–82) years; median (range) number of prior systemic therapies was 4 (1–9). Pts received a median (range) of 2 (1–6) Cami cycles at doses of 20–150 μg/kg. Median (range) treatment duration was 22 (1–178) days. No dose-limiting toxicities were reported. The maximum tolerated dose (MTD) was not reached. All-grade treatment-emergent adverse events (TEAEs) in ≥20% pts were nausea (18 pts; 40.9%), decreased appetite and fatigue (each 16 pts; 36.4%), constipation (13 pts; 29.5%), abdominal pain (11 pts; 25%), and rash (10 pts; 22.7%). The only Grade ≥3 TEAE in ≥10% pts was anemia (5 pts; 11.4%). Grade 3 autoimmune AEs (colitis, immune-mediated AE, systemic inflammatory response syndrome) and neurologic AEs (dysphagia and asthenia, but not GBS) were reported in 3 (6.8%) and 2 (4.5%) pts, respectively. 1 (2.3%) Cami-related TEAE led to treatment withdrawal; no Cami-related TEAEs were fatal. DCR was 25% (95% CI: 11.1, 34.7); 11/44 pts attained stable disease. No pts had CR or PR. **Conclusions:** Dose escalation of Cami monotherapy is complete. The safety profile is encouraging and MTD was not reached. PK/PD data will be presented. 150 μg/kg is the highest dose investigated for single-agent Cami and the highest to be investigated combined with pembrolizumab in selected advanced solid tumors in the current protocol. Funding: ADC Therapeutics SA NCT03621982. Clinical trial information: NCT03621982. Research Sponsor: ADC Therapeutics SA.

ItRECIST adapted efficacy assessment in solid tumors treated with intratumoral immunotherapy. *First Author: Honey Kumar Oberoi, Vall d'Hebron Institute of Oncology (VHIO), Medical Oncology, Vall d'Hebron University Hospital (HUVH), Barcelona, Spain*

Background: The development of human intratumoral therapy (HIT-IT) has surged as a promising strategy to overcome resistance to checkpoint inhibitors (CPI), promoting a stronger tumor-specific immune response while reducing systemic exposure. A broad variety of agents (i.e: oncolytic viruses, toll-like receptors agonists) administered both in superficial- and deep-seated lesions are being currently tested in clinical trials (CT). Due to the local intervention on tumors, radiological assessment by standard RECIST is challenging and new methods of response that capture and integrate the local and systemic response to HIT-IT are needed. We aimed to evaluate the feasibility and clinical utility of itRECIST (Goldmacher et al., 2020) in patients (pts) treated with HIT-IT in early phase CT. **Methods:** Retrospective analysis of a cohort of pts with different solid tumor types enrolled in CT including HIT-IT in our institution between August'18 and January'21. Clinical characteristics were collected. Efficacy in target-injected (T-I) and target-non-injected (T-NI) lesions was assessed by objective response rate (ORR) and disease control rate (DCR), as per itRECIST. Overall disease ORR and DCR were assessed per RECIST 1.1/ iRECIST. Treatment-related adverse events (TRAEs) were assessed with CTCAE v.5.0. ORR was calculated with Clopper-Pearson method. Survival analysis was made using Kaplan-Meier method. **Results:** A total of 37 pts were included. Median age was 66 years, 19 pts (51%) were male, all pts had ECOG 0-1. 24 pts (65%) were CPI-naïve. Median previous lines of therapy was 2 (range [r]: 0-11). All pts (100%) received minimum 1 dose of HIT-IT. 6 pts (16%) were treated with monotherapy and 31 pts (84%) in combination with CPI. Median HIT-IT and CPI doses administered were 4 (r: 1-9) and 2 (r: 1-13), respectively. Injected lesions: cutaneous (16.2%), subcutaneous (21.6%), lymph node (32.4%), liver (29.7%). Median size of T-I lesions was 40 mm (r: 19-260). At data cutoff, 32 pts were evaluable. Median follow-up was 14.4 weeks (r: 1.0-81.1). Per RECIST 1.1, overall ORR was 6% (95% CI, 5-7) and DCR was 38% (95% CI, 21-56). Per itRECIST, ORR was 19% (95% CI, 7-36) and DCR was 63% (95% CI, 44-79) in T-I lesions (n = 32), and 10% (95% CI, 22-27) and 48% (95% CI, 29-67) in T-NI lesions (n = 29). Mean decrease in responding T-I and T-NI lesions was -47% (r: -21 to -100) and -41% (r: -26 to -59), respectively. No non-target (NT) lesion was injected. Median progression-free survival was 7.4 weeks (95% CI, 6.6 – 8.2). Median overall survival was 10.0 months (95% CI, 2.3 – 17.7). Incidence of TRAE was 58% (grade 1-2 IT-related pyrexia 43%; grade 3-4, 5%). No treatment-related deaths were recorded. **Conclusions:** ItRECIST is feasible to implement and adds precision to the radiological assessment of local and distant anti-tumor activity of HIT-IT. No safety issues were detected in our cohort. Research Sponsor: BBVA Foundation.

Targeting innate immunity with BXCL701 in combination with pembrolizumab in patients with advanced solid cancers: Phase 2 basket study. *First Author: Ozgur Karakuzu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BXCL701 is an oral competitive inhibitor of dipeptidyl peptidases (DPPs), primarily DPP8/9, which triggers the inflammasome to alert and prime immune cells, leading to induction of IL-18 and IL-1ß. BXCL701 therefore, can induce an innate immune reaction and tumor inflammation, bridging between innate and adaptive immunity, potentially leading to synergistic anticancer activity when combined with PD-1 antibody pembrolizumab. **Methods:** This is a phase 2, open-label, single-center study (NCT04171219) of oral BXCL701 0.3 mg BID on days 1-14 and intravenous pembrolizumab 200 mg on day 1 of a 21-day cycle with a safety lead-in to evaluate RECIST/iRECIST response rate in patients with advanced solid cancers. After confirming safety and dose limiting toxicities (DLT) in the first 6 patients, additional patients are being enrolled to an immune checkpoint inhibitors (iCPI) naïve cohort and iCPI pretreated cohort. Each cohort is planned to enroll 9 patients in the first stage, and if a partial (PR) or complete response (CR) is observed the cohort is expanded to a total of 17 patients in the second stage. The treatment is considered promising if at least 3 PRs or CRs are observed in a cohort of 17 patients. **Results:** As of February 11, 2021, 16 patients were treated; 5 patients (prostate cancer, endometrial cancer, liposarcoma, basal cell carcinoma, squamous cell carcinoma of unknown primary) were enrolled in the iCPI naïve cohort and 11 patients (leiomyosarcoma [2], squamous cell carcinoma of unknown primary, triple negative breast cancer, uveal melanoma, melanoma, uterine myxoid sarcoma, pleomorphic sarcoma, colorectal cancer, anaplastic astrocytoma, prostate cancer) were enrolled to iCPI pretreated cohort. Among all 16 patients, there was 1 episode of grade 4 hypotension (recovered) and 1 episode of grade 5 hypotension attributed to BXCL701, which resulted in implementation of risk-mitigation strategies such as gradual dose escalation and blood pressure monitoring. In the CPI naïve cohort, of 4 patients with available imaging, 1 had a PR (microsatellite stable endometrial cancer [-62%]) and 1 durable stable disease (SD -10%, basal cell carcinoma on therapy for 6+ months). In the CPI pretreated cohort, of 9 patients with available imaging, 1 had a PR (-31%, uveal melanoma) and 3 durable SD (-22%, pleomorphic sarcoma on therapy for 8+ months; +4%, squamous cell carcinoma of unknown primary on therapy for 6 months; +5%, uterine myxoid sarcoma on therapy for 6 months). **Conclusions:** BXCL701 in combination with pembrolizumab demonstrated encouraging signals of activity in selected difficult-to-treat cancers. Prespecified efficacy endpoints were met in the first stage and both cohorts will proceed to second-stage of the study Clinical trial information: NCT04171219. Research Sponsor: BioXcel Therapeutics.

GS-3583, a novel FLT3 agonist Fc fusion protein, to expand conventional dendritic cells in healthy volunteers. *First Author: Nishanthan Rajakumaraswamy, Gilead Sciences, Inc., Foster City, CA*

Background: Conventional dendritic cells subtype 1 (cDC1) play a vital role in the priming and expansion of tumor specific CD8+ T cells and their recruitment to tumor microenvironment (TME). However, cDC1s are often underrepresented in the TME. Systemic administration of Fms-like tyrosine kinase 3 ligand (FLT3L), a hematopoietic growth factor that binds to FLT3 on myeloid and lymphoid progenitor cells, leads to expansion of cDC1s in the periphery which can then be recruited into the TME. We hypothesize that FLT3 pathway stimulation using GS-3583, a FLT3 agonist Fc fusion protein, has the potential to promote T cell mediated anti-tumor activity. **Methods:** This was a first-in-human placebo-controlled study of GS-3583 in healthy volunteers to evaluate the safety, PK, and PD of escalating single doses (ranging from 75μg to 2000μg) of GS-3583. The study was blinded to the subjects and the investigator. Each dose cohort enrolled 8-12 healthy subjects who received GS-3583 or placebo as single IV infusion at 3:1 ratio. Subjects were observed in the phase 1 unit for 15 days and then for 12 weeks as outpatients. As part of the PD evaluation, we investigated the changes in the number of cDC1s and cDC subtype 2 (cDC2) cells. **Results:** As of 8th Feb 2021, selected safety, PK and PD data from the first 3 cohorts were available. GS-3583 was well tolerated and all subjects had been discharged. To date, there have been no serious or grade 3 or higher adverse events. Preliminary PK analysis suggested dose-dependent increase in GS-3583 exposure (AUC and C_{max}). Preliminary PD analysis shows that administration of GS-3583 resulted in dose-dependent increases in cDC1/cDC2 cells that peaked at day 5 or day 8 and returned to baseline within three weeks of drug administration. **Conclusions:** GS-3583 was safe and well tolerated and induced dose dependent expansion of dendritic cells in the periphery. In patients with cancer, this increase in dendritic cells can be utilized to enhance anti-tumor responses to immuno-oncology therapies. Research Sponsor: Gilead Sciences, Inc.

Safety and efficacy of murine PVSRIPO plus anti-PD-1 immune checkpoint inhibitor (ICI) in a melanoma tumor model. *First Author: Lauren Neighbours, Istari Oncology, Morrisville, NC*

Background: Most patients with advanced melanoma (mel) fail/acquire resistance to ICI, including anti-(α) PD-1. PVSRIPO is a novel intratumoral immunotherapy derived from the Sabin type 1 attenuated poliovirus (PV) that targets CD155, widely expressed on solid tumors and antigen-presenting cells (APCs) of the tumor microenvironment. Therapy leads to direct tumor cell death and type I/III interferon-dominant innate inflammation, mediating priming and recruitment of tumor antigen-specific T cells. Inflammation-mediated upregulation of the PD-1/L1 IC suggests greater anti-tumor response could be achieved with PVSRIPO + αPD-1. The aim of this preclinical study was to evaluate the efficacy and safety of murine PVSRIPO (mRIPO) + αPD-1 in an aggressive mel tumor model (B16-F10.9-OVA in human-CD155 transgenic mice [C56Bl/6]). **Methods:** Mice were randomized to 4 groups (G) of 12: (G1 [control]: vehicle [v] + IgG; G2: v + αPD-1; G3: mRIPO + IgG; G4: mRIPO + αPD-1). Tumor cells (5 x 10^5) were implanted into the right (R) and left (L) flanks. When tumor volume (vol) was ~25 mm^3, 15 μL v or 1 x 10^7 $TCID_{50}$ mRIPO was injected into R (Day 1) and L (Day 4) tumors; αPD-1 or IgG (250 μg, 100 μL ip) was given on Days 1 and 4 and q 3 days until termination (Day 13). Weight, hematology, chemistry, and inflammatory cytokines were assessed pre/post-tumor implantation. Tumor vol was assessed every other day, with gross/histologic exam at termination. **Results:** 47 mice without health issues were euthanized as planned; 1 G1 animal required early euthanasia for tumor ulceration. Microscopic findings: increased mononuclear cell tumor infiltrates (G2 and G4); less severe L tumor growth necrosis in G2, G3, and G4 vs G1. There were no specific treatment-related changes in serum cytokines in G4. See the table below for summary of total tumor vol changes vs control; the most significant reduction was observed in G4. No tumor cells were observed via histopathology at Day 13 in R flanks of 1 mouse in G2; 3 in G3; and 8 in G4; and only G3 (n=1) and G4 (n=5) mice had no evidence of L flank tumor cells, with regression evident before L tumor mRIPO injection (ie, abscopal response). **Conclusions:** mRIPO + αPD-1 had the greatest overall anti-tumor response, and the combination was well tolerated. These results suggest combination therapy is not associated with untoward immune-mediated toxicity and highlight the potential for enhanced efficacy in injected and uninjected tumors. A phase 2 clinical trial of PVSRIPO ± αPD-1 in unresectable αPD-1 refractory mel is enrolling (LUMINOS-102, NCT04577807). Research Sponsor: Istari Oncology.

Resetting the tumor microenvironment to favor anti-tumor immunity after local ablation. *First Author: Corrine Audrey Nief, Duke University, Department of Biomedical Engineering, Durham, NC*

Background: Percutaneous tumor ablation is a non-surgical method of tumor destruction that leaves necrotic tumor debris *in situ*. Tumor associated antigens released after ablation have the potential to initiate a systemic anti-tumor immune response, however the hostile tumor microenvironment hinders antigen presentation and T cell activity. We hypothesized that resetting the tumor microenvironment with oral sodium bicarbonate to decrease tumor acidity and low-dose cyclophosphamide to deplete pro-tumor immune cells would improve the ability of ablation to initiate anti-tumor immunity. **Methods:** Tumor growth, overall survival, and metastatic burden was assessed in orthotopic tumor models of triple-negative breast cancer (67NR, 4T1, and E0771). Tumor ablation was performed on palpable tumors using percutaneous ethanol injection (PEI) with 6% ethylcellulose to improve retention in the tumor. Surgical excision was used as a negative control to test the role of *in situ* tumor debris. Before ablation mice were placed on 200 mM of sodium bicarbonate (SB) in their drinking water and received a single intraperitoneal injection of 200 mg/kg of cyclophosphamide (CP). Mice surviving to 60 days after tumor implant without a primary tumor or signs of metastases were considered "cured" and re-challenged with 50e5 tumor cells in the contralateral mammary pad. T cell dependance was assessed with in vivo CD8 depletions. **Results:** The combination of PEI+SB+CP produced a potent anti-tumor response, curing a majority of mice (5/7 of E0771, 8/12 of 67NR, 7/12 of 4T1). No mice were cured using PEI alone, SB alone, CP alone, or any combination of two therapies (0/51 of E0771, 0/73 of 67NR, 0/75 of 4T1,). Re-challenge tumor growth was hindered in mice cured with PEI+SB+CP. Mice receiving PEI+SB+CP had significantly less metastases and lived longer than mice receiving surgical excision alone or surgical excision with SB+CP. Additionally the anti-metastatic response of PEI+SB+CP was undone when CD8+ T cells were depleted. **Conclusions:** Here the anti-tumor response of local ablation produced by PEI was enhanced by priming the tumor with low-dose CP and oral SB in metastatic breast cancer. These results suggest that tumor ablation with CP and SB can create a T cell dependent, personalized immune response to a tumor using only low-cost, easily accessible supplies, and the host's own tumor. Research Sponsor: National Institutes of Health.

Phase 1 trial of the adenosine A_{2A} receptor antagonist inupadenant (EOS-850): Update on tolerability, and antitumor activity potentially associated with the expression of the A_{2A} receptor within the tumor. *First Author: Laurence Buisseret, Institut Jules Bordet, Brussels, Belgium*

Background: Tumors produce high levels of extracellular adenosine which suppress anti-tumor immune responses. Blocking A_{2A} receptors, predominantly expressed on tumor-infiltrating immune cells, can reverse the immunosuppressive effect of adenosine. Inupadenant is a non brain-penetrant, potent and highly selective small molecule antagonist of the A_{2A} receptor that remains active even at the high adenosine concentrations found in tumors. **Methods:** This is the phase I portion of an ongoing first-in-human, clinical trial (NCT02740985) to evaluate safety/tolerability, pharmacokinetic, pharmacodynamic and anti-tumor activity of inupadenant in adult patients with solid tumors who have exhausted standard treatment options. In addition, tumor biomarkers, including adenosine-pathway markers by immunohistochemistry (IHC), are being evaluated. We present updated results of the dose escalation, new results from the monotherapy expansion and new analysis of tumor biomarkers. **Results:** Overall, 42 patients (21 patients in the dose escalation and an additional 21 patients in a monotherapy expansion) with a median of 3 prior regimens were treated as of the data cut off (DCO, 30Nov20).The dose levels investigated, along with the most frequent (>20%) treatment-emergent adverse events (TEAEs) across all dose levels are presented in the table. 7 AEs led to discontinuation; 2 (atrial fibrillation and myocardial infarction) were considered possibly study drug-related by the investigator. No dose reductions were required. Two partial responses (PRs) were reported: melanoma (NRAS-mutant; received prior immunotherapy), and prostate cancer (received antiandrogen and chemotherapy). At the DCO, both PRs were ongoing with a duration of response >230 days. 12 patients had stable disease (SD) as best response and SD >6 months was observed in 3 patients. Response and stable disease were associated with a higher number of cells expressing the A_{2A} receptor within the tumor at baseline, as measured by IHC. **Conclusions:** Inupadenant monotherapy was generally well-tolerated as of the DCO at a dose of 80 mg twice daily with initial evidence of clinical benefit, including 2 durable PRs in patients who have exhausted standard treatment options. Analysis of pre-treatment tumor biopsies has identified the A_{2A} receptor as a biomarker which may be associated with clinical benefit. Clinical trial information: NCT03873883. Research Sponsor: iTeos Therapeutics.

Tumor-selective activity of XTX202, a protein-engineered IL-2, in mice without peripheral toxicities in nonhuman primates. *First Author: Jennifer O'Neil, Xilio Therapeutics, Waltham, MA*

Background: High-dose recombinant human interleukin-2 (aldesleukin) elicits anti-tumor immunity and is approved for the treatment of renal cell carcinoma and melanoma based on durable complete remissions. However, use of aldesleukin is limited due to treatment-related life-threatening toxicities. Recent second-generation efforts to alleviate toxicities have largely focused on eliminating binding to IL-2Rα, often with half-life extension. We have determined that mice and non-human primates (NHPs) treated with a second generation IL-2 surrogate still experience characteristic dose-limiting toxicities, including vascular leak syndrome. To overcome these toxicities and improve the therapeutic index (TI) of IL-2 as an anti-tumor immunotherapy, we employed protein engineering to generate XTX202, a highly potent third generation masked IL-2. XTX202 is unmasked in the tumor microenvironment by proteolytic activation resulting in full restoration of binding to IL-2Rβ without binding to IL-2Rα. The current study characterizes the therapeutic index of XTX202 versus aldesleukin and a second generation IL-2 surrogate. **Methods:** XTX202 bioactivity was measured using STAT-5 phosphorylation in human PBMCs and reporter cell lines. Anti-tumor efficacy and peripheral immune activation were evaluated in mice bearing syngeneic tumor models. Safety was evaluated in rodents and Cynomolgus monkeys. XTX200, an unmasked half-life extended IL-2 that does not bind to IL-2Rα, was used as a surrogate second generation IL-2. **Results:** Masked XTX202 showed limited IL-2R-dependent STAT-5 signaling *in vitro*. Proteolytic activation of XTX202 resulted in $CD8^+$ T and NK cell activation and over 1000-fold reduction in Treg activation as compared to WT IL-2. XTX202 achieved potent tumor growth inhibition in syngeneic mouse models as a single agent with no evidence of toxicity or peripheral immune activation, thus demonstrating tumor selective activity. XTX202 efficacy in mice at 2 mg/kg dose was equivalent to that achieved with the MTD dose of 0.5 mg/kg of a second generation IL-2 surrogate. XTX202 was well tolerated in NHPs in a 4-week repeat dose study at doses up to 30 mg/kg QW whereas a second generation IL-2 surrogate was not tolerated beyond 0.7 mg/kg QW. Based on these data, XTX202 has a 10 fold improvement in TI vs second generation IL-2. Based on comparative efficacy studies with aldesleukin and literature NHP tolerability data, XTX202 is projected to have a ≥150 fold greater TI than aldesleukin. **Conclusions:** XTX202, a third generation, tumor-selective IL-2, inhibits tumor growth and is well tolerated in repeat dose studies in NHPs at high doses. GLP toxicity studies with XTX202 are underway and first-in-human studies are expected to initiate this year. XTX202 has the potential to be a best-in-class IL-2 immunotherapy by expanding the curative anti-tumor activity of IL-2 while minimizing dose-limiting toxicities. Research Sponsor: Xilio Therapeutics.

Antitumor activity of dostarlimab in patients with mismatch repair-deficient/microsatellite instability–high tumors: A combined analysis of two cohorts in the GARNET study. *First Author: Dominique Berton, GINECO & Institut de Cancerologie de l'Ouest, Centre René Gauducheau, Saint-Herblain, France*

Background: Dostarlimab is an investigational, humanized programmed death 1 (PD-1) receptor monoclonal antibody that blocks interaction with the PD-1 ligands, PD-L1 and PD-L2. GARNET (NCT02715284) is a phase 1 study assessing the antitumor activity and safety of dostarlimab monotherapy in patients with solid tumors. **Methods:** This multicenter, open-label, single-arm study is being conducted in 2 parts: dose escalation and expansion. Here we report on the 2 expansion cohorts that enrolled mismatch repairdeficient/microsatellite instabilityhigh (dMMR/MSI-H) patients. Cohort A1 enrolled patients with advanced or recurrent dMMR/MSI-H endometrial cancer (EC), and cohort F enrolled patients with advanced or recurrent dMMR/MSI-H or $POL\varepsilon$-hypermutated non-EC solid tumors, mainly gastrointestinal (GI) tumors (99 [93.4%] had GI tumors, including 69 [65.1%] with colorectal cancer). Patients received 500 mg IV of dostarlimab every 3 weeks for 4 cycles, then 1000 mg IV every 6 weeks until disease progression or discontinuation. The primary endpoints were objective response rate (ORR) and duration of response (DOR) by RECIST v1.1. Here we report ORR and DOR, by individual cohort and as an overall population, in patients with dMMR tumors identified by immunohistochemistry testing. **Results:** For this interim analysis, an efficacy analysis was performed for the patients who had baseline measurable disease and ≥6 months of follow-up in the study (N = 209). The ORR was 41.6% (95% CI, 34.9%48.6%) for the combined A1+F dMMR cohorts (Table). Responses were durable, and median DOR has not been reached in either cohort (median follow-up: cohort A1, 16.3 months; cohort F, 12.4 months). A total of 267 patients were included in the safety population (all patients who received ≥1 dose; cohort A1, N = 126; cohort F, N = 141). Treatment-related adverse events (TRAEs) were consistent across tumor types. Overall, the most frequently reported any-grade TRAEs were asthenia (13.9%), diarrhea (13.5%), and fatigue (11.2%). The most common grade ≥3 TRAEs were anemia (2.2%), lipase increased (1.9%), alanine aminotransferase increased (1.1%), and diarrhea (1.1%). No deaths were attributed to dostarlimab. **Conclusions:** Dostarlimab demonstrated durable antitumor activity in patients with dMMR solid tumors, with consistent antitumor activity seen across endometrial and nonendometrial tumor types. The safety profile was manageable, with no new safety signals detected. Most TRAEs were low grade and were similar across cohorts. Clinical trial information: NCT02715284. Research Sponsor: GlaxoSmithKline.

Pembrolizumab in microsatellite instability high (MSI-H)/mismatch repair deficient (dMMR) cancers: Updated analysis from phase 2 KEYNOTE-158 study. *First Author: Michele Maio, Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy*

Background: Approval of pembrolizumab for the treatment of unresectable or metastatic MSI-H/dMMR solid tumors that have progressed on prior therapy was supported by data from KEYNOTE-158 (NCT02628067). At the data cutoff of Dec 6, 2018, the ORR was 34.3% among 233 patients (pts) with MSI-H/dMMR solid tumors enrolled in all cohorts of KEYNOTE-158, 77.6% had duration of response (DOR) ≥24 mo, median PFS was 4.1 mo, and median OS was 23.5 mo. We present results from 351 pts enrolled in KEYNOTE-158 cohort K at the data cutoff of Oct 5, 2020. **Methods:** Cohort K of this phase 2, open-label study enrolled adults with any previously treated advanced noncolorectal MSI-H solid tumor, measurable disease per RECIST v1.1, and ECOG PS of 0–1. MSI-H/dMMR status was assessed locally from a tumor tissue sample and defined as ≥1 of 4 MMR proteins absent by immunohistochemistry or as ≥2 allelic loci size shifts of 5 microsatellite markers by PCR. Pts received pembrolizumab 200 mg Q3W for up to 35 cycles or until PD, unacceptable toxicity, investigator decision, or withdrawal of consent. The primary endpoint was ORR per RECIST v1.1 by blinded independent central review (BICR). Secondary endpoints were DOR and PFS per RECIST v1.1 by BICR, OS, and safety. Efficacy was assessed in all pts who received ≥1 dose of treatment with ≥6 mo follow-up; safety was assessed in all treated pts. **Results:** 351 pts were enrolled in KEYNOTE-158 cohort K across multiple tumor types, including endometrial (22.5%), gastric (14.5%), small intestine (7.4%), ovarian (7.1%), cholangiocarcinoma (6.3%), and pancreatic (6.3%). 41.0% had 1 prior line of therapy; 55.6% had ≥2 prior lines. Median time from first dose to database cutoff (Oct 5, 2020) was 37.5 (range, 0.2–55.6) mo; 16.0% were continuing treatment. The ORR among the 321 eligble pts was 30.8% (CR, 27; PR, 72); median DOR was 47.5 mo (Table). Treatment-related AEs occurred in 64.7% of pts (grade 3–5, 12.0%), led to discontinuation in 6.6%, and led to death in 3 pts (myocarditis, pneumonia, and Guillain-Barre syndrome). Immune-mediated AEs and infusion reactions occurred in 20.2% of pts (grade 3–4, 4.3%) and led to death in 2 pts with no other contributing factors (myocarditis [AE start, day 26; death, day 33] and Guillain-Barre syndrome [AE start, day 22; death, day 41]). **Conclusions:** Pembrolizumab demonstrated a high ORR (30.8%), durable clinical benefit, and a manageable safety profile in this heavily pretreated advanced MSI-H/dMMR noncolorectal pan-tumor population. Clinical trial information: NCT02628067. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

	KEYNOTE-158 Cohort K N = 321
Confirmed ORR, % (95% CI)	30.8 (25.8 to 36.2)
Median DOR, mo (range)	47.5 (2.1+ to 51.1+)
- ≥24 mo, %	74.1
- ≥36 mo, %	70.1
Median PFS, mo (95% CI)	3.5 (2.3 to 4.2)
- 36-mo rate, %	24.0
Median OS, mo (95% CI)	20.1 (14.1 to 27.1)
- 36-mo rate, %	39.1

CI, confidence interval. "+" indicates no progressive disease by the time of last disease assessment.

Efficacy and safety of HLX10, a novel anti-PD-1 antibody, in patients with previously treated unresectable or metastatic microsatellite instability-high or mismatch repair-deficient solid tumors: A single-arm, multicenter, phase 2 study. *First Author: Shukui Qin, Chinese People's Liberation Army Cancer Center of Nanjing Bayi Hospital, Nanjing, China*

Background: Microsatellite instability-high/mismatch repair-deficient (MSI-H/dMMR) in cells render them susceptible to immune checkpoint blockages. This study aimed to evaluate the efficacy and safety of HLX10, a fully humanized monoclonal antibody against PD-1, in patients with unresectable or metastatic MSI-H/dMMR solid tumors who have progressed on or been intolerant to standard therapies. **Methods:** In this single-arm, open-label, multicenter, phase 2 study (NCT03941574), patients (18≤ age ≤75 years) with histologically/cytologically confirmed unresectable or metastatic MSI-H/dMMR solid tumors were recruited to receive 3 mg/kg HLX10 every two weeks intravenously for up to 2 years until disease progression, unacceptable toxicity, or patient withdrawal. The primary endpoint was objective response rate (ORR) assessed by IRRC (evaluated every 6 weeks for the first 48 weeks and every 12 weeks thereafter) per RECIST v1.1. Secondary endpoints included ORR assessed by investigators, duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. All eligible patients who received at least one dose of HLX10 were included in the safety analyses. **Results:** As of Jan 9, 2021, 108 patients were enrolled and 68 with locally or centrally confirmed MSI-H were included in the main efficacy analysis population. Among the 68 patients, the median follow-up duration was 7.7 (range: 1.1–16.4) months and the median age was 53.0 (range: 23.0–72.0) years. MSI-H tumor types included colorectal cancer (n = 54), endometrial cancer (n = 5), gastric cancer (n = 4), breast cancer (n = 2), small intestine cancer (n = 2) and fallopian tube cancer (n = 1). IRRC and investigator assessed ORR were 38.2% (95% CI: 26.7–50.8%; 2 complete response) and 35.3% (95% CI: 24.1–47.8%) respectively in the main efficacy analysis population. Median DoR, PFS and OS have not been reached. 105 (97.2%) patients experienced treatment-emergent adverse events (TEAEs), most commonly anemia (34.3%), hypoproteinemia (27.8%) and increased aspartate aminotransferase (25.0%). 53 (49.1%) patients had grade 3 or worse TEAEs, most commonly anemia (8.3%), progressive disease (6.5%), increased γ- glutamyltransferase (5.6%) and intestinal obstruction (5.6%). 52 (48.1%) patients had immune-related adverse events (irAEs) while 10 (9.3%) had grade 3 or worse irAEs. 3 (2.8%) deaths (2 PD and 1 intestinal obstruction) that might be related to the study drug were reported. **Conclusions:** HLX10 provides encouraging antitumor activity with a manageable safety profile in patients with MSI-H/dMMR solid tumors who have progressed on or been intolerant to standard therapies. As an effective tissue-agnostic treatment, HLX10 possesses the potential to improve patients' clinical outcomes. Clinical trial information: NCT03941574. Research Sponsor: Shanghai Henlius Biotech, Inc.

Multi-center phase 1 safety and efficacy study of nivolumab in renal transplant patients with metastatic malignancy. *First Author: John Raymond Zalcberg, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Organ Transplant Recipients (OTR) are generally excluded from trials of immune checkpoint inhibitors (ICI) due to the reported risk of allograft rejection. A recent systematic review of published case series includes only 65 cases. Transplant organ rejection rates of 41% are reported with cancer response rates of 39%. The majority of OTR treated with ICI have had reduction/cessation of immunosuppression (IS) prior to ICI. Isolated IS reduction is associated with organ rejection and therefore either IS manipulation alone and/or ICI could induce organ rejection episodes. **Methods:** Renal OTR with incurable cancer, for whom ICI would normally be used in the general population (without an organ transplant), were eligible if creatinine < 180 umol/l, no donor specific HLA antibodies and ECOG < 2. Treatment was with nivolumab (3mg/kg q 14 days for 5 doses, then 480 mg q 28 days), without manipulation of IS and pre-ICI-exposure alloimmune risk assessment. Treatment continued till progression, patient refusal, or graft rejection. Primary endpoint was rate of irretrievable renal graft rejection. **Results:** 15 patients (9 male:6 female; median age 66.6 years) were enrolled and treated with a median (range) 3(1-42) infusions and with median (range) follow-up of 128 (11-784) days . Tumour types included:1 melanoma; 2 renal tract; 1 hepatocellular carcinoma; 1 Merkel cell; 1 adenocarcinoma lung; 1 MSI high colorectal, 8 squamous cell carcinoma (SCC) head and neck. 2 patients experienced rejection; one at day 28 (2 infusions); one at day 36 (3 infusions). Both had SCC and have had a CR. One is on haemodialysis and alive at 2 years the other a creatinine 450 umol/l. Both rejections treated with steroid, plasma-exchange and anti-thymocyte-globulin (ATG). 1 patient (metastatic bladder cancer) experienced graft loss (at 300 days) due to ureteric-stent bleed and BK-nephritis indirectly related to nivolumab- this patient died of progressive disease at 65 days after nivolumab cessation. Median (range) progression free disease (PD) with ≥ 2 infusions was 300 (68-784+) days. There were 5 CR (1 MSI high colorectal, 4 SCC) median duration of response 13 months and 2 PR (1 SCC 1 bladder)- 1 without PD. **Conclusions:** In this interim analysis, rejection rates in OTR with incurable cancers treated with ICI was 2/15 (13%) when IS is maintained and there is pre exposure alloimmune assessment. The combined CR and PR rate was 7/15 (47%). Clinical trial information: 12617000741381. Research Sponsor: BMS.

Phase I dose escalation of KD033, a PDL1-IL15 bispecific molecule, in advanced solid tumors. *First Author: Jason J. Luke, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: IL-2 and IL-15 signal through the shared IL-2/15 βγ receptor, but unlike IL-2, IL-15 does not expand regulatory T cells (Tregs), does not mediate activation-induced cell death and may have an improved therapeutic index. KD033 is a fusion antibody combining a fully human, high affinity anti-human Programmed Death Ligand 1 (PD-L1) IgG1 antibody with the human IL-15 receptor alpha (IL15Rα) sushi domain and human IL-15 (IL-15). KD033 (or its mouse cross reactive surrogate molecule, srKD033) has been extensively characterized in multiple *invitro* and *in vivo* nonclinical studies. The fusion of anti-PD-L1 antibody to IL-15 significantly increases the maximal-tolerated dose (MTD) of srKD033 in mice compared to free IL-15. In addition, srKD033 has exhibited increased efficacy in rejecting tumors in mice as compared to the combination of its individual components, anti-PD-L1 antibody and IL-15. **Methods:** This is a phase 1, open-label, multiple ascending dose, multi-center clinical trial being conducted in patients with metastatic or locally advanced solid tumors (NCT04242147). The primary objective is to determine the safety and tolerability and the MTD of KD033. Secondary objectives include characterization of PK and immunogenicity, evaluation of CD8 T and NK cell activation and assessment of best overall response and duration of response. KD033 is administered by IV infusion over 30 minutes every 14 days. Accelerated intra-patient dose escalation across the initial three dose levels, followed by 3+3 escalation thereafter, is investigating dose ranges from 3 μg/kg to 600 μg/kg. Efficacy evaluation is planned in an expansion cohort of patients with PD-1/L1 refractory tumors. **Results:** A total of 7 patients have received treatment. Three patients were dosed in Cohort 1 and four patients were dosed in Cohort 2. Through two dose escalation cohorts (3 μg/kg – 25 μg/kg), no dose-limiting toxicities have been reported. Grade 1-2 treatment-related toxicities, when observed, resolved within 24 hours with supportive management. 6 patients are evaluable for treatment response with one patient (adenoid cystic carcinoma) in the first cohort having stable disease for more than 6 months. **Conclusions:** KD033 has been well tolerated early in dose escalation with on-mechanism pharmacodynamics consistent with IL-15 agonism. Clinical trial information: NCT04242147. Research Sponsor: None.

2569 **Poster Session**

A phase 2 study of tislelizumab monotherapy in patients with previously treated, locally advanced unresectable ormetastatic microsatellite instability-high/mismatch repair deficient solid tumors. *First Author: Jian Li, Beijing Cancer Hospital, Beijing, China*

Background: Tislelizumab is an anti-programmed cell death protein 1 antibody engineered to minimize binding to FcγR on macrophages to abrogate antibody-dependent phagocytosis. In early phase clinical studies, tislelizumab monotherapy was generally well tolerated and had antitumor activity in patients (pts) with solid tumors, including microsatellite instability-high (MSI-H) or mismatch-repair-deficient (dMMR) solid tumors such as colorectal cancer (CRC). **Methods:** This single-arm, multicenter, open-label, phase 2 study evaluated the efficacy and safety of tislelizumab monotherapy in adult Chinese pts with previously treated, locally advanced, unresectable or metastatic histologically confirmed MSI-H/dMMR solid tumors by central lab. Pts received tislelizumab 200 mg intravenously every 3 weeks until disease progression, unacceptable toxicity, or withdrawal. Radiological imaging was performed at 9 weeks then every 6 weeks for the first year of therapy and every 12 weeks thereafter. The primary efficacy analysis set was all pts who received any dose of tislelizumab with measurable disease per independent review committee (IRC) at baseline. The primary endpoint was IRC-assessed overall response rate (ORR; RECIST v1.1). Secondary endpoints included duration of response (DoR) and disease control rate. Using a binomial exact test, the null hypothesis of ORR=10% (historical rate) was rejected if 1-sided p≤0.025. **Results:** Between Sep 2018-Aug 2020, 80 pts were enrolled (median age 53 years; range 19-81 years) and 74 were included in the primary efficacy analysis set. At median study follow-up of 11.78 months, ORR by IRC was 45.9% (n=34/74; 95% CI 34.3, 57.9) in all tumor types (1-sided p<0.0001), including 4 complete responses (CR) and 30 partial responses (PR). Observed ORR by IRC was 39.1% (n=18/46; 95% CI 25.1, 54.6) in CRC pts and 57.1% (n=16/28; 95% CI 37.2, 75.5) in non-CRC pts. Of 74 pts, 53 (71.6%) had disease control and 39 (52.7%) achieved CR, PR or durable stable disease by IRC ≥24 weeks. Median DoR by IRC has not been reached; no disease progression was reported in the 34 responders (CR+PR), with 33 responders still on treatment (12-month DoR rate=100%). Treatment-emergent adverse events (TEAEs) ≥Grade 3 occurred in 47.5% (n=38/80) pts, of which 21.3% (n=17/80) were lab abnormalities. Immune-mediated TEAEs ≥Grade 3 were 5% (n=4/80). **Conclusions:** Tislelizumab achieved statistical significance and demonstrated clinically meaningful improvement in ORR in pts with previously treated locally advanced unresectable or metastatic MSI-H or dMMR solid tumors. Treatment effect was consistent and durable across tumor types and endpoints. Tislelizumab was generally well tolerated and no new safety signals were identified. The data support tislelizumab as a new treatment option in this population. Clinical trial information: NCT03736889. Research Sponsor: This study is sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Jessica Jones, PhD, and Kirsty Millar, MSc, of Ashfield MedComms, an Ashfield Health company, and was funded by BeiGene, Ltd.

Mega- and meta-analyses of fecal metagenomic studies in predicting response to immune checkpoint inhibitors. *First Author: Alya Heirali, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: A number of studies have demonstrated that the gut microbiome of responders to immune checkpoint inhibitors (ICI) is compositionally different compared to that of non-responders. However, differences in study design, patient cohorts and bioinformatic analyses make it challenging to identify bacterial species consistently associated with response to ICI across different cohorts and cancer types. **Methods:** We leveraged the statistical power of mega- and meta-analyses to identify bacterial species consistently associated with response to ICI using data from three published fecal metagenomic studies (Gopalakrishnan *et al., Science 2018;* Matson *et al., Science 2018;* Routy *et al., Science 2018).* Metagenomic data was uniformly processed and analyzed using Metaphlan v2.0. We conducted a two-part modelling approach of bacterial species present in at least 20% of samples to account for both prevalence and relative abundance differences between responders/non-responders. **Results:** A total of 190 patients (n = 103 responders; n = 87 non-responders) were included from the three studies. Data from Routy *et al.*, was analyzed as subsets based on tumor type for a total of 4 analyzed cohorts. We identified five species including *Bacteroides thetaiotaomicron*, *Clostridium bolteae, Holdemania filiformis,Clostridiaceae bacterium JC118* and *Escherichia coli* that were concordantly significantly different between responders and non-responders using both meta- and mega-analyses. *B. thetaiotaomicron* and *Clostridium bolteae* relative abundance (RA) were independently predictive of non-response to immunotherapy when data sets were combined and analyzed using mega-analyses (AUC 0.59 95% CI 0.51-0.68 and AUC 0.61 95% CI 0.52-0.69, respectively). **Conclusions:** Despite inter-cohort heterogeneity in tumor type, treatment regimens, and sequencing modalities, meta- and mega analysis of published metagenomic studies identified generalizable bacterial species associated with ICI response or lack thereof. *B.thetaiotaomicron* and *C. bolteae* were predictors of non-response to ICI suggesting the clinical potential of narrow spectrum anti-biotics targeting non-response associated bacterial species to improve outcomes in ICI recipients. Phase 2 study of retifanlimab (INCMGA00012) in patients (pts) with selected solid tumors (POD1UM-203). *First Author: Michele Maio, Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy*

Background: Checkpoint inhibitors (CPIs) are an effective treatment (tx) for many tumor types. Retifanlimab, an investigational humanized anti–PD-1 monoclonal antibody, has shown safety, pharmacology, and clinical activity consistent with the class. POD1UM-203 (NCT03679767) assessed efficacy and safety of retifanlimab in pts with selected solid tumors where CPI monotherapy is highly active. **Methods:** Eligible pts (≥18 y) had tx-naïve metastatic non-small cell lung cancer (NSCLC) with high PD-L1 expression (tumor proportion score ≥50%), cisplatin ineligible locally-advanced/metastatic urothelial cancer (UC) with PD-L1 expression (combined positive score ≥10%), unresectable/metastatic melanoma, or tx-naïve locally advanced/metastatic clear-cell renal cell carcinoma (RCC). Measurable disease (RECIST v1.1) was required. ECOG PS >1 and prior PD-1/PD-L1 directed tx were exclusions. Retifanlimab was administered as an IV infusion at 500 mg every 4 wks over 30 min. Primary endpoint was investigator-assessed objective response rate (ORR). Secondary endpoints were duration of response (DOR), disease control rate (DCR), progression-free survival, overall survival, safety, and pharmacokinetics. **Results:** A total of 121 pts (35 melanoma, 23 NSCLC, 29 UC, 34 RCC) received ≥1 dose of retifanlimab and were included in the analyses. Median duration of tx was 169 d (range, 1–442). The efficacy cut-off for the primary analysis occurred once all pts had been followed for at least 6 mo from the time of initial tx. Confirmed RECIST v1.1 responses were observed in all tumor types (Table) and were consistent with published ORR for other CPIs; median DOR was not reached for any tumor cohort and tx was ongoing at the time of data cutoff for 17, 11, 9, and 15 pts with melanoma, NSCLC, UC, and RCC, respectively. The most common tx-emergent AEs (TEAEs, >10% incidence) were asthenia (17.4%), arthralgia (14.9%), decreased appetite (14.0%), pruritus (12.4%), rash (10.7%), and urinary tract infection (10.7%); majority of TEAEs were low grade (≤ grade 2) and none led to tx discontinuation. Immune-related AEs occurred in 23 pts (19.0%), most common (>1% incidence) were hypothyroidism (7.4%), rash (4.1%), hyperthyroidism (2.5%), and pruritus (1.7%).Immune-related AEs led to dose delay in 5 pts (4.1%), but none led to tx discontinuation and/or dose interruption. **Conclusions:** Retifanlimab demonstrated antitumor activity and was generally well-tolerated in pts with melanoma, NSCLC, UC, or RCC comparable with approved CPIs for these tumor types. These results support ongoing further development of retifanlimab. Clinical trial information: NCT03679767. Research Sponsor: Incyte Corporation Inc.

Efficacy of HX008 in high microsatellite instability/mismatch repair–defificient (MSI-H/dMMR) solid tumors: Results from a multicenter phase II open-label study. *First Author: Jing Huang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: The subsequent treatment choices are limited for the patients with advanced solid tumors who had failed the standard therapies. PD-1 blockade monotherapy demonstrated robust antitumor activity in patients with MSI-H/dMMR. The aim of this study is to identify the efficacy and safety of HX008, an anti-PD-1 monoclonal antibody, in patients with advanced MSI-H/dMMR solid tumors. **Methods:** Eligible patients were age ≥18 years with histologically/cytologically confirmed advanced MSI-H/dMMR solid tumors, who have failed at least one line of standard systemic therapy. MSI-H/dMMR status was assessed centrally. Patients received HX008 200 mg once every 3 weeks until disease progression, unacceptable toxicity, or patient withdrawal. Radiologic imaging was performed 9 weeks after the first treatment, then every 6 weeks for the first year of therapy, and every 12 weeks thereafter. The primary end point was objective response rate (ORR) per RECIST1.1. **Results:** One hundred patients were enrolled from October 2018 to December 2020, with a median age of 53 (range 20-74) years. All of the patients were ≥ second-line patients. The most common cancer types were colorectal cancer (N=74) and gastric cancer (N=10). Median follow-up is 8.97 (range 0.03-25.53) months at the time of data cutoff. Among 86 patients who had reached the initial response evaluation, there were 8 CR, 33 PR, 24 SD, 17 PD and 4 NE. ORR was 47.67% (95%CI 36.79%-58.73%), and DCR was 75.58% (95%CI 65.13%-84.20%). ORR and DCR for the 66 colorectal cancer patients were 50% (95%CI 37.43-62.57%) and 75.76% (95%CI 63.64-85.46%). Median PFS was not reached (95%CI 6.18-NR) for all enrolled patients, while the 6-month and 12-month PFS rates were 62.66% (95%CI 50.98%-72.31%) and 52.70% (95%CI 39.96%-63.94%), respectively. Median OS was not reached. Treatment-related adverse events occurred in 77 patients (77%). Twelve patients (12%) had grade 3 or 4 treatment-related adverse events and there were no grade 5 treatment-related adverse events. The grade 3 or 4 treatment-related adverse events with incidence >1% included anemia (2%) and leukopenia (2%). Immune-related adverse events were observed in 15 patients (15%), including hypothyroidism in 9 patients (all were grade 1-2), and hepatitis, hyperglycemia, myocarditis, creatin kinase/creatin kinase MB increased, hypopigmentation of the vulva, rash, each in 1 patient. **Conclusions:** HX008 as a ≥second-line therapy showed promising efficacy and a manageable safety profile in patients with MSI-H/dMMR advanced solid tumors. Clinical trial information: NCT03704246. Research Sponsor: Taizhou Hanzhong Biomedical Co. LTD.

An exploratory study of nivolumab (nivo) with or without ipilimumab (ipi) according to the percentage of tumoral CD8 cells in advanced metastatic cancer. *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint inhibitors (ICIs) have demonstrated durable clinical responses and improved survival in patients (pts) across numerous indications. Despite this progress, the benefit of ICIs is limited to a minority of overall metastatic cancer patients. There is a critical need for biomarkers agnostic of tumor type to inform which pts will benefit from nivo alone versus ipi/nivo combination treatment. Both pre-treatment tumoral $CD8^+$ cells and recruitment of $CD8^+$ T cells in response to ICIs are associated with improved clinical outcomes in patients treated with anti-PD-1 therapy. [1,2,3,4] Here we report the final results of a prospective clinical study in which pts with varying advanced solid tumors were assigned to nivo, with or without ipi, based on the percentage of tumoral CD8 cells at the time of treatment. **Methods:** We performed a prospective, non-randomized, open-label, multicenter study in which pts with tumoral $CD8^+$ cells $\geq$ 15% ($CD8^+$ high) received nivo 360mg IV Q3W, followed by nivo maintenance 480mg Q4W. Pts with tumoral $CD8^+$ cells $<$ 15% ($CD8^+$ low) received nivo 360 mg IV Q3W, and ipi at 1 mg/kg IV Q3W for 2 doses and then Q6W for 2 doses, followed by nivo maintenance 480 mg IV Q4W until PD or intolerable toxicity. Primary endpoints were Disease Control Rate (DCR: CR, PR, or SD $\geq$ 6 months) and CD8 low to high conversion ($<$ 15% to $\geq$ 15%). Baseline and on-treatment tumor, blood and stool samples were collected for multiomic biomarker analyses. This study was not powered for formal statistical analysis. Up to 200 pts could be enrolled to allow for adaptive exploration of response and CD8 changes. **Results:** N = 79 pts were enrolled:7 in $CD8^+$ high arm (nivo) and 72 in $CD8^+$ low arm (ipi/nivo). The study enrolled a wide variety of primary solid tumors; the most common were gynecological (n = 15), prostate (12), and head and neck (7). DCR was 14% (1/7; 95% CI 1 - 44) and 24% (17/72; 95% CI 15 - 34) in the CD8 high and CD8 low arms, respectively. Of 39 pts in CD8 low arm with an on-treatment biopsy, 14 (36%; 95% CI 22 - 51) had CD8 conversion; 7/14 pts (50%) who converted had DCR. Immune-related AEs (irAEs) were consistent with known safety profile of both drugs. **Conclusions:** Ipi/nivo demonstrated clinical responses and increased CD8% in a range of "cold" tumors with low tumoral CD8 cells. There may be an association between increasing CD8% and response. Baseline high CD8% alone does not appear to be sufficient as a pan-cancer predictive biomarker of response to nivo monotherapy. CD8 conversion, response, and irAEs associated with circulating and stool-based biomarkers are under evaluation as composite biomarkers may improve their predictive value. Clinical trial information: 03651271. Research Sponsor: The Parker Institute for Cancer Immunotherapy.

2574 **Poster Session**

Assessment of cancer-specific microbiome signature of response to immune checkpoint inhibitors. *First Author: Michal Sarfaty, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clinical and preclinical experiments suggest that the gut microbiome can affect outcome in cancer patients treated with immune checkpoint inhibitors (ICI). Most data to date has been in melanoma, so the relationship of the gut microbiome with treatment outcome in other cancers is poorly understood. Here, we evaluated the microbiome composition in correlation to ICI response in patients with metastatic lung, urothelial, or renal cancer, as well as metastatic melanoma. **Methods:** Fecal microbiome samples were obtained from patients with metastatic melanoma, lung, urothelial, or renal cancer immediately before ICI therapy was initiated. Bacterial genomic DNA was isolated and profiled by whole metagenome sequencing. Sequence data were analyzed using a custom implementation of MetaPhlAn2. Response to ICI was defined as partial or complete response or remaining on therapy for more than 6 months. **Results:** Samples were prospectively collected from 94 patients, including metastatic melanoma (n = 17), lung (n = 44), urothelial (n = 23), or renal cancer (n = 10). Treatment included anti-PD(L)1 monotherapy (n = 51), anti-PD1 + anti-CTLA4 combination therapy (n = 17), or a combination of anti-PD1 and chemotherapy (n = 26). Clinical response was observed in 58% of patients, including partial or complete response (45%) and on treatment for more than 6 months (55%, with 31% on treatment for more than 1 year). Although the variance in the composition of pretreatment microbiome samples did not explain response alone (R vs NR, PERMANOVA, p = 0.273), a significant portion of the variance in microbiome composition was explained by the interaction of cancer type and outcome (PERMANOVA, p = 0.014), suggesting a cancer-specific microbiome relationship. Notably, there was some similarity in the signature of NR across three cancer types (lung, urothelial and melanoma). One sample in this NR cluster was from a patient whose metastatic NSCLC was nonresponsive to pembrolizumab and carboplatin/pemetrexed. This microbiome sample was evaluated *in vivo* using subcutaneous MC38 and CT26 tumor models in germ-free mice. In contrast to mice colonized with stool from a healthy donor, mice colonized with stool from this patient yielded a nonresponsive result upon treatment with anti-PD1 or anti-PD-L1 in combination with anti-CTLA4. **Conclusions:** Analysis of the fecal microbiome composition from patients with metastatic lung, urothelial, renal cancer, and melanoma identified a cancer-specific signature of R and NR to ICI. Across three cancer types, a consistent signature of NR was identified and corroborated experimentally in preclinical models. CheckMate 8KX: Phase 1/2 multitumor preliminary analyses of a subcutaneous formulation of nivolumab (± rHuPH20). *First Author: Sara Lonardi, Veneto Institute of Oncology (IOV)-IRCCS, Padua, Italy*

Background: Immunotherapy has transformed cancer survival expectations. Nivolumab (NIVO), a programmed death-1 inhibitor, is approved for intravenous (IV) administration across multiple cancers. BMS is developing a subcutaneous (SC) NIVO formulation with a permeation enhancer, recombinant human hyaluronidase PH20 enzyme (rHuPH20), to allow for more rapid delivery and the potential to decrease treatment burden. We report the first data on pharmacokinetics (PK), pharmacodynamics, safety, and immunogenicity for SC NIVO + rHuPH20. **Methods:** CheckMate 8KX is a phase 1/2 study in checkpoint inhibitor-naïve patients (pts) who were $\geq$ 18 years of age, ECOG PS 0–1, with metastatic/unresectable solid tumors and measurable disease. The primary objective was to describe SC NIVO PK; secondary objectives were safety and immunogenicity. Additional analyses compared exposures to historical IV NIVO (Zhao X, et al. *J Clin Oncol* 2020;31:302–309). In cycle 1, pts in Part A received SC NIVO 720 mg + rHuPH20, and pts in Part B received SC NIVO 720 mg, SC NIVO 960 mg + rHuPH20, or SC NIVO 960 mg. For cycles 2+, pts in Parts A and B received IV NIVO 480 mg every 4 weeks (Q4W). Pts still on study switched to Part C, SC NIVO 1200 mg + rHuPH20 until end of therapy. In Part D, pts received de novo SC NIVO 1200 mg + rHuPH20 Q4W. **Results:** Patient characteristics varied by age, weight, tumor type, and prior treatment. NIVO exposures increased with increasing SC dose (Table). For 960 mg and 1200 mg NIVO + rHuPH20, Cavg and Ctau were above geometric mean exposures for IV NIVO 3 mg/kg every 2 weeks (Q2W), and Cmax was below IV NIVO 10 mg/kg Q2W. In Part C (n = 28), 13 (46.4%) pts experienced any-grade TRAEs with no new/worsening grade 3+ TRAEs or TRAEs leading to discontinuation/death; 7 (25.0%) reported grade 1 local site reactions. In Part D (n = 36), 27 (75.0%) pts experienced any-grade TRAEs, 4 (11.1%) grade 3/4 TRAEs, 2 (5.6%) serious grade 3/4 TRAEs with 1 leading to discontinuation, and no treatment-related deaths; 10 (27.8%) reported grade 1 local site reactions. Anti-NIVO antibodies (Ab) were observed with SC NIVO but not associated with altered PK/safety, or neutralizing Ab. Exploratory biomarker data found increased CD8+ tumor-infiltrating lymphocytes and PD-L1 tumor expression in post-treatment biopsies, similar to IV NIVO. **Conclusions:** Exposures associated with SC NIVO + rHuPH20 doses investigated in CheckMate 8KX were well tolerated, with a safety profile consistent with IV NIVO. Data support evaluation of SC NIVO + rHuPH20 in a phase 3 study. Clinical trial information: NCT03656718. Research Sponsor: Bristol Myers Squibb, Professional medical writing assistance was provided by Katherine Groschwitz, PhD, and Jay Rathi, MA, of Spark Medica Inc, funded by Bristol Myers Squibb.

NIVO exposures by dose with rHuPH20.

Geometric mean NIVO concentration, μg/mL (range)	Ctau	Cavg	Cmax
NIVO 720 mg SC (n = 20[a])	22.2 (4.76–59.6)	36.6 (16.5–76.3)	54.8 (19.9–114)
NIVO 960 mg SC (n = 9)	39.5 (8.06–67.6)	62.2 (26.8–93.3)	84.8 (42.7–128)
NIVO 1200 mg SC (n = 25[b])	51.3 (18.4–96.5)	77.5 (39.1–141)	105 (40.0–245)

[a]n = 22 for Cmax [b]n = 26 for Cmax Ctau = concentration at the end of the dosing interval.

2576 **Poster Session**

Final results of a phase I "RadVax" trial of hypofractionated radiation combined with pembrolizumab in patients with metastatic solid tumors. *First Author: John Nicholas Lukens, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: Many patients treated with anti-PD-1 therapy do not show a clinical response. Preclinical studies suggest that adding hypofractionated radiotherapy (HFRT) to anti-PD1 can increase the efficacy of immunotherapy through several mechanisms including increased antigen presentation. We conducted a prospective trial testing the combination of pembrolizumab and HFRT in patients with metastatic solid tumors. **Methods:** This prospective single-institution phase I trial tested pembrolizumab in combination with HFRT in patients with metastatic cancers (NSCLC, melanoma, pancreas, breast, others) and an ECOG performance status of 0-1. Melanoma and NSCLC patients were required to have progression of disease on anti-PD1, having received $\geq$ 2 doses of anti-PD1 and progression documented by RECIST v1.1. Patients were required to have an index lesion $\geq$1 cm that was amenable to HFRT and at least one other lesion that was not irradiated and could be followed for response using RECIST criteria. Pembrolizumab 200 mg IV every 3 weeks was administered beginning 1 week prior to the first fraction of radiation. The HFRT dose was 8 Gy x 3 fractions or 17 Gy x 1 fraction, determined by randomization during the Expansion phase. The primary objective was the safety of HFRT combined with pembrolizumab, with dose-limiting toxicity (DLT) defined as Grade $\geq$ 3 non-hematological toxicity related to the combination of Pembrolizumab and HFRT. The secondary objective was the radiographic response of metastatic lesions outside the radiation field as measured by RECIST. **Results:** 59 patients aged 27-90 years (median 60) were enrolled from March 2015 to December 2018 (24 in the Safety Phase and 35 in Expansion Phase). 40 patients (67.7%) had treatment-related AEs, of which 4 were grade 3 and none were grade 4. One patient experienced hepatitis, classified as DLT. While most patients did not have a radiologic response, in patients with metastatic melanoma, 7 of 16 (43.8%, exact 95% CI 19.8-70.1%) had an objective response to HFRT + pembrolizumab, including 3 complete and 4 partial responses. Responses are durable with 3/3 complete responders alive with no progression, and 3/4 partial responders alive with 2 having no evidence of progression. Among melanoma patients, only 2 of 7 (29%) responders received ipilimumab prior to enrollment, compared to 8 of 9 (89%) non-responders (p = 0.035). An increase in Ki67+ PD-1+ non-naïve CD8 T-cells was observed in the blood 2 weeks after HFRT, but the magnitude did not correlate with likelihood of response. Responses were observed after either 17 Gy x 1 fraction or 8 Gy x 3 fractions, with no difference in response rate by fractionation. **Conclusions:** This study suggests that HFRT administered with concurrent pembrolizumab is associated with acceptable toxicity and that in patients with metastatic melanoma progressing on anti-PD-1 therapy, this approach yields an ORR of 44%. Clinical trial information: NCT02303990. Research Sponsor: Merck, U.S. National Institutes of Health.

2577 **Poster Session**

A first-in-human phase I dose escalation of YH001, an anti-CTLA-4 monoclonal antibody (mAb) in combination with toripalimab (anti-PD-1 mAb) in patients with advanced solid tumors. *First Author: Vinod Ganju, Peninsula and Southeast Oncology, Frankston, VIC, Australia*

Background: YH001 is a humanized anti -hCTLA-4 IgG1 mAb that relieves CTLA-4-mediated immunosuppression, and thereby enhances the T-cell-mediated antitumor immune response. Pre-clinical data have shown potent anti-cancer activity when combined with anti-PD-1 mAb. **Methods:** This is an ongoing phase 1 dose-escalation study. Patients (pts) with advanced solid tumors received YH001 by IV administration at 0.05 to 6.0 mg/kg for 1 cycle (21 days) then in combination with Toripalimab (anti-PD-1 mAb) at 240 mg Q3W for 4 cycles. An accelerated titration method followed by the standard "3+3" design was utilized to evaluate safety, tolerability and preliminary efficacy. **Results:** As of 31-Dec-2020 data cut-off, 10 pts were enrolled and treated at 0.05 mg/kg (n = 2), 0.1 mg/kg (n = 3), 0.3 mg/kg (n = 3) and 1 mg/kg (n = 2). The median age was 62 years (range 46-74). Baseline ECOG scores were 0 (n = 8), 1(n = 2) with all pts progressed after a median of 2 prior lines of available standard therapy (range 1-4) including 1 pt progressed after immunotherapy of pembrolizumab. There were no dose limiting toxicities (DLT) observed. No severe adverse events (SAEs), Grade (G) 3 or above adverse events (AEs) and AEs leading to treatment discontinuation were reported. Twelve drug related AEs were all G1/2 events including 2 G2 AEs (1 rash maculopapular at 0.05mg/kg, 1 hypothyroidism at 0.1mg/kg), 10 G1 AEs (1 hypotension, 1 dry skin, 1 pruritus at 0.05mg/kg; 1 rash, 1 rash macular, 1 hyperthyroidism, 2 rash pruritus at 0.1mg/kg, 2 fatigues at 0.3mg/kg). Among 7 patients having imaging tumor assessment by RECIST v1.1, there were 4 SD, including 1 at 0.05 mg/kg with tongue carcinoma at week 8 assessment, 1 at 0.1 mg/kg with nasopharyngeal carcinoma at week 8 and 15 assessment, 2 at 0.3 mg/kg with gastroesophageal junction cancer and uterus leiomyosarcoma at week 8. **Conclusions:** YH001 combined with Toripalimab is safe and tolerable up to 1 mg/kg dose level. Updated safety and preliminary efficacy data will be presented. Clinical trial information: NCT04481009. Research Sponsor: Eucure (Beijing) Biopharma Co., Ltd.

Phase I/II study of nivolumab plus vorolanib in patients with thoracic malignancies: Interim efficacy of the SCLC and primary refractory NSCLC cohorts, and safety data across all cohorts. *First Author: Selina K. Wong, Vanderbilt University Medical Center, Nashville, TN*

Background: Combination strategies to improve the efficacy of single agent immune checkpoint inhibitors (ICIs) are increasingly being explored, with one strategy being the addition of vascular endothelial growth factor (VEGF) inhibition. Having shown promise in the treatment of hepatocellular carcinoma and renal cell carcinoma, NCT03583086 is a multi-institutional, phase I/II study of combination vorolanib and nivolumab in both naïve and refractory thoracic tumors that progressed on at least one prior line of platinum-based chemotherapy. Though structurally similar to the tyrosine kinase inhibitor, sunitinib, vorolanib was designed to have a more favorable safety profile with comparable efficacy. Here we present safety data across all cohorts and interim efficacy analyses of the SCLC and NSCLC with primary resistance to ICI-based therapy cohorts, both of which have now completed enrolment. **Methods:** The maximum tolerated dose determined in phase I was vorolanib 200mg daily and nivolumab 240mg q2 weeks. Phase II uses a two-stage MinMax design across 5 cohorts with objective response rate (ORR) as the primary endpoint: NSCLC (ICI naïve, primary refractory, and acquired resistance), SCLC, and thymic carcinoma. Primary refractory is defined as radiographic progression of disease within 12 weeks of ICI initiation. **Results:** As of January 2021, 75 patients have been enrolled across all cohorts. Stage 1 of the SCLC and primary refractory NSCLC cohorts have completed accrual at 18 and 15 patients, respectively. In the SCLC cohort, disease-control rate (DCR) was 7% and no objective responses were achieved among 14 evaluable patients. In the primary refractory NSCLC cohort, DCR was 57% and ORR 7% (1 partial response) among 14 evaluable patients. A total of 140 treatment-related adverse events (TRAEs) have been reported, 13 (9%) were grade 3 and there were no grade 4/5 events. Fatigue (9%), nausea (6%), diarrhea (6%), ALT elevation (5%), and AST elevation (5%) were the most common all grade TRAEs. The most common grade 3 TRAEs were ALT elevation and hypertension. **Conclusions:** This therapeutic strategy of nivolumab plus vorolanib appears to be a well-tolerated combination with a manageable safety profile. Adding VEGF inhibition may offer additional disease control in the setting of NSCLC with primary resistance to ICIs, but neither the SCLC or primary refractory NSCLC cohorts achieved the pre-determined target number of objective responses for progression to stage 2 of the study. Enrolment in the other 3 cohorts as well as exploratory correlatives are ongoing. Clinical trial information: NCT03583086. Research Sponsor: Bristol Myers Squibb, Xcovery.

2579 **Poster Session**

Phase Ib study of BI 836880 (VEGF/Ang2 nanobody) plus ezabenlimab (BI 754091; anti-PD-1 antibody) in patients (pts) with solid tumors. *First Author: Nicolas Girard, Institut Curie, Institut du Thorax Curie-Montsouris, Paris, France*

Background: In preclinical studies, the combination of anti-VEGF/Ang2 and anti-PD-1 therapy has been shown to promote an immunopermissive state, which is supportive of T-cell-mediated tumor cell destruction. BI 836880 is a humanized bispecific nanobody that targets VEGF and Ang2, and ezabenlimab (BI 754091) is an anti-PD-1 antibody. Phase I studies investigating each as monotherapies have reported safety and preliminary antitumor activity. This ongoing Phase Ib study is evaluating the combination of BI 836880 and ezabenlimab in pts with advanced solid tumors. In Part 1 (dose escalation), the combination was feasible in pts with advanced NSCLC, with a recommended Phase II dose (RP2D) of BI 836880 720 mg + ezabenlimab 240 mg IV q3w. Here, we report updated results from Part 2 (expansion phase), which is assessing the antitumor activity and safety of the RP2D. **Methods:** Seven cohorts are currently recruiting pts in Part 2: metastatic (m) NSCLC after checkpoint inhibitor (CPI) monotherapy (Cohort A); mNSCLC after chemotherapy (CT) + CPI (Cohort B); mSCLC after CT ± CPI (Cohort C); 1st and 2nd recurrences of glioblastoma (GBM; Cohort D); immunotherapy-resistant m-melanoma (Cohort E); hepatocellular carcinoma (HCC) after prior sorafenib or lenvatinib ± CPI (Cohort F); and previously untreated/unresectable HCC (Cohort G). Primary endpoint is objective response rate (complete response + partial response [PR]). **Results:** As of January 2021, 196 pts have received BI 836880 plus ezabenlimab (14 in Part 1, 182 in Part 2 [Cohort A, 26; B, 30; C, 19; D, 31; E, 32; F, 28; G, 16]). 134 (68%) pts were male, median age was 63 years and 102 (52%) had prior CPI use. Any grade and ≥G3 adverse events (AEs; any cause) were reported by 160 (82%) and 62 (32%) pts, most commonly (all%/≥G3%) hypertension (20/8), asthenia (20/3), diarrhea, decreased appetite, and nausea (all 11/1). 95 (48%) pts had a drug-related AE, most commonly hypertension and asthenia (both 11%). 6 pts had a G4 AE (non-related: hyperkalemia + cardiac arrest, laryngospasm, gastrointestinal perforation; drug-related: anaphylactic reaction, acute pancreatitis, transaminases increased); 8 pts had a G5 AE (non-related: general physical health deterioration, epilepsy, hemoptysis, cardio-respiratory arrest, hepatic failure, intracranial hemorrhage, COVID-19 pneumonia; drug-related tracheal hemorrhage). 30 (15%) pts had immune-related AEs (3% ≥G3), including hypothyroidism (3%). 11 (6%) pts had an AE leading to discontinuation. Overall, 145 pts were evaluable for response: 9 pts achieved confirmed PR (2 pts in Part 1 and 7 in Part 2 [NSCLC, n = 3; SCLC, n = 1; GBM, n = 1; melanoma, n = 1; and 2nd-line HCC, n = 1]), 87 pts had stable disease and 49 pts had progressive disease. 111 pts remain on treatment. **Conclusions:** BI 836880 plus ezabenlimab had a manageable safety profile. The combination showed preliminary antitumor activity in a range of tumor types. Clinical trial information: NCT03468426. Research Sponsor: Boehringer Ingelheim.

2580 **Poster Session**

Phase I open-label, dose escalation of YH003, an anti-CD40 monoclonal antibody in combination with toripalimab (anti-PD-1 mAb) in patients with advanced solid tumors. *First Author: Jermaine Coward, ICON Cancer Care, South Brisbane, QLD, Australia*

Background: YH003, a recombinant, humanized agonistic anti-CD40 IgG2 monoclonal antibody (mAb) specifically recognizes and agonizes CD40 on the antigen-presenting cells to enhance immune responses. Preclinical data have shown potent anti-cancer activity when combined with anti-PD-1 antibodies. **Methods:** This is an ongoing phase 1 dose-escalation study. Patients with advanced solid tumors receive YH003 by IV administration Q3W as monotherapy at 0.03 to 3.0 mg/kg for the first cycle (21 days) then in combination with Toripalimab at 240 mg Q3W for the 4 subsequent cycles in an accelerated "3+3" design. The safety, tolerability and preliminary efficacy data will be analyzed. **Results:** As of 31 Dec 2020 data cutoff, 9 patients (pts) were enrolled and treated at 0.03 mg/kg (n = 3), 0.1mg/kg (n = 3), and 0.3mg/kg (n = 3). The median age was 63 years (range 33-68). Baseline ECOG scores were 0 (7 pts) and 1 (2 pts) with a median of 2 prior lines therapy (range 1-7). 5 pts had received prior immunotherapy (PD-1/PD-L1 or PD-1+CTLA-4). As of data cutoff, no dose limiting toxicities (DLT) were observed. No Serious Adverse Event (SAE) or AEs leading to treatment discontinuation were reported. Four drug related AEs were reported including one Grade 1 (G1) choroidal thickening (related to YH003) at 0.03 mg/kg, one G1 fatigue (related to YH003) at 0.1 mg/kg, two G1 febrile episodes (one related to YH003 and the other related to combination treatment) at 0.3 mg/kg. Among 5 patients assessable for response, there were 2 SD (one with anti-PDL1 refractory Merkel cell carcinoma at 0.03 mg/kg and one with anti-PD1 refractory NSCLC at 0.1 mg/kg) and 1 PR with anti-PD1/anti-CTLA4 refractory ocular melanoma at 0.1 mg/kg. **Conclusions:** YH003 was well tolerated up to 0.3 mg/kg dose levels when combined with Toripalimab and has shown encouraging antitumor activity in patients with advanced solid tumors. Clinical trial information: NCT04481009. Research Sponsor: Eucure (Beijing) Biopharma Co., Ltd.

2581 **Poster Session**

Anlotinib enhanced penpulimab efficacy through remodeling of tumor vascular architecture and immune microenvironment in hPD-L1/hPD-1 humanized mouse model. *First Author: Yunlong Shan, China Pharmaceutical University, Nanjing, China*

Background: Even though immune checkpoint inhibitor (ICI) such as anti-PD-1 mAb has emerged as effective treatment for tumor regression, the response rate of ICI monotherapy in solid tumor is low. Many studies have demonstrated that the efficacy of combination therapy of ICI and anti-angiogenesis was superior to monotherapy. Penpulimab (AK105), a humanized IgG1 mAb that blocks PD-1 binding to PD-L1, engineered to eliminate FcγR binding and ADCC/ADCP completely. Here, we explore a new combined therapy of penpulimab and anlotinib, an oral multi-targeted tyrosine kinase receptor inhibitor. **Methods:** MC38-hPD-L1 tumor-bearing B-hPD-1 humanized mouse model were conducted to investigate the effects of anlotinib (1 mg/kg, every day, p.o) or penpulimab (5 mg/kg, twice a week, i.p) alone or in combination. Immunofluorescence was applied to elucidate tumor vessel normalization. *In vivo* imaging was conducted to detect the distribution of AF647-labelled penpulimab after anlotinib treatment. Flow cytometry and other techniques were performed to investigate intratumoral immune cells. **Results:** After 3-week treatment, immunotherapeutic administration of anlotinib or penpulimab showed moderate inhibition of tumor growth (tumor volume: 66.5% and 58.4% of control group, respectively), while combined treatment of anlotinib with penpulimab significantly decreased tumor volume to 36.5% of control group. Tissue pathological and blood biochemical results showed no significant toxic and side effects. Immunohistochemistry revealed that anlotinib induced tumor vascular normalization, indicated by decreased $CD31^+$ area, increased α-SMA around tumor vessels and reduced $GLUT1^+$ area. Furthermore, anlotinib markedly enhanced the delivery of AF647-penpulimab into tumors. Combining anlotinib with penpulimab also promoted infiltration and activity of anti-tumoral immune cells by reducing the level of immune checkpoint TIM3 and increasing the IFNγ secretion from T cells. **Conclusions:** Our work provides a strong scientific rationale for the combination therapy of anlotinib and penpulimab to improve tumor microenvironment and immunotherapy, which highlights the clinical potential for this new combined therapy. Research Sponsor: None.

2582 **Poster Session**

Platform trial of ezabenlimab (BI 754091), an anti-PD-1 antibody, in patients (pts) with previously treated advanced solid tumors: Combination with BI 836880, a VEGF/Ang2-blocking nanobody. *First Author: Maen A. Hussein, Florida Cancer Specialists, Lady Lake, FL and Sarah Cannon Research Institute, Nashville, TN*

Background: The combination of anti-PD-1 antibodies with other immunomodulatory or targeted therapies has the potential for synergistic effects. This open-label, Phase II platform trial is assessing ezabenlimab, an anti-PD-1 antibody, in combination with other agents. Here, we report preliminary data from Module C, which assesses ezabenlimab in combination with BI 836880, a humanized bispecific nanobody that targets vascular endothelial growth factor (VEGF) and angiopoietin-2 (Ang2). VEGF and Ang2 play key roles in tumor angiogenesis and have an immunosuppressive effect in the tumor microenvironment. Combining anti-VEGF/Ang2 with an anti-PD-1 therapy promotes an immunopermissive state supportive of T-cell-mediated tumor cell death. **Methods:** Pts are being enrolled into 5 cohorts: locally advanced/metastatic gastric or gastroesophageal adenocarcinoma with $\geq$1 prior treatment (anti-PD-[L]1 naïve; Cohort 1); any advanced/metastatic solid tumor (excluding non-squamous NSCLC or melanoma) with prior anti-PD-(L)1 treatment, which progressed after achieving at least stable disease (SD) for $\geq$4 months (Cohort 2); advanced/metastatic solid tumors with no benefit from prior anti-PD-(L)1 treatment (SD or progressive disease [PD] in $<$ 4 months; Cohort 3); locally advanced/metastatic microsatellite stable (MSS) colorectal cancer with $\geq$1 prior treatment (anti-PD-[L]1 naïve; Cohort 4); advanced MSS and mismatch repair-proficient endometrial carcinoma, which progressed after 1 line of chemotherapy (anti-PD-[L]1 naïve; Cohort 5). Pts will receive BI 836880 720 mg and ezabenlimab 240 mg IV every 3 weeks. The primary endpoint is investigator-assessed objective response (complete response [CR] or partial response per RECIST v1.1). Safety is also being assessed. **Results:** As of Jan 2021, 29 pts have received ezabenlimab plus BI 836880; 26 pts remain on treatment. Cohorts 1/2/3/4/5 included 0/6/3/19/1 pts; median age 63 yrs; 20 (69%) pts were male. Overall, 22 (76%) pts experienced an adverse event (AE; any-cause), most commonly (all%/G3%) nausea (31/3), hypertension (28/7) and fatigue (21/0). No G4/5 AEs were reported; 5 (17%) pts experienced serious AEs. One pt had an immune-related AE (G1 rash). Eighteen (62%) pts had a drug-related AE, most commonly nausea (24%), vomiting, fatigue, and hypertension (all 14%). Three pts had infusion-related reactions (G1, n = 2; G2, n = 1) and 1 pt had an AE that led to treatment discontinuation (non-related G3 bile duct stone). Of 7 pts evaluable for response prior to cycle 3, 5 have SD (Cohort 2, n = 2; Cohort 4, n = 3), and 2 have PD (Cohorts 3 and 4, n = 1 each). Updated data will be presented. **Conclusions:** These preliminary data suggest that ezabenlimab in combination with BI 836880 has a manageable safety profile. Cohorts are continuing to recruit (approximately 30 pts per cohort). Clinical trial information: NCT03697304. Research Sponsor: Boehringer Ingelheim.

2583 **Poster Session**

AdvanTIG-105: Phase 1 dose-escalation study of anti-TIGIT monoclonal antibody ociperlimab (BGB-A1217) in combination with tislelizumab in patients with advanced solid tumors. *First Author: Sophia Frentzas, Medical Oncology, Monash Health, Melbourne, Victoria, Australia, School of Medical and Health Sciences, Monash University, Melbourne, VIC, Australia*

Background: Anti-programmed death 1 (PD-1) therapy has improved clinical outcomes for patients (pts) with advanced solid tumors but unmet needs remain. T-cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibition motif domains (TIGIT) is a co-inhibitory, immune checkpoint receptor. Ociperlimab (OCI; BGB-A1217) is a novel, humanized, monoclonal antibody that binds to TIGIT with high affinity and specificity. OCI has demonstrated competent binding with C1q and all Fcγ receptors and induces antibody-dependent cellular cytotoxicity. Preclinical studies demonstrated dual targeting with OCI and tislelizumab (TIS), an anti-PD-1 antibody, produces synergistic immune cell activation and enhanced anti-tumor activity. **Methods:** AdvanTIG-105 is a phase 1, open label, multicenter, dose-escalation study (NCT04047862) that assessed the safety and preliminary antitumor activity of OCI plus TIS in pts with advanced, metastatic, unresectable solid tumors, for which standard therapy was ineffective or unavailable. Eligible pts had an Eastern Cooperative Oncology Group performance score $\leq$1 and no prior therapy targeting TIGIT. Pts received OCI intravenously (IV) on Day 1 of Cycle 1 and TIS 200 mg IV on Day 8. Pts were monitored for dose-limiting toxicities (DLTs) until Day 28. If tolerated, OCI and TIS were administered sequentially on Day 29 and every 3 weeks (Q3W) thereafter. Pts received escalating doses of OCI (50-900 mg) plus TIS 200 mg. The study objective was determination of recommended phase 2 dose (RP2D) of OCI plus TIS. Study endpoints included assessment of adverse events (AEs), pharmacokinetics and antitumor activity. Data cut-off was October 12 2020. **Results:** 24 pts with various advanced solid tumors received OCI plus TIS. At baseline, pts had undergone a median of 2 prior treatment regimens; 9/24 (37.5%) pts had received prior immunotherapy. Median follow-up time was 17 weeks. No DLTs were observed. 20 pts had $\geq$1 treatment emergent AE (TEAE) and most TEAEs were grade $\leq$2; fatigue (6 pts) and diarrhea (4 pts) were most commonly reported. No pts had grade $\geq$4 TEAEs or TEAEs leading to death. There were 2 grade 3 immune related AEs (colitis and low cortisol). One pt on OCI 450 mg achieved partial response and 9 pts had stable disease. The longest duration of stable disease was 36 weeks (1 pt on OCI 150 mg). After administration, serum concentration of OCI decreased in a biphasic manner. Exposure to OCI increased proportionally with dose, and TIGIT receptor occupancy was sustained at $\geq$50 mg doses. **Conclusions:** OCI in combination with TIS was well tolerated across all doses in pts with advanced solid tumors. The RP2D was OCI 900 mg plus TIS 200 mg Q3W. Clinical trial information: NCT04047862. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Stephanie Pruden, BSc (Hons), of Ashfield MedComms, an Ashfield Health company, and funded by BeiGene, Ltd.

2584 **Poster Session**

IFN-α, IFN-γ, IL-2 combined with TNF-α for predicting efficacy of PD-1 inhibitors combination therapy in patients with solid cancers. *First Author: Penghui Xing, Department of Neurosurgery, Fourth Hospital of Hebei Medical University, Shijiazhuang, China*

Background: PD-1 inhibitors have transformed the treatment landscape for patients (pts) with many advanced malignancies. Combination therapy with PD-1 inhibitors for cancer is a trend. However, Biomarkers for the efficacy of combination therapy remains unknown. In order for the benefited population to be screened out, biomarkers need to be established. we will conduct the following study, to explore the IFN-α, IFN-γ, IL-2 combined with TNF-α for predicting efficacy of PD-1 inhibitors combination therapy. **Methods:** Using postoperative without lesions as control group (n=7). Pts with lesions as the experimental group (n=66). 27 of 66 pts received chemoradiotherapy (group A), 39 of 66 pts received PD-1 inhibitors combined with therapy (group B). IFN-α, IFN-γ, IL-2, TNF-α in peripheral blood of all pts were measured using flow cytometry. **Results:** 1) There was significant difference in proportion above normal concentrations (ANCs) of IFN-α between two groups (57.1% vs 43.5%, $P<0.05$), but there was no significant difference in IFN-γ, IL-2 and TNF-α between two groups (IFN-γ 57.1% vs 52.2%, IL-2 14.3% vs 5.8%, TNF-α 42.9% vs 43.5%, $P>0.05$). 2) The normal ratios of IFN-α, IFN-γ and TNF-α in group B was significantly higher than that in group A (IFN-α 64.1% vs 51.9%, IFN-γ 59% vs 37%, TNF-α 69.2% vs 44.4%, $P<0.05$). The proportion ANCs of IFN-α, IFN-γ, and TNF-α were lower in group A (IFN-α 35.9% vs 63%, $P>0.05$; IFN-γ 41% vs 63%, $P<0.05$; TNF-α 30.8% vs 55.6%, $P<0.05$). However, the proportion ANCs of IL-2 detection was lower (7.4% vs 5.1%). 3) In group B, 21 of 39 pts were evaluable. ORR was 52.4% (11/21) and DCR was 85.7% (18/21). The proportion ANCs of IFN-α, IFN-γ and TNF-α in the pts with PR was higher than that with SD (IFN-α 37.5% vs 28.6%, IFN-γ 37.5% vs 28.6%, TNF-α 50% vs 38.8%, $P<0.05$). 4) We found that the coincidence rate of IFN-α+ IFN-γ and IFN-α+ IFN-γ+TNF-α was higher in group B (Table). **Conclusions:** Our results suggest that the proportion ANCs of IFN-α, IFN-γ, and TNF-α in the pts with lesions were lower than that without lesions, it may be the decrease of immune function with lesions. There was positive correlation between proportion ANCs of IFN-α, IFN-γ and TNF-α and efficacy in these pts. IL-2 was not used as a routine detection indicator. The coincidence rate of IFN-α, IFN-γ combined with TNF-α was higher, it may help predict the outcome of PD-1 inhibitors combination therapy in pts with solid cancers, and helpful to screen the benefit population. Further study is needed. Research Sponsor: None.

Coincidence rate of IFN-α, IFN-γ and TNF-α after treatment in different patients.*

	Non-coincidence rate (%)	Coincidence rate (%)
IFN-α+IFN-γ	14.8	85.2
IFN-α+IFN-γ (+)	15.4	84.6
IFN-α+IFN-γ (+SD)	0	100
IFN-α+IFN-γ (+PR)	0	100
IFN-α+IFN-γ+TNF-α	29.6	70.4
IFN-α+IFN-γ+TNF-α (+)	28.2	71.8
IFN-α+IFN-γ+TNF-α (+SD)	0	100
IFN-α+IFN-γ+TNF-α (+PR)	100	87.5

*IFN-α+IFN-γ, IFN-α+IFN-γ+TNF-α: group A; others: group B.

A phase 1 dose-escalation study of a PD-L1xCD27 bispecific antibody CDX-527 in patients with advanced malignancies. *First Author: Rachel E. Sanborn, Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR*

Background: CDX-527 is a bispecific antibody (BsAb) targeting PD-L1 and CD27 that is designed to block immune checkpoint PD-L1/PD-1 interactions while providing immune costimulation through CD27 signaling. CD27 is a key immunostimulatory molecule that enhances T cell activation, effector function, and survival. Combining anti-PD-L1 and anti-CD27 mAbs synergize in preclinical studies, activating complementary cytotoxic and proliferative gene expression profiles, respectively. Clinical studies demonstrated the safety and biological activity of combining varlilumab, an agonist anti-CD27 mAb, with nivolumab or atezolizumab, along with modest clinical activity of the combinations. CDX-527 is a novel human BsAb containing a neutralizing, high affinity IgG1k PD-L1 mAb and the single chain Fv fragment (scFv) of an agonist anti-CD27 mAb genetically attached to the C-terminus of each heavy chain, thereby making CDX-527 bivalent for each target. Pre-clinical studies demonstrated enhanced T cell activation by CDX-527 and anti-tumor activity of a surrogate bispecific compared to individual mAb combinations. **Methods:** CDX527-01 is a phase 1 first-in-human, open-label, multi-center, dose-escalation (DE) and expansion study evaluating safety, pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity of CDX-527 in patient with advanced solid tumors that have progressed on standard-of-care therapy. The primary study objective is to characterize the safety and tolerability of CDX-527. CDX-527 is administered intravenously Q2W with doses ranging from 0.03 mg/kg up to 10.0 mg/kg or until the maximum tolerated dose. The first 2 cohorts of the DE phase initiate with single patients and subsequent DE cohorts will be conducted in 3+3 manner. Tumor-specific expansion cohorts may be enrolled to further characterize the safety, PK, PD, and efficacy of CDX-527. Tumor assessments are performed Q8W by the investigator per iRECIST. Biomarker assessments include characterizing the effects on peripheral blood immune cells and cytokines, and for the expansion cohorts, the impact of CDX-527 on the tumor microenvironment in paired tumor biopsies. **Results:** To date, 8 patients have received CDX-527 in doses ranging from 0.03 mg/kg to 1 mg/kg and 3 are still on treatment. There has been no drug related SAEs, DLTs or discontinuations due to an AE. Most common treatment related AEs were influenza-like illness, fatigue, and arthralgia (all at 25%). All drug related AEs have been grade 1 or 2. **Conclusions:** Preliminary results indicate that the novel anti-PD-L1xCD27 bispecific antibody CDX-527 up to and including the 1 mg/kg dose level has been well tolerated. Additional data will be presented, including the safety profile at higher dose levels along with clinical activity, as well as PK and PD data. Clinical trial information: NCT04440943. Research Sponsor: None.

The predictive values of loss-of-function variants in histone methyltransferases for response to immune checkpoint inhibitors in solid tumors. *First Author: Naixin Liang, Department of Thoracic Surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: Dysregulation of histone methyltransferases (HMTs) has been reported to play critical roles in cancer development. Previous studies showed that many HMTs were recruited to DNA damage sites where they posttranslationally modified chromatin to regulate chromatin-based DNA damage repair (DDR) activities. We hypothesized that loss-of-function (LOF) variants of HMTs may associate with genome instability and tumor mutational burden (TMB). Thus, we explored the associations of LOF variants in some HMTs with TMB and benefit from immune checkpoint inhibitors (ICIs) in solid tumors. **Methods:** An ICIs treatment cohort from the Memorial Sloan Kettering Cancer Center (MSKCC) was analyzed. The following solid tumor types were enrolled: NSCLC (n = 350), colorectal cancer (n = 110), bladder cancer (n = 215), breast cancer (n = 44), esophagogastric cancer (n = 126), head and neck cancer (n = 139), glioma (n = 117), melanoma (n = 320), and renal cell carcinoma (n = 151). We evaluated 15 HMTs (KMT2A, KMT2B, KMT2C, KMT2D, SETD2, SETD8, EZH1, EZH2, PRDM1, PRDM14, SMYD3, NSD1, WHSC1, WHSC1L1, and DOT1L). **Results:** The data revealed that LOF variants of *KMT2D*, *SETD2*, and *KMT2C* were more frequent in pan-cancer dataset. Furthermore, we found that LOF variants of 7 HMTs, including *KMT2A*, *KMT2B* , *KMT2C*, *KMT2D, NSD1*, *SETD2*, and *EZH2*, were associated with higher TMB ($P < 0.0001$). Then we analyzed the associations between LOF variants and overall survival (OS) after ICIs therapy. The results indicated that LOF variants of *KMT2A* (P = 0.0295), *KMT2B* (P = 0.0329), *KMT2C* (P = 0.0122), and *SETD2* (P = 0.0004) were significantly associated with prolonged median OS for all the enrolled patients. In this cohort, LOF variants of *KMT2A*, *KMT2B*, *KMT2C*, and *SETD2* were most common in bladder cancer, colorectal cancer, colorectal cancer, and renal cell carcinoma, respectively. Then we assessed the predictive values of these four genes for each type of cancer. It was noteworthy that *KMT2C* LOF variants were significantly correlated with longer median OS in colorectal cancer (P = 0.0171), but not in other cancer types. Surprisingly, we did not observe the predictive roles of LOF variants in *KMT2A*, *KMT2B*, and *SETD2* genes for response to ICIs therapy in any types of cancer. **Conclusions:** In pan-cancer dataset, we found that LOF variants of 4 HMTs, such as *KMT2A*, *KMT2B*, *KMT2C*, and *SETD2*, were correlated with better outcomes of ICIs treatment. However, for different types of cancer, only *KMT2C* LOF variants were associated with longer median OS in colorectal cancer, suggesting that it may be used as a predictive biomarker for ICIs efficacy in colorectal cancer. Because the sample sizes of patients with *KMT2A*, *KMT2B*, or *SETD2* LOF variants were small, we did not find the predictive values of LOF variants in these three genes for different types of cancer. Next, we will enroll more patients to address this question. Research Sponsor: None.

2587 **Poster Session**

Association of *KMT2C/D* loss-of-function mutations with tumor infiltrating lymphocytes and response to immune checkpoint inhibitors in solid tumors. *First Author: Ruiqi Liu, Department of Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Dysregulation of HMTs plays an important role in tumorigenesis. KMT2C and KMT2D are enzymatically active scaffold proteins that form the core of mammalian COMPASS complexes, which methylate the histone 3 lysine 4. Both KMT2C and KMT2D are involved in the regulation of gene expression. Therefore, we explored the associations of *KMT2C/D* loss-of-function (LOF) mutations with the expression of immune-related genes, the levels of tumor infiltrating lymphocytes (TILs), and response to immune checkpoint inhibitors (ICIs). **Methods:** *KMT2C/D* LOF mutations were defined as nonsense, frameshift, splice site variants within consensus regions, start lost, and stop lost/gained variants. An ICIs treatment cohort from the MSKCC was used for exploring the associations between *KMT2C/D* LOF mutations and ICIs efficacy. The RNA-Seq data obtained from the TCGA cohort was used for analysis of gene expression and the levels of TILs using *CIBERSORT*. **Results:** In MSKCC pan-cancer dataset, patients with *KMT2C/D* LOF mutations had a relatively longer median overall survival (OS) compared to those with non-LOF mutations, although the result did not reach statistical significance (P = 0.0832). Then we analyzed the predictive roles of *KMT2C/D* LOF mutations for each cancer type. The results showed that the predictive role of *KMT2C/D* LOF mutations for the clinical efficacy of ICIs therapy was only observed in colorectal cancer (P = 0.045). However, we did not find the associations of *KMT2C/D* LOF mutations with ICIs efficacy in bladder cancer, breast cancer, melanoma, glioma, head and neck cancer, renal cell carcinoma, NSCLC, and esophagogastric cancer. Consistently, analysis of TILs in colorectal cancer revealed that *KMT2C/D* LOF was associated with increased infiltration of several types of immune cells, such as CD8+ T cells (P = 0.0001), activated NK cells (P = 0.0001), M1 macrophage (P = 0.0005), M2 macrophage (P = 0.0115), and neutrophils (P = 0.0209). Meanwhile, regulatory T cells (Tregs) (P = 0.0048) and M0 macrophage (P = 0.0043) were dramatically decreased in *KMT2C/D* LOF group for colorectal cancer. Moreover, there were no significant relationships between *KMT2C/D* LOF and the levels of TILs in other cancer types. Our data also demonstrated that KMT2C and KMT2D could regulate the expression of more than 30 immune-related genes in colorectal cancer. **Conclusions:** Our data indicated that *KMT2C/D* LOF mutations were significantly correlated with better outcomes of ICIs therapy in colorectal cancer, suggesting it can be as a useful predictor for response to ICIs in colorectal cancer. Meanwhile, we found the associations of *KMT2C/D* LOF with the levels of TILs in colorectal cancer, but not in other cancer types, indicating that the efficacy of ICIs was consistent with the levels of TILs. Research Sponsor: None.

Risk of immunosuppression and hospitalization after checkpoint inhibitor therapy in patients with cancer and radiation therapy. *First Author: Kate E Lee, Columbia University Vagelos College of Physicians and Surgeons, New York, NY*

Background: Immune checkpoint inhibitors (ICIs) are potent new cancer therapies but can cause serious immune-related adverse events. Radiation therapy (RT) also induces systemic immunologic effects, and data on the interaction and safety of combining ICIs and RT are limited. **Methods:** In this retrospective cohort study using a large medical claims database from 2010 to 2017, we ascertained the risk of immunosuppressive steroid therapy as well as the risk of hospitalization within 180 days of treatment with an ICI in patients with diagnoses of malignant melanoma or lung cancer. Patients were stratified by use of RT within 30 days before and after ICI therapy. ICIs included pembrolizumab, nivolumab, and ipilimumab, while immunosuppressive agents included oral prednisone and intravenous methylprednisolone. **Results:** 2020 patients (218 with RT, 1802 without RT) met inclusion criteria for prednisone analysis, while 3519 patients (361 with RT, 3158 without RT) met inclusion criteria for all other analyses. On univariable analysis, RT was not associated with need for prednisone or methylprednisolone (RR 1.2, 95%CI 0.8-1.9 and RR 1.2, 95%CI 0.7-2.1 respectively). When assessing hospitalization, RT was significantly associated with hospitalization following ICI therapy for certain cancer/drug combinations (RR 1.4, 95%CI 1.2-1.6, $p<0.001$ for lung cancer/PD-1 inhibitors, RR 2.0, 95%CI 1.0-3.5, $p=0.03$ for melanoma/ipilimumab). **Conclusions:** In patients treated with ICIs, receiving RT was not associated with a higher risk of requiring immunosuppressive steroid therapy as compared to not receiving RT. However, in those with ICIs, RT was associated with a higher risk of hospitalization as compared to no RT, though this may be a result of underlying differences in patent severity (more severe disease may require ICI and RT). Research Sponsor: Barry Neustein and Polyflex Inc. to the lung cancer research program in Radiation Oncology at Columbia University, Other Foundation, Louis V. Gerstner, Jr. Scholar Award.

Risk of corticosteroid treatment after ICI treatment across cancer type, ICI, and RT.[a,b]

	Oral Prednisone			IV Methylprednisolone		
	RT	No RT	Relative Risk (95% CI)	RT	No RT	Relative Risk (95% CI)
Melanoma PD-1 Inhibitors	13.6% (3/22)	10.7% (35/326)	1.3 (0.4, 3.8)	0.0% (0/33)	1.4% (7/501)	1.0 (0.1, 16.9)
Lung Cancer PD-1 Inhibitors	10.2% (18/176)	8.4% (96/1145)	1.2 (0.8, 2.0)	4.7% (12/257)	4.9% (78/1591)	1.0 (0.5, 1.7)
All Cancers PD-1 Inhibitors	10.6% (21/198)	8.9% (131/1471)	1.2 (0.8, 1.8)	4.1% (12/290)	4.1% (85/2092)	1.0 (0.6, 1.8)
Melanoma Ipilimumab	5.0% (1/20)	5.4% (18/331)	0.9 (0.1, 6.5)	2.8% (2/72)	1.3% (14/1066)	2.1 (0.5, 9.0)
Melanoma Ipi-Nivo Combo	40.0% (4/10)	32.2% (46/143)	1.2 (0.6, 2.8)	21.1% (4/19)	22.1% (44/199)	1.0 (0.4, 2.4)
All Cancers All ICIs	10.1% (22/218)	8.3% (149/1802)	1.2 (0.8, 1.9)	3.9% (14/362)	3.1% (99/3158)	1.2 (0.7, 2.1)

[a]No values were significantly different at $p<0.05$. [b]The patient populations for prednisone and methylprednisolone are not identical because the separate analyses required distinct inclusion criteria.

Phase Ia/Ib dose-escalation study of IBI110 (anti-LAG-3 mAb) as a single agent and in combination with sintilimab (anti-PD-1 mAb) in patients (pts) with advanced solid tumors. *First Author: Cai Zhou, Shanghai Pulmonary Hospital, Tongji University, Shanghai, China*

Background: Lymphocyte-activation gene 3 (LAG-3) is an immune checkpoint receptor protein that functions to control T cell response, activation and growth. Dual inhibition of PD-1 and LAG-3 may improve anti-tumor effect synergistically. In this first-in-human dose-escalation study, we report the preliminary safety and anti-tumor activity of IBI110 ± sintilimab in pts with advanced solid tumors. **Methods:** Enrolled pts, ECOG PS 0-1, had locally advanced, recurrent or metastatic solid tumors for whom standard therapy had failed. Pts received escalating doses of IBI110 (0.01/0.1/0.3/1/3/10/20mg/kg) IV Q3W in phase Ia and escalating doses of IBI110 (0.3/0.7/1.5/3/5 mg/kg) in combination with sintilimab 200 mg IV Q3W in phase Ib. Crossover from mono to combo was allowed at progression. The objectives were safety and tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity of IBI110 alone or IBI110+sintilimab (per RECIST v1.1). **Results:** Phase Ia: 21 pts (median age: 62 yr [range 43-72]; ECOG PS: 0 [n = 11], 1 [n = 10]) were enrolled. Dose escalation has completed and no dose-limiting toxicity (DLT) was observed in all dose cohorts. The most common treatment-related adverse event (TRAE) was anaemia (19.0%). TRAEs ≥G3 included anaemia (4.8%), ascites (4.8%) and hepatic function abnormal (4.8%). By investigator-assessment, best response was 1 confirmed partial response (PR) (ovarian cancer, 3 mg/kg IBI110 single agent) and 5 stable disease (SD) in monotherapy. After crossing from mono to combo at progression, 5 pts were observed to have SD. Phase Ib: 12 pts (median age: 60 yr [range 33-72]; ECOG PS: 0 [n = 7], 1 [n = 5]) were enrolled. All dose cohorts in dose escalation except IBI110 5mg/kg+ sintilimab have completed DLT observation and no DLT was observed. The most common TRAE was AST increased (41.7%). TRAEs ≥G3 included hyperglycaemia (8.3%), bilirubin conjugated increased (8.3%) and hepatic function abnormal (8.3%). By investigator-assessment, best response was 2 PR (small cell lung cancer and endometrial cancer) and 6 SD. **Conclusions:** IBI110 alone or plus sintilimab has acceptable toxicity and shows preliminary antitumor activity. Clinical trial information: NCT04085185. Research Sponsor: Innovent Biologics, Inc.

2590 **Poster Session**

A phase I trial evaluating NBTXR3 activated by radiotherapy in combination with nivolumab or pembrolizumab in patients with advanced cancers. *First Author: Colette Shen, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Immune checkpoint inhibitors (ICIs) targeting PD-1 are an effective treatment for a variety of cancers. However, the majority of patients (pts) exhibit resistance to ICIs. Overcoming this resistance represents a major challenge in immuno-oncology. Emerging evidence suggests radiation therapy (RT) produces an immunomodulatory effect that may act synergistically with ICIs. However, RT dose and ultimate efficacy are limited by toxicity to surrounding healthy tissues. NBTXR3, a novel radioenhancer administered by direct intratumoral injection (ITI), is designed at the nanoscale to increase RT dose deposit within tumor cells and subsequent tumor cell killing, without increasing toxicity to surrounding healthy tissue. Preclinical data suggest NBTXR3/RT can trigger a local and systemic anti-tumor immune response and overcome anti-PD-1 resistance. NBTXR3/RT combined with anti-PD-1 may prime the immune system to increase the proportion of ICI responders, or convert ICI non-responders to responders. **Methods:** This is a multicenter, open-label, phase I trial [NCT03589339] to evaluate NBTXR3/RT/anti-PD-1 in 3 cohorts: (1) Locoregional recurrent or recurrent and metastatic head and neck squamous cell carcinoma (HNSCC) amenable to HN re-irradiation, and metastases from any primary cancer eligible for anti-PD-1 (nivolumab or pembrolizumab) treatment specifically localized in the lung (2) or liver (3), respectively. Stereotactic body RT (SBRT) is delivered at tumor-site selective doses per standard practice. The primary objective is NBTXR3/RT/anti-PD-1 recommended phase 2 dose in each cohort. Secondary objectives are anti-tumor response (objective response rate), safety and feasibility of NBTXR3 injection. **Results:** Nine pts have been treated: 3 HNSCC, 4 lung, 2 liver. 7/9 pts were anti-PD-1 non-responders. Overall tumor regression was observed in 8/9 pts. NBTXR3/RT/anti-PD-1 resulted in tumor regression in 6/7 pts who had progressed on prior anti-PD-1. A complete response in the injected lymph node lasting over 1 year was observed in 1 anti-PD-1 naïve pt. 2 SAEs related to anti-PD-1 and possibly related to NBTXR3 (G5 pneumonitis, G4 hyperglycemia) were observed in 1 anti-PD-1 naïve HNSCC pt and considered DLTs. This pt also experienced 2 other SAEs related to anti-PD-1 (G4 diabetic ketoacidosis, G4 acute kidney injury). SBRT-related safety profile was as expected. Updated results will be presented. **Conclusions:** Data from this first-in-human phase I trial evaluating NBTXR3/RT/anti-PD-1 in pts with advanced cancers, show NBTXR3 ITI is feasible and well-tolerated. NBTXR3/RT/anti-PD-1 demonstrated promising signs of efficacy. Of particular interest, NBTXR3/RT can overcome ICI resistance in pts having progressed on prior anti-PD-1, supporting further development of NBTXR3 in combination with anti-PD-1 as well as other ICIs. Clinical trial information: NCT03589339. Research Sponsor: Nanobiotix.

Overcoming resistance to anti-PD-1 with tumor agnostic NBTXR3: From bench to bed side. *First Author: Tanguy Y. Seiwert, The University of Chicago Medicine, Chicago, IL*

Background: Despite recent advances, resistance to immune checkpoint inhibitors (ICI), observed in over 80% of treated patients, is currently the main challenge in immuno-oncology. Intense efforts are being made to identify combination therapies that could improve ICI response rates. NBTXR3, a novel radioenhancer administered by direct intratumoral injection (ITI), is designed at the nanoscale to increase radiation therapy (XRT) dose deposit within tumor cells and subsequent tumor cell killing, without increasing toxicity to surrounding healthy tissue. Here we present evidence that NBTXR3 activated by XRT primes the immune system, producing an anti-tumor response, including activation of the cGAS-STING pathway, that overcomes anti-PD-1 resistance both in mice models and patients. **Methods:** Abscopal assays were conducted in immunocompetent mice. Anti-PD-1 sensitive or resistant tumor cell lines, were injected in both flanks of mice. Intratumoral injection of NBTXR3 (or vehicle) followed by XRT was performed in right flank (primary) tumors only. Some mice also received anti-PD-1 injections. Tumor growth was monitored, and tumor immune cell infiltrates analyzed by immunohistochemistry (IHC). Separately, in the phase II/III randomized Act.in.Sarc [NCT02379845] trial patients with locally advanced soft tissue sarcoma (STS) received either NBTXR3+XRT or XRT alone followed by tumor resection. Pre- and post-treatment tumor samples from patients in both groups were analyzed by IHC and Digital Pathology for immune biomarkers. The safety and efficacy (RECIST 1.1/iRECIST) of NBTXR3 plus stereotactic body radiotherapy (SBRT) in combination with anti-PD-1 is being evaluated in three cohorts of patients with advanced cancers [NCT03589339]. **Results:** Pre-clinical studies demonstrated that NBTXR3+XRT induces an immune response not observed with XRT alone and enhances systemic control. IHC showed significant increase of CD8+ T-cell infiltrates in both NBTXR3+XRT treated and untreated tumors compared to XRT alone. Similarly, increased CD8+ T-cell and decreased FOXP3+ Treg density (pre- vs post-treatment) was observed in tumor tissues from STS patients treated with NBTXR3+XRT. Furthermore, NBTXR3+XRT in combination with anti-PD-1 improved local and systemic control in mice bearing anti-PD-1 resistant lung tumors, as well as reduced the number of spontaneous lung metastases. Preliminary efficacy data from the first in human trial of NBTXR3+XRT in combination with anti-PD-1 showed tumor regression in the majority of patients (8/9). Of note, tumor regression was observed in 6/7 pts who had progressed on prior anti-PD-1. **Conclusions:** The clinical efficacy of NBTXR3+XRT has been demonstrated as a single agent. We now demonstrate that it potentiates anti-PD-1 treatment to overcome resistance mechanisms. These results highlight the potential of NBTXR3+XRT to positively impact the immuno-oncology field. Clinical trial information: NCT03589339. Research Sponsor: Nanobiotix.

2592 **Poster Session**

A phase 1/2 study of intratumoral INT230-6 alone (IT-01) or in combination with pembrolizumab [KEYNOTE-A10] in adult subjects with locally advanced, unresectable and metastatic solid tumors refractory to therapy. *First Author: Anthony B. El-Khoueiry, University of Southern California, Los Angeles, CA*

Background: Study IT-01 (KEYNOTE-A10) evaluates INT230-6, a novel formulation of cisplatin (CIS) and vinblastine (VIN) with an amphiphilic cell penetration enhancer designed for intratumoral (IT) administration, alone or in combination with pembrolizumab (PEM), an antibody to PD-1. INT230-6 dosing is set by a tumor's volume. In preclinical studies, INT230-6 increases drug dispersion throughout the tumor, allows drug diffusion into cancer cells and recruits dendritic, CD4 and CD8 T cells. The addition of PEM has been shown to improve these responses in models. Phase 1 data indicated INT230-6 alone induced tumor regression in both injected and non-injected lesions. Considering the large volume of drug injected and retained in the tumor, coupled with immune infiltration on biopsies, RECIST response methodology may not capture the benefit of INT230-6 treatment. **Methods:** IT-01 is an open-label phase 1/2 study, currently enrolling adult subjects with solid tumors in phase 2. INT230-6 was administered IT Q2W for 5 doses alone or with PEM 200mg Q3W. The study seeks to assess the safety and efficacy of IT INT230-6 alone and in combination with PEM. **Results:** 67 subjects have been enrolled (58 mono and 12 INT230-6 + PEM (3 started in mono, then received combo)) having a median of 3 prior therapies (0, 10). Median age was 60 (42, 85). 20+ cancer types were accrued; breast cancer and sarcoma were the most frequent. Over 500 image guided INT230-6 IT injections were given (253 to deep tumors) at doses of 0.3 to 172mL (86 mg CIS, 17.2 mg VIN) in a single session, which are higher amounts than typical IV doses. PK shows that 95% of INT230-6 active agents remain in the tumor. The most common (> 20%) related TEAEs for INT230-6 alone were localized pain (57%), nausea (36%), fatigue (29%) and vomiting (24%); with grade 3 TEAEs (> 1) of localized pain (5%) and anemia (3%). The safety in the combination was similar. There were no related grade 4 or 5 TEAEs. In evaluable monotherapy subjects (n = 43), the disease control rate (DCR) was 65% vs. 100% in PEM subjects (n = 5). Given the range of dose and entering tumor burden, an exploratory analysis of dose relative to tumor burden (TB) showed that subjects receiving a dose of INT230-6 < 50% of their reported TB (n = 30) had a mOS of 3.5 months. While in subjects receiving a dose of INT230-6 to ≥50% of TB (n = 37), mOS has not yet been reached after a median follow up of 9.5 months (HR: 0.26 (0.13,0.51)). **Conclusions:** INT230-6 is well tolerated when administered IT as monotherapy and combined with PEM. Given the challenge in assessing overall response rate following IT delivery, an exploratory analysis suggests prolonged survival for subjects receiving an INT230-6 dose ≥50% of their tumor burden compares favorably to the < 50% group and to literature accounting for prognostic factors (ECOG, LDH, # of metastatic sites). Clinical trial information: 03058289. Research Sponsor: Intensity Therapeutics, Inc.

Nivolumab/ipilimumab primed immunotransplant in post-CAR-T and post-ASCT DLBCL. *First Author: Bailey Gleason Fitzgerald, The Tisch Cancer Institute at Mount Sinai Health System, New York, NY*

Background: Patients with refractory diffuse large b cell lymphoma (DLBCL) have poor outcomes with < 30% surviving for 12 months and especially poor outcomes for those who progress after chimeric antigen receptor T cells (CAR-T) or autologous stem cell transplant (ASCT). These therapies utilize lymphodepleting chemotherapy which induces homeostatic T cell proliferation. We have demonstrated these expanding T cells express high levels of PD1 and CTLA4. In pre-clinical models, addition of dual checkpoint blockade (DCB) with anti-PD1/anti-CTLA-4 to adoptive T cell transfer after lymphodepletion achieved a synergistic anti-tumor effect. Based on these studies, we developed a phase Ib/II study of Nivolumab/Ipilimumab primed "immunotransplant" for relapsed/refractory (R/R) DLBCL (NCT03305445). **Methods:** Phase Ib of the trial enrolled 6 patients with progressive disease following at least one line of standard therapy. Patients received two cycles of DCB with ipilimumab (1mg/kg) and nivolumab (3mg/kg) given at three-week intervals followed by immunotransplant (i.e. peripheral blood T cell harvest, lymphodepletion with fludarabine/cyclophosphamide, T cell reinfusion), followed by two further cycles of DCB and nivolumab maintenance. **Results:** Five patients received at least two cycles of DCB and the autologous T cell transfer, while one patient had progressive disease during initial DCB and required salvage chemotherapy. Treatment emergent AE (TEAE) occurred in 100% of patients. As expected with lymphodepleting chemotherapy, the most common TEAE were neutropenia (66.7% grade 1, 66.7% grade ≥ 3), fatigue (83.3%, 16.7%), fever (66.7%, 0%), and dyspnea (66.7%, 0.0%). One patient (16.7%) died during the intervention period (grade 5 TEAE), though relation to study drug is unclear. Three patients (50.0%) experienced clinical benefit with immunotransplant. One patient (a 58yo M with progression after seven lines of therapy including ASCT and CAR-T) is experiencing partial metabolic response after 4 months on protocol. One 77yo F with multiple prior lines of therapy including ASCT has experienced an extended complete metabolic response, currently 31 months post immunotransplant. A third (a 50yo F) experienced mixed radiographic response, and has not received subsequent therapy 30 months following immunotransplant. **Conclusions:** Nivolumab/Ipilimumab primed immunotransplant is well tolerated in patients with R/R DLBCL for whom there are few treatment options. Preliminary results demonstrate remissions in heavily pre-treated patients, including prior ASCT and CAR-T. Pre-clinical models in melanoma, non-small cell lung cancer, and T cell lymphoma all demonstrate synergy when DCB is administered with lymphodepletion and autologous T cell transfer. These data support further investigation of DCB-primed immunotransplant. Clinical trial information: NCT03305445. Research Sponsor: Bristol Myers Squibb.

2594 **Poster Session**

Safety, pharmacokinetics, pharmacodynamics profiles and preliminary antitumor activity of phase 1b/2a study of NT-I7, a long-acting interleukin-7, plus pembrolizumab in patients with advanced solid tumors: The phase 1b data report. *First Author: Aung Naing, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NT-I7 (efineptakin alfa) is the first-in-class long-acting IL-7 which can increase the number and functionality of T cells in the peripheral blood (PB) of patients (pts). The combination of NT-I7 and pembrolizumab (pembro), a PD-1 Checkpoint Inhibitor (CPI), may augment and broaden the efficacy of CPIs. **Methods:** This is an open-label, phase 1b/2a study in pts with relapsed/refractory (R/R) advanced solid tumors. In the phase 1b (Dose Escalation), which followed the 3+3 design, pts received NT-I7 intramuscularly (IM) at 3 dose levels (DLs): 480, 960, and 1200 μg/kg every 6 weeks (Q6W) plus pembro 200 mg intravenously (IV) Q3W. The objectives of the phase 1b were to evaluate Dose Limiting Toxicity (DLT), determine the Maximum Tolerated Dose (MTD) and/or the Recommended Phase 2 Dose (RP2D), and assess pharmacokinetics (PK), pharmacodynamics, and preliminary antitumor activity. **Results:** As of 12 January 2021, 12 pts were enrolled in the phase 1b: DL1 (n=3), DL2 (n=3) and DL3 (n=6). Median age 58.0 years [43-77], ECOG PS 0 (50%), PS 1 (50%), median number of prior therapies 4 [1-8]. MTD was not reached. One DLT (Grade [G] 3 ALT increased) was reported in DL3. Treatment-related adverse events (AEs) occurred in 11 (91.7%) pts, 11 (91.7%) G1-2 and 4 (33.3%) G3; no G4 or G5 AEs reported. Common treatment-emergent AEs were injection site reaction (n=8, 66.7%), chills (n=7, 58.3%), nausea (n=6, 50%) and pyrexia (n=6, 50%). Preliminary PK analysis showed T_{max} = 24 hours and $T_{1/2}$ = 123 hours for NT-I7 at DL3. NT-I7 + pembro induced dose-dependent lymphocyte proliferation in the PB, with ~ 3-fold increase at DL3, and a corresponding decrease in neutrophil to lymphocyte ratio at 14 days after the 1st treatment. Importantly, increased number of T cells in the tumor microenvironment (TME) was also observed (Table). One pt with metastatic mucosal melanoma who had not responded to prior combination of nivolumab and ipilimumab had a rapid, confirmed partial response with 46% tumor reduction. Patient follow-up continues and updated data will be presented. The combination of NT-I7 1200 μg/kg IM Q6W + pembro 200 mg IV Q3W has been selected as the RP2D. **Conclusions:** The combination of NT-I7 + pembro was well tolerated in pts with R/R advanced solid tumors. NT-I7 + pembro significantly increased T cell numbers in both the TME and the PB, and there was encouraging antitumor activity with the combination in this pt population. These results support continued evaluation of NT-I7 in combination with pembro in pts with R/R advanced solid tumors. The phase 2a of the study is enrolling pts with either CPI-pretreated or CPI-naïve solid tumors (NCT04332653). Clinical trial information: NCT04332653. Research Sponsor: NeoImmuneTech, Inc.

Increased lymphocytes in the TME on treatment (OT) compared to baseline (BL).

Phase II trial of MEDI0457 and durvalumab for patients with recurrent/metastatic HPV-associated cancers. *First Author: Van K. Morris, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Infection with human papillomavirus (HPV) types 16 or 18 drives oncogenesis for the majority of patients (pts) with cervical, anal, and some penile cancers via viral oncoproteins E6 and E7. While anti-PD1/PD-L1 antibodies have activity in pts with HPV-associated cancers, the majority do not derive benefit from these agents as monotherapy. MEDI0457, a therapeutic DNA vaccine containing plasmids for E6 and E7 oncogenes for HPV-16/18 and IL-12 adjuvant, has been shown to be safe and to provoke an immune response against the expressed antigens. We tested MEDI0457 with the anti-PD-L1 antibody durvalumab for pts with recurrent or metastatic HPV-associated cancers with the goal of improving anti-tumor activity. **Methods:** Pts with HPV-16/18 cervical cancer or rare (anal, penile, vaginal, or vulvar) HPV- associated cancers that were recurrent and/or metastatic following standard therapies were eligible. No prior immunotherapy was allowed. Pts received 7 mg of MEDI0457 intramuscularly (weeks 1, 3, 7, 12, and every 8 weeks thereafter) and durvalumab 1500 mg intravenously every 4 weeks starting at week 4. The primary endpoint was best overall response according to RECIST 1.1. Adverse events (AE) were assessed using CTCAE v4.03. A Simon two-stage phase 2 trial (Ho: p < .15; Ha: p≥.35) using a one-sided alpha = .05 and beta = .20 was conducted. ≥2 responses were needed in both the "cervical" and non-cervical cohorts during the first stage in order for the trial to proceed. Median progression-free survival (PFS) and overall survival (OS) were estimated via Kaplan-Meier. **Results:** 41 pts were screened between 11/2018-10/2020. 21 pts (12 cervical, 7 anal, 2 penile) were treated. All 21 were evaluable for toxicity and 19 for response. Median age was 49 years (range, 29-75), and 18 (86%) were female. There were 17 squamous cell carcinomas (SCC) and 4 cervical adenocarcinomas. Grade ≥3 AEs occurred in 3 (14%) pts and included transaminitis, elevated lipase/amylase, hyponatremia, and neutropenia. No AE required study discontinuation. Overall response rate (ORR) was 21% (95% CI, 6-46%) and disease control rate (DCR) was 42% (95% CI, 20-67%). There was one patient with a complete response, 3 with partial response, and 4 with stable disease. All responses were noted among SCCs (1 cervical, 2 anal, 1 penile). Median duration of response among responders is 16 months (range, 11-27). Median PFS was 3.7 months (95% CI, 2.8-9.2), and median OS was 13.5 months (95% CI, 10.1-NA). 6-month PFS rate was 36% (95% CI, 20-65). **Conclusions:** The combination of MEDI0457 and durvalumab demonstrated acceptable safety/tolerability in pts with advanced HPV-16/18 cancers. Despite a clinically meaningful DCR, the low ORR among pts with cervical cancer led to study discontinuation for futility. Correlative studies are ongoing to characterize pts with prolonged disease control with study treatment. Clinical trial information: NCT03439085. Research Sponsor: AstraZeneca.

Preliminary data from QUILT 3.055: A phase 2 multi-cohort study of N803 (IL-15 superagonist) in combination with checkpoint inhibitors (CPI). *First Author: John M. Wrangle, Johns Hopkins Univ School of Medcn, Baltimore, MD*

Background: There is currently a paucity of treatment options for checkpoint relapsed patients who have had an initial response but subsequently progress. N803, a novel IgG1 Fc-engineered IL-15-complexed protein may rescue checkpoint activity in a checkpoint independent manner via its selective enhancement of natural killer cell (NK) and CD8+ T cell number and function, without stimulation of T regs and MDSCs. **Methods:** QUILT 3.055, (NCT03228667) a phase 2b study of N803 plus investigator choice CPI in 11 tumor types: NSCLC, SCLC, Urothelial carcinoma, HNSCC, Merkel cell carcinoma, Melanoma (single PD-1/PD-L1 CPI or w/ ipilimumab), Renal cell carcinoma (RCC), Gastric cancer, Cervical cancer, Hepatocellular carcinoma, Microsatellite instability-high (MSI-H)/ mismatch repair deficient (dMMR) solid tumors, with a heterogeneous mix of prior therapies. We present interim data for 135 patients treated with CPI alone or in combination with chemotherapy as their most recent prior therapy. Trial inclusion required investigator assessed progression on last line of therapy, patients had either CR with relapse or partial response or stable disease for 6 months with progression as their most recent result of checkpoint therapy. Patients with hyperprogression or best initial response of progression were excluded. Subjects received N803 15mck/kg SC q 3 weeks in combination with the same checkpoint inhibitor on which they had their most recent progression. **Results:** Preliminary data from 135 patients (60% NSCLC) with treatment with checkpoint and N-803 following progression on the same checkpoint show CR 0%, PR 8%, Stable Disease 51%, Progression 29%, response unevaluable 12% to date. A PR or SD was seen in all subgroups. Median PFS 3.9 months (95% CI: 2.6,5.0). Median OS 13.8 months (95% CI: 11.8, 16.3) N-803 is well tolerated with grade 1-2 common N-803 treatment related adverse events (TRAE) were injection site reaction (68%), chills (32%) fatigue (26%), pyrexia (26%), flu-like illness (14%), nausea (12%) and no other individual AE > 10%. Grade 3 N-803 TRAE were 12% but no individual grade 3 AEs were greater than 5%. **Conclusions:** N803 demonstrates low toxicity in patients previously treated with CPI and promising efficacy of cessation of progression and induction of response and durable stable disease in patients who had previously progressed on a CPI containing regimen in multiple tumor types and different CPIs. Clinical trial information: NCT03228667. Research Sponsor: ImmunityBio.

Evaluating the role of immune-checkpoint inhibitor (ICI) combinations in patients (pts) with unselected "cold" tumors enrolled in early clinical trials (CT). *First Author: Omar Saavedra, Department of Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: In order to improve the expected response rate (ORR) of less than 10% in cold tumors, several ICI combinations are being evaluated in clinical trials. However, most of these trials don't require any biomarker and pts are included based solely in histology. We aimed to assess the benefit of ICI combinations in pts with unselected cold tumors included in early CT. **Methods:** ICI naïve pts with cold tumors treated from 2015 to 2021 with ICI combinations in early CT at VHIO were reviewed. Clinico-pathological data and anti-tumor activity were extracted from a prospective database. ORR was defined as per RECIST v1.1 and clinical benefit rate (CBR) as complete/partial response (CR/PR) + stable disease (SD) for ≥ 4 months (m). Kaplan Meier estimates of progression-free survival (PFS) and overall survival (OS) were calculated and a Cox model according to LIPI (Lung Immune Prognostic Index = baseline LDH and derived neutrophil to lymphocyte ratio) was constructed. Immune-related adverse events (irAE) were classified as per CTCAE v.4.03. Hyperprogressive disease (HPD) was evaluated using RECIST v1.1 (Matos *et al,* 2020). **Results:** Out of 97 pts, median age was 62y, 61% had ECOG 0 and 29.8% had LIPI 0 (good prognostic score). Most pts had microsatellite stable (MSS) colorectal cancer (60.8%) or ovarian cancer (14.4%). Regimens included anti-PD1/L1 + another ICI in 69% (most commonly anti-LAG3 [26,8%] and CD40 agonist [20.9%]), anti-PD1/L1 + other molecule in 21.7% (most commonly SHP2 inhibitor [33.3%] and anti p53-HDM2 [28.5%]) and bispecific antibodies in 9.3% (anti-PD1/L1 + anti-LAG3 or CD137 agonist). No patient achieved a response. CBR was 15.3% (11 pts with MSS colorectal cancer, 2 ovarian cancer, 1 olfactory neuroblastoma, 1 paraganglioma). 33 pts (34%) presented irAE, 15 pts (15.5%) had irAE ≥ G2, 4 pts (4.1%) had G3 irAE (dry mouth, hypertransaminasemia, myocarditis and neutrophils count decreased) and 1 patient (1%) had G4 hyperglicemia. 58 pts (59.7%) had progressive disease (PD) as best response, 19 of these pts (32.7%) presented irAE. Overall, 20 pts (20.6%) met definition of HPD, representing 34.4% of pts with PD as best response. Median PFS for overall and CBR population were 1.9 m (CI95% 1.7-2.0) and 5.9 m (5.4-NR), respectively. Median OS for overall population was 7.6 m (5.9-9.5), with a trend for improved OS if LIPI good score vs. others (12.6 m vs. 6.2 m, hazard ratio 1.9, (CI 95% 1.1-3.3), p = 0.02). Among hyperprogressors, median OS was 5.33 m (3.39 - NR) and significantly worse LIPI scores (intermediate [1] or poor [2]) were observed as compared to pts with CBR (75% vs 53.3% p = 0.001). **Conclusions:** ICI combinations demonstrated very limited activity in pts with unselected cold tumors. However, the risk for irAE and HPD remain substantial. Further drug-biomarker co-development strategies are urgently needed to increase the risk benefit ratio for these pts. A pan-cancer analysis of MUC family genes as potential biomarkers for immune checkpoint therapy. *First Author: Yang Li, Department of Respiratory and Critical Care Medicine, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*

Background: Mucin (MUC) is a family of high-molecular weight glycoproteins and increased mucin production occurs in many malignant tumors. Recent studies have found relationship between mutations of some MUC family genes and efficacy of immunotherapy. Here, we explored the associations of MUC family genes (MUC2, MUC3A, MUC4, MUC5B, MUC6, MUC12, MUC16, MUC17, MUC19) mutation with ICI response based on multidimensional data from multiple solid tumors. **Methods:** 15 solid tumor types of TCGA genomic data for 6138 patients was used to evaluate tumor mutational burden (TMB) differences between MUC family genes mutation group and wildtype group. TMB was calculated as the total count of nonsynonymous mutations in coding sequence. Neoantigens of 3039 samples across 11 solid tumor types were obtained from The Cancer Immunome Atlas. A pan-cancer immunotherapy cohort (Broad/Dana-Farber, Nat Genet 2018, N = 249) was used to explore the relationship between mutations of MUC family genes and its efficacy of immunotherapy. **Results:** The most common mutated MUC genes (frequency > 5%) were MUC16 (25.3%), MUC17 (10.8%), MUC5B (10.5%), MUC4 (8.6%), and MUC2 (5.1%). The data between MUC mutation group and wild type group showed a significant difference ($P < 0.01$) in TMB. Median TMB across fifteen tumors in MUC mutation group and wild type group is 7.04 mutations per Mb and 2.07 mutations per Mb, separately. The TNB between two group is also showed a significant difference ($P < 0.01$). Median TNB across nine types tumor in MUC mutation group and wild type group is 121.5 neoantigens and 34.0 neoantigens, separately. A multivariable analysis across the pan-cancer cohort using Cox proportional-hazards regression demonstrated that KMT2C mutation was associated with better OS (hazard ratio, 0.66; 95%CI, 0.45-0.99; P = 0.042), adjusting for sex and cancer type. **Conclusions:** The results indicated that MUC family genes mutation was associated with a higher TMB and TNB. Analysis of immunotherapy cohort data showed MUC family was associated with better OS. These findings indicate that these genes mutation may serve as a predictive biomarker for ICI in solid tumor patients. Research Sponsor: None.

Real-world pan-cancer landscape of frameshift mutations (FSM) and their role in predicting responses to immune checkpoint inhibitors (ICI) in patients (pts) with tumors with low tumor mutational burden (TMB). *First Author: Vaia Florou, Huntsman Cancer Institute University of Utah, Salt Lake City, UT*

Background: Pembrolizumab was recently approved in tumors with TMB ≥10 mut/Mb. FSM can complement TMB in predicting ICI responses. We obtained a real-world dataset of genomic alterations from 250,813 samples to examine the distribution of TMB and FSM across a variety of malignancies. We then conducted a multi-institutional retrospective review of pts treated with ICI. **Methods:** Database samples were sequenced by Foundation Medicine using hybrid capture genomic profiling to evaluate all classes of genomic alterations in at least 315 genes. The clinical cohort included pts with metastatic solid malignancies who received ICI and had undergone commercial next-generation sequencing (NGS). Pts were classified into four distinct groups: TMB-L (< 10mut/Mb)/ FS-A (absent FSM), TMB-H (≥10mut/Mb)/ FS-A, TMB-L /FS-P (present, ≥1 FSM) and TMB-H/FS-P. Progression-free survival (PFS), overall survival (OS), and response rate (RR) were compared between the groups. **Results:** 246,252 MSS and 4,561 MSI-High samples were segregated by histology and divided into four distinct groups based on the TMB and FSM. For the MSS cohort the distribution was: TMB-L/FS-A (N = 111,065, 45%), TMB-H/FS-A(N = 15,313, 6%), TMB-L /FS-P (N = 98,389, 40%) and TMB-H/FS-P (N = 21,485, 9%). In the ICI-treated clinical cohort, there were 230 pts in 12 histology groups; 212 had information on TMB and FSM. The most common primary sites were GI (N = 39), melanoma (N = 37), GU (N = 32) and H&N cancer (N = 21). 159 pts received single ICI and 53 dual ICI. 196 tumors were MSS, 11 MSI, and 5 unknown. Group distribution: TMB-L/FS-A 80 pts (38%), TMB-L/FS-P 57pts (27%), TMB-H/FS-A 36pts (17%), TMB-H/FS-P 39pts (18%). FS-P was associated with higher RR 23.81 vs. 12.8 % (p = 0.02). Regardless of TMB, the median PFS for FS-P vs. FS-A was 7.9 and 4.0 mo, respectively ($p < 0.01$). TMB-L/FS-P had superior PFS (5.1 mo) compared to TMB-L/FS-A (3.6 mo) group ($p < 0.01$). The 15-month PFS probability was 12% for TMB-L/FS-A vs. 38% for TMB-L/FS-P. No statistically significant difference was detected in OS between the groups. From the pan-cancer cohort, histologies with more than 40% of samples in the TBM-L/FS-P (MSS) group were: CRC, RCC, PDAC, biliary, breast, esophageal, and endometrial cancers. Additional genomic data will be presented. **Conclusions:** FSM are frequently found on commercial NGS testing in tumors that are MSS and TMB-L. The presence of FSM may complement TMB in predicting benefit from immunotherapy. If validated in additional cohorts, FSM presence could be utilized to identify pts that may benefit from ICI, particularly for tumors with low TMB. Research Sponsor: None.

Association of KMT2C mutations with favorable outcomes with immune checkpoint inhibitors across multiple tumor types. *First Author: Chunling Liu, The Affiliated Tumor Hospital of Xinjiang Medical University, Urumchi, China*

Background: The KMT2 (lysine methyltransferase) family of histone modifying proteins play important roles in regulating developmental pathways, and mutations in the genes encoding these proteins have been strongly linked to many solid tumor cancers. Recently, there is emerging evidence that KMT2 family genes are involved in sensitivity to immune checkpoint inhibitors (ICIs) by modulating the immune environment. Here we explored the relationship between KMT2C mutation and its efficacy of immunotherapy. **Methods:** 1661 patients with next-generation sequencing (NGS) and immunotherapy data obtained from MSKCC clinical cohort were used to explore the association with KMT2C mutation and TMB and efficacy of ICIs. TMB was defined as the total number of somatic nonsynonymous mutations in the coding region. NGS data of 6624 pan-cancer patients who also detected MSI and PD-L1 expression from the Chinese clinical dataset were also analyzed relevance of mutation and these immune-related indicators. **Results:** In total, 9.81% (163/1661) patients in MSKCC cohort harbored KMT2C mutation. In the Chinese cohort, the KMT2C mutation ratio (11.19%, 741/6624) was similar to MSKCC. The TMB level of KMT2C mutation group in both MSKCC cohort and Chinese pan-cancer patient cohort was significantly higher than wild-type group ($P < 0.001$). A multivariable analysis across the pan-cancer cohort using Cox proportional-hazards regression demonstrated that KMT2C mutation was significantly associated with better OS (hazard ratio, 0.69; 95%CI, 0.52-0.90; P = 0.006), and association remained significant with bladder (P = 0.039), colorectal (P = 0.024), melanoma ($P < 0.001$) and renal ($P < 0.001$), adjusting for cancer age, sex, metastases or primary. In addition, in Chinese cohort, KMT2C mutation was associated with higher PD-L1 positive expression (≥1%) (P = 0.01203) and MSI-H ($P < 0.001$). **Conclusions:** KMT2C mutation shows impressive association with efficacy of ICIs. Meanwhile, KMT2C-mutant group has a higher TMB, PD-L1 expression and MSI-H. These results indicated that KMT2C mutation may serve as a good potential biomarker of ICI benefit in patients with multiple cancer types. Research Sponsor: None.

MSIFinder: A python package for detecting MSI status using random forest classifier. *First Author: Tao Zhou, AcornMed Biotechnology Co., Ltd., Beijing, China*

Background: Microsatellite instability (MSI) is a common genomic alteration in several tumors, such as colorectal cancer, endometrial carcinoma, and stomach, which is characterized as microsatellite instability-high (MSI-H) and microsatellite stable (MSS) based on a high degree of polymorphism in microsatellite lengths. MSI is a predictive biomarker for immunotherapy efficacy in advanced/metastatic solid tumors, especially in colorectal cancer (CRC) patients. Several computational approaches based on target panel sequencing data have been used to detect MSI; However, they are considerably affected by the sequencing depth and panel size. **Methods:** We developed MSIFinder, a python package for automatic MSI classification, using random forest classifier (RFC)-based genome sequencing, which is a machine learning technology. We included 19 MSI-H and 25 MSS samples as training sets. First, RFC model were built by 54 feature markers from the training sets. Second. The software was validated the classifier using a test set comprising 21 MSI-H and 379 MSS samples. **Results:** With this test set, MSIFinder achieved a sensitivity (recall) of 0.997, a specificity of 1, an accuracy of 0.998, a positive predictive value (PPV) of 0.954, an F1 score of 0.977, and an area under curve (AUC) of 0.999. We discovered that MSIFinder is less affected by low sequencing depth and can achieve a concordance of 0.993, while exhibiting a sequencing depth of 100×. Furthermore, we realized that MSIFinder is less affected by the panel size and can achieve a concordance of 0.99 when the panel size is 0.5 m (million base). **Conclusions:** These results indicated that MSIFinder is a robust MSI classification tool and not affected by the panel size and sequencing depth. Furthermore, MSIFinder can provide reliable MSI detection for scientific and clinical purposes. Research Sponsor: None.

Summary of classification performance of MSIFinder, mSINGS and MSIsensor.

Tools	Sen.	Spe.	Acc.	PPV	F1	AUC
MSIFinder	0.997	1.000	0.998	0.954	0.977	0.9999
msings	0.983	0.950	0.981	0.730	0.826	0.985
MSIsensor	0.959	0.944	0.958	0.586	0.723	0.985

Sen: Sensitivity; Spe: Specificity; Acc: Accuracy; PPV: positive predictive value; F1: F1 score; AUC: Area Under Curve.

A cancer organogram test as a guide for oncology treatments in SOLID tumors: An analysis of 628 tests in 419 patients. *First Author: Astrid Margossian, SEngine Precision Medicine, Seattle, WA*

Background: A CLIA-certified organoid based drug sensitivity assay (a cancer organogram) has been developed for all solid tumors. An actionable report of organogram sensitivities to endocrine, chemotherapy and targeted agents, produced a drug sensitivity score as a tool to inform therapy decision making. Objectives: To evaluate the success rate of organoid derivation, the organogram drug responses across cancer types and to analyze the impact of the organogram report on therapeutic decision making. **Methods:** From 2016 to 2020, 628 cancer organograms were performed, with 513 tumor samples from 419 cancer patients. Within 48 hours of collection, fresh samples of tumor cells obtained from core biopsies, surgical excisions, or fluids were cultured, the majority as 3D organoids. Drug screens were performed with a library of up to 220 drugs, and dose-response was evaluated across a range of concentrations for each drug. Organogram sensitivity was ranked as response in five categories based on SPM Score: Exceptional (SPM15/14), Good (13/12), Moderate to Low (11/9), and None(< 9). 118 drugs on average were tested per screen (range: 68-152), so in a total of 628 organograms, more than 70,000 individual drug trials have been performed. The median turnaround time was 28 days (range: 19.5-51.5). **Results:** Of the 513 collected samples, 314 were fresh specimens: 96 core biopsies, 151 surgical specimens, and 67 fluids (pleural effusions or ascites), with an organoid derivation success rate of 58.3%, 78%, and 88%, respectively. Overall success rate in organoid derivation was 70.2%. Samples with poor viability and low tumor cell count (22%) were rejected. The primary cancer types tested were ovarian (n = 92, 17.9%), breast (n = 73, 14.2%), colorectal (n = 70, 13.6%), pancreatic (n = 51, 9.9%), cholangiocarcinoma (n = 42, 8.1%), and other solid tumors (n = 185, 36%). Median age of patients was 56 years old (range: 5-83), most of them heavily pretreated. 20.45% of drugs screened had exceptional and good responses (SPM score 15-12) (SD: 17.92%). We reviewed genomic data from 374 third-party genomic reports. The most frequent genomic alterations found were *TP53* (n = 143, 38.2%), *BRCA1* and *BRCA2* (n = 47, 12.5%) *CDKN2A* (n = 42, 11.2%), *FGFR1/2/3/4* (n = 41, 10.9%), and *PIK3CA* (n = 38, 10.1%). Post-test treatment information is available for a subset of 61 patients. The treating physician made an organogram-guided therapeutic decision in 32/44 patients with post test treatment drugs scored (72%). **Conclusions:** The cancer organogram test has a high rate of success in generating an actionable report that identifies therapies for patients with limited therapeutic options, including those with no known genomic biomarkers. The organogram guided selection of therapeutics for a significant subset of patients, nearly 4 times the rate reported with genomic testing alone. Research Sponsor: Sengine Precision Medicine.

Relationship between DICER1 mutations and immunotherapy biomarkers in solid tumors. *First Author: Jie Gao, The Department of Hepatobillary Surgery, Peking University People's Hospital, Beijing, China*

Background: Dicer1 functions as a tumor suppressor in mouse models. In humans, somatic mutations are associated with many cancers in adults, and patients with DICER1 syndrome with *DICER1* germline mutations are susceptible to childhood cancers. *DICER1* is the core caner-intrinsic CTL-evasion gene, especially positive correlate with innate anti-PD-1 resistance signature or IPRES signature and hERV expression which involved in sensitivity and resistance to ICIs. Nevertheless, the association between mutations in *DICER1* and the Chinese patients, the relationship between *DICER1* mutations with immunotherapy biomarkers are unknown. **Methods:** NGS and clinical data were collected from 10953 Western pan-cancer patients (TCGA cohort). A 539-gene panel targeted sequencing assay was performed on FFPE tumor samples from 3514 Chinese pan-cancer patients (Chinese cohort). Both *DICER1* mutation ratio and TMB were calculated on the two cohorts following the same criteria.DNA NGS testing (MSI-high vs low/stable (MSS)) in Chinese cohort were included. NGS data of 3514 patients who also detected PD-L1 expression from Chinese clinical dataset were analyzed to explore the association with mutation and PD-L1. The survival information was collected from 1661 pan-cancer patients to analyze the association between *DICER1* mutation and efficacy of immunotherapy (MSKCC cohort). **Results:** In total, 2.91% (319/10953) patients in TCGA harbored *DICER1* mutation; in the Chinese cohort, the *DICER1* mutation ratio (2.67%, 94/3514) was similar to TCGA. The top 5 mutant *DICER1*-associated cancer types in Chinese cohort were lung cancer, colon adenocarcinoma, liver cancer, uterine corpus endometrial carcinoma , melanoma. In both cohorts, TMB level of mutation group was significantly higher than wild-type group ($p < 0.001$). The ration of mutation group in MSI-H (50%) and MSI-L (23.53%) was significantly higher than wild-type group in Chinese cohort (2.17%) ($p < 0.001$). In addition, the ratio of PD-L1 positive expression ($\geq$1%) in mutation group (48.94% , 46/48) was significantly higher than wild-type in Chinese cohort (38.48% ,1316/2104) ($p < 0.05$). The survival probability of mutation group was significantly longer than wild-type group in immunotherapy. **Conclusions:** The results indicated that *DICER1* mutation was associated with a higher TMB, MSI-H and PD-L1 expression level in Chinese patients. Patients with *DICER1* mutations may benefit more from ICIs. Research Sponsor: None.

YAP1 mutation as a novel predictor of response to anti-PD-1/PD-L1 treatment in pan-cancers. *First Author: Wei-guo Xu, Department of Respiratory and Critical Care Medicine, Mianyang Central Hospital, Mianyang, China*

Background: YAP1 is the main downstream target of the Hippo pathway and acts as a transcriptional coactivator to regulate development processes. YAP1 amplification is a potentially useful biomarker for predicting treatment outcomes and identifying patients with a high risk of relapse who should be closely monitored in nonsurgical esophageal squamous cell carcinoma (ESCC). YAP1 overexpression has been identified in multiple solid cancers, which consistently correlated with unfavorable clinical outcomes. Previous work suggested that YAP1 alterations may enrich for responses to immune checkpoint inhibitors (ICI), validation of these findings in needed. **Methods:** Using 539-gene target-capture next generation sequencing, we analyzed the YAP1 mutation in 3547 tumor tissue or plasma ctDNA samples from different patients, and the public database of TACG was also compared. Data from MSK-IMPACT study (n = 1661, anti-PD-(L)1/CTLA-4 mono/ combined therapy) was retrieved and analysed. In survival analysis, Kaplan-Meier curves were compared by log-rank test, and the hazard ratio (HR) was determined through a multivariable Cox regression model. **Results:** In clinical cohort, the frequency of YAP1 mutation in 3547 tumor tissue or plasma ctDNA samples from different patients was 0.62 % (22 in 3547). Meanwhile, the frequency of YAP1 mutation in TCGA cohort was 0.90 % (99 in 10953). We further analyzed Kaplan-Meier curves from MSK-IMPACT study (n = 1661, anti-PD-(L)1/CTLA-4 mono/ combined therapy). In MSK-IMPACT cohort, mutation of YAP1 was associated with higher TMB ($P = 0.022$) and higher mutation count ($P = 0.017$) in pan-cancers. YAP1 mutation was associated with prolonged overall survival (OS) trend compared with YAP1 wt in pan-cancers ($P = 0.15$; HR, 2.209, 95% CI, 0.7109-6.8639). **Conclusions:** In our study, the frequency of YAP1 mutation was investigated in clinical and TCGA cohort, which might provide useful information to guide precision medicine. YAP1 mutation may serve as a novel predictor of response to anti-PD-1/PD-L1 treatment in pan-cancers via upregulating TMB and mutation count. Research Sponsor: None.

Pan-cancer analysis of *CD274* (PD-L1) mutations in 314,631 patient samples and subset correlation with PD-L1 protein expression. *First Author: Richard S.P. Huang, Foundation Medicine, Inc, Cambridge, MA*

Background: The effects of non-amplification short variant (SV) mutations in *CD274 (PD-L1)* on PD-L1 protein expression and immune checkpoint inhibitor (ICPI) therapy are unknown. Here, we present a retrospective analysis of *CD274* mutations detected by comprehensive genomic profiling (CGP) and correlate these results with tumor-cell PD-L1 immunohistochemistry (IHC)-based expression assessment to better understand the relationship between mutations and protein expression of PD-L1. **Methods:** FoundationOne CGP was performed on hybridization-captured, adaptor ligation-based libraries using DNA and/or RNA extracted from 314,631 tumor samples that were sequenced for up to 406 cancer related genes and select gene rearrangements. PD-L1 IHC was performed on a subset of cases (n = 213) using the DAKO 22C3 PD-L1 IHC assay and scored with the tumor proportion score (TPS). **Results:** Overall, the prevalence of *CD274* SV mutations was low (0.3%, 1,081/314,631) with 577 unique variants. The most common *CD274* SV mutations were R260H (n = 51), R260C (n = 18), R125Q (n = 12), C272fs*13 (n = 11), R86W (n = 10), and R113H (n = 10). The prevalence of *CD274* mutations varied depending on tumor type with diffuse large B-cell lymphoma (1.9%, 19/997), cutaneous squamous cell carcinoma (1.6%, 14/868), endometrial adenocarcinoma (1.0%, 36/3740), unknown primary melanoma (0.9%, 33/3679), and cutaneous melanoma (0.8%, 32/3874) having the highest frequency of mutations. Ultraviolet exposure was likely a mechanism for *CD274* SV mutations in cutaneous tumors with high frequencies of ultraviolet mutational signatures (cutaneous squamous cell carcinoma [84.6%, 11/13], cutaneous melanoma [93.8%, 30/32], and unknown primary melanoma [100%, 32/32]), and microsatellite instability (MSI) was likely a mechanism for development of *CD274* mutations in non-serous endometrial adenocarcinoma. Of the R260H cases concurrently tested with PD-L1 IHC, most (81.8%, 9/11) had no PD-L1 expression, which contrasts to the five E237K cases where most (80%, 4/5) had PD-L1 expression. This difference in protein expression of these two mutations was significantly different (p = 0.036). It was notable that nearly all samples (88.9%, 16/18) with a clonal truncating variant (nonsense or frame shift indel) and PD-L1 testing showed a PD-L1 TPS score $\leq$1, whereas three of four samples with sub-clonal truncating variants had TPS scores $\geq$5. **Conclusions:** We defined the landscape of *CD274* mutations in a large cohort of tumor types that can be used as a reference for examining *CD274* mutations as potential resistance biomarkers for ICPI. Furthermore, we presented novel data on the correlation of *CD274* mutations and PD-L1 protein expression, providing important new information on the potential functionality of these mutations and can serve as a basis for future research. Investigating the various predictive values of *POLE/POLD1* mutations for response to immune checkpoint inhibitors (ICIs) in different solid tumors. *First Author: Yanling Niu, Genetron Health (Beijing) Technology, Co. Ltd., Beijing, China*

Background: Both POLE and POLD1 encode the catalytic subunit of polymerase enzyme complexes involved in DNA replication and repair. The mutations of *POLE* and *POLD1* have been shown to be oncogenic and lead to DNA repair defects and elevated tumor mutation burden (TMB). And patients with *POLE/POLD1* mutations are more likely to benefit from ICIs therapy. Previous studies have shown that TMB has divergent predictive value for response to ICIs therapy in different cancer types. We hypothesized that the associations between *POLE/POLD1* mutations and ICIs efficacy are also varied in different solid tumors. Therefore, we explored the prediction values of *POLE/POLD1* mutations in some cancer types. **Methods:** The ICIs treatment cohort from Memorial Sloan Kettering Cancer Center (MSKCC) was selected to analyze the association of *POLE/POLD1* mutations with ICIs efficacy. TCGA cohort was enrolled for characterizing tumor infiltrating lymphocytes (TILs) with CIBERSORT. The patients were classified into two groups: *POLE/POLD1* mutations (Mut) and wildtype (WT). Overall survival (OS) after ICIs therapy was estimated with Kaplan-Meier method. **Results:** In MSKCC pan-cancer dataset, patients with *POLE/POLD1* mutations had significantly longer median OS after ICIs therapy (34.00 vs 19.00 months, P = 0.0143), indicating that *POLE/POLD1* mutations were associated with better immunotherapy outcomes. Then we analyzed the predictive roles in each cancer type. Notably, we found the associations of *POLE/POLD1* mutations with longer median OS in NSCLC (Undefined vs 12.00 months, P = 0.05) and esophagogastric cancer (27.00 vs 15.00 months, P = 0.05). However, the associations between *POLE/POLD1* mutations and ICIs efficacy were not observed in bladder cancer, melanoma, glioma, head and neck cancer, renal cell carcinoma, and colorectal cancer. Furthermore, our data showed that the median TMB was significantly higher in the Mut group for NSCLC (20.2 vs 6.9 muts/Mb, P $<$ 0.0001) and esophagogastric cancer (21.4 vs 5.6 muts/Mb, P $<$ 0.0001). In TCGA esophagogastric cancer cohort, *POLE/POLD1* mutations were correlated with decreased naive B cells (P = 0.0306) and increased activated memory CD4+ T cells (P = 0.0224). In TCGA NSCLC cohort, *POLE/POLD1* mutations were correlated with elevated gamma delta T cells (P = 0.0219). These data suggested that *POLE/POLD1* mutations were also involved in the infiltration of some immune cells. **Conclusions:** Although *POLE/POLD1* mutations were associated with better ICIs efficacy for all the enrolled patients, the prolonged OS was only found in the Mut group for NSCLC and esophagogastric. These data suggested that *POLE/POLD1* mutations may be a useful predictor for ICIs efficacy in these two types of cancer. Moreover, *POLE/POLD1* mutations were correlated with the level of TILs in NSCLC and esophagogastric. The finding was consistent with the efficacy of immunotherapy. Research Sponsor: None.

Artificial intelligence-powered spatial analysis of tumor-infiltrating lymphocytes predicts survival after immune checkpoint inhibitor therapy across multiple cancer types. *First Author: Jeanne Shen, Department of Pathology, Stanford University School of Medicine, Stanford, CA*

Background: Tumor infiltrating lymphocytes (TIL) are a potential tumor-agnostic biomarker for immune checkpoint inhibitor (ICI) therapy. We previously reported the clinical application of an artificial intelligence-powered spatial TIL analyzer, Lunit SCOPE IO, for predicting ICI treatment outcomes in advanced non-small cell lung cancer (NSCLC). Here, we expand the clinical application of Lunit SCOPE IO as a tumor-agnostic ICI biomarker across multiple cancer types. **Methods:** Lunit SCOPE IO was trained and validated with a 2.8 x 10^9 micrometer^2 area and 5.9 x 10^6 TILs from 3,166 H&E Whole-Slide Images (WSI) of multiple cancer types, annotated by 52 board-certified pathologists. The Inflamed Score (IS) was defined as the proportion of all tumor-containing 1 mm^2-size tiles within a WSI classified as being of the inflamed immune phenotype (high TIL density within cancer epithelium). We first evaluated the correlation between the IS and TMB, MSI-H, and immune cytolytic activity (*GZMA* and *PRF1*) across 22 cancer types from The Cancer Genome Atlas (TCGA, n = 7,467). Subsequently, the correlation between the IS and overall survival after ICI treatment was evaluated in a real-world dataset of patients with 9 different tumor types (n = 1,013), retrospectively collected from Stanford University Medical Center, Chonnam National University Hospital, Samsung Medical Center, and Seoul National University Bundang Hospital. **Results:** Lunit SCOPE IO accurately detected CE, CS, and TILs with an area under the receiver-operating-characteristic curve of 0.970, 0.949, and 0.925, respectively. In the TCGA pan-cancer cohort, Lunit SCOPE IO's IS correlated significantly with immune cytolytic activity (Spearman rho = 0.504, $p < 0.001$), TMB-high ($\geq$ 10 mutations/Mb, fold change 1.39, $p < 0.001$) and MSI-H (fold change 1.45, $p < 0.001$). The IS-positive proportions of microsatellite-stable (MSS) and TMB-low cases were 42.5% and 17.1%, using the thresholds of IS $\geq$ 20% and $\geq$ 50% as presumptive clinical cutoffs. In the real-world ICI clinical dataset (n = 1,013), an IS $\geq$ 20% correlated significantly with favorable overall survival after ICI treatment (cancer type-adjusted hazard ratio [HR] 0.70, 95% confidence interval [CI] 0.59-0.83, $p < 0.0001$). Furthermore, this association remained significant after the exclusion of NSCLC patients (n = 519) (adjusted HR 0.68, 95% CI 0.53-0.86, $p = 0.0016$) indicating that the effect was not driven solely by one major tumor type. **Conclusions:** The Inflamed Score (IS), as evaluated by Lunit SCOPE IO, correlates with favorable overall survival after ICI treatment across multiple tumor types. AI-powered spatial TIL analysis of the tumor microenvironment may be able to detect a significant proportion of ICI responders, and offers promise as a new companion diagnostic, particularly in patients with MSS/TMB-low tumors. Research Sponsor: Lunit Inc.

Awareness and utilization of tumor mutation burden (TMB) as a biomarker for administration of immuno-oncology (I-O) therapeutics by practicing community oncologists in the United States (U.S.). *First Author: Kristin M. Zimmerman Savill, Cardinal Health, Dublin, OH*

Background: TMB, a measurement of the number of mutations carried by tumor cells, is emerging as a biomarker for the identification of patients who may benefit from certain I-O-based therapies. TMB-high (TMB-H) tumors, defined by the detection of $\geq$10 mutations/megabase (mut/Mb) in tumor cells using a tissue-based assay such as the FoundationOneCDx (F1CDx) assay (Foundation Medicine, Inc.), may be more likely to respond to some I-O therapies. Higher neoantigen loads of TMB-H tumors have been proposed to contribute to increased responsiveness of TMB-H tumors to certain I-O therapeutics. Pembrolizumab was approved by the FDA on June 16, 2020 for the treatment of adult and pediatric patients with unresectable or metastatic TMB-H tumors, as determined by F1CDx, based on results from the KEYNOTE-158 trial (NCT02628067), which demonstrated that 50% of patients with TMB-H tumors had response durations of $\geq$24 months, with objective response rates in TMB-H vs. non-TMB-H patients of 29% and 6%, respectively (Marabelle et al, The Lancet Oncology, 2020). This survey-based study aimed to evaluate awareness and utilization of TMB as a biomarker for I-O therapeutics among practicing community oncologists in the U.S. **Methods:** Questions related to awareness and utilization of TMB as a biomarker for I-O therapeutics were developed by two medical oncologists (AG and BF) and presented to community oncologists in a web-based survey prior to virtual meetings held between October and November 2020. Descriptive statistics were used to analyze the results. **Results:** Of the 193 participating providers geographically distributed across the U.S., 15% reported being unaware of either the concept of TMB in I-O therapy or how to use the information clinically. 39% of these providers reported testing $\leq$25% of patients with advanced cancer for TMB, including 8% who do not test for TMB at all. Misconceptions regarding TMB identified among participating providers included the belief that high TMB is considered to be $>$ 5 mut/Mb among 20% of providers, that TMB is essentially the same as MSI-high among 8% of providers, and that there are no therapies with FDA approval based on TMB among 15% of providers. Further, 37% of the participants did not identify pembrolizumab as an agent approved for the treatment of solid tumors based on TMB-H status. **Conclusions:** These findings demonstrate that there is a knowledge gap regarding the definition of TMB, testing for TMB, as well as implementation of TMB status in clinical decision making. Education directed towards community oncology providers regarding TMB and its use as a predictive biomarker for I-O therapy may improve its utilization and adoption in solid tumors to improve patient outcomes. Research Sponsor: Cardinal Health.

Comprehensive genomic and transcriptomic profiling (CGTP) to predict pembrolizumab (P) benefit in patients (pts) with advanced solid tumors (STs). *First Author: Dan Rhodes, Strata Oncology, Ann Arbor, NC*

Background: P is approved in many ST types, however predictive biomarkers and the proportion of pts who benefit vary widely. Biomarkers beyond PD-L1 immunohistochemistry and comprehensive genomic profiling (CGP) based tumor mutation burden (TMB) may improve benefit prediction. We determined if treatment data and CGTP collected in an ongoing observational trial (NCT03061305) could predict pan-ST P benefit. **Methods:** Eligible advanced ST pts had QC-passing TMB and expression data from multiplex PCR based tissue CGTP on FFPE tissue (StrataNGS and an investigational test) and documented P treatment $>$ 1 month. Real-world time to next treatment (TTNT) was defined as time in months from therapy start to new therapy start (after stopping initial therapy) or death. TMB and gene expression biomarker association with P TTNT was evaluated. Backward stepwise regression was performed to fit a multivariate Cox proportional hazards model; pts were assigned to four score groups (IRS 1-4) based on overlapping TTNT curves from 8 equal bins. P TTNT were compared between IRS groups by log-rank test. A chemotherapy (C) comparator cohort was established from C TTNT for pts in this cohort. Results were stratified by ST type, P mono vs. C combo, and TMB status. **Results:** 610 pts (254 [41.6%] NSCLC; 356 [58.4%] from 23 other ST types) with CGTP and P treatment were identified; P TTNT was highly correlated to overall survival (n=146; Pearsons r^2=0.75). By univariate analysis of TMB and 9 expression biomarkers, TMB, two independent *PD-L1* expression amplicons, and *PD-L2* expression were significantly associated with P TTNT (all $p \leq 0.002$). The most significant multivariate model included 5 variables, with 1) increasing TMB, *PD-L1*, and *PD-L2*, and 2) decreasing *TOP2A* (proliferation) and *GZMA* as P TTNT predictors. Median P TTNT, but not C TTNT (345 courses from 254 pts), differed significantly by IRS group (Table). Median P TTNT by IRS group did not significantly differ by non-small cell lung vs. other ST type or P mono vs. C combo (both $p > 0.05$); excluding TMB-high patients, median P TTNT was still significantly longer in IRS groups 3/4 vs. 1/2 (p = 5.0e-4). Across 19,623 total evaluable pts in NCT03061305, 12.2% were in IRS groups 3/4 and outside of P approved ST types/TMB-low. **Conclusions:** CGTP in an observational trial cohort demonstrated that TMB, *PD-L1* and *PD-L2* independently predicted pan-ST P benefit as assessed by OS-validated TTNT. A multivariate CGTP signature predicted P benefit relative to C across ST types. If further validated, such a signature may enable improved P benefit prediction. P versus C TTNT by IRS group. Clinical trial information: NCT03061305. Research Sponsor: Strata Oncology.

YAP1 transcription factor expression to define subsets of cancers with T-cell inflamed phenotype in a pan-tumor analysis across 33 tumor types. *First Author: Bhakti Dwivedi, Emory University Department of Biostatistics and Bioinformatics, Atlanta, GA*

Background: Immune checkpoint blockade (ICB) has become an established treatment option for the majority of solid tumors. PD-L1 expression, tumor mutation burden (TMB) and mismatch repair (MMR) deficiency are established but suboptimal predictive markers to select patients for ICB therapy. The identification of better predictive biomarkers to complement existing biomarkers is an area of need. We previously identified Yes Associated Protein 1 (YAP1) gene expression as a marker of inflamed tumor phenotype in small cell lung cancer. We sought to elucidate the role of YAP1 as a tumor agnostic biomarker of inflamed tumor phenotype. **Methods:** We obtained the publicly available TCGA normalized RSEM expression data (version dated September 29, 2019) from the GDC legacy archive (https://portal.gdc.cancer.gov/legacy-archive) for this analysis. We used the shinySISPA method (https://bbisr.shinyapps.winship.emory.edu/shinySISPA/) to classify the primary tumor samples into YAP1 high or low on the basis of the normalized expression profile for YAP1 gene. The T-cell–inflamed gene expression profile score for each sample was calculated as weighted sum of the normalized expression values of the 18 genes (*PSMB10, HLA-DQA1, HLA-DRB1, CMKLR1, HLA-E, NKG7, CD8A, CCL5, CXCL9, CD27, CXCR6, IDO1, STAT1, TIGIT, LAG3, CD274, PDCD1LG2, CD276*) as originally published in the Patent filed under "WO201609437" and validated as a predictor of clinical efficacy in patients treated with anti PD1 immunotherapy drug, pembrolizumab. **Results:** A total of 11283 samples from 33 different histologic tumor types contained in the TCGA database were included in this analysis. A small but meaningful subset of cases 271 (2%) were classified as YAP1 high with a wide range in proportion of YAP1 high tumors of 0.67% to 12.09% across the 33 histologic tumor types. Adrenocortical, cholangiocarcinoma, chromophobe RCC, DLBCL, and mesothelioma had a high rate of YAP1 high tumors ($>$ 10% of cases) . Overall trend showed a higher median interferon gamma GEP score in YAP1 high versus YAP1 low tumors with a GEP score of 11.2 vs. 10.7 respectively. A minority of histologic tumor subtypes (HNSCC, clear cell RCC, sarcoma, uterine carcinosarcoma, testicular GCT, melanoma, mesothelioma and ovarian cancer) showed a reverse trend of lower GEP score in association with YAP1 high status. Ongoing validation of these findings in an independent cohort of clinical samples and correlation of YAP1 status with other predictive biomarkers (TMB, PD-L1 and MSS status) will be presented at the meeting. **Conclusions:** YAP1 is highly expressed in a small but meaningful subsets of cancers and is associated with the inflamed phenotype in the majority of cancers. YAP1 expression is most common in rarer tumor types and in histologic types where currently available biomarkers have not been shown to predict the benefit of ICB. Research Sponsor: U.S. National Institutes of Health.

Therapeutic effect of DDR pathway with different functional annotations for immune checkpoint inhibitor. *First Author: Wei Nie, Shanghai Chest Hospital, Shanghai, China*

Background: DNA damage response and repair (DDR) pathway-related gene mutations have been reported to predict the efficacy of immune checkpoint inhibitor (ICI). However, therapeutic effect of DDR pathway with different functional annotations is not fully studied. Here we explore the relationship of DDR pathway with different functional annotations and clinical outcomes in public cohorts of immunotherapy and chemotherapy. **Methods:** Genetic testing and clinical outcomes data were obtained from the public clinical cohorts across 10 tumor types. 232 DDR pathway-related gene were assigned to eight pathway according to the literature. Nine predictive models for the mutation pathogenicity were included in the analysis, of which at least five returned positive results were defined as deleterious mutations. All annotations were according to the American College of Medical Genetics (ACMG) standards and guidelines. To explore the association between DDR pathways and ICI, DDR pathway mutation is grouped. Patients, who harbored mutations in two or more DDR pathways and meanwhile had deleterious mutation in at least one DDR pathway, were enrolled in group A. Patients, who harbored deleterious mutations in only one DDR pathway or had only uncertain significance mutations, were enrolled in group B. Patients with no DDR gene mutations were enrolled in Group C. We analyzed relation of the group and survival outcomes in four public cohorts. **Results:** Of 4 clinical cohort analyzed, the group A treated with ICI has the best PFS or OS outcomes. However, the comparison of group B and group C is not coincide across different cohorts. Treatment is the key factor that influents the relation of DDR pathway mutations and clinical outcomes. As shown in POPLAR/OAK cohort, patients in group C has the best PFS (p=0.0381) or OS (p=0.0350) outcome when treated with chemotherapy, but patients in group A has the best PFS (p=0.0083) or OS (p=0.0222) outcome when treated with ICI. **Conclusions:** When treated with ICI, patients with at least one deleterious mutation and another deleterious or uncertain significance mutation has the best PFS or OS outcomes, but not for chemotherapy. Our study suggested that DDR pathway with deleterious mutations might be a potential predictive factor for immunotherapy. Research Sponsor: None.

First-in-human, phase I study of PF-06753512, a vaccine-based immunotherapy regimen (PrCa VBIR), in biochemical relapse (BCR) and metastatic castration-resistant prostate cancer (mCRPC). *First Author: Karen A. Autio, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Therapeutic vaccines targeting PC-associated antigens represent attractive approaches in combination with immune checkpoint inhibitors (ICI). Safety/antitumor activity of PF-06753512 (PrCa VBIR) was evaluated in a phase I, dose-escalation and expansion study in patients (pts) with BCR prior to ADT and in pts with mCRPC either prior to or after failure of novel hormone therapy. PrCa VBIR consists of: 1) priming immunization with a replication-deficient adenoviral vector (AdC68) expressing PSA, prostate-specific membrane antigen and prostate stem cell antigen; 2) boosts with plasmid DNA (pDNA) encoding the same antigens by IM electroporation; 3) ICI given subcutaneously, including anti CTLA-4 antibody tremelimumab (TRM) and anti PD-1 antibody sasanlimab (SSL). **Methods:** AdC68 ± ICI(s) were given on months (mos) 1 and 5 and pDNA ± ICI(s) on mos 2–4 and 6–8. After 8 mos, maintenance pDNA + ICI(s) were given every 1 or 2 mos. In Part A (6 escalation cohorts), pts with mCRPC received AdC68 (4 or 6x10e11 viral particles) + pDNA 5 mg ± ICIs (TRM alone 80 mg; TRM 40 or 80 mg + SSL 130 or 300 mg). In Part B (3 expansion cohorts), pts with mCRPC received AdC68 6x10e11 + pDNA 5 mg + TRM 80 mg + SSL 300 mg; pts with BCR received similar vector and pDNA + TRM 80 mg ± SSL 130 mg. Primary objectives: Assess overall safety (CTCAE v4.03), determine expansion dose. Secondary objectives: Anti-tumor activity (RECIST v1.1, Prostate Cancer Working Group 3, PSA 50 response) and immune response. (Note: Database remains open, some queries pending). **Results:** As of Sept 15, 2020, 91 pts were treated in dose-escalation (n=38) and expansion (n=53; BCR=35, mCRPC=18). Immune responses (ELISpot) were positive in some pts. Grade (G) 3 or 4 treatment-related adverse events (TRAEs) developed in 38.5% (35/91) of pts. G5 TRAEs occurred in 2 pts (n=1 G4 myasthenia gravis + G5 pulmonary embolism; n=1 G5 myocarditis). irAEs were more frequent in BCR compared to mCRPC. See the table for efficacy data. **Conclusions:** Vaccination with PrCa VBIR had a manageable safety profile. TRAEs increased when 2 ICIs were given. Some pts with BCR experienced durable PSA-50 responses without ADT; patients with mCRPC had few objective tumor responses, but had prolonged median rPFS. PrCa VBIR appears to stimulate antigen-specific immunity and results in noticeable antitumor activity, particularly in androgen sensitive disease. Clinical trial information: NCT02616185. Research Sponsor: Pfizer.

2613 **Poster Session**

Long term results from a phase 1 trial of GEN-009, a personalized neoantigen vaccine, combined with PD-1 inhibition in advanced solid tumors. *First Author: Maura L. Gillison, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: GEN-009 is an adjuvanted personalized cancer vaccine containing up to 20 neoantigens selected by ATLAS, an *ex vivo* bioassay screening autologous T cells for immune responses against both neoantigens as well as Inhibigens. Inhibigen-specific T cells suppress immunity and have been shown to accelerate tumor progression in mice and are avoided in GEN-009. In cohort A, all patients immunized in the adjuvant setting with GEN-009 monotherapy developed immune responses. Nearly all (99%) of selected peptides were immunogenic: *ex vivo* $CD4^+$ and $CD8^+$ fluorospot responses specific for 51% and 41% of immunized peptides, respectively. Seven of 8 patients continue without progression with a median follow up of 18 months. **Methods:** GEN-009 is being evaluated in patients (pts) with advanced cancer who received standard-of-care (SOC) PD-1 inhibitor as monotherapy or in combination therapy during vaccine manufacturing. Five vaccine doses were administered over 24 weeks in combination with a PD-1 CPI. Patients who progressed prior to vaccination received alternative salvage therapy followed by GEN-009 in combination. Peripheral T cell responses were measured by fluorospot assays in *ex vivo* and *in vitro* stimulation. **Results:** 15 pts received GEN-009 in combination with a PD-1 inhibitor; 1 patient received GEN-009 monotherapy. Median number of neoantigens per vaccine was 14 (5-18). GEN-009-related adverse events were limited to vaccine injection site reactions and mild myalgias or fatigue. Longitudinal evaluation of *ex vivo* T cell responses revealed that sequential vaccination with GEN-009 had an overall additive effect on the robustness of IFNγ secretion and responses were persistent for at least 6 months in some patients. Epitope spread was detected in CPI sensitive patients, but not in CPI refractory patients receiving salvage therapy. Three patients who responded to PD-1 inhibition followed by disease stabilization then demonstrated further reduction after GEN-009 vaccination that could represent vaccine effect. Eight of 9 CPI responsive patients are progression-free from 3 to 10 months after first vaccine dose. Four of 7 CPI refractory patients have experienced unexpected prolonged stable disease after vaccination of up to 8 months after vaccination. 2 of 2 patients with available samples lost all evidence of circulating tumor DNA including non-targeted neoantigens. **Conclusions:** Vaccination with GEN-009 in combination with anti-PD-1 CPI in patients with advanced solid tumors shows little additive toxicity. Preliminary data demonstrate induction of broad neoantigen-specific immune responses and epitope spreading in the presence of PD-1 CPI. Broad immunity against tumor specific targets and encouraging patient outcomes support further study. Clinical trial information: NCT03633110. Research Sponsor: Genocea Biosciences.

2614 **Poster Session**

Phase I trial to determine safety and immunogenicity of amplivant, a synthetic toll-like receptor 2 ligand, conjugated to two HPV16 E6 synthetic long peptides. *First Author: Frank M. Speetjens, Leiden University Medical Center, Department of Medical Oncology, Leiden, Netherlands*

Background: Therapeutic vaccines based on synthetic long peptides (SLPs) have a great potential for immunotherapy of cancer patients as these SLPs include both human leukocyte antigen (HLA) class I and II epitopes and no patient selection for HLA types is required. The antigen-induced immune response can be strengthened with immune stimulating additives. Amplivant (AV) is a synthetic Toll-like receptor 2 ligand which can be directly conjugated to tumor peptide antigens. In preclinical studies, AV-conjugation to antigens led to both enhanced antigen presentation by dendritic cells and T-cell priming and caused superior induction of effective anti-tumor responses. Moreover, AV-conjugated SLPs showed a 100 times higher immune response compared to unconjugated SLP. The current study is a first-in-human trial to investigate safety and immunogenicity of AV-conjugated human papillomavirus (HPV)16-SLPs. **Methods:** A dose escalation phase I trial was performed in 24 patients with HPV16 positive (pre-) malignant lesions. AV was conjugated to two SLPs derived from the most immunodominant regions of the HPV16 E6 oncoprotein. Four dose groups (1, 5, 20 or 50 μg of each peptide) in 6 patients each were studied. The vaccine was injected three times intradermally in DMSO / water with a three-week interval. Adverse events (AE) were collected according to CTCAE v4.0 up to 26 weeks. Peptide-specific T-cell immune responses were determined in blood samples taken before and after vaccination using complementary immunological assays (proliferation assay, IFNγ-ELISPOT and cytokine bead array). **Results:** Toxicity after three AV-conjugated HPV16-SLP vaccinations was limited to CTCAE grade 1 or 2, with predominantly inflammation at the vaccination site and sometimes flu-like symptoms, which generally resolved within one day. Dose increase resulted from no AE in the lowest dose group to mild/moderate AE in all vaccinated persons in the highest dose group. In the lowest dose group, minor vaccine-induced T-cell responses were observed in three of six vaccinated persons. In the highest dose group, all patients displayed a strong HPV16-specific T-cell response after vaccination. The induced T-cell response against HPV16 lasted until the end of the trial. **Conclusions:** This first-in-human study showed that AV conjugated to SLPs can safely be used as an intradermal therapeutic vaccine. AV-conjugated HPV16-SLP was able to induce robust HPV16-specific T-cell immunity in patients treated for HPV16 positive (pre-) malignancies without any other vaccine adjuvant or formulation. Increase in dose resulted in both a higher number of mild adverse events as well as stronger T-cell immunity. Clinical trial information: NCT02821494. Research Sponsor: None.

2615 **Poster Session**

A phase 1b study of personalized neoantigen vaccine plus pembrolizumab in adults with advanced cancer. *First Author: Aaron Miller, UCSD Moores Cancer Center, La Jolla, CA*

Background: Neoantigens (NeoAg) are key targets for personalized immunotherapy but efficient methods for their systematic identification and therapeutic targeting remain elusive. We developed a methodology to reliably identify and verify somatic alteration-derived neoantigens based on natural T cell responses against them which formed the basis of an individualized therapeutic vaccine strategy. **Methods:** This is a phase Ib study to assess the immunogenicity, safety and early clinical activity of personalized synthetic long peptides (PSLP) cancer vaccines in combination with pembrolizumab for patients with treatment refractory metastatic solid tumors or PSLP vaccine alone as an adjuvant treatment with patients with no evidence of disease (NED) that incorporates patient-specific NeoAg identified by an HLA-agnostic, functional T-cell assay (see table). **Results:** At the time of data cutoff, a total of 5 patients had been treated on ARM-A, 5 patients on ARM-C and 2 patients on ARM-D. AES possibly attributed to personalized vaccine (PSLP), or pembrolizumab, or both include: Grade 1: Arthralgia (1); Diarrhea (1); Fever (4); Fatigue (7); Generalized muscle weakness (1); Headache (2); Nausea (1); Confusion (1); Injection site reaction (5); Rash maculo-papular (3); Flu like symptoms (5); Myalgia (1); and Grade 2: Diarrhea (1); Fatigue (1); Hyperhidrosis (1); Hypothyroidism (1); Injection site reaction (1); Proteinuria (1); Renal and Urinary – other (1); and Grade 3: Colitis (1). For the 9 patients with at least 1 radiographic assessment at the time of analysis 6 had a best response of stable disease (SD) and 3 had progressive disease (PD). Immune monitoring of peripheral blood specimens consistently demonstrated that NeoAg-specific T cell responses were enhanced following administration of PSLP vaccine. On-treatment biopsies demonstrated immune-editing with the variant allele frequency of targeted mutations decreasing following administration of the PSLP vaccine. **Conclusions:** Taken together, these data meet the trial primary endpoint by demonstrating PSLP vaccines targeting NeoAg identified using the HLA-agnostic pipeline augment effector T cell function against these targets. Clinical trial information: NCT02287428. Research Sponsor: None.

ARM	PSLP	Adjuvant	Vaccinations	Pembrolizumab
A	5 NeoAg (max)	Montanide	3 doses SQ every 3 weeks	200 mg every 3 weeks

2616 **Poster Session**

A phase 1 study of an off-the shelf, multi-neoantigen vector (ADXS-503) in subjects with metastatic non-small cell lung cancer (NSCLC) progressing on pembrolizumab as last therapy. *First Author: Missak Haigentz, Atlantic Health System Cancer Care, Morristown, NJ*

Background: ADXS-503 (A503) is an off-the-shelf, attenuated Listeria monocytogenes (Lm)-based immunotherapy bioengineered to elicit potent T cell responses against 22 tumor antigens commonly found in NSCLC (i.e., 11 hotspot mutations and 11 tumor-associated antigens, TAAs). Pembrolizumab (Pembro) is a programmed death receptor-1 (PD-1)- blocking antibody approved for the treatment of advanced lung cancer. A503 and Pembro have complementary mechanisms of immune activation and reversal of immune tolerance. **Methods:** A phase 1 study of A503 ± Pembro has been conducted in patients (pts) with metastatic squamous or non-squamous NSCLC. In dose-escalation part B, A503 was added-on to Pembro within 12 weeks of the first scan showing disease progression per RECIST criteria v1.1. Both, A503 (1 $x10^8$ CFU) and Pembro (200 mg) were infused by IV every 3 weeks until disease progression or limiting toxicity. The dose-escalation cohort has established safety, tolerability and immunogenicity of the combination therapy and it has been further expanded to evaluate efficacy (Goldman JW *et.al.*, SITC 2020). **Results:** Nine pts have been treated and evaluated in Part B. Pembro + A503 combo has been well tolerated and without immune related AEs. Of the nine evaluable pts, one has achieved partial response (PR) and 3 stable disease (SD), yielding an overall response rate (ORR) of 11% and disease control rate (DCR) of 44%. Two patients have had clinical benefit for over 12 months (i.e., one PR and one SD) and both of them had been on Pembro therapy for 2 years before enrollment. The two other pts with SD have sustained it for almost 6 months thus far. Seven pts have been evaluated for immunogenicity. In all pts there was a transient release of pro-inflammatory cytokines and proliferation of cytotoxic- and memory-CD8+ T cells. Seven evaluable pts had antigen-specific T cells within 1-2 weeks after starting therapy and 4/7 showed antigen spreading. **Conclusions:** ADXS-503 as an add-on therapy to Pembro at disease progression has been well tolerated and it has induced antigen specific-T cell responses and durable disease control in 44% of pts. Part B cohort is currently enrolling additional pts to further explore the potential reversal of Pembro resistance with ADXS-503. Clinical trial information: NCT03847519. Research Sponsor: ADVAXIS INC.

A phase 1 open label trial of intravenous administration of MVA-BN-Brachyury vaccine in patients with advanced cancer. *First Author: Peter Joseph DeMaria, Genitourinary Malignancy Branch, NCI, NIH, Bethesda, MD*

Background: Brachyury is a member of the T-box family of transcription factors which is overexpressed in several tumor types and has been associated with treatment resistance, epithelial to mesenchymal transition and metastatic potential. MVA-BN-Brachyury vaccine is a vector-based therapeutic cancer vaccine which demonstrated immunogenicity and safety in previous clinical trials. Preclinical studies suggested that IV administration of vaccines can induce superior CD8 + T-cell responses as compared with SC or IM routes. This is the first-in-human study to evaluate safety and tolerability of IV administration of this vaccine. **Methods:** Patients with metastatic or unresectable locally advanced malignant solid tumors were treated with MVA-BN-Brachyury vaccine in a phase 1, open-label, 3+3 dose-escalation study. Eligible patients received a total of three vaccine doses intravenously Q3W at $1x10^7$ (DL1), $1x10^8$ (DL2), or $1x10^9$ infections units (Inf.U) (DL3). Patients were admitted for 48 hours for observation after each dose and had imaging at baseline and 1 and 3 months after the last vaccine dose. Primary objective was to determine the safety and tolerability and establish the recommended phase 2 dose (RP2D). Immune assays were performed in the first 10 enrolled patients. **Results:** In 13 patients (10 chordoma, 1 small cell breast, 1 prostate, 1 colorectal cancer), no dose-limiting toxicities were observed. Right upper quadrant abdominal pain was the only grade 3 TRAE. All other TRAEs were grade 1 or 2; most common was cytokine release syndrome (four grade 2 and one grade 1. As of Feb 2021, 9 patients completed treatment and two planned restaging scans: 5 patients had PD (3 in DL1 and 2 in DL2), 3 had SD (2 in DL2 and 1 in DL3) and 1 had PR (DL3) as their best treatment response per RECIST 1.1. One patient with advanced sacral chordoma had significant reduction of ulcerated skin metastases after 2 doses, followed by 33% shrinkage at the end of trial. Two chordoma patients with SD reported significant pain improvement. Multifunctional Brachyury, CEA, and MUC1 specific T cells were increased after vaccination in in 60%, 67%, and 50% of patients, respectively. **Conclusions:** MVA-BN-Brachyury IV vaccine is safe across all tested dose levels and suggesting activity in chordoma at DL3 for which this vaccine was granted FDA orphan drug designation. Mild cytokine release syndrome (rigors, chills, fever and hypotension) has been observed in 5 patients and managed with IV fluids and steroids in 2 patients. A dose 1×10^9 Inf.U (DL3) was selected for RP2D based upon available safety data. Further research is pending to evaluate clinical benefit and immunogenicity. Clinical trial information: NCT04134312. Research Sponsor: U.S. National Institutes of Health, CRADA with Bavarian Nordic, Inc.

2618 **Poster Session**

Long-term follow up of patients with mesothelioma treated with dendritic cell therapy in three phase I trials. *First Author: Daphne W Dumoulin, Department of Pulmonary Medicine, Erasmus MC Cancer Institute, University Medical Center, Rotterdam, Netherlands*

Background: Immunotherapy targeting PD-(L)1 has become indispensable in the treatment of many malignant tumors. Recently, checkpoint inhibition using anti-PD-1 in combination with anti-CTLA-4 was proved to be effective in patients with malignant pleural mesothelioma (MPM). However, the minority of patients benefit from this treatment. The lack of immunotherapy efficacy in the majority of patients with mesothelioma can be explained by the fact that mesothelioma is a tumor with an "immune-desert" phenotype, meaning a non-inflamed tumor characterized by low T-cell infiltration. By administration of dendritic cells (DCs), which were cultured, activated, and exposed to antigens ex-vivo, this "immune-desert" phenotype might be turned into an "inflamed" phenotype. Previously, we performed and published three phase I trials using activated DCs, which support this concept. Here, we report the long-term survival of the patients treated with DCs in these three phase 1 studies. **Methods:** We collected the survival data of the phase 1 trials using DC therapy in patients with MPM. In the first two trials, DCs loaded with autologous tumor lysate were used, while in the third allogeneic tumor lysate was used to load the DCs (Mesopher). **Results:** Between 2006 and 2015, in the three studies combined, 29 patients with MPM were treated with DC vaccination. At data cut-off, the median OS was 27 months (95% confidence interval (CI): 21 – 47 months). OS at 2 years was 55.2% (95% CI: 39.7%-76.6%), OS at 5 years was 20.7% (95% CI: 10.1%-42.2%). **Conclusions:** The long-term follow up of MPM patients treated with DC vaccination in the three separate phase 1 trials show a promising signal, with a 2-year OS of over 50% and a 5-year OS of over 20%. In addition, 2 patients are alive after 10 years of treatment. In our opinion, these findings show the potency of DC vaccination therapy in long-term activation of the immune system. DC vaccination therapy in patients with MPM is currently being investigated in a large, randomized phase II-III trial (NCT03610360) and in pancreatic cancer. Additional biomarker studies, as well as treatment combinations with for example ICI, could further improve the outcomes of DC-vaccination therapy. Clinical trial information: NCT02395679. Research Sponsor: Dutch Cancer Society (to KWF) and ZonMW (grant number 95104006).

Overall survival analysis based on the Kaplan Meier curves.

	Median OS (95% CI)	OS – 2 years (95% CI)	OS – 5 years (95% CI)
Overall	27 months (21 - 47)	55.2% (39.7% - 76.6%)	20.7% (10.1% - 42.2%)
Study 1	15 months (15 - Inf)	20.0% (5.8% - 69.1%)	10.0% (1.6% - 64.2%)
Study 2	26 months (20 - Inf)	60.0% (36.2 – 99.5%)	30.0% (11.6% - 77.3%)
Study 3	31 months (28 - Inf)	88.9% (70.6% - 100%)	22.2% (6.6% - 75.4%)

2619 **Poster Session**

Final report and long-term outcomes: Phase I trial of a HER2 intracellular plasmid-based vaccine in HER2+ advanced stage breast cancer. *First Author: Mary L. Disis, University of Washington, Seattle, WA*

Background: Vaccination with the intracellular domain (ICD) of HER2 in pre-clinical models is both immunogenic and protective against the development of mammary tumors. This study (NCT00436254) was designed to examine the safety and optimal immunogenic dose of a DNA-based vaccine encoding the HER2 ICD in subjects with HER2+ breast cancer. **Methods:** Sixty-six patients with stage III or IV HER2 + breast cancer in remission or with stable bone only disease were enrolled into three vaccine arms: 1 (10mcg dose of plasmid), 2 (100mcg) and 3 (500mcg). Vaccines were administered i.d. monthly for three immunizations. Endpoints included safety and optimal dose. HER2 specific IFN-gamma immune responses were evaluated and DNA persistence at the vaccine site was assessed. Toxicity and clinical outcomes were followed for 10 years. **Results:** The majority of vaccine-related toxicity was grade 1 (89%) and grade 2 (11%) and was not significantly different between the three dose arms. All Arms developed HER2 ICD immunity after vaccination, however, patients in Arm 2 and Arm 3 had significantly better immune responses (of higher magnitude and at most time points) than patients in Arm 1 ($p=0.003$ and $p<0.001$, respectively) after adjusting for baseline factors. At 60 weeks, the number of patients who maintained the greatest fold-difference in HER2 ICD immune responses from their baseline was highest in Arm 2 (73%) when compared to Arm 1 (47%) and Arm 3 (45%). Associations between ICD responses and plasmid DNA persistence at the vaccine site were estimated via linear regression models. HER ICD immunity after the end of immunizations, relative to baseline, was significantly lower in patients with DNA persistence at week 16 compared to those without persistence ($p=0.02$). Patients at the highest dose demonstrated the greatest incidence of plasmid persistence (92%) as compared to 33% in Arm 1 and 10% in Arm 2. The median time of follow-up was 118.6 months (Arm 1), 99.7 months (Arm 2), and 73.5 months (Arm 3). The median OS and PFS has not been reached in any Arm and did not differ with respect to treatment arm (Log-rank p-value 0.36 for OS, and 0.63 for PFS). However, we observed a separation of Kaplan-Meier curves for OS from about 40 months and curves for PFS from about 30 months, and the separation maintained until the end of the study for Arm 2 versus Arm 1 and Arm 3. One patient in Arm 2 developed lymphocytic colitis 2.2 years from enrollment deemed possibly related to vaccination. **Conclusions:** An intermediate dose (100mcg) of vaccine was immunogenic and associated with persistence of immunity at 60 weeks. A randomized phase II trial of the HER2 ICD plasmid-based vaccine in the neoadjuvant setting is in development. Clinical trial information: NCT00436254. Research Sponsor: U.S. National Institutes of Health.

2620 **Poster Session**

A phase I clinical trial investigating the telomerase vaccine UV1 in combination with pembrolizumab in patients with advanced melanoma. *First Author: Yousef Zakharia, University of Iowa and Holden Comprehensive Cancer Center, Iowa City, IA*

Background: UV1, a telomerase peptide-based vaccine, consists of 3 long peptides (15-30 aa) representing a 54 aa sequence in the catalytic unit of the reverse transcriptase subunit of telomerase (hTERT). UV1 contains both CD4 and CD8 epitopes, and immunogenicity is shown in 78% of HLA unselected patients (pts.) in prior studies. UV1 induced expansion of hTERT specific CD4+ T cells that might be relevant in tumors expressing telomerase, theoretically enabling enhanced checkpoint efficacy in pts. with insufficient spontaneously primed T cells. Reciprocally, checkpoint inhibitor may support the UV1-induced T cells and provide increased effector activity, as these cells may be restricted by intrinsic and tumor-induced suppressor mechanisms. **Methods:** UV1 was combined with standard of care pembrolizumab in pts. with advanced melanoma. The primary objective of this phase I, multicenter study (NCT03538314), was to evaluate safety and tolerability of UV1 in combination with standard pembrolizumab. Secondary objective was evaluation of response rate (RR) according to iRECIST. Pts. received, in a serial manner, adjuvant GM-CSF and UV1 (300μg) intradermally followed by pembrolizumab. The first 3 UV1/GM-CSF doses were given during week 1, and from week 2 in combination with pembrolizumab (Q3W). Two different doses of GM-CSF were investigated: 37.5μg (20 pts. cohort 1) and 75μg (10 pts. cohort 2). Totally 8 UV1/GM-CSF vaccinations per pt. were planned (14 weeks). **Results:** In total 30 pts. were enrolled; cohort 1 (N = 20); cohort 2 (N = 10). The abstract reports cohort 1 results. The majority of adverse events (AEs) reported was grade 1 or 2 (48%, 41%). Main AEs were fatigue (8%), injection site reaction (5%), diarrhea (4%) and pyrexia (3%). 18% and 30% of AEs were possibly/definitely related to UV1 or pembrolizumab, respectively. Three patients experienced SAE, one (inflammatory arthritis) was considered possibly related to UV1. No severe allergic reactions were observed. Pembrolizumab was continued after completion of UV1 treatment in 14 pts. for a mean of 8.2 months (range 3-21). Four pts. discontinued pembrolizumab due to PD, one for irAE and one for unknown reason. The RR was 60%, with 5 CRs, and the 1-year survival rate 85 %. **Conclusions:** Results from cohort 1 (N = 20) show that the treatment of UV1 together with pembrolizumab was safe and well tolerated in patients with advanced melanoma. Updated data with minimum 18 months follow-up will be presented at the conference. Cohort 2 results will be presented at a later stage. Clinical trial information: NCT03538314. Research Sponsor: Ultimovacs ASA.

Adverse effects of COVID-19 vaccination among cancer patients: Results from an Internet-based survey. *First Author: Brian Loew, Inspire, Arlington, VA*

Background: The rapid development of safe and effective vaccines against SARS-CoV-2 may stem the global COVID-19 pandemic. However, since individuals with cancer were under-represented during clinical vaccine trials, experience with COVID-19 vaccines among cancer patients is limited. **Methods:** An internet-based survey was conducted January 15 - February 10, 2021 among members of the Inspire online health community. The 63-item survey was emailed to members of the Inspire community who had opted-in for research. **Results:** Out of 19,152 respondents, 4895 (25%) self-reported a cancer diagnosis. Of these, 1337 (27%) were receiving active therapy. Cancer respondents were 66% female, 77% white, 44% college educated, with a median age range 55-65 years. 88% had solid tumors and 12% hematologic malignancies. 241 (5%) had prior COVID-19 and 148 (3%) thought they had had it but were not tested. Among cancer patients with COVID-19 approximately 30% reported ongoing late symptoms. At the time of survey, 1335 (27%) cancer patients had received a COVID-19 vaccine (Moderna 51% Pfizer-BioNTech 46%, Astra-Zeneca 3%, Other/unknown >1%). Following the first injection, 63% had local adverse events (AEs): injection site pain (51%), swelling (8%), redness (6%), and itching (4%). 34% reported systemic AEs including myalgia (32%), fatigue (18%), headache (12%), joint pain (5%), and chills (5%). 199 (15%) had received the second (booster) vaccination. 76% reported local AEs including pain (69%), swelling (14%), itching (8%), and redness (7%). 67% reported systemic AEs including fatigue (49%), myalgia (30%), headache (29%), chills (23%), fever (16%), joint pain (15%), and nausea (12%). AEs were comparable to the clinical trial results obtained from the general population (fda.gov/media/144245/download & 144434/download). **Conclusions:** In this internet-based survey drawn from the Inspire online health community 1335 cancer patients reported receiving COVID-19 vaccinations. By self-report the vaccines were well tolerated with AEs patterns mimicking clinical trial results conducted in the general population. These safety results should be reassuring to cancer patients although attention to COVID-19 vaccine efficacy is required (and will be studied during follow-up surveys). Research Sponsor: Inspire.

	Pfizer clinical trial	Moderna clinical trial	Cancer with Pfizer	Cancer with Moderna
First dose local AEs	79%	84%	58%	68%
First dose systemic AEs	59%	55%	36%	33%
Second dose local AEs	73%	89%	73%	79%
Second dose systemic AEs	70%	79%	60%	74%

Risk factors for immune mediated adverse events with immune checkpoint inhibitors. *First Author: Ari Pelcovits, Brown University, Providence, RI*

Background: Immune checkpoint inhibitors (ICIs) are associated with unique toxicity - immune-related adverse events (irAEs). irAEs are common, occurring in nearly 30 % of patients (pts) in clinical trials. Risk factors for irAEs remain largely unknown, with limited evidence to guide risk stratification for these pts. **Methods:** In this historical cohort study, we identified 400 pts receiving ICIs at our institution between 1/1/2015 - 12/31/2019 and followed them until progression, death, or study end date. Using modified Poisson and multinomial logistic regression we assessed irAEs (yes/no; none/grade 1-2/grade 3-4) as a function of independent risk factors in separate models. These included age, PDL-1%, steroid use in the 2 weeks (S2wks) prior to ICI, concurrent chemotherapy, combination ICI use, and pre-ICI creatinine (Cr) and absolute lymphocyte count. We constructed sample weights using sociodemographic and clinical factors to account for confounding by indication and mortality-related censoring. **Results:** 367 pts (median age: 68 yrs) had complete data for analysis comprising 55% men and 89% white. 111 (31%) experienced an irAE during the study period (median time to first event: 81 days). Risk was greatest for the youngest and oldest pts on ICI. In weighted models, Pts ≤59 yrs were 3 times as likely to experience an irAE relative to those aged 60-68 (95% CI: 1.18,7.41; Table). Additionally, for each 1 unit increase in Cr, risk of irAE increased by 19% (95% CI: 1.08,1.28). Precision of weighted estimates was impacted by limited pt comparability across factors of interest and overall sample size. While not statistically significant (RR: 2.04;95% CI:0.92,4.53) 70.6% of pts on combination ICIs experienced an irAE compared with 20.3% on one ICI. Similarly, while not statistically significant, 15.4% of pts with PDL-1 >49% experienced a grade 3/4 irAE compared with 7.7% of pts with PDL-1<1%. **Conclusions:** In this real-world analysis of irAEs, younger age and elevated creatinine were risk factors for development of irAEs. Further research leveraging larger data sources is needed to examine PDL-1% as a potential risk factor of irAE. Research Sponsor: None.

	irAE vs. No irAE[1] RR (95% CI)	Grade 1/2 irAE vs. No irAE[2] OR (95% CI)	Grade 3/4 irAE vs. No irAE[2] OR (95% CI)

Safety, pharmacokinetics, efficacy, and preliminary biomarker data of first-in-class BI 765063, a selective SIRPα inhibitor: Results of monotherapy dose escalation in phase 1 study in patients with advanced solid tumors. *First Author: Stéphane Champiat, Gustave Roussy Cancer Campus, Department of Drug Development (DITEP), Villejuif, France*

Background: BI 765063 is a humanized IgG4 monoclonal antibody antagonist of SIRPα (Signal Regulatory Protein α), which blocks the "don't eat me" signal of the SIRPα/CD47 axis, a critical innate immune checkpoint. SIRPα is expressed on myeloid cells. BI 765063 binds to the V1 SIRPα allele with high affinity and to the V2 SIRPα allele with low affinity. BI 765063 lacks SIRPγ binding to preserve T-cell activation. We report results of the completed BI 765063 monotherapy dose escalation in patients with advanced solid tumors. **Methods:** This study involves a step 1 dose escalation to determine the dose-limiting toxicities (DLT) and maximum tolerated dose (MTD), then a step 2 dose-confirmation expansion at recommended phase 2 dose. In Step 1, BI 765063 ascending doses, given IV every 3 weeks, were tested using a Bayesian Logistic Regression Model (BLRM) approach with overdose control. The endpoints were safety, pharmacokinetics, receptor occupancy (RO) in peripheral $CD14^+$ monocytes and efficacy (RECIST 1.1). **Results:** Fifty patients (26 V1/V1, 24 V1/V2) received at least one dose of BI 765063. The most frequent tumors were ovarian (9), colorectal (8), lung (5), breast (4), melanoma (3), and kidney (3). No DLTs were reported up to the highest dose tested. MTD was not reached. The most frequent related adverse events were infusion related reaction (IRR) (46%), fatigue (12%), headache (10%), arthralgia and diarrhea (8% each). All related adverse events were mild to moderate, except one case of IRR Grade 3. No related anemia nor thrombocytopenia were observed. BI 765063 showed dose proportional exposure and full RO saturation in Cycle 1 after the fourth dose level. Clinical benefit was observed in 21/47 (45%) patients evaluable per RECIST 1.1. One patient with hepatocellular carcinoma (HCC) with liver and lung metastases and 7 prior lines of therapy showed a durable partial response maintained for 27 weeks treatment (ongoing). The baseline tumor biopsy of this patient showed high CD8 T-cell and macrophage infiltration. There was an increase in CD8 T-cell infiltration and activation on treatment. An increase in PD-L1 expression on tumor cells 2 weeks after first dosing was also observed. Analysis of paired tumor biopsies in other patients is ongoing. **Conclusions:** The first-in-class SIRPα inhibitor BI 765063 was well-tolerated, showed monotherapy activity, and sustained RO saturation. A durable partial response was observed in an advanced HCC patient. The on-treatment biopsy of the responder showed an increase in CD8 T-cell infiltration and activation. PD-L1 expression on tumor cells also increased. BI 765063 dose escalation in combination with ezabenlimab (anti-PD1 antibody) is ongoing. Clinical trial information: NCT03990233. Research Sponsor: OSE Immunotherapeutics; Boehringer Ingelheim.

A phase 1/2 open-label study of KY1044, an anti-ICOS antibody with dual mechanism of action, as single agent and in combination with atezolizumab, in adult patients with advanced malignancies. *First Author: Manish R. Patel, Sarah Cannon Research Institute, Florida Cancer Specialists, Sarasota, FL*

Background: KY1044, is a fully human IgG1 anti ICOS antibody designed to stimulate Teffs and to deplete ICOS high Tregs in the tumor microenvironment. **Methods:** Patients with advanced/metastatic malignancies received escalating doses of KY1044 as a single agent and in combination with atezolizumab 1200 mg by IV infusion every 3 weeks until disease progression or unacceptable toxicity. Dose escalation was guided by a modified toxicity probability interval design. The primary objective was to determine safety, tolerability, and maximum tolerated dose. Cohorts that were tolerated were later enriched with more subjects. AEs were classified according to CTCAE v5 and efficacy measures performed according to RECIST v1.1 every 8 weeks for the first 16 weeks and then every 12 weeks. **Results:** As of 16-Dec-2020, a total of 103 patients have been enrolled in the study (38 patients as monotherapy in 6 cohorts at doses ranging from 0.8 to 240 mg and 65 in combination with atezolizumab in 5 cohorts at doses 0.8 – 80 mg). 63% and 55% of patients received ≥4 prior anti-cancer therapies in the single agent and combination cohorts, respectively. All cohorts were completed without DLTs during the first 21 days of treatment. In the KY1044 single agent cohorts, 47.4% of patients experienced treatment-related AEs (TRAEs), all were grades 1 or 2. In the combination cohorts, TRAEs were observed in 58% of patients. Most of the TRAEs were grade 1 or 2 apart from 8 TRAEs that were ≥grade 3 occurring in <8% of patients. Infusion-related reactions, pyrexia and lymphopenia were the most commonly occurring TRAEs in ≥10% of patients. TRAE leading to dose interruptions occurred in 1 patient in the single agent cohort and in 4 patients in the combination cohort. Only 1 patient discontinued treatment due to myositis that was considered related to the combination. Preliminary KY1044 PK data from 69 patients agree with the PK model predictions. Median treatment duration for all enrolled patients was 9 weeks. Treatment duration ≥16 weeks was observed in 24% (9/38) and 27% (17/64) patients in the single agent and combination cohorts, respectively. Five objective responses, including 1 CR in triple negative breast cancer (TNBC) and 4 PRs in TNBC, head and neck squamous cell carcinoma, penile and pancreatic cancer were observed. Four of the 5 responding patients were still on treatment at the data cut, with 3 patients on treatment for >43 weeks (range 45 to 66 weeks). **Conclusions:** KY1044 is well tolerated as single agent and in combination with atezolizumab. Objective responses have been observed in this phase 1 part of the study. The phase 1 expansion and phase 2 part of the study is ongoing. Clinical trial information: NCT03829501. Research Sponsor: Kymab.

Real world experience with standalone immunotherapy regimens: Immune-related adverse events, healthcare utilization and cost among patients with commercial or Medicare Advantage insurance. *First Author: Krishna Soujanya Gunturu, Lahey Hospital and Medical Center, Burlington, MA*

Background: Immunotherapy is a fast growing class of cancer therapy. We evaluated the rates of immune-related adverse events (irAEs), healthcare utilization, and costs up to 1 year post-index among patients using monotherapy (PD-1/PD-L1 inhibitor) and combination therapy (PD-1/PD-L1 with CTLA-4 inhibitors). **Methods:** We reviewed claims from the HealthCore Integrated Research Database (HIRD), which contains commercially insured/Medicare Advantage members and captures clinical, utilization, and cost measures. We analyzed both the monotherapy (M) and combination therapy (C) cohorts focusing on members with ≥ 6 months of baseline continuous medical and pharmacy coverage. Descriptive and multi-variate analyses were performed. **Results:** The C cohort had 904 and M had 9,084 patients, with mean ages of 58 and 64 years, respectively. Prominent cancer types were melanoma for C and lung for M. The most common incident irAEs (%) for C vs. M were: endocrinopathies (27.7, 14.7), hepatitis (17.1, 7.7), nephritis (21.0, 14.0), neuropathy (6.6, 7.0), followed by colitis, dermatitis, and myocarditis. After adjustment, C therapy showed greater risk of all-cause inpatient admissions (OR 2.27, 95% CI 1.93, 2.66), all-cause emergency department (ED) visits (OR 1.55, 95% CI 1.33, 1.81) and irAE-related visits (See table). Mean adjusted all-cause cost difference for C vs M was +$43,747 (95% CI $38,440, $49,427). In age ≥65 subset, 222 received C and 4,208 received M. C therapy patients had more irAE-related hospitalizations (45.3% vs. 57.7%, p=0.0004). Costs were similar to the main cohort. **Conclusions:** C therapy showed greater incident irAE rates, increased utilization and medical costs compared to M therapy. Limitations include less precise ascertainment of irAEs in claims data and generalizability only to those with commercial or Medicare Advantage insurance. Our study highlights the increased toxicity and cost tradeoffs involved in choosing combination immunotherapy over monotherapy. Research Sponsor: Anthem Inc.

KY1044 to target the ICOS pathways inducing intratumoral Treg depletion and agonism of effector T cells: Preliminary pharmacodynamic markers from a phase 1/2 multicenter trial. *First Author: Chia-Chi Lin, National Taiwan University Hospital, Taipei, Taiwan*

Background: Inducible T-cell co-stimulator (ICOS) is an important co-stimulatory receptor on effector T cells (Teffs) that also promotes tumor growth due to its high expression on regulatory T cells (Tregs). KY1044 is a fully human IgG1 that targets ICOS, acting via a dual mode of action (MoA) by depleting $ICOS^{high}$ Tregs and stimulating $ICOS^{Low}$ Teffs. A Phase 1/2 clinical trial (NCT03829501) is currently assessing the safety and preliminary efficacy of KY1044, as a single agent and in combination with atezolizumab, in subjects with advanced relapsed/refractory malignancies. Using longitudinal blood samples and tumor biopsies, we aim to correlate KY1044 target engagement levels with pharmacodynamic (PD) properties (e.g. dual MoA) in the tumor microenvironment (TME) and the circulation. **Methods:** Phase 1 subjects were enrolled in dose escalation and enrichment cohorts to evaluate the effect of KY1044 as monotherapy (0.8 – 240 mg) Q3W and in combination (0.8 – 80 mg) with atezolizumab (1200 mg) Q3W. PBMCs, plasma and tumor biopsies were collected over the first 3 cycles to confirm target engagement and KY1044 MoA. The sample analysis included: immunohistochemistry (IHC) of tumor samples (ICOS, FOXP3 and CD8); circulating T cell immunoprofiling and receptor occupancy by chip-cytometry; PBMC and tumor sample pre- and post-treatment transcriptomic analysis; and the assessment of circulating cytokines (e.g. GM-CSF). **Results:** As assessed in PBMCs, full/prolonged ICOS target engagement on T cells was confirmed in subjects receiving a flat dose of 8 to 240 mg, while partial/transient saturation was observed at lower doses (0.8-2.4 mg). The target engagement was not affected by atezolizumab. The immune cell profiling showed changes in some populations, but there was no significant depletion of peripheral $ICOS^+$ cells. In contrast, pre- and post-treatment IHC analysis of $ICOS^+/FOXP3^+$ cells in tumor biopsies confirmed a KY1044-dose dependent reduction of $ICOS^+$ Tregs and maintenance of $CD8^+$ T cells in the TME. Together, this resulted in an increased intratumoral $CD8^+/ICOS^+$ Treg ratio at all doses, plateauing from subjects receiving a flat KY1044 dose of 8 mg. KY1044-dependent agonism was indirectly assessed by measuring circulating cytokine levels. A post-dosing transient induction of GM-CSF was evident in subjects dosed with KY1044 at the 0.8 and 2.4 mg dose, whereas minimal induction was observed at dose of 8 mg and higher. **Conclusions:** LongitudinalPDdata confirmed the expected KY1044 MoA, namely ICOS Treg depletion and increased CD8/ICOS Treg ratio in the TME as well as T cell co-stimulation. The observed PD responses are currently being further explored in a more homogenous patient population. Research Sponsor: Kymab.

Association and prevalence of venous thromboembolism in cancer patients with COVID-19: A single healthcare system experience. *First Author: Aneesha Ananthula, Louisiana State University, New Orleans, LA*

Background: There are increasing reports of thromboembolic complications in patients with COVID-19 infection. According to a meta-analysis of 28,173 patients, the prevalence of venous thromboembolism (VTE) in hospitalized COVID-19 patients ranges from 7.9% to 22.7% based on the severity of COVID-19. Cancer and anti-cancer therapies are known risk factors for thrombosis. Another study based on registry data reported the overall prevalence of VTE in hospitalized COVID-19 patients with cancer to be 14.5%. Our study aimed to assess the prevalence of VTE in cancer patients diagnosed with COVID-19 as well as the association between VTE and cancer in the setting of COVID-19 infection in a large predominantly urban healthcare system. **Methods:** We utilized a cohort data query tool in the electronic medical record at University Medical Center in New Orleans, Louisiana to identify patients >17 years of age with a hospital or clinic visit in the LCMC Health system between March 1, 2020 and December 31, 2020 which were considered the base population for the study. Cancer patients were identified via the cancer registry tool. Patients with COVID-19 were identified using the abnormal COVID-19 PCR test result search field. An encounter diagnosis of deep venous thrombosis (DVT) or pulmonary embolism (PE) was used to identify patients with VTE. Odds ratios, p-values, and corresponding confidence intervals (CI) were calculated using 2x2 contingency tables. **Results:** In our database, we identified 3,807 patients with a diagnosis of COVID-19 and 9,560 with a cancer diagnosis. 158,812 patients had neither COVID-19 nor cancer. There were statistically significant greater odds of developing VTE in all subgroups compared: COVID-19 alone vs neither (OR 2.43), cancer alone vs neither (OR 3.8), and COVID-19 and cancer vs neither (OR 10.65). **Conclusions:** COVID-19 and cancer are both risk factors for VTE. Based on our study, appears that cancer has the greater effect on VTE compared with COVID-19 infection. Also, there is possibly a synergistic effect between COVID-19 and cancer, which further increases the likelihood of VTE. This study is a preliminary analysis. Further investigation is warranted in the form of either variable adjusted analysis of the same data, individual chart review, or a prospective study. Research Sponsor: None.

Cohort [VTE n = prevalence%]	Odds ratio	CI	P value
COVID-19 [84 = 2.29%] vs none [1520 = 0.96%] *cancer excluded	2.43	1.95–3.04	<0.0001
Cancer [334 = 3.54%] vs none [1520 = 0.96%] *COVID-19 excluded	3.8	3.37–4.29	<0.0001
COVID-19 and cancer [14 = 9.33%] vs neither [1520 = 0.96%]	10.65	6.13–18.51	<0.0001

Priming immunotherapy with radiotherapy (RT) in advanced non-small cell lung cancer (NSCLC) and head and neck squamous cell cancer (HNSCC): Interim analysis of phase II clinical trial. *First Author: Aasems Jacob, University of Kentucky, Lexington, KY*

Background: Preclinical models demonstrate that combined RT with immune checkpoint inhibitor (ICI) results in specific CD8+ T-cell phenotype associated with a tumor-reactive population resulting in significant tumor response. Sequential treatment could allow radiation to release tumor antigens from immune inaccessible areas and provide robust anti-tumor immune response with ICI. We report an interim analysis of the phase II clinical trial evaluating the efficacy and safety of the combination. **Methods:** Advanced NSCLC and HNSCC patients who had initiated on FDA approved single-agent ICI were eligible. Patients were given SBRT (BED >100Gy) or 30 Gy fractionated RT delivered as a 3-dimensional dose to a single metastatic site within 14 days of the first ICI dose. Primary objective was 6-month PFS and secondary objectives were safety and tolerability, 1Y PFS and OS. This interim analysis was done after enrollment of 43 patients. **Results:** Between 10/2017 to 1/2021, 43 patients were enrolled, and 38 included in this analysis. Median age was 62 years; 26 patients were male. 9 patients received ICI for NSCLC as first-line, 7 for NSCLC second-line and 22 for HNSCC second-line. 24 patients received pembrolizumab and 14 nivolumab; 21 had SBRT and 17 fractionated RT. Median follow up duration was 11.8m (range: 2.7 - 31.4m) for patients without progressive disease (PD). 10 patients were off-study, 7 continuing treatment. 15 died and 26 had PD. 14 patients died of malignancy and cause of death for one patient was unknown. 6-month PFS was 49.19% with median PFS of 5.5 months. (table) Fifty-two grade-3-5 adverse events (AEs) were reported among 21 subjects. Most common were transaminitis (n=15), lymphopenia (n=8), and GI side effects (n=4). Treatment related AEs included 19 grade-3 events, and none were grade 4/5. Two grade-5 AEs were from PD (oral bleeding and unspecified). There were 20 grade-1/2 and 3 grade-3 immune related adverse events (IRAEs). No grade-4/5 IRAEs were reported. Two patients discontinued treatment due to grade 3 transaminitis. **Conclusions:** Interim analysis shows that 6m PFS was acceptable with majority of patients being second-line metastatic HNSCC who historically had mPFS of 2.1-2.3 months and mOS 7.7-8.4 months in Checkmate-141/KEYNOTE-040 trials. Hence, the combination is of further interest and accrual will continue to reach the goal. The combination therapy was tolerable without unexpected AEs. Majority of deaths were from disease progression. No treatment related grade 4/5 adverse events were reported. Two patients discontinued treatment due to grade-3 IRAE. Clinical trial information: NCT03313804. Research Sponsor: University of Kentucky Markey Cancer Center's Cancer Center Support Grant.

Median PFS, OS and survival probabilities in the study population.

	PFS	OS
Median follow-up duration	11.8m	11.5m
Median	5.5m	19.27m
Survival Probability		
6m	49.19%	77.68%
12m	32.20%	57.37%
24m	21.46%	40.16%

The Tim3-galectin-9 interactions in the tumor microenvironment of nasopharyngeal cancer. *First Author: Dora Lai Wan Kwong, The University of Hong Kong, Hong Kong, China*

Background: The complex cell interactions within the tumor microenvironment (TME) have become a crucial point in cancer research. Yet, the cell interactions might not only depend on the frequency of immune cells, but also on the inter-individual distances as cells might interact via soluble factors and/or cell-cell contact. Accordingly, the mapping of TME has recently gained importance. The aim of this study is to investigate the alternations between galectin-9 (G9) and its natural immunosuppressive receptor, T cell immunoglobulin and mucin domain 3 (Tim3) in nasopharyngeal cancer (NPC). **Methods:** Using multiplexed quantitative immunofluorescence, we measured the levels of G9 and Tim3 in 95 NPC patients cancerous and 8 normal specimens in tissue microarray format. Cell densities and cell-to-cell distances were quantified. The interaction between G9-expressing tumor cell lines and T cells were also studied. **Results:** G9-expressing tumor cells were detected in all NPC cases and were significantly higher than normal tissue. Elevated G9 was associated with shorter overall survival (OS: 89% vs 70.5% at 7 years, p: 0.019). Incremental percentages of $Tim3^+$ cells were shown in top 10% cases strongly positive for G9-expressing tumor cells. The number of $Tim3^+$ cells was calculated at 15μm intervals from the nearest G9-expressing tumor cells, of which a significant difference of $Tim3^+$ cells was observed at the 0-15μm distance from G9-expressing cell in cancerous compared to normal tissues. Epithelial short distances were associated with a unfavourable prognosis. Observed short distance were hypothesized to represent $Tim3^+$ cells actively interacting with G9-expressing tumor cells. Accordingly, *In vitro* cocultured of G9-ovexpressing NPC cell lines induced Tim3 expression on T cells which suppressed the T-cell mediate cytotoxicity on tumor cells. **Conclusions:** Our findings indicate a specific preexisting profile of $Tim3^+$ and G9-expressing tumor cells and demonstrated that $Tim3^+$ cells were mainly found intratumorally within 15μm of a NPC cell. The relevance of $Tim3^+$ and $G9^+$ distances reflect a potential marker of their functional interaction. Our results could have important implications for clinical therapeutic strategies. Since high G9 expression have poorer OS, they would deserve a different therapeutic strategy. Research Sponsor: Health and Medical Research Fund.

Safety of AK117, an anti-CD47 monoclonal antibody, in patients with advanced or metastatic solid tumors in a phase I study. *First Author: Hui Kong Gan, Austin Health, Heidelberg, VIC, Australia*

Background: AK117 is a novel humanized IgG4 monoclonal antibody (mAb) targeting CD47, a macrophage immune checkpoint that allows tumor cells to evade immune destruction by phagocytic cells. CD47 is a target expressed in many cancers. However, the initial dose of anti-CD47 therapy may be limited by severe anemia due to ubiquitous CD47 expression on senescent red blood cells (RBCs). Here, we present encouraging preliminary AK117 safety and receptor occupancy (RO) data from an ongoing dose-escalation study in patients (pts) with advanced or metastatic solid tumors. **Methods:** This is a first-in-human, phase 1a/1b, multicenter, open label, single arm, dose escalation and dose expansion study of AK117 administered intravenously to adult pts with resistant/refractory advanced or metastatic solid tumors or lymphomas. In the dose escalation phase (phase 1a), an accelerated titration followed by a 3+3+3 design was used to assess the safety and tolerability of AK117 monotherapy (dose range 0.3 mg/kg to 45 mg/kg); and determine the maximum tolerated dose (MTD). AK117 was administered QW on a 28-day treatment cycle and dose limiting toxicity (DLT) observation period. Tumor assessments per RECIST v1.1 were performed once every 8 weeks (2 cycles). **Results:** As of 15 Feb 2021, 15 pts were enrolled in phase 1a with DLT evaluation of the 30 mg/kg cohort currently in progress. There were no DLTs up to 20 mg/kg QW AK117, inclusive. Five treatment-related adverse events (TRAEs) occurred in 4 subjects as shown in the table below. All pts with TRAEs continue to receive AK117, except the pt on 1 mg/kg AK117 who discontinued due to disease progression. G2 anemia and G1 thrombocytopenia occurred after Cycle 1 in a pt (liposarcoma, 10 mg/kg cohort), who had a medical history of anemia (hemoglobin 119 g/L at screening). No hematological TRAEs were seen in other pts, including those who received 20 mg/kg AK117 QW. There were no infusion-related reactions (IRRs) or grade ≥ 3 TRAEs. Target engagement in the periphery was confirmed by measuring CD47 RO of AK117 on RBCs and T lymphocytes. 100% RO on RBCs and T lymphocytes was achieved after the first dose and continued to Day 8 (prior to second dose) in the 10 mg/kg and 20 mg/kg cohorts. **Conclusions:** AK117 is safe and well-tolerated up to 20 mg/kg QW, inclusive, with no IRRs or severe TRAEs observed. There were no hematological TRAEs, except in a pt with baseline G1 anemia receiving 10 mg/kg AK117. Unlike other anti-CD47 therapies, AK117 does not require a lower 'priming' dose to prevent anemia. Safety evaluation of the 30 mg/kg dose level is in progress. Full and durable RO in the periphery was seen at 10 mg/kg and above. Further evaluation of AK117 in combination with AK104, an anti-PD-1/CTLA-4 bispecific antibody, shall commence imminently. Clinical trial information: NCT04349969. Research Sponsor: Akeso Biopharma, Inc.

Phase 1 dose escalation study of MGC018, an anti-B7-H3 antibody-drug conjugate (ADC), in patients with advanced solid tumors. *First Author: Sekwon Jang, Inova Schar Cancer Institute, Fairfax, VA*

Background: MGC018 is an investigational ADC with a duocarmycin payload linked to an anti-B7-H3 monoclonal antibody (mAb). B7-H3 is expressed on multiple solid tumors with limited normal tissue expression. It is hypothesized that MGC018 may exert activity against B7-H3-expressing tumors with an acceptable safety profile. Studies demonstrate that B7-H3 is a significant factor in progression and events of metastasis of multiple tumor types, including melanoma. **Methods:** This phase 1 study characterizes safety, maximum tolerated or maximum administered dose, pharmacokinetics, immunogenicity, and tumor response per RECIST v1.1 of MGC018 in a 3+3+3 dose escalation design in patients with advanced solid tumors. MGC018 was administered intravenously (IV) every 3 weeks. **Results:** The study enrolled 29 patients of multiple tumor types, which included 3 melanoma patients refractory to ≥2 prior lines of checkpoint therapy. The study completed 5 of 6 planned dose cohorts (0.5 mg/kg - 4 mg/kg) as of the data cutoff of 21 January 2021. The final cohort of 4 mg/kg has 3 patients with ongoing treatment and follow-up at the date of submission. Dosing MGC018 IV every 3 weeks resulted in minimal serum accumulation. At least 1 treatment emergent adverse event occurred in 29 patients (100.0%); most common (≥25%) were anemia, neutropenia, fatigue, hyperpigmentation, infusion related reaction, nausea, and palmar plantar erythrodysesthesia. Two dose-limiting toxicities occurred; one grade 4 neutropenia (2 mg/kg) and one grade 3 fatigue lasting 7 days (4 mg/kg). No febrile neutropenia was reported. The 3 melanoma patients had reductions in target lesion sum of 24.4%, 27.5%, and 35% (unconfirmed partial response) and remain on treatment as of the data cutoff. The recommended phase 2 dose was determined to be 3 mg/kg. **Conclusions:** Results to date demonstrate a manageable safety profile, with early evidence of clinical activity in pretreated metastatic melanoma. Cohort expansion is ongoing using a recommended phase 2 dose of 3 mg/kg IV every 3 weeks. The planned enrollment includes advanced metastatic castrate-resistant prostate cancer, melanoma, triple-negative breast cancer, and non-small cell lung cancer. Clinical trial information: NCT03729596. Research Sponsor: MacroGenics, Inc.

Comparison of checkpoint inhibitor treatment-related cutaneous adverse events in racial and ethnic minority and Caucasian cohorts at Memorial Sloan Kettering Cancer Center. *First Author: Amaris Geisler, CUNY School of Medicine, New York, NY*

Background: Immune-related cutaneous adverse events (irCAEs) are the most common and often the first toxicity of immune checkpoint inhibitors (CPIs). In the general population, irCAEs occur on average within 3.6 weeks of treatment initiation and most commonly manifest as maculopapular rash, lichenoid rash, and pruritus. Less is known about these irCAEs in racial and ethnic minority patients. The purpose of this study is to compare the irCAEs of cohorts of Caucasian and racial and ethnic minority patients at Memorial Sloan Kettering Cancer Center. **Methods:** Herein, we conducted a retrospective chart review of racial and ethnic minority patients treated with CPIs between 2012-2019 at Memorial Sloan Kettering Cancer Center. irCAEs were graded using the Common Terminology Criteria for Adverse Events (CTCAE) v5.0. These were compared to a Caucasian cohort matched by demographics and cancer therapy regimen. **Results:** One hundred ten racial and ethnic minority patients presented to dermatology for irCAEs. Our population consisted of 59 (53.6%) females and 51 (46.4%) males with a mean age of 59 (range 20-85). Of the patients who were seen by dermatology, 63/110 were Asian (57.3%) followed by 34/110 African American (30.9%), and 1 Native American. Twelve patients were of Hispanic ethnicity (10.9%), which included those of both African American and Caucasian race. The 110 patients that were evaluated by dermatology had 221 cutaneous adverse events. Rash (96, 43.4%), pruritus (40, 18.1%), and xerosis (23, 10.4%) were most frequently diagnosed (average time from treatment start to presentation was 125 days). Dermatology identified 87 (39.3%) grade 1, 103 (46.6%) grade 2, 30 (13.5%) grade 3, and 1 (0.4%) grade 4 events. There were 17 (15.5%) treatment interruptions, including 7 patients who required permanent discontinuation. In the Caucasian cohort, mean time to onset was 228 days (range 1-1500). Dermatology identified 48 (43.6%) grade 1, 44 (40.0%) grade 2, 18 (16.4%) grade 3, and 0 (0.0%) grade 4 events, with maculopapular rash (55, 50.0%) and pruritus (25, 22.7%) most frequently diagnosed. **Conclusions:** Our findings suggest that irCAEs occur frequently in cancer patients from racial and ethnic minority groups, with similar grade and morphology as Caucasian patients. When irCAEs develop in this population, the diagnosis occurred later than what has previously been reported, possibly due to these patients seeing MSK oncologists with an established dermatology consultation system and insight into how to manage these patients on their own. Prospective evaluation of underrepresented minorities receiving CPI therapy is warranted in order to identify risk factors and therapeutic strategies for these untoward events, so that optimal cancer care may be delivered. Proton pump inhibitor use (PPI) in patients treated with immune checkpoint inhibitors (ICI) for advanced cancer: Survival and prior therapy.

First Author: Marium Husain, The Ohio State University Medical Center, Columbus, OH

Background: Emerging data suggest that concomitant medications (CM) influence response to ICI. CM impact the host microbiome which may mitigate tumor-immune responsiveness. PPI use in patients treated with ICI has been associated with worse survival. Few data exist regarding the effects of PPI use in terms of prior chemotherapy or in risk for immune related adverse events (irAE) (e.g., colitis). **Methods:** This retrospective study of patients with advanced cancer treated with ICI between 2011 and 2019 was conducted at The Ohio State University. Patients who received ICI as either single agent or combination were included. Clinical data was abstracted from chart review, including CM, toxicity, and survival. Overall survival (OS) was evaluated to date of death or last contact. Associations between OS and proton pump inhibitor (PPI) use were studied using log-rank tests and Cox regression analyses overall and by the groups of whether prior chemotherapy was administered and timing from chemotherapy to ICI. The associations between PPI and incidence of irAE (overall and colitis) were assessed by chi-square tests. **Results:** We identified 1,091 patients treated with ICI, of whom 415 (38%) received PPI at time of ICI. Most common cancers were NSCLC and melanoma; most common therapy was PD1/L1 (Table). PPI use was associated with shorter OS in patients treated as first line therapy (HR = 1.46, 95% CI = [1.11, 1.91], p=0.006) and in second line and beyond (HR = 1.30, 95% CI = [1.10, 1.53], p=0.002). PPI use was associated with shorter OS in patients treated with ICI for those without prior chemotherapy (HR = 1.47, 95% CI = [1.17, 1.86], p=0.001). When evaluated by timing from chemotherapy to ICI, PPI use was associated with shorter OS only in patients where last chemotherapy was $>$ 1 year from ICI (HR = 1.99, 95% CI [1.15, 3.45], p=0.014) but not for patients with chemotherapy within 1 year of ICI (HR = 1.01, 95% CI = [0.79, 1.29], p=0.960). The use of PPI was not associated with incidence of irAE (p=0.317) or colitis in particular (p=0.781). **Conclusions:** PPI use was associated with shorter survival in patients treated with ICI across a broad variety of cancers and in first line of therapy or beyond. In patients with recent chemotherapy ($<$1 year), PPI use was not associated with survival, which may be due to disruption of the microbiome by chemotherapy. Further study is needed to determine the impact of CM (e.g, PPI), on outcomes of patients treated with ICI. Research Sponsor: U.S. National Institutes of Health.

Initial findings of the first-in-human phase I study of AGEN2373, a conditionally active CD137 agonist antibody, in patients (pts) with advanced solid tumors.

First Author: Anthony W. Tolcher, NEXT Oncology, San Antonio, TX

Background: CD137 is a member of the tumor necrosis factor receptor superfamily that functions as a potent co-stimulator of both adaptive and innate immune cells, thus making it an attractive target for cancer immunotherapy. The development of first-generation anti-CD137 antibodies has been hampered by limited clinical activity or dose-limiting hepatotoxicity. AGEN2373 is a novel, conditionally active CD137 agonist antibody designed to selectively enhance tumor immunity while mitigating side effects associated with systemic activation of CD137. Here we report the initial findings from the first-in-human evaluation of AGEN2373 in pts with advanced solid cancers. **Methods:** Pts received AGEN2373 on day 1 of a 28-day cycle (Q4W dosing), with cycles repeated until progression, intolerable toxicity or investigator/patient decision. Dose-escalation followed a standard 3+3 scheme, with planned dosing of 0.03, 0.06, 0.3, 1.0, 2.0, and 3.0 mg/kg. The primary objective was to determine the safety, tolerability, and dose-limiting toxicity (DLT) of AGEN2373 as monotherapy. Secondary objectives included pharmacokinetics (PK) and preliminary clinical activity. Adverse events (AEs) were reported per CTCAE v5.0 and DLTs evaluated within a 28-day window. For PK analyses, serum AGEN2373 concentrations determined using a validated bioanalytical assay and simultaneously analyzed by an NLME model. Antitumor activity was assessed using RECIST v1.1. **Results:** As of January 21 2021, 19 pts (median age 54.4 years, range 33-74; 11 men, 8 women; 7 with prior immunotherapy) have been treated with AGEN2373 Q4W at escalating doses from 0.03 – 2.0 mg/kg across 5 cohorts. Eleven pts (57.9%) experienced treatment-related AEs; none were grade 3 or higher. The most common events were fatigue (4 pts, 21.1%) and nausea (2 pts, 10.6%). No DLTs have been observed. Importantly, no drug-related elevations in liver transaminases (ALT, AST) or bilirubin beyond 1 grade have been seen. AGEN2373 PK were consistent with linear elimination. Prolonged disease stabilization as best response occurred in 5 pts (26.3%; range, 6-41 weeks); three of which were seen in heavily pretreated pts with metastatic leiomyosarcoma, including one who had progressed on prior combination checkpoint immunotherapy. Enrollment into the 3.0 mg/kg cohort is continuing. **Conclusions:** AGEN2373 demonstrates good tolerability in pts with advanced solid tumors, with a safety profile characterized by a lack of hepatotoxicity frequently observed with CD137-targeting antibodies. These findings underscore the suitability of AGEN2373 as a potential partnering agent for other immunomodulatory agents, including planned expansion as combination therapy with balstilimab (anti-PD-1). Clinical trial information: NCT04121676. Research Sponsor: Agenus Inc.

2635 **Poster Session**

Late immune-related adverse events with immune checkpoint inhibitors.

First Author: Andrew Ip, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: Immune Checkpoint Inhibitors (ICIs) are associated with unique immune-related adverse events (irAEs). IrAEs can occur at any timepoint of ICI treatment. Late irAEs are not well reported in the literature. Herein, we attempt to characterize irAEs that occur 6-month, one year and two years after ICI treatment initiation. **Methods:** We identified patients treated with ICIs (anti-CTLA-4, anti-PD(L)-1 either alone or in combination or with chemotherapy) across Hackensack Meridian Health hospital and MedStar Georgetown University Health systems from 12011 to 4/2018. Patients' baseline demographics, treatment history, and irAEs were collected from EHR. CTCAE V4.03 was used to grade irAEs. **Results:** We identified 1332 patients treated with 1443 unique ICIs. The ICI therapies were nivolumab 38% (543), pembrolizumab 23% (332), ipilimumab plus nivolumab 12% (180), ipilimumab 11% (161), Atezolizumab 3% (47) and others 13% (180). Tumor types were lung cancer 34% (496), melanoma 27% (389), GI cancers 6% (92), kidney cancer 6% (87), and other cancers 26% (379). The median age was 66 (21-87), age $>$75 37% (541), Caucasian 67% (970). We identified a total of 911 any grade irAEs among 37% (552) therapies. Among, 911 irAEs, grade 1-2, grade $\geq$3 and unknown grade irAEs were 39% (572), 12% (182) and 11% (157), respectively. The most common any grade irAEs were skin rash 22% (202), colitis 13% (120), and hepatitis 12% (108). 84% of all irAEs and 85% of $\geq$ Grade 3 irAEs occurred within 6 months of treatment initiation. Of the 350, patients on active treatment at six months, 37 % (132) and 7% (26) developed any grade and grade $\geq$3 irAEs, respectively. irAEs that had $>$ 10% of their occurrences after six months were skin rash and colitis 14% each. Other common irAEs were hypothyroidism, hepatitis, joint pain, pruritis and pneumonitis at 7% each. Among 170 patients on active treatment at one year, 37% (62) and 7% (12) developed any grade and grade $\geq$3 irAEs respectively. irAEs with $>$10% incidence after one year of treatment were rash 19% and hepatitis 13%. **Conclusions:** Our RWE findings suggest although 85% irAEs occurs within the first six months of treatment, late irAEs can occur with ICI treatment. The incidence and pattern of late irAEs appears similar to early irAEs, (e.g., skin rash, colitis, hypothyroidism and hepatitis) with pneumonitis being a notable exception. It is uncertain if these results will be influenced by changing patterns of ICI use (e.g. different diseases and/or regimens) over time. Research Sponsor: U.S. National Institutes of Health.

Pattern of any grade, grade $\geq$ 3, and select irAEs over time.

	Any grade irAEs % (N=911)	Grade $\geq$ 3 irAEs % (N=182)	Any grade Colitis % (120)	Any grade Hepatitis % (108)	Any grade Rash % (202)	Any grade Pneumonitis % (54)

Cardiovascular toxicity incidence following immune checkpoint inhibitors in randomized clinical trials: A systematic review and meta-analysis.

First Author: Camila Bragança Xavier, Hospital Sírio-Libanês, São Paulo, Brazil

Background: Immune checkpoint inhibitors (ICIs) are widely used in oncology and may be associated with a variety of immune-related toxicities. Cardiovascular (CV) adverse effects (AEs) are underreported in randomized clinical trials (RCTs), and the real risk associated with ICIs use has yet to be defined. Therefore, we aimed to investigate the incidence and risk of cardiovascular toxicities in patients receiving ICIs, using an up-to-date meta-analysis of prospective RCTs. **Methods:** We conducted a systematic search of the literature from January 1st, 2010 until July 1st, 2020 to identify RCTs testing ICIs for solid tumors, either in monotherapy or in combination between them. Our initial search yielded a total of 21,249 relevant publications. For CV AEs incidence estimation, we included phase III RCTs testing PD-1, PD-L1, CTLA-4 inhibitors or any combination of these agents. For relative risk (RR) assessment, we included phase II or phase III RCTs testing the same agents and with placebo or best supportive care (BSC) as the comparator. Data were extracted by independent reviewers following *Preferred Reporting Items for Systematic Reviews and Meta-analyses* (PRISMA) guidelines. CV AEs were categorized based on the *Common Toxicity Criteria* (CTCAE) and stratified by ICIs type. Analyses were conducted using random effects model. **Results:** After screening and eligibility assessment, a total of 21,118 patients (67 cohorts from 57 trials) were available for this meta-analysis. We categorized the cohorts by ICIs regimen as monotherapy with a PD-1 inhibitor (35 cohorts; 10,241 patients), PD-L1 inhibitor (12 cohorts; 3,755 patients), CTLA-4 inhibitor (11 cohorts; 4,135 patients), and combination therapy (9 cohorts; 2,987 patients). Incidence measures are described in the table. Deaths from any CV cause occurred in 0.20% of the patients (95%CI 0.10%; 0.20%). For RR analysis, we included 12 cohorts from 11 RCTs. Risk of experiencing all grade AEs was numerically higher among patients who received ICIs than placebo or BSC (RR 1.16; 95%CI 0.98; 1.37; p=0.09). When only grade 3-5 CV AEs were considered, ICIs were associated with increased risk (RR 1.36; 95%CI 1.06; 1.73; p= 0.01). Additional analyses were conducted to estimate the RR of individual CV AEs including arrhythmia, cardiac arrest, heart failure, stroke, hypertension, myocardial infarction, myocarditis, pericardial events, and thromboembolic events. None of the analysis identified a significant additional risk. **Conclusions:** This meta-analysis corroborates the preclinical rationale of worsen CV risk related to ICIs use. Research Sponsor: None.

ICI TYPE	ALL GRADE CV AEs (95% CI)	HIGH GRADE CV AEs (95% CI)
CTLA-4 inhibitor	8.30% (7.50%–9.10%)	4.80% (4.20%–5.50%)
PD-1 inhibitor	10.50% (10.00%–11.00%)	5.00% (4.50%–5.40%)
PD-L1 inhibitor	10.40% (9.50%–11,5%)	5.50% (4.80%–6.30%)
COMBINATION	15.87% (14.60%–17.20%)	6.30% (5.50%–7.20%)

2637 **Poster Session**

Infections in cancer patients treated with immune checkpoint inhibitors: Data from randomized trials. *First Author: Cinzia Solinas, Azienda Tutela della Salute Sardegna, Nuoro, Italy*

Background: Febrile neutropenia and infections are well studied complications of chemotherapy (CT) and some targeted agents employed in oncology. Less is known about the risk of infection associated with the use of immune checkpoint inhibitors (ICIs) in cancer patients. The present systematic review and meta-analysis was performed to address this question in patients diagnosed with solid tumors enrolled in randomized trials employing ICIs as experimental treatment. **Methods:** The Cochrane Library, EMBASE, and Pubmed databases were searched from inception through December 1st, 2020. Randomized clinical trials comparing any ICI alone, with CT, or with other agents *vs* CT, placebo, or other agents in patients with solid tumors were included. Two independent reviewers used a standardized data extraction and quality assessment form. Discordant cases were discussed with a third independent investigator. The following information was extracted: baseline study characteristics, including the primary tumor, author, year of publication, type of trial, type of disease, and the type of therapy (experimental and control arms); and the incidence of any-grade (grades [G] 1–5), low-grade (G1–2), and high-grade (G3–4), fatal event (G5) infections, and type of event. Random or fixed-effect models were used according to the statistical heterogeneity. **Results:** 36 randomized clinical trials were deemed eligible. The total population reached 21451 patients. In the pooled analysis, the use of ICIs was associated with a similar risk of all-grade infections (relative risk, RR = 1.02; 95% CI 0.84–1.24; P = 0.85) compared to non-ICI treatments (G1-5 events: 9.6 *vs.* 8.3%). When the ICIs alone arms were compared to CT, the experimental arms were associated with a 42% less risk of all-grade infections (RR = 0.58, 95% CI 0.4–0.85; P = 0.01; N = 18 studies). Compared to CT, the combination of ICIs and CT increased the risk of all-grade infections (RR = 1.37, 95% CI 1.23–1.53; P < 0.01; N = 13 studies) and severe infections (RR = 1.52, 95% CI 1.17–1.96; P < 0.01; N = 12 studies). Fatal infections were similar in the experimental and control arms (0.5%). **Conclusions:** In patients with advanced solid tumors, when ICIs were administered with CT, the risk of all-grade and G3-5 infections was significantly increased. Compared to CT alone, ICIs were safer and their use should be recommended for frail patients. Further studies are required to identify high-risk patients and evaluate the need for CT dose reduction or prophylactic myeloid growth factors use. Research Sponsor: None.

2638 **Poster Session**

Age affects the efficacy of immune checkpoint inhibitors in patients with advanced cancer. *First Author: Yongjie Wang, The Affiliated Hospital of Qingdao University, Qingdao, China*

Background: Immune checkpoint inhibitors (ICIs), such as programmed death(ligand)1 (PD-(L)1) and cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) inhibitors, have dramatic effects on treatment in patients with various malignancies. High tumor mutation burden (TMB) is predictive of clinical response to ICI in multiple cancer types. Although age-related immune dysfunction might induce difference on the efficacy of ICIs between younger and older patients, the potential effect of age on the efficacy of ICIs remains little known and controversial. Herein, we aimed to analysis the association between age and the efficacy of ICIs based on MSKCC cohort. **Methods:** We screened out 1661 patients having complete information with advanced cancer, whose tumors underwent next-generation sequencing (NGS) detection and who were treated with at least one dose of ICI in MSKCC cohort. All patients were divided into two groups according to age, the younger group (age ≤50-year old) and the older group (age > 50-year old). We further analyzed the differences in overall survival (OS) and TMB between the two groups. The pooled hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated via Cox regression model for OS and P-values were calculated via the Wilcoxon sign test for TMB. We analyzed the effect of age on ICI in lung cancer using the same way. **Results:** In 1661 patients with cancer in our study, 312 (19%) younger and 1349 (81%) older patients were found. The pooled HRs for OS was 1.28 (95% CI: 1.09-1.52) in younger group compared with older group. In 1661 patients with cancer, there was 350 (21%) patients with lung cancer, including 30 (9%) younger and 320 (91%) older patients. The pooled HRs for OS was 1.45 (95% CI: 0.95-2.23) in younger group compared with older group in lung cancer. In addition, TMB in older group was higher than in younger group and significant difference of TMB was found via the Wilcoxon sign test (p = 2.6e-10) between the two groups, especially in lung cancer (p = 1e-4). **Conclusions:** Our study assessed the impact of age on the efficacy of ICIs using the threshold of 50 years old for the first time and we founded that patients in older group had higher TMB and longer OS than younger group. Improving tolerability of pembrolizumab with weight based dosing: A meta-analysis. *First Author: Nabeela Khan Patail, Stony Brook University Hospital, Stony Brook, NY*

Background: Pembrolizumab, a PD-1 immune checkpoint inhibitor (ICI), has demonstrated significant clinical activity in various cancers. Despite a favorable toxicity profile, discontinuation due to adverse events including immune related adverse events (irAE) has been reported. We conducted a meta-analysis of published clinical trials to evaluate the tolerability of pembrolizumab in cancer patients. **Methods:** A systematic review was conducted of relevant studies from the databases of PubMed and abstracts presented at American Society of Clinical Oncology (ASCO) from June 2015 until September 2020. Eligible studies included prospective clinical trials that reported a discontinuation rate due to adverse effects. Incidence, relative risk and 95% confidence intervals (CI) were calculated by employing fixed or random effects models. **Results:** A total of 6,380 patients with a variety of hematologic and solid malignancies from 20 studies of pembrolizumab were included for analysis. The overall rate of pembrolizumab discontinuation due to adverse events was 8.2% (95% CI: 6.4-10.4%). The discontinuation rate of pembrolizumab was not significantly lower than the chemotherapy controls, with RR of 0.84 (95% CI: 0.58-1.12, p = 0.33). However, the discontinuation rate of pembrolizumab was significantly higher compared to placebo control with RR of 2.20 (95% CI: 1.36-3.54, p < 0.001), and significantly lower compared to ipilimumab with RR of 0.58 (95% CI: 0.34-0.99, p = 0.04) respectively. The discontinuation rate varied widely among different tumor types with the lowest rate of 0.8% (95% CI: 0.2-3%) in gastric cancer, and the highest of 13.5% (95% CI: 10.8-16.8%) in head and neck squamous cell carcinoma. Interestingly, the discontinuation rate varied with pembrolizumab dosing, with the fixed dosing of 200mg being 9.2% (95% CI: 6.9-12%) and the weight-based dosing being 6.5% (95% CI: 4.8-8.8%). The weight-based dosing was associated with a significantly lower discontinuation rate compared to controls with RR of 0.62 (95% CI: 0.47-0.81, p < 0.0001), while the fixed dosing had similar discontinuation rate with RR of 1.03 (95% CI: 0.89-1.20, p = 0.67). **Conclusions:** The tolerability of pembrolizumab may be comparable to chemotherapy in cancer patients and may vary with its dosing. Future studies are warranted to evaluate the impact of different dosing. Research Sponsor: None.

2640 **Poster Session**

Pan-Canadian cohort of immune checkpoint inhibitor-induced insulin-dependent diabetes mellitus (CANDIED). *First Author: Thiago Pimentel Muniz, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Endocrine immune-related adverse events (irAEs) are frequent with immune checkpoint inhibitors (ICIs); however, ICI-related insulin-dependent diabetes mellitus (IDDM) is a rare but serious endocrine irAE. We describe the characteristics of patients who developed ICI-related IDDM across five academic Canadian cancer centres. **Methods:** In this multicentre, retrospective study, we included both patients who developed IDDM and patients with non-IDDM (NIDDM) or pre-DM who became insulin-dependent while on treatment with ICI. We collected data on primary tumor type, ICI regimen (single agent or combination), time to development of IDDM from ICI initiation, comorbidities, laboratory parameters at the time of IDDM diagnosis, tumor response and survival. A p value < 0.05 was considered statistically significant. **Results:** We identified 27 patients between July 2016 and August 2019. Median age was 60 (39-79) years, 20 (74%) were male, 15 (55%) had melanoma and 4 each (15%) non-small cell lung cancer (NSCLC) and renal cell carcinoma. Seven (26%) patients had prior NIDDM or pre-DM; 5 (18%) had an auto-immune disease (2 psoriasis, 2 inflammatory bowel disease, and 1 systemic lupus erythematosus). Laboratory parameters at presentation and management of IDDM are presented in the Table. Mean A1c was not statistically different between patients with or without prior NIDDM or pre-DM (8.4% vs. 8.6%; $p = 0.9$). All IDDM events were irreversible; 1 (4%) patient died of diabetic ketoacidosis. At time of IDDM diagnosis, 17 (63%) patients were receiving single agent anti-PD1 and 10 (37%) anti-PD1-based combinations (7 anti-CTLA-4, and 3 other compounds). Median time for development of IDDM from ICI initiation was 2.7 months (95% CI 0.2-5.3). Patients receiving combination ICI developed IDDM earlier than those treated with single agent (1.4 vs 4.8 months; $p = 0.05$). Amongst patients with metastatic disease (n = 24), 9 (38%) had a complete response and 7 (29%) had a partial response. Two patients (8%) were treated in the adjuvant setting; 1 (4%) received consolidation ICI. IDDM led to ICI discontinuation in 12 (44%) patients. After a median follow up of 21 months from ICI initiation, median survival was 30 months (95% CI NE) and was not reached in patients with melanoma and NSCLC. **Conclusions:** ICI-related IDDM is a rare and typically irreversible irAE that occurs early in the course of treatment and develops earlier with combination ICI. In this cohort, patients who developed ICI-related IDDM had a high tumor response rate and prolonged survival, especially melanoma and NSCLC patients. Prospective evaluation of autoantibodies to predict development of IDDM is ongoing. Research Sponsor: None.

Glucose, mean (SD)	33 μmol/L (15.6)
A1c (17 patients), mean (SD)	8.5% (1.9)

Real-world outcomes of treatment with immune checkpoint inhibitors in unique patient cohorts: Elderly, non-caucasian race, poor performance status, obese, chronic viral infections, and autoimmune diseases. *First Author: Neil J. Shah, Memorial Sloan Kettering Cancer, New York, NY*

Background: Immune Checkpoint Inhibitors (ICI) have revolutionized current cancer treatment. Nevertheless, outcomes data across various patient cohorts are lacking. To address this knowledge gap, we conducted a comprehensive analysis of real-world data (RWD) that included patient cohorts traditionally underrepresented in clinical trials. **Methods:** We identified patients (pts) treated with ICI (anti-CTLA-4, anti-PD(L)1 or their combination at 6 US academic and community hospitals from 1/2011 – 4/2018. Clinical data obtained from EHR and CTCAE V4.03 was used to define immune-related adverse events (irAEs). **Results:** A total of 1332 pts treated with 1443 unique ICI treatments were included in the cohort. The median age was 66 (21-87), Male 58% (827), Caucasian 70% (1004), African American (AA) 16% (232), other race 14% (207), ECOG PS 0,1 79% (1130), chronic viral infection 5% [hepatitis B (24), hepatitis C (32) and HIV (17)], with BMI > 30 22% (287) and autoimmune disease (AID) 15% (215). Lung cancer (NSCLC) 34% (423), and melanoma 27% (389) were top 2 tumor types and nivolumab 38% (544), pembrolizumab 23% (332), and ipilimumab plus nivolumab 12% (180) were the most common ICI treatments. Overall survival (OS) was worse for patients with ECOG ≥2 (0.34 - 0.63) vs. ECOG 0,1 (1.27 - 1.73, P <0.001), and better with AID (1.21 - 2.63) vs. no AID (0.90 - 1.24, P=0.01) and Caucasian (1.02 - 1.45) vs AA (0.72 - 1.30, P=0.02). No difference in OS was noted for sex, other races, h/o chronic viral infection or obesity. We performed an analysis of OS and irAEs restricted to NSCLC patients (n=423); (N=447 unique ICI treatments); age >75 27% (120), AA 28% (124), Female 50% (224), ECOG PS ≥2 23% (104), BMI >30 15% (62), chronic viral infections 10% (44), and AID 14% (62). The ICI therapies were nivolumab 55% (245), pembrolizumab 23% (102), and atezolizumab 6% (27) and 16% (others). Data is contained in the table. **Conclusions:** Overall, in our RWD, OS appeared to be similar across above cohorts except poor OS for pts with ECOG ≥2. irAEs also appeared to be similar across cohorts except less with ECOG ≥2. In NSCLC cohort, we noted similar findings except less irAEs in Male cohort. Prospective studies are needed to confirm the above findings. Research Sponsor: U.S. National Institutes of Health.

NSCLC (N=447)	Overall survival Hazard Ratio	P value	Any grade IrAEs	P value univariate	Adj. P value multivariable
18-75 vs. Age > 75	0.90	0.5	29% vs. 40%	0.03	0.078
Male vs. Female	0.87	0.33	26% vs. 38%	0.01	0.046
Caucasian vs. AA	0.76	0.08	35% vs. 24%	0.08	N/A
No Chronic viral infections vs. Yes	1.19	0.48	31% vs 41%	0.23	N/A
No autoimmune disease vs. Yes	0.68	0.07	30% vs 45%	0.03	0.07
ECOG PS 0,1 vs. ECOG PS ≥2	1.96	0.01	36% vs. 20%	0.005	0.004
BMI 12 -30 vs. >30-60	1.10	0.60	30% vs. 36%	0.47	N/A

Maintenance immunosuppressive therapy with resumption of immune checkpoint inhibitor treatment to reduce recurrence of immune-mediated colitis. *First Author: Hamzah Abu-Sbeih, University of Missouri, Kansas City, MO*

Background: Immune-mediated colitis (IMC) may limit immune checkpoint inhibitors (ICI) treatment. Current guidelines recommend consideration of resuming ICI when IMC symptoms subside to ≤ grade 1. We aimed to investigate the effect of maintenance immunosuppressive therapy (IST) on the outcome of IMC in patients who resume ICI therapy. **Methods:** We retrospectively studied patients who resumed ICI therapy after adequate treatment of IMC from March 2015 to June 2020 at MD Anderson Cancer Center. Relevant demographic, oncologic, and ICI data were collected and analyzed. Univariate logistic regression analysis was conducted to assess risk factors of IMC recurrence. **Results:** We included 102 patients with a median age of 61 years. 66% were males and 97% were Caucasians. 48 patients (47%) received IST maintenance in conjunction with ICI resumption and 54 patients did not. Symptoms of IMC recurred in 28 patients, 8 (17%) in the concurrent IST group and 20 (37%) in the other group. Compared to no concurrent IST group, patients on concurrent IST were more likely to have received combined ICI regimen (60% vs 41%, p = 0.003) and more initial ICI doses (9 vs 5 doses, p = 0.030). Concurrent IST group had significantly longer ICI treatment duration on resumption (72 vs 62 days, p = 0.023), more ICI resumed doses (5 vs 4 doses, p = 0.038), and lower IMC recurrence (17% vs 37%, p = 0.027). Patient who received more IST doses, both therapeutic and prophylactic, had lower rate of IMC recurrence (OR 0.72, p = 0.012; table). IST maintenance treatment (OR 0.34, p = 0.024) was associated with lower IMC recurrence rate after ICI resumption. Vedolizumab was the predominant IST used. Overall survival was comparable among the two groups (p = 0.934). **Conclusions:** Concurrent IST treatment with ICI resumption after IMC was associated with significantly lower IMC recurrence and more extended ICI treatment while reserving similar overall survival to patients without IST maintenance therapy. Future prospective randomized trial of concurrent IST is still merited for further clarification. Research Sponsor: None.

Univariate logistic regression analysis for risk factors of IMC recurrence.

Characteristic	OR (95% CI)	*P*

Outcomes of immune checkpoint inhibitor-mediated colitis: Multicenter cohort study. *First Author: Hamzah Abu-Sbeih, University of Missouri, Kansas City, MO*

Background: Immune checkpoint inhibitor (ICI)-mediated colitis (IMC) is a common and serious adverse event. Although small series have described the clinical presentation of IMC, large multicenter series that integrate clinical, endoscopic, and histologic findings are lacking. **Methods:** We retrospectively assessed patients who received ICI and had endoscopically confirmed IMC from 2010 to 2019. IMC was graded based on the CTCAE version 5.0 criteria. Multivariate logistic regression analyses were conducted to assess factors associated with recurrence of IMC symptoms and long duration of corticosteroids use (> 70 days). **Results:** 675 patients were included. 387 patients were males (57%). Median age was 63 years. Melanoma was the most common cancer type (327; 48%). Most (365; 54%) patients received CTLA-4 inhibitor ICI, as monotherapy or in combination with PD-(L)1. Median time from ICI therapy to IMC was 62 days. IMC was grade 2 in 335 (50%) patients, Grade 3 in 181 (27%), and grade 4 in 16 (3%). 155 (23%) patients had mucosal ulceration on endoscopy, 91 of them had severe features (deep, large, or multiple ulcers); 336 (50%) patients had non-ulcerative inflammation. The rest had normal endoscopic findings with histologic inflammation. Most patients were admitted to the hospital for management of IMC (405; 60%) and 16 (3%) needed ICU-level of care. Treatment included corticosteroids in 577 (85%) patients (median duration 52 days), TNF inhibitor in 245 (36%), and vedolizumab in 90 (13%). 202 (32%) patients had recurrent IMC after resolution of symptoms. On multivariate logistic regression, factors associated with IMC recurrence and long (> 70 days) duration of corticosteroid therapy were grade of IMC (p = 0.049), treatment with infliximab or vedolizumab (p = 0.044), presence of mucosal ulceration (p = 0.034), or features of active histologic inflammation (p = 0.076). Of note, patients with mucosal ulceration received infliximab or vedolizumab more frequently ($p < 0.001$). For patients with grade 2 IMC, mucosal inflammation on endoscopy and delay in performing endoscopy with time from IMC onset to endoscopy more than a month were associated with IMC recurrence and longer duration of corticosteroid use (p = 0.029 and $p < 0.001$, respectively). 16 (3%) patients had colonic perforation, 7 of them underwent surgical resection. No IMC-related death occurred. **Conclusions:** IMC is a clinically significant adverse event that can lead to premature termination of ICI therapy with high rates of hospital admission. Rarely, it results in colonic perforation requiring surgical intervention and ICU admission. Our data suggest that there is a utility of endoscopic and histologic evaluation in the prediction of worse outcomes from IMC. This finding is particularly important for grade 2 IMC as current guidelines do not recommend endoscopic evaluation for this group. Research Sponsor: None.

Pancreatic volumes in immune checkpoint inhibitor-induced diabetes. *First Author: Rebecca Jeun, Baylor College of Medicine, Houston, TX*

Background: Immune checkpoint inhibitor-mediated insulin dependent diabetes (ICI-DM) is a rare and irreversible adverse event often presenting with life-threatening diabetic ketoacidosis (DKA). Pancreatic volume changes have been studied in classic Type 1 and Type 2 diabetes as a surrogate for functional β-cell mass. In this study, we investigate longitudinal changes in pancreatic volumes in patients who develop ICI-DM. **Methods:** Among patients with ICI-DM seen at our institution between 2014 and 2020, 20 patients who had serial CT scans of the abdomen and pelvis before and after ICI DM diagnosis were identified for inclusion in this study. Demographic data and clinical variables were obtained from the electronic medical record. Weight-adjusted pancreatic volumes were calculated from CT scans at three time points. The most recent CT scan prior to ICI initiation was used as baseline, the CT scan immediately prior to ICI DM diagnosis was used as a midpoint, and the most recent CT scan prior to the end of the study period was used as the final time point for comparison. **Results:** Median age was 63 years old (range 35 to 83). Renal cell carcinoma and melanoma were the most common cancer types. Male gender predominated (80%). 18/20 patients were on a PD-1 inhibitor with the remaining two on a PD-L1 inhibitor. After initiation of ICI therapy there was a variable response in pancreatic volumes prior to the diagnosis of ICI-DM with 20% patients experiencing a volume loss of > 10% and 25% experiencing a volume gain of > 10%. Volume loss nor volume gain prior to diabetes diagnosis was associated with presentation with DKA. 9/13 (69%) of patients who had pancreatic enzymes checked at diagnosis of ICI-DM had elevated levels. Pancreatic atrophy with a median volume loss of 41% was seen in all patients at a median of 14.9 months (range 3-77 months) after ICI-DM diagnosis. Most had more than 20% volume loss from baseline to most recent scan with no correlation in degree of volume loss with the time interval. There was no evidence of pancreatic ductal dilation, increased pancreatic fat nor any changes consistent with chronic pancreatitis. **Conclusions:** This study shows a variable response in pancreatic volumes after initiation of ICI in patients who progress to developing ICI-DM, though most had a significant decline in volume after the diagnosis of ICI-DM with long-term pancreatic atrophy. As β-cell mass is thought to comprise 1-2% of the pancreas, these findings may suggest both endocrine and exocrine compartment changes because of ICI-DM, though exocrine dysfunction has not been clinically described in this patient population. As these patients receive frequent imaging during treatment, fluctuations in pancreatic volumes with new or worsening hyperglycemia may portend the onset of ICI-DM and clinicians should have a low threshold to screen for this diagnosis as many will present with life-threatening DKA. Incidence of hepatitis associated with addition of immune checkpoint blockade to conventional solid tumor therapy: A meta-analysis of phase 3 randomized clinical trials. *First Author: Yu Fujiwara, Department of Medicine, Icahn School of Medicine at Mount Sinai, Mount Sinai Beth Israel, New York, NY*

Background: Immune checkpoint blockade (ICB) has emerged as a promising treatment strategy for many solid tumors. Although safe for many patients, ICB causes immune-related adverse events (irAEs) including hepatitis, which may result in morbidity and treatment disruption. Severe hepatitis requires immunosuppression, including corticosteroids and mycophenolate mofetil. We conducted a meta-analysis of clinical trials to investigate the effect of adding ICB to conventional solid tumor therapy on the incidence of hepatitis. **Methods:** Phase 3 randomized clinical trials (RCTs) comparing ICB and conventional therapy to conventional therapy alone were chosen by database search on PubMed, Embase, Web of Science, and Cochrane Library. The odds ratios [OR] of any-grade and grade ≥3 hepatitis, elevated aspartate aminotransferase (AST), and elevated alanine aminotransferase (ALT) were calculated. Meta-analysis was conducted to determine the incidence of hepatitis, elevated AST, and elevated ALT among patients receiving ICB and those receiving conventional therapy alone. Subgroup analysis based on the mechanism of ICB (Cytotoxic T-lymphocyte-associated protein 4 [CTLA-4] inhibitor, programmed cell death protein 1 [PD-1] inhibitor, and programmed death-ligand 1 [PD-L1] inhibitor) was also conducted. **Results:** A total of 29 randomized controlled trials (RCTs) enrolling 18,829 participants were analyzed. Incidence of hepatitis was derived from 24 RCTs enrolling 15,183 patients, and incidence of grade ≥3 hepatitis was derived from 22 RCTs enrolling 13,846 patients. Incidence of elevated AST was extracted from 18 RCTs, and incidence of elevated ALT was extracted from 20 RCTs. Addition of ICB to conventional therapy was associated with an increase in incidence of any-grade hepatitis (OR 2.54, 95% confidence interval [CI] 1.82-3.55) and grade ≥3 hepatitis (OR 4.22, 95% CI 2.51-7.11). The addition of ICB was also associated with an increase in incidence of elevated AST (any grade: OR 2.19, 95% CI 1.59-3.03; grade ≥3: OR 3.18, 95% CI 1.85-5.48) and elevated ALT (any grade: OR 2.08, 95% CI 1.47-2.92; grade ≥3: OR 2.41, 95% CI 1.40-4.14). Subgroup analysis based on the mechanism of ICB demonstrated increased incidence of grade ≥3 hepatitis associated with CTLA-4 inhibitor, PD-1 inhibitor, and PD-L1 inhibitor therapy (OR 2.78, 95% CI 1.26-6.14; OR 6.30, 95% CI 2.23-17.78; OR 4.73, 95% CI 1.83-12.23, respectively). No significant difference of heterogeneity was observed among subgroups (I^2= 0%, p = 0.43). **Conclusions:** Addition of ICB to conventional solid tumor therapy was associated with increased incidence of any-grade and severe hepatitis, and elevations of AST and ALT, regardless of the mechanism of ICB. Clinicians should weigh the risk of liver toxicity when considering addition of ICB therapy in patients with solid tumors. Research Sponsor: None.

A first-in-human, multicenter, open-label, phase 1 study of ATOR-1017, a 4-1BB antibody, in patients with advanced solid malignancies. *First Author: Gustav J. Ullenhag, Akademiska Sjukhus, Uppsala, Sweden*

Background: ATOR-1017 is a human agonistic IgG4 antibody targeting the co-stimulatory receptor 4-1BB (CD137). It is developed to activate T cells and natural killer cells in the tumor environment, leading to immune-mediated tumor cell killing. This is a first-in-human, multicenter, phase 1 study (NCT04144842). **Methods:** In this study, ATOR-1017 is administered intravenously every 21 days as a single agent to patients with solid malignancies. ATOR-1017 is administered until confirmed progressive disease, unacceptable toxicity or withdrawal of consent. The primary objective of the study is to determine the maximum tolerated dose, assessed by adverse events (AEs) and dose limiting toxicities (DLTs), and the recommended phase 2 dose. Secondary objectives include pharmacokinetics, immunogenicity and clinical efficacy, assessed with CT scans using response criteria for use in studies testing immunotherapeutics (iRECIST). The study uses a single cohort design for doses up to 40 mg, and thereafter a modified 3+3 design. **Results:** The first patient was dosed in December 2019; by 22 Jan 2021, twelve patients have been exposed to ATOR-1017. The following dose levels have been evaluated; 0.38 mg; 1.5 mg; 5 mg; 15 mg; 40 mg and 100 mg. Dose escalation is ongoing, and the 200 mg dose level is under evaluation. The maximum tolerated dose has not been reached. The following cancer types are included; ovarian cancer (n = 1), choroidal melanoma (n = 3), anal cancer (n = 1), cholangiocarcinoma (n = 1), gastrointestinal stromal tumor (n = 1), breast cancer (n = 1), pancreatic cancer (n = 1), adenoid cystic cancer (n = 1), malignant melanoma (n = 1), colorectal cancer (n = 1). Drug-related AEs were reported in 5 out of 12 patients; one patient experienced a grade 3, all others were grade 1 or 2. There have been two episodes each of chest pain (grades 2 and 3) and headache (grades 1 and 2). Single cases of pyrexia, upper abdominal pain, mouth ulceration, nausea, leukopenia, neutropenia, cytokine release syndrome (CRS), arthralgia, neck pain, and rash were also reported. No DLTs have been observed in the study to date. The median age of the patients were 48.5 years (range 34-76). Patients received a median of 2 prior lines of therapy (range 1-4). The median time on study were 15 weeks (range 0.14-51). Six patients are on study, and six patients have discontinued treatment. Reasons for discontinuation include; investigator decision (n = 1), confirmed disease progression (n = 1), withdrawal of consent (n = 1), death due to disease progression (n = 1) and other reason (n = 2). Preliminary PK data show dose-proportional kinetics up to 100 mg. Best response has been stable disease. **Conclusions:** ATOR-1017 is safe and well-tolerated up to 100 mg. Dose escalation continues and the current dose level is 200 mg. Clinical trial information: NCT04144842. Research Sponsor: Alligator Bioscience.

Consensus disease definitions for the spectrum of neurologic immune related adverse events. *First Author: Amanda C Guidon, Harvard Medical School, Boston, MA*

Background: Expanding FDA-approved indications for immune checkpoint inhibitors in patients with cancer has resulted in both therapeutic success and immune related adverse events (irAEs). Neurologic irAEs (irAE-Ns) have an incidence of 1-12% and a high fatality rate relative to other irAEs. Lack of standardized disease definitions and accurate phenotyping leads to syndrome misclassification and impedes evidence-based treatments and research progress. The objectives of this study were to develop consensus guidance for an approach to irAE-Ns including disease definitions and severity grading. **Methods:** A working group of 4 neurologists drafted irAE-N consensus guidance and definitions, which were reviewed by the Neuro irAE Disease Definition Panel, consisting of neurologists, oncologists, neuro-oncologists and irAE subspecialists. A modified Delphi consensus process was used, with 2 rounds of anonymous ratings by panelists and 2 virtual meetings to discuss areas of controversy. Panelists rated content for usability, appropriateness and accuracy on 9-point scales in electronic surveys and provided free text comments. The working group aggregated survey responses and incorporated them into revised definitions. Consensus was based on numeric ratings using the RAND/UCLA Appropriateness Method with prespecified definitions. **Results:** Twenty-seven panelists from 15 academic medical centers voted on a total of 53 rating scales (6 general guidance, 24 central and 18 peripheral nervous system disease definition components, 3 severity criteria and 2 clinical trial adjudication statements); of these, 77% (41/53) received first round consensus. After revisions, all items received second round consensus. Consensus definitions were achieved for 7 core disorders: irMeningitis, irEncephalitis/Encephalomyelitis, irDemyelinating disease, irVasculitis, irNeuropathy, irNeuromuscular junction disorders and irMyopathy. For each disorder, 6 sub-classifications are described: disease subtype, diagnostic certainty, severity, autoantibody association, exacerbation of pre-existing disease or de novo presentation and present or absent concurrent irAE. **Conclusions:** These disease definitions standardize irAE-N classification. They are being incorporated into a multi-institutional registry that our group has initiated to study irAEs. Given consensus on their accuracy and usability from a representative panel group, we anticipate that they can be used broadly across clinical and research settings. A risk stratification model for toxicities in phase 1 immuno-oncology (P1-IO) trials. *First Author: Alberto Hernando-Calvo, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada*

Background: Despite an exponential increase in the number of potential targets in the immuno-oncology (IO) field, lack of risk models to predict toxicities remains a challenge in early drug development. We proposed a risk stratification strategy and investigated whether different IO classes may be associated with incremental risk of toxicities. **Methods:** A systematic search for IO studies from 01/2014 to 10/2020 was conducted. Among the 12053 abstracts screened, 254 reporting phase I-IO trials were selected. Type of IO treatment (IO monotherapy [mono] vs IO combination [comb]), therapeutic class (e.g. IO, molecularly targeted agents [MTA]), and dose escalation method (rule-based, model-based and model-assisted) were collected. A risk scoring model was developed after expert consensus: treatment-related deaths (1:yes, 0:no), incidence of G3/G4 treatment related adverse events (TRAE) or treatment emergent adverse events (TEAE) (0 if 1-29%,1 if ≥30-49%, 2 if ≥50%), incidence of ≥G2 cytokine release syndrome (1:yes, 0:no), incidence of ≥G2 encephalopathy (1:yes 0:no) and incidence of dose-limiting toxicity (DLT) (0:no, 1:lab, 2:clinical). Risk categories were defined by summing all points (0 = low, 1-2 = intermediate, 3+ = high) and were correlated with type of IO treatment, therapeutic class and dose escalation method. **Results:** Of 254 P1-IO trials reviewed, 228 (90%) were scorable, 26 were not (25 due to lack of AE data). Up to 10/26 (38%) of non-scorable studies were cell therapies. Among the 228 scorable studies, 120 (53%) scored 0, 65 (28%) scored 1-2, 43 (19%) scored 3+; 24 (11%) and 125 (55%) did not provide no. of pts with G3/G4 TRAEs or TEAEs respectively. A significant association was observed between risk categories and therapeutic class ($p<0.001$) (see table). Additionally, IO-MTA and IO-IO were both associated with an increased risk of toxicity as compared to IO-mono (OR=3.91 (95%CI 1.7-9.2), p=0.002) and (OR=2.79 (95%CI 1.2-6.5), p=0.02) respectively. There was no association between dose escalation method and risk of toxicity (p=0.95), but 182 (92%) used rule-based methods. **Conclusions:** Our results suggest that different IO classes are associated with different risks of toxicity. This risk classification strategy may guide future clinical trial design. Additionally, standards for reporting toxicities in P1-IO trials are urgently needed. Research Sponsor: None.

IO class	N	Score = 0	Score = 1-2	Score = 3+
AntiPD-1/PD-L1 (mono)	20	11 (55)	7 (35)	2 (10)
AntiPD-1/PD-L1 (comb)	22	5 (23)	9 (41)	8 (36)
AntiCTLA-4	8	1 (13)	4 (50)	3 (37)

Prevalence of hyperprogressive disease (HPD) mutations and correlations to immune-related biomarkers in a large pan-cancer Chinese cohort. *First Author: Shengli Yang, Department of Thoracic Surgery, Foshan First People's Hospital, Foshan, China*

Background: Immune checkpoint blockade (ICI) therapies have demonstrated inspiring clinical efficacy in multiple types of cancer. However, a subset of patients suffered rapid tumor growth after ICI treatment, which is known as hyperprogressive disease (HPD). Although the mechanism of HPD has not been fully elucidated, some genomic alterations, such as CDKN2A/CDKN2B loss and MDM2/MDM4 amplification were reported to occur in tumors with ICI-related HPD. We analyzed the prevalence of these four "HPD mutations" and their association with PD-L1 expression, TMB, and occurrence of driver gene mutations in a large pan-cancer Chinese cohort. **Methods:** Patients whose tumor tissues were subjected to molecular profiling using targeted next-generation sequencing from January 2017 – November 2020 were included. Single nucleotide variants (SNV), copy number variants (CNV), insertion/deletions (indels) and fusions were called. PD-L1 expression was stratified by CPS 5. Fisher's exact test were conducted to compare the frequencies of biomarkers and Mann-Whitney U test was used to compare the TMB level between the "HPD mutations" group and their wild-type counterpart. **Results:** 45,785 patients of 22 types of cancer were queried. Across all 22 cancers, CDKN2A loss and CDKN2B loss were most commonly seen in ESCA (23.3%, 19.8%), while with the lowest frequency in PRAD (0.18%, 0.18%). MDM2 gain and MDM4 gain occurred most frequently in SARC (14.6%) and BRCA (3.3%), respectively, with the lowest frequency in COAD (0.05%, 0.07%). PD-L1 positive (CPS≥5) rates were similar in CDKN2A/B loss, MDM2/4 amp and wild-type groups in the whole cohort (26.1%, 25%, 27.7%). Enrichment of PD-L1 positivity was not observed in HPD-mutant groups in a specific cancer type. Compared with wild-type group, CDKN2A/B loss significantly correlated with higher TMB levels in NSCLC and SARC ($p < 0.05$) while MDM2/4 amp correlated with lower TMB levels in NSCLC, BTC, and STAD ($p < 0.05$). In NSCLC, SNV in EGFR, TP53, KEAP1, NFE2L2, STK11, PIK3CA, and SMARCA4 genes were significantly enriched in the CDKN2A/B loss group, while SNV in EGFR, RBM10, AR, KDR genes, and fusion in RET were significantly enriched in MDM2/4 amp group. **Conclusions:** HPD mutations were significantly associated with TMB level and occurrence of some driver genes, but were not correlated with PD-L1 expression. Our results revealed the immune-related molecular characteristics in tumors with HPD mutations, providing more insights into the exploration for mechanism of HPD. Research Sponsor: None.

Pembrolizumab patient reported benefits: A perspective based on multiple tumors. *First Author: Elise Wu, Merck, North Wales, PA*

Background: Pembrolizumab is a programmed death ligand receptor-1 (PD-L1) treatment indicated for multiple tumors. Patient-reported outcomes (PRO) benefit has only been reported at the tumor level, while a holistic review of PRO effects across tumor types has been missing. We performed a systematic review of PRO to assess the overall health-related quality of life (HRQoL) among cancer patients treated with pembrolizumab across multiple tumors. **Methods:** We systematically searched PRO evidence published from January 2014 to April 2020 across approved pembrolizumab indications using Embase, MEDLINE, and CENTRAL. Eligible studies were required to assess cancer patients treated with pembrolizumab (200 mg or 2mg/kg Q3W) and report PROs and/or HRQoL. The PRO evidence was summarized into three categories: short-term (≤Week 12), mid-term (Week 13-Week 24), and long-term (Week 25-Week 52). A clinically meaningful difference in HRQoL is defined as at least a 10 points improvement or deterioration relative to baseline; a change between ± 10 points is defined as stable. **Results:** We screened 1,262 citations, of which 16 publications reported EORTC QLQ-C30 data; 10 (9 trial-based studies; 1 observational study) of 16 publications reported global health status (GHS) mean change from baseline (CFB) across six indications. Within trial based studies in first-line setting (n=3 studies), the short-term, mid-term, and long-term GHS changes from baseline vary from 0.5 to 2.1, 1.2 to 8.4, and 1.6 to 2.5, respectively. For second-line plus setting (n=6 studies), GHS changes vary from -3.3 to 8.6, -1.0 to 10.9, and -0.9 to 9.2, respectively. Eight trial-based publications reported EORTC QLQ-C30 domain data as CFB. Short- or mid-term mean changes in functioning domain data showed improvement or stability in emotional, cognitive, role, and social functioning. Short-term deterioration in physical functioning was observed for 1 study, whereas physical functioning remained stable for other studies. For symptom domains, deterioration was not observed in any studies; mid-term improvement was reported by one study each in fatigue, dyspnea, and appetite loss; 2 studies reported mid-term improvement in pain. **Conclusions:** This is the first study that presented pembrolizumab PRO evidence at the product level. This study suggests that most pembrolizumab-treated patients maintained or improved HRQoL relative to baseline at pre-defined timepoints. This review's limitations include potential publication bias and lack of meta-analytic methods in reporting results. Nevertheless, these findings provide additional information about pembrolizumab's benefits to physicians and patients from a patient-centric perspective. Research Sponsor: Merck.

Pseudoprogression and cancer immunotherapy: A seven year retrospective study of rate, temporal course, and predictive markers in an Irish tertiary referral center. *First Author: Kate McKendry, Department of Medical Oncology, Dublin, GA, Ireland*

Background: Immunotherapy is a relatively new treatment strategy which has achieved unprecedented clinical efficacy in many advanced malignancies. However, the pattern of tumour response to immunotherapy is distinct from other therapies and poses major challenges to clinicians. One such challenge is pseudoprogression. The aim of this study was to assess the current management of patients on immunotherapy with radiological evidence of disease progression at first restaging imaging in an Irish cancer centre, and to determine the rate, time course, and predictive markers of pseudoprogression in those patients treated beyond progression (TBP). **Methods:** Patients treated with immunotherapy for metastatic malignancy in MMUH between March 2013 and September 2020 were retrospectively drawn. Inclusion required follow-up restaging imaging every 4-12 weeks for the duration of treatment. Patterns of response during immunotherapy were established from radiology reports and categorized as stable (SD), response (R), mixed disease (MD), or progressive disease (PD). Pseudoprogression was defined as progression/ mixed disease at first restaging compared to baseline followed by subsequent response/stable disease. **Results:** The cohort of 228 patients was comprised of 80 NSCLC, 74 melanoma, 25 RCC, 19 gynaecological, 14 gastrointestinal, 6 breast, 1 ESSCLC, and 9 other cancer patients. Median age was 61.16 (IQR 49.47-69.44). Therapeutic agents were anti-PD1 alone (176) or in combination with targeted therapy (6) or CTLA4 (13), CTLA4 alone (15), and anti-PD-L1 alone (13) or in combination with chemotherapy (5). At first restaging, the number (%) classified as SD, R, MD, and PD, respectively, was 29 (12.8), 62 (27.2), 16 (7), and 76 (33.3). Treatment was stopped prior to restaging in 44 (19.3) cases. Of the 92 patients with mixed/ progressive disease, 41 were TBP and 51 were not treated beyond progression (NTBP). Evidence of radiological progression and worsening performance status (PS) were the most common reasons given by clinicians for NTBP. Of those TBP, 20 had subsequent response/stable disease, occurring at a median of 105.50 (range 58.0-420) days after the initial restaging scan and giving an overall pseudoprogression rate of 8.8%. At one year, 100% of the pseudoprogression group was alive. The neutrophil-lymphocyte ratio (NLR) was significantly lower in the pseudoprogression group compared to those with true progression ($p = 0.006$). There was no significant difference in performance status between the two groups. **Conclusions:** Pseudoprogression on cancer immunotherapy is real but uncommon, with an overall incidence of 8.8%. It can occur any time up to 420 days after initial progression and indicates a high likelihood of > 1 year survival. A low NLR may be a useful predictor of pseudoprogression but a technological solution is likely needed. Research Sponsor: None.

Proton pump inhibitors and antibiotics impact on toxicities and clinical outcomes in cancer patients treated with immunotherapy. *First Author: Haniel alves Araujo, Instituto do Càncer do Estado de São Paulo (ICESP), São Paulo, Brazil*

Background: Gut microbiome dysbiosis impairs systemic immune responses and recent evidence suggests its critical role in patients (pts) treated with immune checkpoint inhibitors (ICI). Proton pump inhibitors (PPI) and antibiotics (ATB) may alter the microbiome and their impact on clinical outcomes and toxicities requires further investigation. **Methods:** This retrospective cohort included consecutive metastatic cancer pts treated with ICI with palliative intent. We reviewed pts' records, concomitant medication and toxicities graded by CTCAE 4.0. Pts with PPI or ATB exposure were analyzed according to previous use (pPPI and pATB, ≤60 days to ICI) and concomitant use (cPPI and cATB). We estimated median overall survival (mOS) and progression free survival (PFS) by Kaplan–Meier and used a Cox proportional-hazards model to adjust for differences in baseline characteristics. Toxicities and ATB/PPI interaction was calculated using Pearson Chi-square method. **Results:** We enrolled 216 pts with a median age of 59 years, mostly ECOG-PS 0 (34%) or 1 (58%). ICI employed were mostly anti-PD-1 (60.2%), anti-CTLA-4 (16.2%) and anti-PD-L1 (12.5%). Most frequent primary tumor sites were lung n = 39 (18.1%), gastrointestinal n = 34 (15.7%) and melanoma n = 33 (15.2%). Half of the pts (108) received ATB and 114 (52.8%) PPI. Compared to control, pPPI group n = 57 (26.4%) had shorter mOS (11.6m vs 19.7m, $p < 0.001$) and PFS (2.8m vs 8.5m, $p < 0.001$), but no statistically significant difference in toxicities grade ≥3 and/or leading to ICI discontinuation (36% vs 29.1%; p = 0.29). cPPI n = 100 (46.3%) depicted a negative impact on mOS (12.1m vs 17.0m; p = 0.01), PFS (4.3m vs 7.1m; p = 0.04) and augmented toxicities (42% vs 19%; $p < 0.001$). pATB n = 34 (15.7%) had shorter OS (6.9m vs 19.3m, $p < 0.001$) and PFS (3.2 vs 7.2m, p = 0.005) and higher incidence of toxicities (45.9% vs 28.1%; p = 0.04). cATB use n = 92 (42.6%) did not impact OS (12.1m vs 15.6m; p = 0.32) or PFS (5.5m vs 5.9m; p = 0.82), but had a higher incidence of toxicities: 37% vs. 24.2% (p = 0.05). Multivariate analyses confirmed that pATB therapy and pPPI respectively remained as independent prognostic variables associated with OS (HR 2.39; 95% CI, 1.60-3.59; $P < .001$ and HR 1.73; 95% CI 1.23-2.44; P = 0 .002) and PFS (HR 1.72; 95% CI, 1.14-2.61; P = 0.01 and HR 2.36; 95% CI 1.67 - 3.34; $P < 0$ .001) adjusted by performance status, age and line of treatment. **Conclusions:** These data suggest that concomitant use of PPI and ATB is associated with increased toxicities in ICI treated pts. pPPI and pATB can negatively impact OS and PFS and merit clinician's attention. Research Sponsor: None.

2653 **Poster Session**

Impact of pharmacodynamic biomarkers in immuno-oncology (IO) phase 1 clinical trials. *First Author: Abdulazeez Salawu, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada*

Background: Pharmacodynamic biomarkers (PD) are considered fundamental for go/no-go decisions in phase 1 trials. Despite an increase in the availability of blood-based biomarker assays, the requirement of invasive non-diagnostic research tumor biopsies for trial eligibility remains common. In the immuno-oncology (IO) era, the impact of PD analysis for the confirmation of biologic activity and recommended phase 2 dose (RP2D) has not been investigated. **Methods:** Phase 1 studies from 01/2014 to 12/2018 were reviewed. Among 12053 abstracts screened, a total of 143 phase I-IO trials were identified. Characteristics of studies that included on-treatment PD biomarkers (tissue-derived, blood-based and radiomic) were extracted and analyzed. Outcomes from the biomarker data in terms of proof of mechanism/biologic activity and statistically significant correlation with clinical benefit (objective response or survival) were collected. Authors' statements on the influence of PD results on RP2D were also noted. **Results:** Out of 143 phase 1 IO trials, 107 (75%) were monotherapy. The most frequent IO evaluated were vaccines (41%), cell therapy (16%), immunomodulators (13%) and cytokines (7%). Of the 36 combination studies, 20 (61%) included a second IO drug while 16 (39%) included molecular-targeted agents. Only 18 of 143 studies (12%) did not report any PD data. Of the remaining 125 studies, tissue-derived PD (t-PD) biomarkers alone, blood-based PD (b-PD) biomarkers alone, both t-PD and b-PD biomarkers, and imaging biomarkers were tested in 3 (2%), 97 (78%), 25 (20%), and 7 (6%), respectively. Demonstration of proof of mechanism/biologic activity only were reported in 16/28 (57%), 80/122 (66%) and 4/7 (57%) of the t-PD, b-PD and imaging biomarker studies, respectively. Significant correlation with clinical benefit was reported in 2/28 (7%), 7/122 (6%) and 0/7 (0%) of the t-PD, b-PD and imaging biomarker studies, respectively; these involved 4 vaccines (1 in combination with PD1 blockade), 1 cell therapy and 1 oncolytic virus (in combination with CTLA4 blockade). Among 35 b-PD studies with negative results, 5 also performed t-PD biomarkers, all with negative results. Notably, 3 out of 10 t-PD studies with negative results reported concurrent positive b-PD results. Based on the published reports, authors stated that biomarker results helped with RP2D determination in 16/28 (57%) of t-PD and 78/122 (64%) of b-PD studies. **Conclusions:** Our results suggest that in the IO era, most studies perform PD analysis, with similar proportions of t-PD and b-PD showing proof of mechanism/biologic activity. IO PD biomarkers have limited correlation with clinical benefit. Many authors considered IO PD biomarkers to be relevant in RP2D decisions, but this needs confirmation by other measures of impact. With continued technological developments utilizing circulating biomarkers, b-PD may ultimately replace many t-PD tests in future IO studies. Research Sponsor: None.

2654 **Poster Session**

Impact of multidisciplinary severe immunotherapy complication service on outcomes for cancer patients receiving immune checkpoint inhibition. *First Author: Leyre Zubiri, Massachusetts General Hospital, Boston, MA*

Background: The exponential increase in FDA-approved indications for immune checkpoint inhibitors (ICI) in cancer care has resulted in therapeutic success but also in the occurrence of immune-related adverse effects (irAEs) that can represent a significant clinical challenge. On October 3 2017, the Massachusetts General Hospital (MGH) implemented the Severe Immunotherapy Complications (SIC) Service, a multi-disciplinary care team for patients hospitalized with irAEs. The objectives of this study were to evaluate the impact of SIC Service on 1) healthcare utilization and 2) patients outcomes. **Methods:** Using pharmacy and hospital admission databases, a list of patients was identified that both received ICI for a malignancy and were hospitalized with severe irAEs in the period prior to initiation of the SIC service and after SIC initiation. The pre-SIC period was defined as an admission between 4/2/2016 through 10/3/2017, and the post-SIC period as an admission from 10/3/2017 through 10/24/2018. The rate of readmission after the index hospitalization was the primary outcome. Secondary outcomes included lengths of stay (LOS) for both initial irAE admissions and readmissions, use of corticosteroids and non-steroidal second-line immunosuppression, ICI discontinuation, and inpatient mortality in the pre- and post-SIC periods. **Results:** Among 1169 patients treated in the pre-SIC service intervention period; 127 were hospitalized for irAE. Among 1159 patients treated in the post-SIC intervention 122 were hospitalized for irAE. SIC Service implementation was associated with a significant reduction in irAE readmission rates (post-SIC 14.8% vs. pre-SIC 25.9%; odds ratio [OR], 0.46; 95% CI, 0.22-0.95; p=0.036). The length of stay, rates of corticosteroid use, second-line immunosuppression, and ICI discontinuation for irAE, as well as inpatient mortality rates were not significantly different before and after SIC Service implementation. **Conclusions:** This is the first study to report that establishing a highly subspecialized care team focused on irAEs can be associated with improved clinical outcomes for patients receiving ICI therapy. Such care teams may play an essential part in optimizing irAE care. Research Sponsor: None.

2655 **Poster Session**

Patients with steroid-refractory toxicity following immune checkpoint inhibitors: Frequent hospitalizations and long duration of illness. *First Author: Mia Bothwell, Massachusetts General Hospital, Boston, MA*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of cancer with significantly improved outcomes, but these agents have a unique spectrum of toxicities known as immune-related adverse events (irAEs). The recommended treatment for non-endocrine toxicities is steroid based. However, a subset of patients (pts) is steroid-refractory and requires second-line immunosuppression. There is very little evidence regarding this population. In this retrospective study we report the 1) incidence 2) type of treatment used 3) natural history and 4) potential predictors of steroid-refractory irAE at a major academic medical center. **Methods:** The Research Patient Database Registry at Mass General Brigham was used to identify pts treated with an ICI from 1/5/2017 to 6/1/2019. Pharmaceutical records identified a subset of the cohort received a second-line immunosuppressive agent within a 15-month period after ICI. For pts with steroid-refractory irAE additional information was collected: demographics, ICI regimen, type/#/and severity of irAE, clinical characteristics, # of admissions, length of stay (LOS), amount and duration of steroid therapy, second line immunosuppression type, treatment discontinuation rates, response, and outcome of re-challenge. Multivariate logistic regressions were used to predict risk of refractory toxicity and study the association of different variables (age, sex, race, marital status, cancer and ICI types) with refractory toxicities. **Results:** We identified 61 pts (1.4%) with steroid-refractory irAEs (48 colitis, 4 myocarditis, 6 pneumonitis, 3 neurologic) out of the total ICI cohort (N=4,325). 60.7% received ICI monotherapy. 24.6% received ICI in the adjuvant setting. Median length of steroid duration was 68 days with max of 1135 days. Despite use of second line immunosuppression, 25.8% of pts were never able to discontinue steroids. Majority of pts (72.1%) had at least one hospitalization with median LOS of 7.5 days. 93.4% of pts permanently discontinued the ICI responsible for the irAE. Thirteen pts (21.3%) were later re-challenged with ICI and 7 (53.8%) of these developed a subsequent irAE. Anti-CTLA-4 therapy was associated with a 10-fold risk of refractory toxicity compared to PD-1 ($p<.05$). Best tumor response was complete response in 21.3% and partial response in 26.2%. Among different cancer types, melanoma was most strongly associated with refractory events (OR 2.97 in comparison to thoracic malignancy). **Conclusions:** Refractory toxicity is uncommon but leads to high rates of ICI discontinuation, frequent hospitalizations, and a long duration of illness with exposure to prolonged and high-doses of steroids. There is an urgent need for further investigation into predictive factors for steroid-refractory toxicity given that ICI is being used more frequently and in earlier lines of treatment. Research Sponsor: None.

TPS2656 **Poster Session**

Zanidatamab, an anti-HER2 bispecific antibody, plus chemotherapy with/without tislelizumab as first-line treatment for patients with advanced HER2-positive breast cancer or gastric/gastroesophageal junction adenocarcinoma: A phase 1B/2 trial-in-progress. *First Author: Keun Wook Lee, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, South Korea*

Background: Zanidatamab is a novel HER2-targeted antibody that binds two distinct extracellular domains of HER2, allowing for multiple mechanisms of action including enhanced binding, clustering, receptor internalization and downregulation; this results in inhibition of ligand-dependent and -independent proliferation and potent activation of antibody-dependent cellular cytotoxicity. Zanidatamab monotherapy is well tolerated and has shown promising anti-tumor activity in patients (pts) with pre-treated advanced HER2-positive cancers, and was well tolerated in a Phase I trial (NCT02892123). Tislelizumab is an investigational anti-programmed death-1 (PD-1) antibody engineered to minimize binding of $Fc\gamma R$ on macrophages in order to abrogate antibody-dependent phagocytosis, which is a potential mechanism of T-cell clearance and resistance to anti-PD-1 therapy. Tislelizumab is well tolerated and has anti-tumor activity alone and in combination with chemotherapy in pts with advanced solid tumors. The highly immunogenic nature of HER2 tumors has led to the development of therapies combining anti-HER2 therapies with immune checkpoint blockade. **Methods:** This open-label, two cohort Phase 1B/2 study (NCT04276493) is designed to evaluate zanidatamab as a first-line therapy with chemotherapy in pts with HER2-positive metastatic breast cancer (mBC; cohort 1) or with chemotherapy + tislelizumab in pts with HER2-positive advanced gastric/gastroesophageal junction adenocarcinoma (GC/GEJC; cohort 2). Weight-based dosing (cohorts 1a and 2a) and flat dosing (cohorts 1b and 2b) regimens of zanidatamab are being investigated. In cohort 1 (n = 20), pts with treatment-naïve HER2-positive (IHC3+ or ISH amplified) mBC will receive intravenous (IV) zanidatamab 30 mg/kg (cohort 1a) or 1800 mg (cohort 1b), plus IV docetaxel 75 mg/m^2 once every 3 weeks (Q3W). In cohort 2 (n = 30), treatment-naïve pts with HER2-positive (IHC3+ or IHC2+ with ISH amplification) advanced GC/GEJC will receive IV zanidatamab 30 mg/kg (cohort 2a), or 1800 mg (pts $<$ 70kg; cohort 2b) or 2400 mg (pts $\geq$ 70kg; cohort 2b), plus IV tislelizumab 200 mg and chemotherapy (CAPOX regimen: oral capecitabine 1000 mg/m^2 twice daily [days 1–14] and IV oxaliplatin 130 mg/m^2 [day 1]) Q3W. For cohort 2 there is a six pt safety lead-in phase, followed by dose expansion after approval by the safety monitoring committee. Primary endpoints are the safety profile and objective response rate. Secondary endpoints include duration of response, time to response, progression-free survival, disease control rate, and overall survival. Clinical trial information: NCT02892123. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Shannon Galgani, MSci, of Ashfield MedComms, an Ashfield Health company, and funded by BeiGene, Ltd.

TPS2657 **Poster Session**

SGNTGT-001: A phase 1 study of SEA-TGT, an effector-function enhanced monoclonal antibody (mAb), in advanced malignancies (trial in progress). *First Author: Elena Garralda, Hospital Vall d'Hebron, Barcelona, Spain*

Background: T-cell immunoreceptor with Ig and ITIM domains (TIGIT) is an inhibitory immune checkpoint receptor expressed on subsets of T cells and NK cells. SEA-TGT is an effector-function enhanced human mAb that targets TIGIT with pico-molar affinity and blocks TIGIT's interaction with CD155 and CD112. SEA-TGT was developed to have amplified binding to and engagement of Fcγ receptors. Enhanced effector function increases TIGIT+ T-regulatory cell depletion, enhances innate immune cell activation, and augments naïve and memory CD8+ T-cell responses. Preclinically, SEA-TGT elicits superior anti-tumor immune responses compared to other TIGIT mAbs without effector-enhanced backbones, with curative anti-tumor activity as monotherapy and in combination with other immune-modulators. **Methods:** This phase 1, open-label, multicenter, dose-escalation/expansion study (NCT04254107) is assessing the safety, tolerability and preliminary activity of SEA-TGT monotherapy in up to 205 adults (≥18 years) with histologically or cytologically confirmed relapsed, refractory, or progressive metastatic solid tumors (non-small cell lung, gastric/GE junction carcinomas, cutaneous melanoma, head and neck squamous cell carcinoma, bladder cancer, ovarian cancer or triple-negative breast cancer) or lymphomas (classical Hodgkin lymphoma, diffuse large B-cell lymphoma, or peripheral T-cell lymphoma, not otherwise specified). SEA-TGT will be infused on Day 1 of 21-day cycles. In Part A, the safety and tolerability of SEA-TGT will be assessed in ~25 subjects to identify the maximum tolerated dose and recommended phase II dose (RP2D). In Part B, the safety and antitumor activity of the RP2D will be assessed in ~180 subjects in disease-specific expansion cohorts. Primary endpoints are adverse events, laboratory abnormalities, dose-limiting toxicities, and dose-level safety and activity. Secondary endpoints are objective response (OR) rates, duration of OR, complete response, progression-free survival, overall survival, PK, and antidrug antibodies. Exploratory biomarkers of SEA-TGT-mediated pharmacodynamic (PD) effects, PK-PD correlations, and correlative analyses of predictive and PD measurements with response, toxicity, and resistance will be explored. The study was opened April 2020 and is enrolling across sites in North America and Europe. Clinical trial information: NCT04254107. Research Sponsor: Seagen Inc.

TPS2658 **Poster Session**

A phase I, first-in-human clinical trial of the GDF-15 neutralizing antibody CTL-002 in subjects with advanced-stage solid tumors (ACRONYM: GDFATHER). *First Author: Ignacio Melero, Universidad de Navarra, Center for Applied Medical Research (CIMA), Pamplona, Spain*

Background: Growth and differentiation factor 15 (GDF-15) is a TGF-β superfamily member physiologically expressed mainly in placenta and linked to feto-maternal tolerance. Under pathophysiologic conditions, prevention of excessive immune cell infiltration during tissue damage and cachexia induction have been ascribed to GDF-15. A recent study [Haake et al. AACR2020; Abstract #5597] elucidated a mechanism by which GDF-15 inhibits LFA-1 activation on CD8+ T cells, thus interfering with effector T cell recruitment to tissues. Importantly, several cancer entities secrete high levels of GDF-15, correlating with poor prognosis and reduced overall survival [reviewed in Front Immunol 2020 May 19;11:951]. To block this effect the GDF-15 neutralizing antibody CTL-002 was generated. In preclinical models CTL-002 demonstrated potent effector T cell shifting into tumor tissue by neutralizing GDF-15. **Methods:** This is a phase 1, first-in-human (FIH), two-part, open-label clinical trial of intravenous (IV) administration of CTL-002 given as monotherapy and in combination with an anti-PD-1 antibody in subjects with advanced-stage, relapsed/refractory solid tumors who relapsed post or were refractory to a prior anti-PD-1/PD-L1 therapy. Eligible subjects have exhausted all available approved standard treatments. Further key eligibility criteria include having received at least one prior anti-PD1/-PD-L1 treatment and having relapsed on or after it or having been refractory to it, and presenting with a biopsy-accessible tumor for serial biopsy taking. The trial is termed GDFATHER, for "GDF-15 Antibody-mediaTed Effector cell Relocation". Main endpoints are safety of CTL-002 monotherapy and CTL-002 combination with an anti-PD-1 antibody, pharmacokinetics, pharmacodynamics (e.g. degree of GDF-15 neutralization achieved and change in immune-cell number and composition in the tumor tissue) as well as preliminary clinical efficacy (tumor mass reduction; anticachexia effect) In part A of the trial (dose escalation) up to 24 subjects will receive escalating doses of CTL-002 IV (0.3 – 20 mg/kg) in a ,,mono-followed-by-combination"-design with CTL-002 given as monotherapy and followed by combination with an anti-PD-1 checkpoint inhibitor. In part B (expansion) up to 5 cohorts with up to 25 subjects per cohort with defined tumor entities expected to be GDF-15 dependent will be treated to determine the recommended phase 2 dose (RP2D) and further evaluate safety and preliminary efficacy of CTL-002 monotherapy and the combination. The study was initiated in December 2020 and enrolled the first patient on Dec 09, 2020. Cohort 1 has been completed without DLT and enrollment for cohort 2 began in February 2021. Clinical trial information: NCT04725474. Research Sponsor: CatalYm GmbH.

TPS2659 **Poster Session**

A phase 1/2, open-label, dose-escalation, safety and tolerability study of NC410 in subjects with advanced or metastatic solid tumors. *First Author: Martin Gutierrez, John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, NJ*

Background: Leukocyte-Associated Immunoglobulin-like Receptor (LAIR)-1 and LAIR-2 are members of the Leukocyte Receptor Complex (LRC) (An & Brodsky, 2016). LAIR-1 is a co-inhibitory receptor expressed on several subsets of immune cells, and functions to delimit immune responses (Meyaard et al., 1997). LAIR-2 is a secreted protein with homology to the transmembrane protein LAIR-1 (Lebbink et al., 2008). In cancer, it is hypothesized that LAIR-1 expression on several subsets of leukocytes prevents optimal immune responses by limiting both innate and adaptive immune functionality. LAIR-1 serves to suppress anti-tumor immunity through the inhibition of stimulatory signaling pathways. Specifically, LAIR-1 is a checkpoint and adhesion receptor on T cells that limits T cell activation and increases adhesion to collagens (Meyaard, 2008). LAIR-2 is capable of blocking LAIR-1 functional interactions with ligands, resulting in improved immune function on multiple immune cell subsets. Dysregulation of LAIR-1 ligands in the tumor microenvironment results in excessive production of collagens and complement C1q as well as altered forms of collagens, that leads to immune inhibition through binding to LAIR-1+ immune cells . NC410 is a dimeric form of the LAIR-2 protein fused to a human Fc domain of the immunoglobulin (Ig) subtype IgG1. The rationale for developing NC410 as a cancer therapeutic is based on nonclinical data demonstrating LAIR-1 signaling blockade can improve the immune response. Because LAIR-2 binds to ligands shared with LAIR-1 with increased affinity, NC410 acts as a decoy receptor for LAIR-1 ligands releasing suppression from myeloid cells and T cells and promoting anti-tumor immunity. NC410 may also mediate remodeling of the tumor extracellular matrix, further contributing to anti-tumor activity. **Methods:** This is a multi-center, first in human, phase 1/2, open-label, single-armed study to determine the safety and tolerability, define maximum tolerated dose (MTD) and/or pharmacologically active dose, assess preliminary efficacy, and explore predictive and pharmacodynamic biomarkers of NC410 in subjects with advanced or metastatic solid tumors. Key eligibility criteria include measurable disease based on RECIST v1.1 and being able to consent for collection of biopsies at screening and on treatment. Phase 1 is a classic 3+3 dose escalation design to determine the safety, tolerability, DLT, MTD and recommended phase 2 dose (RP2D) (NCT04408599). Ongoing exploratory analyses include the assessment of predictive biomarkers associated with treatment benefit, and pharmacodynamic markers associated with study drug activity. Phase 2 is going to enroll ovarian, colorectal, NSCLC, H&N, and gastric carcinomas and other tumors depending on biomarker data available from the Phase 1 part of the study. Clinical trial information: 04408599. Research Sponsor: NextCure Inc.

TPS2660 **Poster Session**

A phase 1, first in human study of adenovirally transduced autologous macrophages engineered to contain an anti-HER2 chimeric antigen receptor (CAR) in subjects with HER2 overexpressing solid tumors. *First Author: Joshua Bauml, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: Adoptive T cell therapies have led to remarkable advances among patients with hematologic malignancies, but not in those with solid tumors. Macrophages are actively recruited into, and abundantly present in the solid tumor microenvironment (sTME). Tumor- associated macrophages typically evince immunosuppressive behavior, but when engineered to be proinflammatory, may be an ideal vector to administer adoptive cellular therapy in solid tumors. Furthermore, insertion of a CAR confers on the macrophages the ability to selectively recognize and phagocytose antigen overexpressing cancer cells. Additionally, CAR macrophages reprogram the sTME and present neoantigens to T cells, leading to epitope spreading and immune memory. Human Epidermal Growth Factor Receptor 2 (HER2) is overexpressed in many cancers, including but not limited to breast and gastroesophageal cancers (Table). CT-0508 is a cell product comprised of autologous monocyte-derived pro-inflammatory macrophages expressing an anti-HER2 CAR. Pre-clinical studies have shown that CT-0508 induced targeted cancer cell phagocytosis while sparing normal cells, decreased tumor burden and prolonged survival in relevant models. CT-0508 cells were safe and effective in a semi-immunocompetent mouse model of human HER2 overexpressing ovarian cancer. **Methods:** This is a FIH phase 1 study to evaluate safety, tolerability, cell manufacturing feasibility, trafficking, and preliminary evidence of efficacy of investigational product CT-0508 in approximately 18 subjects with locally advanced (unresectable) or metastatic solid tumors overexpressing HER2 who have failed available therapies including anti-HER2 therapies when indicated. Filgrastim will be used to mobilize autologous hematopoietic progenitor cells for monocyte collection by apheresis. The CT-0508 CAR macrophage product will be manufactured, prepared and cryopreserved from mobilized peripheral blood monocytes. The study is enrolling Group 1 subjects, who will receive CT-0508 infusion split over D1, 3 and 5. Subjects will be continually assessed for acute and cumulative toxicity. Dose limiting toxicities will be observed and addressed by a Safety Review Committee. Group 2 subjects will follow, and will receive the full CT-0508 infusion on D1. Pre and post treatment biopsies and blood samples will be collected to investigate correlates of trafficking, persistence, TME modulation, immune response and safety. Clinical trial information: NCT04660929. Research Sponsor: Carisma Therapeutics.

HER2 positivity frequencies across tumor types.

Tumor	HER2 positive %*
Bladder	8–70
Breast	11.0–25.0
Cervical	2.8–3.9
Colorectal	1.6–5.0
Esophageal	12.0–14.0
Cholangiocarcinoma	6.3–9.0
Gallbladder	9.8–12.8
Gastric	7.0–34.0
Ovarian	26
Salivary mucoepidermoid	17.6
Salivary duct	30–40
Testicular	2.4
Uterine	3.0

TPS2661 **Poster Session**

Master protocol to assess safety and recommended phase 2 dose of next generation NY-ESO-1–specific TCR T-cells in HLA-A*02 patients with synovial sarcoma or non-small cell lung cancer (Substudies 1 and 2). *First Author: Adam Jacob Schoenfeld, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Letetresgene autoleucel (lete-cel; GSK3377794) is an autologous T-cell therapy using a genetically modified T-cell receptor (TCR) to improve recognition of cancer cells expressing NY-ESO-1/LAGE-1a. Next generation NY-ESO-1 TCR T-cell therapies, such as GSK3901961 and GSK3845097, integrate added genetic modifications to enhance anticancer activity. GSK3901961 co-expresses the CD8α chain to stabilize TCR-human leukocyte A (HLA) class I interactions on CD4+ T cells, improving T-cell persistence and helper functions such as Type 1 T-helper antitumor responses. GSK3845097 co-expresses a dominant negative transforming growth factor-β (TGF-β) type II receptor to reduce TGF-β pathway activation and maintain T-cell proliferation, cytokine production, and cytotoxicity in the tumor microenvironment. A first-time-in-human master protocol (NCT04526509) will evaluate safety, tolerability, and recommended phase 2 dose (RP2D) of these and possible subsequent therapies. Substudy 1 will assess GSK3901961 in patients (pts) with advanced non-small cell lung cancer (NSCLC) or synovial sarcoma (SS). Substudy 2 will assess GSK3845097 in pts with advanced SS. **Methods:** Each substudy includes a dose confirmation stage to assess RP2D and a dose expansion stage. Key inclusion criteria are age $\geq$18 y; measurable disease per RECIST v1.1; HLA-A*02:01, A*02:05, or A*02:06 positivity; NY-ESO-1/LAGE-1a tumor expression; advanced (metastatic/unresectable) SS with t(X;18) translocation and anthracycline-based therapy receipt/completion/intolerance (SS only); and Stage IV NSCLC, receipt of $\geq$1 prior line(s) of standard of care (SOC) therapy including programmed death receptor- or ligand-1 inhibitors, and SOC chemotherapy receipt/intolerance (Substudy 1 only). Key exclusion criteria are prior malignancy that is not in complete remission or clinically significant systemic illness; prior receipt of gene/NY-ESO-1–specific therapy or allogenic stem cell/solid organ transplant; central nervous system metastases (SS only); and actionable genetic aberration and receipt/failure of $\geq$3 systemic therapy lines (Substudy 1 only). Primary endpoints are safety (adverse events) and tolerability (dose-limiting toxicities). Secondary endpoints include investigator-assessed overall response rate, duration of response, and maximum expansion/persistence and phenotype of infiltrating transduced T cells. Exploratory endpoints include laboratory parameters, overall survival, and anti-GSK3901961 or -GSK3845097 titers as applicable. Analyses will be descriptive. The substudies are enrolling. Funding: GSK (209012; NCT04526509). Editorial support was provided by Eithne Maguire, PhD, of Fishawack Indicia, part of Fishawack Health; funded by GSK. Previously presented at AACR 2021 (CT219). Clinical trial information: NCT04526509. Research Sponsor: GlaxoSmithKline (209012).

TPS2662 **Poster Session**

A phase 1 study to evaluate chimeric antigen receptor (CAR) T cells incorporating a chlorotoxin tumor-targeting domain for patients with MMP2+ Recurrent or progressive glioblastoma (NCT04214392). *First Author: Behnam Badie, City of Hope National Medical Center, Duarte, CA*

Background: Glioblastoma (GBM) is the most common and most aggressive primary brain tumor. Around 294,900 new cases are diagnosed globally with 241,000 deaths each year. The 5-year survival is only 5%. Median overall survival from first recurrence is only 5-8 months. There is no established standard of care for recurrent GBM. City of Hope (COH) has developed and optimized a CAR T cell therapy utilizing the chlorotoxin peptide (CLTX) as the CAR's tumor recognition domain against GBM. CLTX-CAR T cells specifically and broadly target GBM through recognition of a receptor complex including membrane-bound matrix metalloprotease 2 (MMP-2). CLTX-CAR T cells do not exhibit off-tumor recognition of normal human or murine cells and tissues in preclinical models. In *in vitro* studies, COH evaluated patient-derived brain tumor (PBT) cell lines for CLTX binding and expression of IL13Rα2, HER2 and EGFR, three targets of CAR T cell trials for GBMs. Strong CLTX binding to tumor cells was observed in of the majority of primary GBM lines, independent of these other antigens. In preclinical studies using *in vivo* mouse models, a single intratumoral (ICT) injection of CLTX-CAR T cells (1×10^6 CAR+ T cells) exhibited robust anti-tumor activity against ffLuc+ PBT106 tumors orthotopically-engrafted in NSG mice. Overall, when compared to mice treated with mock-transduced Tn/mem (no CAR) T cells, the CLTX(EQ)28ζ/CD19t+ T cells reduced tumor burden and significantly increased survival. Taken together, these preclinical findings support the potential safety and efficacy of CLTX-CAR T cells, and provide the rationale for clinical testing of this therapy. As cellular heterogeneity intrinsic to GBM likely contributes to resistance to therapy and limited response rates, CLTX-CAR T cells may provide greater tumor eradication in a higher proportion of patients with GBM. **Methods:** This study is a phase 1, single center, safety and maximum tolerated dose (MTD) finding study of CLTX-CAR T cells for subjects with MMP2+ recurrent or progressive GBM. A safety lead-in of 3−6 participants receiving CLTX-CAR T cells by ICT delivery will be completed first. Subsequently, subjects would receive cells administered through both ICT and intraventricular (ICV catheters) (i.e. dual delivery) in two dose schedules. Subjects will be evaluated for safety and tolerability, and may continue to receive treatment until disease progression. Time to progression, overall survival, and disease response by Response Assessment in Neuro-Oncology (RANO) criteria, will be evaluated and descriptively compared to historical data. The study is actively enrolling patients. Clinical trial information: NCT04214392. Research Sponsor: U.S. National Institutes of Health.

TPS2663 **Poster Session**

Phase I study of adoptive immunotherapy for advanced MUC1* positive breast cancer with autologous T cells engineered to express a chimeric antigen receptor, huMNC2-CAR44 specific for a cleaved form of MUC1 (MUC1*). *First Author: Jennifer M. Specht, University of Washington, Seattle, WA*

Background: Chimeric antigen receptor (CAR) T cell therapy targeting CD19 results in marked tumor regression for patients with CD19+ malignancies. It would be ideal to extend the success of CAR-T cell therapy to epithelial cancers. MUC1* is a post-translationally modified/cleaved form of mucin 1 (MUC1) that is frequently expressed on breast tumors, functions as a growth factor receptor, and a promising antigen for CAR-T cell therapy. Minerva Biotechnologies developed a CAR (huMNC2-CAR44) which recognizes MUC1* and does not bind to full-length or MUC1* negative cells. huMNC2-CAR44 product consists of autologous T cells transduced with a lentiviral vector encoding humanized MNC2-scFv (MUC1* targeting head), sequences from CD8 ? leader, hinge and transmembrane domains, 4-1BB and CD3ζ domains. **Methods:** NCT04020575 is a phase I study evaluating the safety of adoptively transferred autologous T cells genetically modified to express huMNC2-CAR44 in patients with metastatic MUC1* positive breast cancer. After screening, leukapheresis is performed, CD8+ and CD4+ T cells are selected, transduced with huMNC2-CAR44, expanded, and antigen stimulated *in vitro*. Lymphodepletion with cyclophosphamide and fludarabine is followed by infusion of huMNC2-CAR44 CAR-T cells in escalating doses (3.3×10^5 CAR+ T cells/kg – 1×10^7 CAR+ T cells/kg). Key inclusion criteria include metastatic breast cancer of known ER, PR and HER2 status, MUC1* membrane expression $>$ or = 30% with 2+ staining by IHC, measurable or evaluable disease, receipt of standard systemic therapies known to confer benefit, age $>$ 18, informed consent, adequate organ function, and KPS $>$ or = 60%. Patients with active autoimmune disease, uncontrolled infection, anticipated survival $<$ 3 months, and/or untreated CNS metastases are not eligible. The primary objective is to identify the maximum tolerated (MTD) dose of huMNC2-CAR44 T cells by CTCAE v5 and Lee criteria. Secondary objectives include persistence and phenotype of adoptively transferred huMNC2-CAR44 T cells and preliminary antitumor activity. Exploratory objectives include trafficking of huMNC2-CAR44 T cells to tumor sites, effector function of huMNC2-CAR44 T cells *in vivo*, association between tumor MUC1* expression and huMNC2-CAR44 T cell persistence and response, change in tumor immune microenvironment by multiplex IHC in pre- and post-treatment tumor biopsies. Dose escalation is completed using a "3+3" design. Once the MTD has been determined, up to 15 more patients will be enrolled in each of 3 expansion cohorts (Luminal, HER2 positive, and TNBC) to inform future huMNC2-CAR44 T cell trials. Study is open to screening and enrollment in dose escalation. Up to 69 patients may be enrolled in dose escalation and expansion phases. Clinical trial information: NCT04020575. Research Sponsor: Minerva Biotechnologies, Other Foundation.

TPS2664 **Poster Session**

A phase 1 study of RTX-321, an engineered red blood cell as an artificial antigen-presenting cell expressing HLA-A*02 with the HPV-16 E7 peptide and 4-1BB ligand with membrane-bound IL-12 for the treatment of HPV 16-positive cancers. *First Author: Johanna C. Bendell, Sarah Cannon Research Institute/Tennessee Oncology PLLC, Nashville, TN*

Background: High-risk strains of HPV (HPV 16/18) have been associated with the development of multiple cancers, and the associated viral antigens are validated targets from immunotherapy approaches. We engineered red blood cells into allogeneic, off-the-shelf, artificial antigen-presenting cells (aAPCs) that express a human papillomavirus (HPV) 16 E7 peptide bound to human leukocyte antigen (HLA)-A*02:01, the costimulatory molecule 4-1BB ligand (L), and the cytokine interleukin (IL)-12 on the cell surface. This aAPC, RTX-321, activated HPV specific T-cells and promoted effector function *in vitro.* In animal models using a murine surrogate system, this aAPC approach resulted in robust antigen-specific T-cell expansion, NK cell expansion, tumor control, memory formation and antigen spreading, which led to a broad and robust antitumor immune response. The presence of 4-1BBL and IL-12 induced minimal toxicities in these models due to restriction of the biodistribution of the aAPC to the vasculature and spleen. RTX-321 is a potential *in vivo* cellular immunotherapy for treating HPV 16-positive cancers including cervical, head and neck and anal cancers. **Methods:** The RTX-321-01 study is a phase 1 multi-center, dose-escalation study of RTX-321 administered intravenously every 3 weeks in HLA-A*02:01-positive patients with relapsed or refractory HPV 16-positive cancers of the cervix or anal canal, or squamous cell cancers of the head and neck (HNSCC). Patients with cervical cancer or HNSCC will undergo testing for the presence of the HPV 16 virus or provide confirmation from archival tumor tissue prior to enrollment. Patients with anal cancer will not be required to have prospective determination of HPV 16-positive status prior to enrollment given the high incidence in this indication (approximately 80-85 percent of anal cancers). Approximately 18 patients will be enrolled across dose level cohorts to identify the recommended phase 2 dose (RP2D) of RTX-321, followed by RP2D expansion cohorts in specific indications. The starting dose is 1 billion ($1x10^9$) cells administered intravenously every 3 weeks (Q3W) and the dose will escalate by half-log increments, following a Bayesian logarithmic regression model (BLRM) with overdose control. Translational studies will investigate the activation and expansion of HPV16 E7 antigen-specific responses as well as broad innate and adaptive responses in multiple peripheral blood samples over the first 3 cycles of therapy as well as in optional paired tumor biopsies. At this time, the study is open and enrolling patients in the first dose escalation cohort (NCT04672980). Clinical trial information: NCT04672980. Research Sponsor: Rubius Therapeutics.

TPS2665 **Poster Session**

Identification of a microbiome signature predicting immune checkpoint inhibitor outcomes across multiple cancer types in the MITRE study. *First Author: Philippa Gail Corrie, Department of Oncology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom*

Background: The gut microbiome is implicated as a biomarker of response to immune checkpoint inhibitors (ICIs), based on preclinical mouse models and preliminary observations in limited patient series. Furthermore, early reports suggest faecal microbial transfer may have therapeutic potential, converting ICI non-responders to responders. So far, identification of specific responsible bacterial taxa has been inconsistent between published studies, which limits future application. By culturing and metagenomic sequencing of stool sample bacteria, our group has identified a unique microbiome signature, which appears to be predictive of response to ICIs across all key published series as well as our own melanoma patient series (Robinson M *et al*, J Immunother Cancer 2020;8(suppl 3):A404). Because the patient numbers in all published series remain low, we are now further exploring and validating this microbiome signature in a larger scale study across several different cancer types. **Methods:** MITRE (Microbiome Immunotherapy Toxicity and Response Evaluation) is a UK NIHR portfolio multi-centre prospective study funded jointly by Cancer Research UK and Microbiotica (NCT04107168). Up to 1800 patients receiving ICIs will be recruited over a 5-year period. In the first stage, 300 patients with advanced melanoma (cohort 1: anti-PD1 monotherapy, cohort 2: anti-PD1+anti-CTLA-4 combination), renal cancer (cohort 3: anti-PD(L)1+kinase inhibitor, cohort 4: anti-PD1+anti-CTLA-4 combination) and non-small cell lung cancer (cohort 5: anti-PD(L)1 monotherapy, cohort 6: anti-PD(L)1+chemotherapy+anti-angiogenic) are being recruited, 50 patients to each cohort. A cohort-specific, simulation-based power calculation will then be performed, guiding subsequent recruitment. Stool and blood are collected prior to treatment, at 3, 6 and 12 months, or disease progression (whichever is sooner), as well as after any grade >3 immune-related adverse events. Patients collect and freeze their own stool samples which are cultured and subjected to shotgun metagenomic sequencing. Plasma, whole blood, buffy coat, RNA and PBMCs are being stored, for correlative studies. Any tumour, or organ biopsies, taken prior to and during treatment are also being collected. Clinical data collection includes treatment, disease response (using RECIST criteria) and toxicity. The primary outcome measure is 1 year progression-free survival. Patients are also asked to invite a household member to be part of the study control group. Recruitment started in July 2020. The Covid-19 pandemic hindered recruitment last year, but the protocol was amended to incorporate a Covid-19 substudy (to document testing, infection and vaccination) and adapt processes for remote trial delivery as much as possible. As of February 2021, 7 sites have opened, 17 patients and 5 household controls have been recruited. Clinical trial information: NCT04107168. Research Sponsor: Cancer Research UK, Pharmaceutical/Biotech Company.

TPS2666 **Poster Session**

Phase I/Ib study with INT-1B3, a novel LNP-formulated micro-RNA (miR-193a-3p mimic) therapeutic for patients with advanced solid cancer. *First Author: Nuria Kotecki, Institut Jules Bordet, Bruxelles, Belgium*

Background: MicroRNAs (miR) are naturally-occurring small non-coding RNA molecules involved in the regulation of gene expression and their dysregulation plays a fundamental role in several pathological conditions including cancer. The miR-193a-3p acts as a tumor suppressor and is downregulated in many cancer types. INT-1B3 is a novel lipid-nanoparticle (LNP) formulated 1B3, a 22-nucleotide double stranded chemically-modified miR-193a-3p mimic. INT-1B3 showed significant tumor growth inhibition in a large panel of human and syngeneic tumor models. It directly targets tumor cells and the tumor microenvironment by specific modulation of multiple signaling pathway components. Furthermore, in syngeneic mice models for e.g. TNBC (4T1) and HCC (H22), INT-1B3 was able to modulate the immune tumor microenvironment by turning 'cold' tumors into 'hot' tumors *via* upregulation of cytokines (e.g., IL-2 and IFN-g), decreasing immunosuppressive cells/Treg (e.g., CD4+ /LAG3+ and CD3+ /FoxP3+) and triggering cytotoxic CD8+ T cell-mediated long-term memory immune protection against rechallenge with tumor cells. These preclinical results suggest potential clinical benefit in a broad range of cancer indications, and a reduced potential to develop drug resistance due to its multi-targeted mode of action. **Methods:** This is a 2-part, multi-center, open-label, multiple ascending dose, first-in-human, clinical study to evaluate the safety, pharmacokinetics, pharmacodynamics, and preliminary efficacy of INT-1B3 in the treatment of patients with advanced solid tumors. The phase 1 part follows a 'hybrid' 3+3 study design in 'all-comer' cancer patients enrolled and treated in cohorts to define the recommended phase 2 dose (RP2D). Upon completion of the dose escalation phase of the study, 2 expansion cohorts are planned to further confirm the safety, tolerability, and preliminary efficacy of the RP2D of INT-1B3 in patients with hepatocellular carcinoma and triple negative breast cancer. Major eligibility criteria include evaluable disease according to RECIST 1.1 and no more than one prior line of anti-PD-1/PD-L1 therapy. Patients will receive INT-1B3 *via* 60-min i.v. infusions twice a week in 21-day cycles. The first patient was enrolled on January the 14th 2021. Clinical trial information: NCT04675996. Research Sponsor: InteRNA Technologies BV.

TPS2667 **Poster Session**

Phase 1/2 study of the novel SUMOylation inhibitor TAK-981 in adult patients (pts) with advanced or metastatic solid tumors or relapsed/refractory (RR) hematologic malignancies. *First Author: Arkadiusz Z. Dudek, University of Minnesota, Department of Medicine, Division of Hematology, Oncology, and Transplantation, Minneapolis, MN, Regions Cancer Care Center, HealthPartners, Saint Paul, MN*

Background: SUMOylation, a posttranslational modification analogous to ubiquitination, attaches a small, ubiquitin-like modifier (SUMO) to target proteins. SUMOylation plays a central role in regulating type I interferon (IFN-I)-dependent innate response and functions to constrain the innate immune response, which can impair tumor immune surveillance. TAK-981 is a first-in-class, small-molecule inhibitor of SUMO-activating enzyme subunit 2 (SAE2). Inhibition of SAE2 by TAK-981 disrupts SUMOylation, thereby allowing innate immune system activation. In *ex vivo* assays, TAK-981 increased phagocytic activity of monocyte-derived macrophages, increased natural killer cell cytotoxicity, and induced markers of dendritic cell activation and maturation via IFN-I signaling. In syngeneic mouse models, TAK-981 resulted in antitumor activity, including complete remissions, and a sustained, protective antitumor immune response. **Methods:** This first-in-human study of single-agent TAK-981 comprises two parts. Phase 1 primary objectives are to determine safety and tolerability, and to select a recommended phase 2 dose (RP2D); secondary objectives are to assess preliminary antitumor activity, characterize pharmacokinetics (PK), and explore pharmacodynamic (PD) biomarkers. This phase will enroll ~70 pts with untreatable locally advanced or metastatic solid tumors or RR lymphoma. The phase 2 primary objective is to evaluate preliminary efficacy at the RP2D in ~132 pts with non-squamous non-small cell lung cancer, cervical cancer, microsatellite-stable colorectal cancer, or CD20+ RR diffuse large B-cell lymphoma or follicular lymphoma. Pts receive TAK-981 via a 1-hour intravenous infusion on days 1, 4, 8, and 11 in 21-day cycles until unacceptable toxicity, pt withdrawal, or death. Dose escalation is proceeding from 3 mg, guided by an adaptive 3+3 design combined with Bayesian logistic regression modelling with overdose control, plus consideration of other safety, clinical, PK, and PD data. The RP2D will be based on the maximum tolerated dose (MTD) or on a biologically effective dose (BED) that is ≤MTD. The BED is defined as a dose at which there is evidence of drug-target engagement and inhibition of SUMOylation, plus: induction of cytokines/chemokines and/or IFN-I signature in tumor or blood; evidence of increased T cell infiltration in tumor; or antitumor activity. PK/PD modeling in the BED range is ongoing and will be used in RP2D determination. Clinical trial information: NCT03648372. Research Sponsor: Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

TPS2668 **Poster Session**

Association of combined phase I/II study of a novel bicyclic peptide and MMAE conjugate BT8009 in patients with advanced malignancies with Nectin-4 expression. *First Author: Meredith McKean, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: BT8009 is a Bicycle Toxin Conjugate (BTC), a novel class of chemically synthesized molecules, comprising a bicyclic peptide targeting Nectin-4 tumor antigen, linked to cytotoxin (monomethyl auristatin E [MMAE]) via a valine-citrulline (val-cit) cleavable linker. Nectins (Nectin-1, -2, -3, and -4) and nectin-like molecules (Necl) are Ca2+ independent immunoglobulin-like cell adhesion molecules. Recent studies have shown the importance of Nectin-4 in several human cancers, including lung, ovarian, breast and bladder cancer; however, the precise roles and clinical relevance of Nectin-4 in tumors remain largely unknown. The Nectin-4 targeted enfortumab vedotin, linked to MMAE via a val-cit linker, is highly active in late-stage bladder cancer and demonstrates notable additional clinical activity as a single agent and in combination with pembrolizumab[1]. Skin toxicities, bone marrow suppression, peripheral neuropathy and diabetes have been associated with enfortumab, with some of these toxicities already noted with MMAE-bearing antibody therapies. We anticipate a similar toxicity profile for BT8009 in clinical studies. BT8009 exhibited a favorable preclinical profile and was effective in a range of cell-derived xenograph tumor models. **Methods:** Study BT8009-100 (NCT04561362) will evaluate safety and tolerability of weekly and every other week BT8009 administration, alone and in combination with q4w nivolumab. Determination of both a realistic phase 2 dose and a sequence will also be key to further exploration of safety and efficacy signals, along with an early examination of the role of baseline immunohistochemistry-ascertained levels of tumor Nectin-4. Patients will be recruited with advanced solid tumors associated with Nectin-4 expression after exhausting SOC options (i.e., bladder, breast, pancreatic, head and neck, gastric, esophageal and ovarian). Patients must have available tumor tissue, acceptable hematologic and other critical organ function and be willing to participate. Appropriate ethical and regulatory approvals and advice will be in place and adhered to. Exclusion criteria include uncontrolled brain metastases, uncontrolled hypertension, concomitant CYP3A4 inhibitors and significant history of autoimmune disease for the nivolumab cohorts. PK serial collections will be taken on D1 through D15. Radiologic tumor assessments for response per RECIST will be taken every two months. 1. Enfortumab Vedotin. FDA_data. 761137Orig1s000MultiDisclipline R.pdf (fda.gov). Clinical trial information: NCT04561362. Research Sponsor: Bicycle Therapeutics.

TPS2669 **Poster Session**

Trial in progress: A phase 1b study of sotorasib, a specific and irreversible KRAS^{G12C} inhibitor, as monotherapy in non-small cell lung cancer (NSCLC) with brain metastasis and in combination with other anticancer therapies in advanced solid tumors (CodeBreaK 101). *First Author: David S. Hong, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Kirsten rat sarcoma viral oncogene homolog(*KRAS*) p.G12C mutation is an oncogenic driver mutation in several solid tumors. Sotorasib is a specific, irreversible, small molecule inhibitor of KRAS^{G12C} that has demonstrated durable clinical benefit in NSCLC, with mild and manageable toxicities. The combination of sotorasib with other anticancer therapies may enhance antitumor efficacy. This master protocol is designed to evaluate safety, tolerability, pharmacokinetics (PK), and efficacy of multiple sotorasib combinations in patients (pts) with *KRAS*p.G12C mutated solid tumors. Herein, we overview 1 monotherapy and 11 combination cohorts. **Methods:** This is a phase 1b, open-label study evaluating sotorasib alone and in combination regimens (Table) in pts with advanced *KRAS* p.G12Cmutated solid tumors. Dose exploration will evaluate the safety and tolerability of sotorasib alone and in combination regimens; dose expansion will then verify the safety and tolerability profile of sotorasib regimens and assess antitumor efficacy. Key eligibility criteria include locally-advanced or metastatic solid tumor with *KRAS* p.G12C mutation identified through molecular testing in pts who have received ≥1 lines of prior systemic therapy. Primary endpoints include dose-limiting toxicities and treatment-emergent or treatment-related adverse events. Secondary endpoints include PK profile of combination regimens and efficacy (eg, objective response, disease control, duration of response, progression-free survival, and duration of stable disease assessed per RECIST 1.1). Enrollment began in December 2019 and is ongoing. Clinical trial information: NCT04185883. Research Sponsor: Amgen Inc.

Advanced tumor types	Treatment arms
NSCLC with brain metastasis	Sotorasib monotherapy
NSCLC	Sotorasib + TKI
	Sotorasib + anti-PDL1 therapy
	Sotorasib + chemotherapeutic regimen
	Sotorasib + anti-PD1 therapy
Colorectal cancer	Sotorasib + anti-VEGF therapy + chemotherapeutic regimen
All solid tumors	Sotorasib + MEK inhibitor ± EGFR inhibitor
	Sotorasib + anti-PD1 therapy
	Sotorasib + SHP2 inhibitor
	Sotorasib + anti-EGFR therapy ± chemotherapeutic regimen
	Sotorasib + CDK inhibitor
	Sotorasib + mTOR inhibitor

CDK = cyclin-dependent kinase; EGFR = epidermal growth factor receptor; MEK = mitogen-activated protein kinase; mTOR = mammalian target of rapamycin; PD1 = programmed cell death protein-1; PDL1 = programmed death-ligand 1; SHP2 = Src homology region-containing protein tyrosine phosphatase 2; TKI = tyrosine kinase inhibitor; VEGF = vascular endothelial growth factor.

TPS2670 **Poster Session**

A phase 1 dose-escalation study of intravenously (IV) administered TAK-676, a novel STING agonist, alone and in combination with pembrolizumab in patients (pts) with advanced or metastatic solid tumors. *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: Immuno-oncology therapies, including immune checkpoint inhibitors (CPIs), are revolutionizing cancer treatment. However, primary and secondary resistance to CPIs remains a significant challenge. CPI resistance has been associated with reduced interferon (IFN) signaling, altered antigen presentation, and an immunosuppressive tumor phenotype. Stimulating innate immune cells to develop a proinflammatory tumor environment that activates IFN signaling and downstream adaptive antitumor immune mechanisms is predicted to overcome such resistance. Stimulator of Interferon Genes (STING) is a key mediator of type 1 IFN-dependent innate immune modulation. Most STING agonists evaluated clinically have required intratumoral administration, which has significant logistical challenges and excludes many pts whose tumors are not accessible for injection. TAK-676 is a novel STING agonist under clinical investigation as an IV administered systemic therapy in pts with solid tumors. **Methods:** The primary objective of this study is to determine the safety and tolerability of TAK-676 alone and in combination with pembrolizumab. Secondary objectives are to: determine the pharmacologically active dose and recommended phase 2 dose; characterize TAK-676 pharmacokinetics; assess preliminary antitumor activity; and assess STING agonism gene signature induction. An exploratory objective is to assess immune cell activation and clinical response. The study comprises a single-pt safety lead-in with single-agent (SA) TAK-676 0.1 mg IV, followed by dose escalation using Bayesian Logistic Regression Model design. Dose escalation will start in the combination arm when ≥2 dose levels in the SA arm have been evaluated and considered safe. In both arms, pts will receive TAK-676 on days 1, 8, and 15 in 21-day cycles for up to 1 year. In the combination arm, pts will also receive pembrolizumab 200 mg IV on day 1 of each cycle. Adult pts with histologically confirmed advanced or metastatic solid tumors who have no standard therapeutic options or are intolerant to them, with an Eastern Cooperative Oncology Group (ECOG) performance status 0–1, and ≥1 Response Evaluation Criteria in Solid Tumors (RECIST) v.1.1- evaluable lesion are eligible; pts with tumors that have relapsed, are refractory or naïve to anti-programmed death 1 (PD-1) or anti-programmed death ligand 1 (PD-L1) therapy are eligible for the combination arm. Planned enrollment is ~76 pts; recruitment is ongoing. Clinical trial information: NCT04420884. Research Sponsor: Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

TPS2671 **Poster Session**

Trials in progress: A phase 1, open-label, dose-escalation, pharmacokinetic, safety and tolerability study of the selective TAM kinase inhibitor PF-07265807 in patients with advanced or metastatic solid tumors. *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MERTK is a receptor tyrosine kinase from the tumor-associated macrophage kinase (TAMK) family that regulates key aspects of immune homeostasis and responses to infection. MERTK inhibition may lower the threshold for immune activation thereby promoting antitumor activity. Agents with some degree of MERTK inhibitory activity have been investigated in the clinic, but are limited by poor potency in patients (pts) and significant off-targets effects. PF-07265807 (ARRY-067) is a selective small-molecule inhibitor of the TAMKs MERTK and AXL. In preclinical models, PF-07265807 monotherapy shows antitumor activity that results in long-term cures and resistance to tumor re-challenge when combined with anti-programmed cell death protein 1/programmed death-ligand 1 (anti-PD-1/PD-L1) antibodies. This first-in-human study will evaluate the safety, tolerability, pharmacokinetics (PK) and preliminary anti-tumor activity of PF-07265807 in pts with selected advanced or metastatic solid tumors. This study will also explore the potential utility of PF-07265807 in combination with anti-PD-1/PD-L1 antibodies. **Methods:** This is a phase 1, open-label, multi-center, dose-escalation study (NCT04458259) to evaluate the safety, PK and tolerability of PF-07265807. Eligible participants will be adult pts with selected advanced or metastatic solid tumors who are intolerant or resistant to standard therapy. Other key eligibility criteria: measurable disease by RECIST 1.1 or non-measurable disease; Eastern Cooperative Oncology Group performance status 0–2; adequate bone marrow, renal and liver function; and resolved acute effects of any prior therapy. Successive cohorts of pts will receive escalating doses of PF-07265807 starting from 25 mg QD. Each cycle will be 21 days in duration (14 days on/7 days off). Study drug treatment will continue until disease progression or unacceptable toxicity, whichever occurs first. For dose escalation, a Bayesian logistic regression model will be used to model the relationship of dose-limiting toxicities (DLTs) to PF-07265807 dose. This model, along with escalation with overdose control, will guide the dose escalation of PF-07265807 after the completion of the DLT observation period (first two cycles of treatment, i.e. 42 days) of each cohort, until determination of the maximum tolerated dose/recommended phase 2 dose (MTD/RP2D). After the MTD/RP2D is identified, the safety and efficacy of combined PF-07265807 and anti-PD1/PD-L1 treatment will be explored. Primary endpoints: incidence of DLTs, treatment-emergent adverse events and laboratory abnormalities. Secondary endpoints: PK parameters of PF-07265807, objective response rate and duration of response. The study began enrolling pts in September 2020 and is still recruiting. Clinical trial information: NCT04458259. Research Sponsor: Pfizer.

TPS2672 **Poster Session**

Phase 1, first-in-human trial of JTX-8064, an anti-LILRB2/ILT4 monoclonal antibody, as monotherapy and in combination with anti-PD-1 in adult patients with advanced solid tumors (INNATE). *First Author: Kyriakos P. Papadopoulos, START-San Antonio, San Antonio, TX*

Background: Leukocyte Immunoglobulin-like receptor B2 [LILRB2; immunoglobulin-like transcript 4 (ILT4)] is an immunoinhibitory protein expressed on the surface of myeloid cells and is a therapeutic target of interest in immuno-oncology. Published data showed that antagonism of LILRB2 resulted in the repolarization of human macrophages from an M2 (suppressive) to M1 (pro-inflammatory) phenotype, and enhancement of anti-tumor immunity in a mouse model (Chen 2018). JTX-8064 is a novel humanized IgG4 monoclonal antagonist antibody that selectively binds LILRB2 and prevents it from binding its ligands, classical and non-classical MHC I molecules. By blocking the ability of LILRB2 to bind HLA-A/B and/or HLA-G, a marker of immunotolerance on cancer cells, JTX-8064 has been shown to enhance pro-inflammatory cytokine production in macrophages (Cohen 2019). Additionally, blocking HLA-A/B-LILRB2 binding with JTX-8064 may augment antigen presentation and has been shown to lead to enhanced T cell activation and IFNg production (McGrath 2021). Using an ex vivo tumor explant model, we observed an IFNg-associated pharmacodynamic response in tumor tissue treated with JTX-8064 and a PD-1 inhibitor (PD-1i) that was not observed with PD-1i alone. Biomarkers were identified that predicted this JTX-8064 driven response (Hashambhoy-Ramsay 2020). It is hypothesized that JTX-8064 is a novel macrophage immune checkpoint inhibitor that may overcome mechanisms of resistance to PD-1i in tumors not responsive to JTX-8064 or PD-1i alone. **Methods:** The primary objectives of this open-label, phase 1, first-in-human, multicenter trial are to determine the safety and tolerability, and the recommended phase 2 dose (RP2D) of JTX-8064 as a monotherapy and in combination with a PD-1i, JTX-4014 (a Jounce investigational agent) or pembrolizumab, in patients with advanced solid tumors (NCT04669899). The INNATE study will consist of 4 stages: 1) JTX-8064 monotherapy dose escalation, 2) JTX-8064 dose escalation in combination with a PD-1i, 3) JTX-8064 monotherapy in indication-specific expansion cohorts and 4) JTX-8064 in combination with a PD-1i in indication-specific expansion cohorts. Stages 1 and 2 will employ an innovative interval i3 + 3 design with Bayesian decision framework to guide dose escalation. Safety, pharmacokinetic and receptor occupancy data will be considered during dose escalation. INNATE will assess pharmacodynamic and potential predictive biomarkers of response, and the expansion cohorts will explore multiple patient populations, including PD-(L)1i sensitive and PD-(L)1i-resistant (primary or acquired) patients to address current unmet medical needs. Enrolment in INNATE began in January 2021. Clinical trial information: NCT04669899. Research Sponsor: Jounce Therapeutics.

TPS2673 **Poster Session**

A phase 1, multicenter, open-label, dose-escalation, safety, pharmacodynamic, pharmacokinetic study of Q702 with a cohort expansion at the RP2D in patients with advanced solid tumors. *First Author: Angela Tatiana Alistar, Atlantic Health System, Morristown, NJ*

Background: Immune checkpoint inhibitors directly targeting T cell activation have been successfully used in the treatment of various malignancies, nevertheless, the durable ORRs are low for certain indications. The low ORRs have been attributed to the immune suppressive tumor microenvironment (TME), composed of innate immune suppressive components such as tumor associated macrophages (TAM) and myeloid-derived suppression cells (MDSC). The potential contributions of innate immune modulation to anti-tumor immunity, suggest the need for the novel strategies to elicit a more efficient/robust immune response against the targeted malignant cells. Axl, Mer and CSF1R receptor tyrosine kinases play vital roles in promoting an immune suppressive TME by affecting TAM and MDSC populations and by decreasing antigen presentation on tumor cells. Q702 is a novel Axl/Mer/CSF1R inhibitor, able to modulate the TAM and MDSC population leading to CD8+ T cell activation and to increase antigen presentation of the tumor cells in syngeneic animal models. Q702, as a monotherapy, shows significant tumor growth inhibition in multiple syngeneic tumor models, and demonstrates synergistic effects with anti-PD-1 treatment particularly in high myeloid containing tumor models. Interestingly, intermittent administration of Q702 monotherapy demonstrates a more favorable immune cell population changes, possibly through preventing immune exhaustion secondary to negative feedback with continuous activation. These results suggest that Q702 monotherapy or in combination with existing therapies have a good potential to become a novel treatment strategy for patients with advanced solid tumors. **Methods:** "A Phase 1, Multicenter, Open-label, Dose-Escalation, Safety, Pharmacodynamic, Pharmacokinetic Study of Q702 with a Cohort Expansion at the RP2D in Patients with Advanced Solid Tumors. (NCT04648254)" is open and recruiting patients at 4 US investigative sites. Patients with histologically or cytologically confirmed advanced or metastatic solid tumors, that have progressed following SOC or for which there is no SOC which confers clinical benefit are being enrolled in this study. The study follows a standard dose escalation. The study will enroll up to 78 patients. The primary endpoint is to establish safety, PK profile and define the recommended phase 2 dose. The secondary and exploratory endpoints include establishing pharmacokinetic/pharmacodynamic relationship, potential biomarkers and preliminary anti-tumor activity. Clinical trial information: NCT04648254. Research Sponsor: Qurient Co. Ltd.

TPS2674 **Poster Session**

Phase 1 first-in-human study of ABBV-184 monotherapy in adult patients with previously treated acute myeloid leukemia or non-small cell lung cancer. *First Author: Abraham Avigdor, Institute of Hematology, Sheba Medical Center, Ramat Gan, Israel, and Sackler Faculty of Medicine, Tel Aviv University, Tel-Aviv, Israel*

Background: Survivin, a member of the inhibitor of apoptosis protein family, is an attractive therapeutic target in cancer, due to its broad expression in solid tumors and hematologic malignancies but limited expression in normal tissues. Elevated survivin expression is associated with an increased invasive phenotype and worse clinical outcomes. ABBV-184 is a first-in-class T-cell receptor (TCR)/anti-cluster of differentiation 3 (CD3) bispecific molecule. It is composed of a soluble TCR that binds to a survivin-derived peptide bound to the class I MHC allele HLA-A2:01 expressed on tumor cells and to the CD3 receptor on T cells. Preclinical data have demonstrated that treatment with ABBV-184 results in T-cell activation, proliferation, and redirected cytotoxicity of HLA-A2:01–positive target cell lines. This first-in-human trial evaluates ABBV-184 monotherapy in patients with previously treated acute myeloid leukemia (AML) or non-small cell lung cancer (NSCLC). **Methods:** Patients (≥18 years, Eastern Cooperative Oncology Group performance status ≤2, HLA-A2:01 restricted genotype) with relapsed or refractory AML or NSCLC are currently enrolling in this phase 1 multicenter, open-label trial (NCT04272203), which includes parallel dose-escalation and dose-expansion phases for both diseases. Primary objectives are to determine the recommended phase 2 dose (RP2D) of ABBV-184 (dose escalation) and to assess its preliminary efficacy (dose expansion). Secondary objectives include safety, tolerability, pharmacokinetics (PK), and immunogenicity assessments (dose escalation and dose expansion) and duration of response (dose expansion). Patients will receive intravenous infusion of ABBV-184 once weekly. Dose escalation of ABBV-184 is guided by a Bayesian optimal interval design and the RP2D will be determined on the basis of clinical safety, PK, and pharmacodynamic data. For patients with AML, disease assessment is performed according to modified European LeukemiaNet-International Working Group criteria. For patients with NSCLC, response will be assessed using Response Evaluation Criteria In Solid Tumors (RECIST) v1.1 and immune RECIST. Treatment can continue until disease progression or intolerable toxicity. Biomarker assessments will include longitudinal profiling of peripheral blood immune cells and cytokines, analysis of HLA-A2 and survivin levels on AML bone marrow blasts and NSCLC tumor biopsies, and retrospective correlations of biomarker data with antitumor activity. Enrollment initiated in Sep 2020, with 7 patients enrolled as of Jan 2021. Clinical trial information: NCT04272203. Research Sponsor: AbbVie, Inc.

TPS2675 **Poster Session**

A phase I study of AK119, an anti-CD73 monoclonal antibody, in combination with AK104, an anti-PD-1/CTLA-4 bispecific antibody, in patients with advanced or metastatic solid tumors. *First Author: Ben Markman, Alfred Hospital, Melbourne, Australia*

Background: AK119 is a humanized IgG1 monoclonal antibody (mAb) that selectively binds to and inhibits the ectonucleotidase activity of CD73, a cell surface enzyme that converts adenosine monophosphate (AMP) into adenosine. Adenosine has been shown to facilitate tumor-mediated evasion. CD73 inhibition may therefore reduce adenosine accumulation and promote anti-tumor immunity. AK104 is a recombinant humanized IgG1 bispecific antibody that simultaneously binds to programmed cell death protein 1 (PD-1) and cytotoxic T- lymphocyte-associated antigen protein 4 (CTLA-4). Preliminary data from phase I and II studies suggest that AK104 has encouraging anti-tumor activity in selected tumor types and an improved safety profile compared to the co-administration of anti-PD-1 plus anti-CTLA-4 mAbs. Preclinical studies show that CD73 inhibition synergistically increases the anti-tumor activity of PD-1 and CTLA-4 immune checkpoint inhibitors (ICIs). Published early clinical data suggests that anti-CD73 therapy in combination with ICIs produces improved clinical outcomes. Thus, AK119 plus AK104 is postulated to have synergistically enhanced anti-tumor activity compared to the administration of anti-CD73 monotherapy or ICIs alone. **Methods:** This is a phase 1a/1b, first-in-human, multicenter, open-label study in patients with advanced solid tumors that are refractory to standard therapies. The primary objective is to assess safety, tolerability and dose limiting toxicity; and to determine the Maximum Tolerated Dose (MTD) or Maximum Administered Dose (MAD) of AK119 in combination with AK104. Secondary objectives are to evaluate antitumor activity, PK and AK119 immunogenicity. The dose-escalation phase will evaluate 5 dose levels of AK119 (1mg/kg to 40 mg/kg Q2W IV) in combination with 6mg/kg AK104 Q2W IV using a 3+3+3 study design. Eligible pts will receive a single dose of AK119 on COD1 of a 14-day "lead-in" period. Thereafter, from C1D1 pts will receive AK119 in combination with AK104 on a 28-day cycle, until unacceptable toxicity, confirmed progressive disease, subject withdrawal, or for a maximum of 24 months. The "lead-in" period is only applicable for dose-escalation cohorts. Any dose-escalation cohort not exceeding the MTD may be expanded to a maximum of 18 subjects with selected solid tumor types for further evaluation of safety, PK/ PD, immunogenicity, and preliminary anti-tumor activity. Cohort 1 is currently in progress with the first patient enrolled in January 2021. For the dose-expansion phase, cohorts of pts with advanced/metastatic pancreatic cancer or MSS/pMMR colorectal cancer will be enrolled. Cohorts of other tumor types may be added based on emerging pharmacodynamic and anti-tumor response data. Clinical trial information: NCT04572152. Research Sponsor: Akeso Biopharma, Inc.

TPS2676 **Poster Session**

A phase 1b study of nivolumab in patients with autoimmune disorders and advanced malignancies (AIM-NIVO). *First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Nivolumab is an anti-PD1 monoclonal antibody approved for treatment of an increasing number of solid tumors and hematological malignancies. However, patients (pts) with history of autoimmune disorders are excluded from the majority of clinical trials testing immune-checkpoint inhibitors (ICI) such as anti-PD1/anti-PD-L1 antibodies. Consequently, the risks of flare ups, worsening of pre-existing autoimmune disorders or risk of de-novo immune related adverse events (irAEs) in pts with dysfunctional immune systems and tumor types who otherwise stand to benefit from ICI therapy are largely unknown, posing a challenge for oncologists. We are conducting a phase Ib study to test the hypothesis that nivolumab can be safely administered to pts with varying severity of Dermatomyositis, Systemic Sclerosis, Rheumatoid Arthritis, Systemic Lupus Erythematosus, Inflammatory Bowel Disease, Multiple Sclerosis and other autoimmune disorders (AIM-Nivo). **Methods:** AIM-Nivo is an open-label, multi-center ongoing phase Ib study with nivolumab 480mg IV every 28 days in pts with autoimmune diseases and advanced malignancies (NCT03816345). The study has autoimmune disease-specific cohorts overseen by a multidisciplinary group of experts. The primary objective is to assess the overall safety and toxicity profile of nivolumab in pts with autoimmune disorders and advanced malignancies. Secondary objectives are to evaluate the antitumor efficacy; the impact of nivolumab on the autoimmune disease severity indices; and to explore potential biomarkers of response, resistance, or toxicity for each of the autoimmune disease-specific cohorts. Key overall inclusion criteria include age ≥18 years, histologically confirmed advanced or metastatic malignancies in which ICI are approved or have shown clinical activity. Key overall exclusion criteria include prior therapy with anti-PD-1/PD-L1 antibodies. Specific eligibility criteria are defined for each disease-specific cohort. For each autoimmune disorder, severity level of the disease as defined by disease-specific severity indices will be assessed, and up to a total of 12 pts will be included in each disease cohort at each severity level (max 36 pts per cohort). Primary endpoints are dose-limiting toxicities, adverse events (AEs) and serious AEs. Continuous monitoring of toxicity will be conducted. Key secondary endpoints are best objective response per RECIST1.1; progression free and overall survival; and cohort specific tumor tissue, blood, and non-tumor tissue-based biomarkers. The AIM-Nivo trial opened in May 2019 and is enrolling pts through the National Cancer Institute Experimental Therapeutics Clinical Trials Network (ETCTN), Early Drug Development Opportunity Program (EDDOP), and Create Access to Targeted Cancer Therapy for Underserved Populations (CATCH-UP) sites. Clinical trial information: NCT03816345. Research Sponsor: U.S. National Institutes of Health.

TPS2677 **Poster Session**

An open-label phase 1b/2 study of surufatinib in combination with tislelizumab in subjects with advanced solid tumors. *First Author: Arvind Dasari, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Surufatinib (S) is an inhibitor of VEGFR1, 2, & 3; FGFR1; and CSF-1R. In two phase 3 randomized trials (SANET-ep; NCT02588170 & SANET-p; NCT02589821) S demonstrated a manageable safety profile and statistically significant efficacy. Patients (pts) with extrapancreatic neuroendocrine tumors (epNETs) achieved a median progression free survival (PFS) of 9.2 v 3.8 months (mo) (hazard ratio [HR] 0.334; p<0.0001), and pts with pancreatic NETs (pNETs) achieved a median PFS of 10.9 v 3.7 mo (HR 0.491; p=0.0011), with S v placebo, respectively. S was recently approved for the treatment of pts with epNET in China. Tislelizumab (T) is a humanized immunoglobulin G4 anti-PD-1 monoclonal antibody engineered to minimize binding to Fc-gamma-receptor on macrophages. T is approved in China in combination with chemotherapy for squamous non-small cell lung cancer and has conditional approval for Hodgkin's lymphoma and locally advanced or metastatic urothelial carcinoma with PD-L1 high expression. The objective of this study is to evaluate the safety and efficacy of combination therapy with S and T, which may have synergistic effects, where inhibition of angiogenesis along with stimulation of an immune response may enhance the overall antitumor activity. **Methods:** This study (NCT04579757) will include pts, ≥18 years of age, with advanced metastatic solid tumors, who have an Eastern Cooperative Oncology Group performance status of 0 or 1 and have progressed on or are intolerant to standard therapies. The primary objective of part 1 (dose escalation) will be to evaluate the safety and tolerability of S and T to determine the recommended phase 2 dose of the combination. The starting dose in part 1 will be 250 mg of S, orally, daily, and 200mg of T, intravenously, every 3 weeks. The dose of S will be escalated during part 1, while the dose of T will remain fixed. Endpoints include dose limiting toxicities, treatment emergent adverse events, serious adverse events, adverse events leading to discontinuation, electrocardiograms, clinical laboratory abnormalities and vital signs. Antitumor activity will be evaluated as a secondary objective. Six to 12 pts will be enrolled. The primary objective of part 2 (dose expansion) will be to evaluate the objective response rate (ORR) of S in combination with T per RECIST v1.1. The endpoint will be ORR at 12 weeks. Key secondary endpoints include PFS, disease control rate, duration of response, safety endpoints, and PK parameters. Approximately 95 pts with indications of interest will be enrolled: colorectal cancer, neuroendocrine tumors (thoracic and gastroenteropancreatic), small-cell lung cancer, gastric cancer, and soft tissue sarcoma (undifferentiated pleomorphic sarcoma and alveolar soft part sarcoma). Enrollment in the United States is open and ongoing, and enrollment in Europe is planned for fourth quarter 2021. Clinical trial information: NCT04579757. Research Sponsor: Hutchison MediPharma Limited.

TPS2678 **Poster Session**

Combination of atezolizumab and pirfenidone in second-line and beyond NSCLC: A phase I/II study. *First Author: Takefumi Komiya, Hematology/Medical Oncology, Parkview Cancer Institute, Fort Wayne, IN*

Background: Checkpoint inhibitors (CPI) targeting the PD1/PD-L1 axis significantly improved patient outcomes in stage IV non-small cell lung cancer (NSCLC). However, these patients will eventually develop resistance and progression. There is a need to identify novel treatment options. Poor response to PD-L1 antibody was correlated with increase in cancer-associated fibroblasts (CAF), which is known to interact with cytotoxic T cells (CTLs) by suppressing their function in a manner similar to regulatory T cells (Tregs). Production of cytokines by CAFs leads to impaired antitumor immunity by impairing CTL function (TGF beta) and prevent recruitment/mobilization of CTLs into tumors. These effects suggesting that CAF can be a therapeutic target in lung cancer resistant to checkpoint inhibitors. Pirfenidone (P) is approved to treat pulmonary fibrosis with anti-fibrotic effect by blocking the differentiation of fibroblasts into CAFs and suppress the production of TGF beta and TGF beta-induced signaling pathways/collagens. Atezolizumab is a humanized immunoglobulin (Ig) G1 monoclonal antibody that targets PD-L1 and inhibits the interaction between PD-L1 and its receptors, PD-1 and B7-1 (CD80), both of which function as inhibitory receptors expressed on T cells. We proposed a phase I/II trial to test the combination of atezolizumab (A) with P in patients with recurrent non-small cell lung cancer (NSCLC) after progression with CPI. The primary objective of phase I is to determine the maximum tolerated (MTD) dose of P in combination with A and assess the safety and tolerability of this combination. The secondary objective is to determine the efficacy of AP in all NSCLC participants treated in this study. Exploratory objectives include the measurement of circulating levels of TGF beta and research in expression of CAF related proteins. **Methods:** The initial phase I will enroll 3 patients using P at 801 mg po TID. A will be at 1200mg iv every 3 weeks. If there is ≤ 1 DLT, the study will proceed to phase II If there are 2- 3 DLT, P will be reduced to 534 mg TID. If there is ≤ 1 DLT, then this dose will proceed to phase II. If there is 2-3 DLT, then the study will be terminated. The phase II will enroll 16 patients to assess efficacy. Main inclusion criteria are patients with recurrent NSCLC after progression with first-line therapy CPI with or without chemotherapy, measurable disease, ECOG 0-2, and adequate organ function. Clinical trial information: NCT04467723. Research Sponsor: Genentech.

TPS2679 **Poster Session**

Immune Resistance Interrogation Study (IRIS): A prospective comprehensive multi-omic analysis in patients with intrinsic and acquired resistance to immunotherapy. *First Author: Sofia Genta, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Immune checkpoint inhibitors (ICI) have demonstrated efficacy in a wide variety of cancers. Nevertheless, only a small proportion of patients derive a durable benefit. Mechanisms underlying primary and acquired resistance are still incompletely understood. They comprise tumor-intrinsic factors such as genomic and transcriptomic changes; upregulation of immunosuppressive subsets; T cell exhaustion; and promotion of an immune-tolerant tumor microenvironment. The collection of tumor biopsy at disease progression (PD) is challenging both in clinical and research settings as this often occurs at the time of treatment discontinuation. However, the analysis of these samples can lead to novel strategies to prevent or reverse immune resistance. Thus, the current approach to begin a profiling study with patients at the time of PD on ICI enables access and interrogation of such samples. **Methods:** IRIS is a prospective, investigator-initiated trial at the Princess Margaret Cancer Centre that aims to extensively characterize the genomic, transcriptomic, epigenetic and immunophenotypic profiles of tumors with primary versus acquired resistance to ICI-based therapy. Primary resistance is defined as PD at the first on-treatment imaging, whereas acquired resistance is defined as PD occurring after an initial partial or complete response or following disease stability lasting ≥6 months. Additional objectives include the evaluation of radiomic parameters on standard radiological imaging, investigation of fecal microbiome, generation of patient-derived organoids and facilitation of data and sample sharing with the research community. The planned samples size is 100 patients. A one-time fresh tumor biopsy, blood and stool samples and archival tissue (when available) are collected at the time of PD on ICI (baseline) from all the participants. Longitudinal blood samples are obtained every 2-3 months (around the time of tumor imaging) until PD in patients receiving a subsequent treatment. Subjects who are not amenable for therapy undergo blood collections at the time of further PD. Molecular characterization of tumor samples includes: DNA/RNA sequencing, Assay of Transposase Accessible Chromatin (ATAC)-sequencing, Cellular Indexing of Transcriptomes and Epitopes (CITE)-sequencing, multiplexed immunohistochemistry and flow cytometry. Results of NGS performed on the first biopsy core are returned to patient and physician. Key eligibility criteria include diagnosis of solid tumor, progression to ICI as the most recent line of treatment and disease amenable to core needle biopsy. The IRIS trial, activated in October 2020, is currently open to enrollment. As of January 2021, 21 patients have been enrolled and a total of 92 tissue cores, 42 blood and 20 stool samples have been collected. Clinical trial information: NCT04243720. Research Sponsor: Princess Margaret Cancer Center institutional founding.

TPS2680 **Poster Session**

Personalized DNA neoantigen vaccine in combination with plasmid IL-12 and pembrolizumab for the treatment of patients with advanced hepatocellular carcinoma. *First Author: Mark Yarchoan, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Hepatocellular carcinoma (HCC) is the fourth most common cause of cancer-related death. Immune checkpoint inhibitors targeting PD-1 have limited activity in HCC as monotherapy, with response rates ranging from 14-17%. Tumor neoantigens derived from tumor-specific mutations can be incorporated into personalized therapeutic cancer vaccines to prime T cell responses, potentially enhancing responses to anti-PD1 therapy. DNA vaccines have been shown to elicit strong CD8 and CD4 T cell responses in preclinical and clinical trials. In preclinical studies, DNA-encoded neoantigen vaccines have shown induction of CD8 T cells against 50% of predicted high affinity epitopes with the ability to impact tumor growth. GNOS-PV02 is a personalized DNA vaccine, encoding up to 40 patient-specific neoantigens. In the GT-30 trial, it is used in combination with INO-9012 (plasmid-encoded IL-12) and pembrolizumab for the treatment of advanced HCC. **Methods:** The GT-30 trial (NCT04251117) is a single-arm phase I/II clinical trial to assess the safety, immunogenicity, and preliminary efficacy of GNOS-PV02 in combination with INO-9012 and pembrolizumab in patients with advanced HCC. Twenty-four patients are anticipated to be enrolled. Patients are recruited upon diagnosis or during first-line treatment with tyrosine kinase inhibitors (TKI). Tumors are biopsied for exome and transcriptome sequencing. The tumor specific vaccine is designed, optimized and manufactured during first-line therapy. Each vaccine encodes up to 40 neoantigens, which includes all detected neoantigens for the majority of HCC patients. After progression or intolerance with first-line therapy, patients can commence trial therapy with concurrent personalized vaccine and pembrolizumab. GNOS-PV02 + INO-9012 are administered Q3w for the first 4 doses and Q9w thereafter until disease progression. Pembrolizumab is delivered Q3w until disease progression. Immunogenicity of each of the vaccine epitopes will be determined by ex vivo ELISpot and flow cytometry. Clinical activity is assessed by RECIST1.1 at baseline and every 9 weeks. Serial biopsies will be obtained at 9 weeks and upon disease progression to evaluate changes in the exome, transcriptome and changes to the tumor microenvironment. Clinical trial information: NCT04251117. Research Sponsor: Geneos Therapeutics.

TPS2681 **Poster Session**

Phase I study investigating the safety of stereotactic body radiotherapy (SBRT) with anti-PD-1 and anti-IL-8 for the treatment of multiple metastases in advanced solid tumors. *First Author: Lilit Karapetyan, UPMC HCC, Pittsburgh, PA*

Background: Anti-PD-(L)1 immunotherapy improves outcomes for patients across various cancers; however, many patients do not benefit. Previous studies combining multi-site SBRT with anti-PD1 have confirmed feasibility and revealed induction of interferon signaling by SBRT. Elevated levels of serum IL8 (sIL8) associate with lack of response to anti-PD1 and we have observed that elevated IL8 is strongly associated with lack of response to immunotherapy and SBRT combinations. Overcoming IL8 induced epithelial-mesenchymal transitioning and trafficking of myeloid derived suppressor cells in tumor microenvironment therefore represents a promising strategy to overcome resistance. BMS-986253 is a fully human neutralizing antibody that binds to sIL8. The combination of BMS-986253 and nivolumab was safe in patients with advanced solid tumors. The present study aims to evaluate safety and preliminary efficacy of combining BMS-986253 with nivolumab and SBRT in patients with advanced solid tumors, Melanoma (MEL) and Renal Cell Carcinoma (RCC). **Methods:** This is a phase 1 open label single arm study (CT.gov: NCT04572451) which will include safety and efficacy cohorts. Patients will receive SBRT in 1-4 tumor lesions, in 3 or 5 fractions, at the total of 30 or 45 or 50 Gy based on the irradiated organ site. This will be followed by intravenous (IV) nivolumab (480mg q4 weeks (W)) and IV BMS-986253 (2400mg q2W) within seven days of completing SBRT. In the initial safety portion of the clinical trial, we will include 30 patients with advanced/metastatic solid tumors in order to evaluate safety. The primary endpoint of dose limiting toxicity will be assessed by continual Bayesian monitoring. The toxicities will be attributed to combination of SBRT/Immunotherapy as opposed to individual components. The secondary objective of the study is efficacy with an endpoint of objective response rate (ORR) as assessed by RECIST v1.1 in Mel and RCC. We will include 20 patients with MEL and RCC and compare against a historical benchmark of 20% ORR as sufficient signal of activity for further study. ORR will be assessed for association with serum IL-8 levels and radiation-induced changes in peripheral blood T cell populations. Clinical trial information: NCT04572451. Research Sponsor: Bristol Myers Squibb.

3000 **Oral Abstract Session**

A first-in-human phase 1 study of a novel PARP7 inhibitor RBN-2397 in patients with advanced solid tumors. *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute, Denver, CO*

Background: Targeting cytosolic nucleic acid sensing pathways and the Type I interferon (IFN) response is an emerging therapeutic strategy in oncology. PARP7 is a member of the monoPARP class of enzymes and a newly identified negative regulator of nucleic acid sensing in tumor cells. PARP7 expression is increased by cellular stress and aromatic hydrocarbons, and the *PARP7* gene is amplified in multiple cancers. RBN-2397 is a potent, selective inhibitor of PARP7. In preclinical models, RBN-2397 restored Type I IFN signaling in tumors, caused complete tumor regressions, and induced adaptive immunity. **Methods:** Patients (pts) with advanced solid tumors were treated with RBN-2397 on either a continuous or 14-of-21-day intermittent schedule using a 3+3 dose escalation design. Primary objective: establish MTD and/or RP2D. Secondary obj.: safety, activity, PK of unmicronized/micronized tablets. Exploratory obj.: Pd. **Results:** As of 4 January 2021, 47 pts were treated: 25 pts in the intermittent schedule (25 to 500 mg BID) and 22 patients in the continuous schedule (100 to 400 mg BID). The most frequent RBN-2397-related AEs (all grades) were dysgeusia (26%), decreased appetite (13%), fatigue (11%), and diarrhea (11%). Gr 3/4 RBN-2397-related AEs all occurred in 7 pts (15%) at doses $\geq$ 200 mg: diarrhea (2 pts, 4%), increased ALT, AST, and bilirubin (1 pt, 2%), and fatigue, anemia, neutropenia, and thrombocytopenia in 1 pt (2%) each. The 2 DLTs were Gr 3 febrile neutropenia (400 mg continuous schedule) and Gr 4 increase in ALT/AST (500 mg intermittent schedule). Plasma exposures generally increased dose dependently with the majority at or above the projected efficacious range based on animal studies. All evaluable baseline tumor biopsies showed evidence of PARP7 expression as measured by mRNA in situ hybridization (n = 11; Median tumor H score: 128). In 5 evaluable tumor biopsy pairs, increases in interferon-stimulated gene expression were observed post RBN-2397, consistent with activation of Type I IFN. CXCL10 mRNA increased in all evaluable on-treatment biopsies (1.5 to 8-fold). Several on-treatment biopsies showed enrichment for immune response gene sets that was accompanied by an increase in CD8+ T cells and Granzyme B expression, evidence for induction of an adaptive immune response post RBN-2397. This increase in immune response related genes and CD8+ T cells was observed in a pt with metastatic squamous NSCLC who has been on study for 16+ months. 1 pt with HR+, HER2- breast cancer achieved a confirmed PR at 100 mg and 8 pts had SD for $\geq$18 weeks (RECIST 1.1). **Conclusions:** To date, RBN-2397 is well tolerated and demonstrates dose dependent increases in plasma exposures, evidence of target inhibition, and preliminary signs of clinical activity. Determination of MTD/RP2D is imminent and study expansion is planned to evaluate safety and efficacy in squamous NSCLC, HNSCC, HR+ breast cancer, and PARP7 amplified tumors. Clinical trial information: NCT04053673. Research Sponsor: Ribon Therapeutics Inc.

3001 **Oral Abstract Session**

First-in-human biomarker-driven phase I trial of the potent and selective glutaminase-1 (GLS1) inhibitor IACS-6274 (IPN60090) in patients (pts) with molecularly selected advanced solid tumors. *First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Glutamine metabolism is frequently deregulated in different cancers, including tumors harboring *KEAP1*/*NFE2L2* mutations or those expressing low Asparagine Synthetase (ASNS) levels. IACS-6274 is a potent oral GLS1 inhibitor discovered at MD Anderson Cancer Center with excellent pharmacokinetics (PK) and antitumor activity in biomarker-defined preclinical models. **Methods:** Pts with advanced solid tumors received IACS-6274 BID at escalating doses using a phase 1 BOIN design. PK and pharmacodynamic (PD) studies were conducted in serial tumor and/or blood samples. Peripheral glutamine metabolism was assessed in peripheral blood mononuclear cells (PBMC) to assess glutamine metabolism via 13C-isotope labelling. Predictive biomarker studies included tumor analyses for *KEAP1*, *NFE2L2*, *STK11*, *NF1* mutations and IHC for ASNS loss. **Results:** 22 pts with advanced ovarian (n=8), NSCLC (n=7), melanoma (n=2), leiomyosarcoma, gastric, anal, endometrial and HNSCC (all n=1) received IACS-6274 at 20 (n=1), 40 (n=1), 80 (n=1), 120 (n=4), 180 (n=11) or 240 (n=4) mg BID. Molecular alterations assessed included pts with ASNS loss (n=6), *STK11* (n=5), *KEAP1* (n=5), *NFE2L2* (n=4) and *NF1* (n=1). Prior lines of therapies: 2-4 (n=12); $\geq$5 (n=10). Common IACS-6274-related adverse events included G1-2 photopsia (n=7), photophobia (n=7), increased creatinine (n=4) and AST (n=4). Less common G3 toxicities at 180 and 240 mg included reversible nausea (n=3), vomiting and fatigue (n=2). Dose-limiting toxicities of G3 acute renal failure and PRES syndrome were seen in one patient at 240mg BID, which fully resolved. Plasma exposures showed a dose-dependent increase across doses with observed half-life ~12 hrs. Patients at 180mg displayed steady-state exposures at C1D14 with Cmax of 45.8 μM +/- 18.6 μM and average AUC(0-12hrs) of 382.48 h*μM +/- 159.27 h*μM. Glutamate to glutamine ratios decreased in PBMC samples in pts at C1D14 vs baseline; pts at 120, 180 and 240 mg had inhibition of 82.5% ($P<0.0001$), 83.9% ($P<0.0001$) and 85.3% ($P<0.0001$), respectively, exceeding doses predicted to be efficacious in preclinical models. A robust PK/PD relationship was established across doses ($P<0.0001$). The recommended phase 2 dose was 180mg BID. Best RECISTv1.1 response was stable disease (SD) in 17 of 20 evaluable pts. Disease control rate at 12 weeks was 60%. Durable RECISTv1.1 SD $\geq$6 months +/- tumor regression were seen in pts with advanced ASNS-loss ovarian cancer (n=2), PD-1/L1-exposed melanoma (n=2) and *NF1* mutant leiomyosarcoma (n=1). **Conclusions:** IACS-6274 was well tolerated at biologically active doses with good human PK, significant PD target modulation and preliminary antitumor activity observed. The clinical trial assessment of rational combinations to maximize benefit in molecularly-selected pts is initiating. Clinical trial information: NCT03894540. Research Sponsor: Commonwealth Foundation for Cancer Research, The University of Texas MD Anderson Cancer Center.

3002 **Oral Abstract Session**

Phase 2 study of DRD2 antagonist/ClpP agonist ONC201 in neuroendocrine tumors. *First Author: Peter Meade Anderson, Cleveland Clinic Foundation, Cleveland, OH*

Background: ONC201, an imipridone with specificity for the dopamine-like DRD2 receptor and the mitochondrial protease ClpP, imparts anti-cancer effects via up-regulation of TRAIL/DR5, dual AKT/ERK pathway inhibition, and promotion of an integrated stress response. Select neuroendocrine tumors are known to secrete dopamine and harbor elevated DRD2 expression, which is most pronounced in pheochromocytoma-paraganglioma (PC-PG). **Methods:** This investigator-initiated single center trial (NCT03034200) enrolled 10 patients with metastatic PC-PG to cohort A and 12 patients with other neuroendocrine tumors to cohort B. The primary endpoint was response using MRI or CT, PET-CT and/or PET-MRI imaging defined as CR + PR + SD $>$ 3 months by RECIST criteria assessed by investigator. Secondary endpoints included progression-free survival, overall survival and safety. ONC201 was administered at 625 mg by oral capsules once each week. CT scans and tumor markers (plasma chromogranin and metanephrines) were followed at 6 weeks, 3 months and then every 3 months. Patients with clinical benefit could receive stereotactic body radiotherapy (SBRT) for non-indicator (e.g. bone) metastases. The data cutoff for this analysis is December 1, 2020. **Results:** In Arm A (n = 10; all paraganglioma) 5 patients exhibited a PR and 2 additional patients exhibited SD $>$ 3 months. Median duration of therapy for patients was 9 months (range: 1.5-33) with 5 patients $>$ 1 year. In Arm B (n = 12) there were 1 PR and 2 SD $>$ 3 months. Median duration of therapy was 3 months (range: 1-33). The partial response occurred in a patient with desmoplastic small round cell tumor who remains on treatment for $>$ 2 years. There was no instance of dose modification or discontinuation due to treatment-related adverse events. **Conclusions:** ONC201 is well tolerated at 625mg weekly in adults with advanced neuroendocrine tumors and is associated with clinical benefit that includes tumor response, particularly in paraganglioma patients. A more intense schedule of 2 daily doses each week is under evaluation, in addition to other neuroendocrine tumors. Clinical trial information: NCT03034200. Research Sponsor: Anderson Sarcoma Research Funds (T56428).

3003 **Oral Abstract Session**

Efficacy and safety of zenocutuzumab in advanced pancreas cancer and other solid tumors harboring NRG1 fusions. *First Author: Alison M. Schram, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NRG1 fusion proteins are oncogenic drivers in pancreas cancer and other solid tumors. They bind HER3, leading to HER2/HER3 heterodimerization and oncogenic transformation. The activity of zenocutuzumab (MCLA-128; zeno), a bispecific antibody targeting NRG1 fusion signaling in *NRG1* fusion positive (*NRG1+*) cancers, is being evaluated in the ongoing global multicenter phase 2 part of the eNRGy study and a global early access program (EAP). **Methods:** Enrolled patients (pts) have advanced *NRG1+* pancreas cancer, non-small cell lung cancer (NSCLC), and other solid tumors previously treated with standard therapy, are $\geq$ 18 years-old, have ECOG $\leq$1, adequate organ function, and measurable disease (RECIST v1.1). Zeno dosing: 750 mg IV every 2 weeks until progression or unacceptable toxicity. Primary endpoint: investigator (INV)-assessed objective response rate (ORR). Secondary endpoints: ORR per central independent radiologist review, duration of response (DOR), and safety. Tumor imaging is conducted every 8 weeks. **Results:** 51 pts with *NRG1+* cancer have received zeno, 37 in the eNRGy study and 14 pts in the EAP. As of 12 Jan 2021, treatment is ongoing in 27/51 pts (8/13 pancreas, 10/25 NSCLC, 9/13 other solid tumors). Among the 51 pts, 10 pts with pancreas cancer, 18 pts with NSCLC, and 5 pts with other solid tumors had measurable disease and had the opportunity for $\geq$1 tumor assessment (TA) and are included in this analysis. Among the 10 pts with pancreas cancer, median age was 49 y (range 34-72), 50% were male, 6/4 pts had ECOG 0/1, and all had metastatic disease and were *KRAS* wild-type. The median number of prior therapies was 3 (range 1-6). The INV-assessed confirmed ORR was 40% (4/10; 90% CI, 15;70), and for this cohort of pts, responses occurred at the first TA. Tumor regression was seen in 7/10 pts, and the disease control rate was 90% (90% CI, 61-100). A CA 19-9 decline of $\geq$ 50% was observed in 9/9 (100%) pts. DOR is pending. In the overall *NRG1+* population, tumor regression was observed in 25 of 33 pts and confirmed INV-assessed responses were seen in 9 of 33 pts (ORR 27%; 90% CI, 15;43), including in pts who previously received afatinib. Zeno was well tolerated with no pts requiring dose reduction for toxicity. Across all cohorts, for individual AEs, grade 3 events were reported in $\leq$5% of pts, and there was a notable lack of cardiotoxicity and severe gastrointestinal or skin toxicity. Updated data from all cohorts (pancreas, NSCLC, other solid tumors) will be presented. **Conclusions:** Zeno induces rapid and major radiologic tumor regression and biomarker responses in heavily-pretreated metastatic *KRAS* wild-type *NRG1+* pancreas cancer, with minimal toxicity. Zeno is a promising novel targeted therapeutic option for pts with *NRG1+* cancers. Clinical trial information: NCT02912949. Research Sponsor: Merus NV.

3004 **Oral Abstract Session**

MyPathway HER2 basket study: Pertuzumab (P) + trastuzumab (H) treatment of a large, tissue-agnostic cohort of patients with HER2-positive advanced solid tumors. *First Author: Funda Meric-Bernstam, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *HER2* (*ERBB2*) amplification and/or overexpression is observed in 2–3% of solid tumors, and is often associated with more aggressive disease. Thus far, HER2-targeted therapies are FDA-approved only for breast, gastric, and gastroesophageal cancers. MyPathway (NCT02091141) is a non-randomized, phase 2a multi-basket study assessing the activity of FDA-approved targeted therapies in non-indicated advanced solid tumors with relevant molecular alterations. We report results from the MyPathway HER2 basket, comprising a large, tissue-agnostic cohort of patients (pts) with HER2-altered tumors treated with P + H. **Methods:** Pts in this analysis were aged ≥18 years and had HER2-amplified and/or overexpressed tumors. Pts received P (840-mg IV loading dose, then 420-mg every 3 weeks [q3w]) + H (8-mg/kg IV loading dose, then 6-mg/kg q3w). The primary efficacy endpoint was investigator-assessed objective response rate (ORR). Other endpoints included disease control rate (DCR, defined by objective response or stable disease >4 mos) and duration of response (DOR). Subgroup analyses were completed by tumor type and *KRAS* status. **Results:** Pts were fully enrolled from April 14, 2014 to June 15, 2020. By January 22, 2021, 260 pts were efficacy-evaluable. Confirmed ORR (cORR) was 23.1% (60/260, including 5 complete responses; 95% confidence interval [CI] 18.1–28.7), DCR was 44.2% (115/260, 95% CI 38.1–50.5), and median DOR was 7.9 mos (95% CI 6.2–9.3). In 199 pts with wild-type *KRAS* tumors, cORR was 25.6% (51/199, 95% CI 19.7–32.3), DCR was 48.7% (97/199, 95% CI 41.6–55.9), and median DOR was 8.3 mos (95% CI 6.2–10.8). In comparison, in 26 pts with *KRAS*-mutated tumors, cORR was 3.8% (1/26, responder had colorectal cancer; 95% CI 0.1–19.6), DCR was 3.8% (1/26, 95% CI 0.1–19.6), and DOR was 2.7 mos. *KRAS* status was unknown in 35/260 pts (cORR 22.9% [8/35, 95% CI 10.4–40.1]; median DOR 6.7 mos [95% CI 2.5–12.7]). Clinical outcomes by tumor type are shown in the Table. **Conclusions:** P+H was active in a wide variety of *KRAS* wild-type HER2-amplified/overexpressed tumor types, but had limited activity in *KRAS*-mutated tumors. Clinical trial information: NCT02091141. Research Sponsor: F. Hoffmann-La Roche/Genentech.

Initial results from a dose finding study of TNO155, a SHP2 inhibitor, in adults with advanced solid tumors. *First Author: Irene Brana, Vall d'Hebron University Hospital, Vall d'Hebrón Institute of Oncology, Barcelona, Spain*

Background: SHP2 transduces signals from activated receptor tyrosine kinases to downstream pathways including MAPK. TNO155 is a selective, allosteric, oral inhibitor of SHP2. **Methods:** CTNO155X2101 (NCT03114319) is an ongoing first-in-human, open-label dose escalation/expansion trial of TNO155 in adults with advanced solid tumors. The primary objective is to characterize the safety and tolerability of TNO155 and identify regimen(s) for future study. Secondary assessments included pharmacokinetics, pharmacodynamics, and preliminary clinical efficacy. Here we present data from TNO155 single agent escalation. **Results:** As of 10/26/2020, 118 patients received TNO155 in variable schedules: once (QD; 1.5–70 mg; n = 55) or twice daily (BID; 30–50 mg; n = 25) in a 2 weeks on/1 week off (2w/1w) cycle; or QD in a 3w/1w cycle (30–60 mg; n = 32), or continuously (40 or 50 mg QD; n = 6). The most common cancer diagnoses treated were colorectal (54%), gastrointestinal stromal tumor (16%), non-small cell lung (12%), and head & neck (8%). The median number of prior antineoplastic therapies was 4 (range 1–10). Overall 109 patients (92%) have discontinued study treatment, 94 (80%) for progressive disease and 6 (5%) for adverse events (AEs). TNO155 showed rapid absorption (median day 1 T_{max} ~1.1 hours), an effective median $T_{1/2}$ of ~34 hours, and near dose-proportional exposure at day 14 (power model: AUC_{τ} beta = 1.09 [90% CI 1.02–1.16]). AEs were mostly Grade 1/2 and generally consistent with on-target effects of SHP2 inhibition. The most common treatment-related AEs (all grades) were increased blood creatine phosphokinase (n = 33, 28%), peripheral edema (n = 31, 26%), diarrhea (n = 31, 26%), and acneiform dermatitis (n = 27, 23%). The most common treatment-related Grade ≥3 AEs were decreased platelets (n = 5, 4%), increased aspartate aminotransferase, diarrhea, and decreased neutrophils (each n = 4, 3%). The best observed response was stable disease (SD) per RECIST 1.1, reported in 24 (20%) patients, with a median duration of SD of 4.9 months (range 1.7–29.3). Evidence of SHP2 inhibition, as measured by change in *DUSP6* expression by qPCR in paired pre- vs. on-treatment tumor samples, was seen in the majority of patients treated with TNO155 doses ≥20 mg/day (≥25% reduction, 38/42 [90%]; ≥50% reduction, 25/42 [60%]). Analysis of tumor whole-transcriptome RNA sequencing data is ongoing. **Conclusions:** TNO155 shows favorable pharmacokinetic properties and promising early safety and tolerability data at doses with evidence of target inhibition. The optimal dose using several schedules is still under evaluation. Studies of TNO155 in combination with other agents, including nazartinib (mutant-selective EGFR inhibitor[i]), adagrasib (KRAS G12Ci), spartalizumab (anti-PD-1 antibody), ribociclib (CDK4/6i), and dabrafenib (BRAFi) with LTT462 (ERKi), are ongoing (NCT03114319, NCT04330664, NCT04000529, NCT04294160). Clinical trial information: NCT03114319. Research Sponsor: Novartis.

3006 **Oral Abstract Session**

First-in-human phase I/II study of CYT-0851, a first-in-class inhibitor of RAD51-mediated homologous recombination in patients with advanced solid and hematologic cancers. *First Author: Ryan Lynch, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Homologous recombination (HR) is an essential, high-fidelity mechanism to repair DNA double strand breaks (DSBs). Inhibition of HR in cancer cells leads to accumulation of unrepaired DSBs and tumor cell death. This is the first reporting of the first-in-human study of CYT-0851, an oral, first-in-class, small molecule inhibitor of RAD51-mediated DNA repair. **Methods:** Patients (pts) with advanced hematologic and solid tumors were treated with continuous 28-day cycles of increasing doses of CYT-0851 with an accelerated titration and 3+3 trial design. Primary objectives included safety, maximum tolerated dose (MTD), recommended Phase 2 dose (RP2D) (Phase 1), and antitumor activity (Phase 2). Secondary and exploratory objectives included pharmacokinetics (PK), pharmacodynamics (PD) and predictive biomarkers of response. **Results:** As of an 8 Dec 2020 data cutoff (DCO), 23 pts with advanced cancers (Sarcoma n = 8, Breast n = 4, Non-Hodgkin's Lymphoma n = 5; Pancreas n = 3; Ovarian n = 2; mucoepidermoid carcinoma n = 1) were enrolled in 6 cohorts (15 mg, 20 mg, 30 mg, and 45 mg BID; 90 mg and 130 mg QD). No pts experienced a dose-limiting toxicity and escalation continues per protocol to identify the MTD. 6 pts (26.1%) experienced a CYT-0851-related adverse event with only Gr 1/2 nausea (n = 3, 13%) and constipation (n = 2, 8.7%) occurring in > 1 pt. There has been no reported CYT-0851-related myelosuppression, serious adverse events, study discontinuation, or death. Preliminary PK analyses showed dose proportional systemic exposure with a half-life of ~3 days supporting transition from BID to QD dosing. PD effects were observed with increases in γH2AX in on-treatment circulating tumor cells compared to baseline at exposures associated with preclinical anti-tumor activity. Ten pts were response evaluable prior to the DCO. Two partial responses by Lugano and RECIST v1.1 criterion were achieved in pts with DLBCL (-74%) and myxofibrosarcoma (-30%) at 45 mg BID with treatment ongoing at 126+ and 250+ days. An additional two pts, with pancreatic cancer (-19%) and follicular lymphoma (-42%) had stable disease with tumor shrinkage at 45 mg BID for 111 and 99+ days. **Conclusions:** CYT-0851, a first-in-class inhibitor of RAD51-mediated HR, is well tolerated, with linear PK, target-directed PD effects and promising antitumor activity across different tumor types. CYT-0851 is the first DNA-damage repair (DDR) therapeutic with demonstrated clinical activity in both hematologic malignancies and solid tumors. Dose escalation continues to establish the RP2D, with planned expansion in 7 disease-specific cohorts in hematologic and solid cancers. Clinical trial information: NCT03997968. Research Sponsor: Cyteir Therapeutics.

3007 **Oral Abstract Session**

A phase Ib trial of belvarafenib in combination with cobimetinib in patients with advanced solid tumors: Interim results of dose-escalation and patients with NRAS-mutant melanoma of dose-expansion. *First Author: Sang Joon Shin, Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea*

Background: Belvarafenib, a potent, selective RAF dimer (type II) inhibitor, exhibits clinical activity in $BRAF^{V600E}$- and NRAS-mutant (NRASm) melanoma patients. The combination of belvarafenib and cobimetinib more potently and durably suppressed MAPK pathway output and tumor growth than currently approved BRAF/MEK inhibitors in RAS- or RAF-mutant tumor xenograft models. This interim results of phase 1b trial evaluated the safety, tolerability, pharmacokinetics, and anti-tumor activity of belvarafenib in combination with cobimetinib in dose-escalation and NRASm melanoma patients among the 9 indication-specific expansion cohorts. **Methods:** Patients with locally advanced or metastatic solid tumors harboring RAS or RAF mutation were enrolled in the dose-escalation stage, and the recommended doses were explored in the indication-specific expansion stage. Patients in the dose-escalation stage were given belvarafenib (100–300mg BID) in combination with cobimetinib (20–40mg QD) and the dose of subsequent cohorts was decided by a traditional 3+3 design and safety profile. Primary objectives were to evaluate the safety and tolerability, to estimate the maximum tolerable dose, and to identify the RP2D of the combination. **Results:** A total of 32 patients enrolled were evaluated for safety analysis; 19 were enrolled in 4 cohorts in the dose-escalation stage and 13 NRASm melanoma patients were enrolled in the indication-specific expansion stage (cut-off date: 2020-7-24). There were 3 DLTs (G3 colitis, G3 diarrhoea, G3 nausea) in 2 patients at the starting dose of belvarafenib 200mg BID continuously and cobimetinib 40mg QD 21/7 schedule. Belvarafenib dose was escalated to 300mg BID with cobimetinib 20mg QD, which did not result in DLTs. The most common treatment-emergent adverse events that occurred in ≥30% of 32 patients were dermatitis acneiform, diarrhoea, constipation, and increase in blood creatine phosphokinase. Two combination doses were explored in the indication-specific expansion stage. Out of the 9 indication-specific expansion cohorts, NRASm melanoma patients exhibited promising efficacy signal; 5 patients reached partial responses (PRs) out of 13, giving a response rate of 38.5%. Among them, 11 had been previously treated with checkpoint inhibitors (CPIs), including 5 (45.5%) who achieved PR. The median PFS was 7.3 months and 5 patients remained on the treatment at the cut-off date. **Conclusions:** Belvarafenib in combination with cobimetinib showed acceptable tolerability and encouraging efficacy in NRASm melanoma, and in those with prior CPI treatment. Further research is ongoing in other cohorts (Clinicaltrial.gov, NCT03284502) and in NRASm melanoma (reference GO42273 by clinicaltrials.gov ID number). *S.J.S and J.L contributed equally to this work. Clinical trial information: NCT03284502. Research Sponsor: Hanmi Pharm.

3008 **Oral Abstract Session**

BOS172738, a highly potent and selective RET inhibitor, for the treatment of *RET*-altered tumors including *RET*-fusion+ NSCLC and *RET*-mutant MTC: Phase 1 study results. *First Author: Patrick Schoffski, Department of General Medical Oncology, Leuven Cancer Institute, University Hospitals Leuven, Leuven, Belgium*

Background: *RET* (REarranged during Transfection) gene alterations (mutations and fusions) leading to constitutive kinase activity are identified as drivers of disease progression in multiple tumor types, including non-small cell lung cancer (NSCLC) and medullary thyroid cancer (MTC). BOS172738 is an investigational, potent, selective oral RET kinase inhibitor. This next-generation inhibitor was designed with nanomolar potency against RET and >300-fold selectivity against vascular endothelial growth factor receptor 2, to maximize the potential therapeutic window. **Methods:** NCT03780517 is a phase 1 study consisting of a dose-escalation and dose-expansion phase. During the escalation, 67 patients with *RET*-altered advanced solid tumors received once-daily oral doses of BOS172738 (10-150 mg). Intra-patient dose escalation was allowed as was over-accrual to dose levels deemed to be safe. Study endpoints were safety (CTCAE v. 4.03), tolerability and confirmed overall response rate (ORR; RECIST 1.1). The data cutoff was Dec. 11, 2020. **Results:** BOS172738 exhibited a favorable safety profile (n=67) for long-term administration with most treatment-emergent adverse events (TEAEs) classified as grade ≤2 and deemed unrelated to drug. The most common TEAEs were creatinine phosphokinase (CPK) increase (54%), dyspnea (34%), facial edema, aspartate aminotransferase elevation, anemia (25% each), neutropenia, diarrhea (22% each), fatigue (21%), and constipation (20%). BOS172738 was not associated with hypertension or significant hepatoxicity. BOS172738 demonstrated broad anti-tumor activity with an investigator-assessed ORR of 33% (n=18/54), a NSCLC ORR of 33% (n=10/30), MTC ORR of 44% (n=7/16, including 1 complete response) and one patient with *RET* fusion+ pancreatic cancer reported a partial response. Responders included patients with brain metastases with one patient whose brain lesion decreased by 43%. The median duration of response has not been reached. Many patients remain on study, including the longest of 659 days, at data cutoff. BOS172738 exhibited dose-dependent exposure (AUC, C_{max}), rapid absorption (median T_{max} 1 to 4.5 h), and an extended half-life (approximately 65 hours) maximizing target coverage. **Conclusions:** BOS172738 is a highly potent and selective RET inhibitor with a differentiated safety profile and clinical activity against *RET*-altered tumors, including patients with brain metastases. BOS172738 continues to be evaluated in patients with NSCLC, MTC, and in patients previously treated with other selective *RET* inhibitors. Clinical trial information: NCT03780517. Research Sponsor: Boston Pharmaceuticals.

3009 **Poster Discussion Session**

Prevalence of inferred clonal hematopoiesis (CH) detected on comprehensive genomic profiling (CGP) of solid tumor tissue or circulating tumor DNA (ctDNA). *First Author: Emmanuel S. Antonarakis, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: The increased use of ctDNA CGP has paralleled increased detection and interest in CH, which can confound CGP results from ctDNA or tissue, and can be associated with hematologic and cardiovascular morbidity. However, paired-depth sequencing of white blood cells (WBC) for confirmation of CH is not widely available. We here study the prevalence of inferred CH (iCH), which refers to incidental detection on routine clinical CGP of variants attributable to CH due to their known CH association and their negligible prevalence in solid tumors. **Methods:** A database of clinical CGP results was reviewed, including two 324-gene NGS panels for tumor tissue (FoundationOne CDx) and plasma ctDNA (FoundationOne Liquid CDx). Analysis was limited to NSCLC, breast, prostate, colorectal, and pancreatic cancers. iCH was defined as any pathogenic mutation in *ASXL1*, *DNMT3A*, and *TET2*, and prespecified mutations in *JAK2*, *SF3B1*, *U2AF1*, *MYD88*, *IDH2*, *MPL*, *CBL*. Variant allelic frequency (VAF) > 2% was considered clinically significant and VAF > 10% was considered high risk. **Results:** 100,905 total cases were studied; median age was 65 for tissue CGP and 68 for ctDNA. iCH was more commonly detected in ctDNA (1468/2891, 51%) than in tissue (9416/97993, 10%). Among cases with any iCH detected, multiple iCH mutations were seen more commonly in ctDNA (640/2891, 22%) than in tissue (987/98014, 1%). Focusing on clinically significant iCH (> 2% VAF), prevalence remained higher in ctDNA (22%, 637) than in tissue (8%, 7878), while the higher sensitivity of ctDNA testing identified more low level iCH (< 2% VAF, 40% in ctDNA, 2% in tissue). Across cancer types, iCH > 2% was consistently more common in ctDNA (Table). As expected, prevalence of iCH > 2% increased with age (continuous variable, $p < 0.001$). High risk iCH (> 10% VAF) was seen in 4% of total cases (most commonly *ASXL1*, *TET2*, *DNMT3A*); 1% of all cases had multiple clinically significant iCH variants (> 2% VAF). Focusing on a subset of 439 cases with both tissue and ctDNA results (median 1.5 months between samples), 290 iCH mutations were detected in ctDNA (median VAF 1%) but only 38 in tissue (median VAF 9%). **Conclusions:** Inferred CH is common on somatic CGP of cancer patients, with a high prevalence in ctDNA likely due to the deeper sequencing depth and WBC contamination. For the minority of patients with high VAF iCH, further research is needed to understand whether this might be representative of an occult hematologic condition deserving of further evaluation. Interim results of PATHFINDER, a clinical use study using a methylation-based multi-cancer early detection test. *First Author: Tomasz M. Beer, Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: PATHFINDER (NCT04241796) is an interventional, prospective study evaluating implementation of a blood-based multi-cancer early detection (MCED) test that uses targeted methylation-based cfDNA analysis to detect multiple cancer types and simultaneously predict cancer signal origin (CSO). We present a prespecified interim analysis of PATHFINDER evaluating an MCED test in a clinical setting. **Methods:** Participants (pts; ≥50y) were enrolled into 2 risk cohorts: non-elevated and elevated (smoking history, prior cancer [> 3y post treatment], or genetic predisposition). MCED test results (cancer signal detected/not detected) were returned to investigators; pts with a signal detected also received a CSO prediction and underwent further diagnostic testing by their medical team. The primary objective was to assess the extent of diagnostic testing needed to achieve diagnostic resolution (eg, time to resolution, number/type of tests). Secondary endpoints included positive predictive value (PPV) and a measure of test satisfaction (following diagnostic resolution [signal detected] and post test [signal not detected]). **Results:** PATHFINDER consented 6796 pts before closing accrual on 12/4/20; as of October 6, 2020, 4086 consented, 4047 enrolled, and 4033 analyzable pts were included in the interim analysis (62.4% female, 92.1% white). Two study-related adverse events (anxiety of mild severity) were reported. Cancer signal was detected in 1.5% (62/4033) of pts; 40/62 reached diagnostic resolution to date. Kaplan-Meier estimate of median time to resolution was 78 (95% CI, 54-151) days. Among 40 pts that reached diagnostic resolution, ≥1 imaging test was performed in 93% (37/40); ≥1 invasive procedure was performed in 72% (13/18) versus 18% (4/22) of pts with diagnostic resolution of cancer versus no cancer, respectively. Based on results to date, PPV was 45% (95% CI, 30.7-60.2%; 18/40). Of 18 cancer diagnoses, 11 were solid tumors (3 stage IV, 6 stages I-III, 1 metastatic recurrence, 1 missing stage), and 7 were hematologic malignancies (1 stage IV, 4 stages I-III, 2 without AJCC stage). Accuracy of the top CSO prediction in true positives was 82.4% (95% CI, 59.0-93.8%; 14/17). Most pts were satisfied with the test (43.7% extremely satisfied, 30.7% very satisfied, 14.6% satisfied). Signal detection rate and test satisfaction were similar in the 2 risk cohorts; PPV tended to be higher in the elevated risk cohort, as expected. **Conclusions:** An interim analysis of this return of results study demonstrated promising MCED test results. Of 40 pts achieving diagnostic resolution, nearly half had a diagnostic workup confirming cancer; CSO was predicted with high accuracy for detected cancers. Taken together with the rarity of adverse events and high test satisfaction, these results support the feasibility of clinical implementation. Full enrollment cohort data will be available at the meeting. Clinical trial information: NCT04241796. Research Sponsor: GRAIL, Inc.

Circulating tumor DNA to investigate resistance mechanism and clone evolution of ALK TKI treated lung adenocarcinoma. *First Author: Gang Hua, Department of Cardiothoracic Surgery, HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China*

Background: Sequential treatment with first-, second-generation ALK TKI followed by third-generation TKI (lorlatinib) have been widely applied to *ALK*-positive lung cancer. However, acquired resistance is often driven by secondary *ALK* mutations, which are needed to be further explored. Circulating tumor DNA, a non-invasive approach, can detect tumor-derived DNA from multiple metastatic sites and has become a promising strategy for assessing the genetic evolution of tumors and analyzing TKI resistance. **Methods:** Post-progression plasma specimens were collected and sequenced with a targeted gene panel from a total of 116 patients underwent *ALK* TKI treatment with from February 2014 to April 2020. The ALK TKIs administrated in this cohort included crizotinib (first-generation), ceritinib (second-generation), alectinib (second-generation), brigatinib (second-generation), ensartinib (second-generation) and lorlatinib (third-generation). **Results:** In this *ALK*-positive lung adenocarcinoma cohort, 49.1% were female and the rest were male with a median age of 52 (range 20 to 79). More than half of patients received more than one line of ALK TKI treatment. The most frequent *ALK* fusion type is *EML4-ALK* including *EML4-ALK* v1(E13; A20, 37/116, 31.9%) and *EML4-ALK*v3(E6a/b; A20, 49/116, 42.2%). *TP53* (29.1%, 41/141) was the most frequently mutated gene other than *ALK*. Frequently identified secondary mutations in patients progressing on *ALK* inhibitors were *ALK* mutations L1196M and G1202R. *ALK* G1202R was more common in patient with v3 fusion than in v1 (25.8% vs 0%; P< .001) while *ALK* L1196M was more common in v1 than in v3 (20.8% vs 3.2%; P= .005). Meanwhile, G1202R was identified at higher ratio in patients progressed on second-generation ALK TKI than first- and third-generation ALK TKI (11.3% vs 0% and 9.1%) whereas L1196M was more found in patients progressed on first-generation ALK TKI (9.1% vs 1.9% and 4.5%). Other identified secondary mutations were *ALK* F1174C/V/L, E1210K/Q, D1269A, D1203N and L1122M/V. Compound *ALK* mutations (≥2 concurrent *ALK* mutations) were more common in patients relapsed on third-generation ALK TKI lorlatinib (36.4%) compared to first- (12.1%) and second-generation (20.8%) ALK TKIs. Using serial plasma specimens, clone evolution analysis showed that five patients developed compound *ALK* mutations after sequential ALK TKI treatments and two novel *ALK* compound lorlatinib-resistant mutations D1203N+I1171N and F1174C+G1202R were identified. **Conclusions:** Genotyping of sequential post-progression plasma specimens reveals that treatment with sequential first-, second-, and third-generation ALK inhibitors can accelerate the accumulation of ALK resistance mutations and may lead to treatment-refractory compound ALK mutations. The selection for optimal first-line TKI is very important to achieve a more efficacious long-term strategy and prevent the emergence of on-target resistance. Research Sponsor: None.

BRCA reversion mutations in a pan-cancer cohort to reveal _BRCA_-dependence in select noncanonical _BRCA_-mutant histologies. *First Author: Yonina R. Murciano-Goroff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Loss of *BRCA1/2* function leads to homologous recombination deficiency (HRD) and can enhance platinum and PARP inhibitor sensitivity in breast, pancreas, prostate, and ovarian cancers. In *BRCA*-associated cancers, resistance can result from the development of *BRCA1/2* reversion mutations, which restore *BRCA1/2* function. By contrast, a *BRCA* mutation may be an incidental finding in other tumor histologies. **Methods:** To determine the distribution of reversion mutations in a pan-cancer cohort, the MSK-IMPACT clinical sequencing cohort was mined to identify patients who had both a germline *BRCA1/2* mutation and a frameshift somatic reversion mutation that restored *BRCA1/2* function. Whole exome resequencing was used to detect HRD signatures. Chart review enabled collection of data on treatment history in patients consented to germline testing. **Results:** Of the 33,277 patients with matched tumor and normal sequencing profiled in this study, 861 patients were found to have germline pathogenic *BRCA1/2* alterations, including 347 (40%) in *BRCA1* and 514 (60%) in *BRCA2*. Somatic *BRCA1/2* driver alterations were also found in tumor tissue from an additional 447 patients, with 156 (35%) having *BRCA1* mutations, and the remainder having alterations in *BRCA2* (65%). Among the 1,308 germline or somatic *BRCA1/2* mutant tumors, we identified reversion mutations in 12 patients, all of whom were germline carriers of *BRCA1/2*, comprising 3 *BRCA1* and 9 *BRCA2* tumors. 7 patients consented to germline testing enabling review of clinical characteristics and treatment history, 5 of whom received PARP inhibitor or platinum-therapy prior to reversion detection. Ten of 12 tumors with reversion mutations were in canonical *BRCA*-associated cancers. Interestingly, reversion mutations were also found in patients with lung adenocarcinoma (n=1) and gastroesophageal junction adenocarcinoma (n=1). In both these non-canonical histologies, the reversion was detected following progression on platinum-based therapy. Whole exome resequencing of the lung tumor revealed the classic somatic molecular phenotypes of HRD that are characteristic of *BRCA*-dependent tumors, including in terms of large-scale transitions, HRD-loss of heterozygosity, signature 3, and the number of telomeric allelic imbalance score. **Conclusions:** Matched tumor and normal sequencing from a large cohort of patients with diverse cancer histologies reveals that reversion mutations are found across *BRCA*-associated cancer types. In rare cases, reversionmutations in *BRCA1/2* following platinum-based therapy may be indicative of prior *BRCA*-dependence in select non-canonical tumor histologies. Feasibility of whole-genome sequencing in routine clinical practice. *First Author: Kris Samsom, Netherlands Cancer Institute, Department of Pathology, Amsterdam, Netherlands*

Background: In the next few years numerous drugs will be approved for defined genomic targets, most of these in a tumor agnostic manner. Identifying patients who can benefit from this is critical for the future success of precision medicine, ideally using a single comprehensive test to detect all possible biomarkers. The WIDE study (WGS Implementation in standard cancer Diagnostics for Every cancer patient) aimed to evaluate the feasibility, clinical validity (primary endpoints) and added value (secondary endpoint) of clinical grade Whole Genome Sequencing (cWGS) in routine clinical practice. **Methods:** cWGS was prospectively performed on 1,200 consecutive patients with (suspected) metastatic cancer. Tumor material was obtained during routine clinical procedures for both Standard-Of-Care (SOC) and cWGS. Next to securing a high quality specimen for SOC diagnostics, multiple frozen sections per patient were evaluated to identify the sample most suitable for WGS. cWGS was conducted independently of, but in parallel with SOC diagnostics, which included SOC molecular diagnostics (MolDx) for 48% of patients. cWGS and MolDx results were compared and discussed in a dedicated tumor board. Additional tests for resolving discordances were applied when needed. **Results:** cWGS was successfully performed in 69% (841/1217) of samples with a technical success rate of 97% (841/871). An insufficient amount of tumor cells ($< 20\%$) was the main reason for not completing cWGS (25%, 310/1217). cWGS turn-around-time (TAT), due to continuous improvements to the clinical procedure and cWGS pipeline over the course of the study, decreased to 10 working days. A total of 856 genomic biomarkers identified by SOC MolDx could be compared to cWGS results. Initial analyses of discordances revealed an error rate of 2.1% (18/856) for cWGS compared to a 1.0% (8/856) error rate for SOC MolDx. After optimizing cWGS and SOC pipelines based on these findings, error rates dropped to 0.6% (5/856) and 0.7% (6/856) for cWGS and SOC MolDx, respectively. Overall, cWGS identified clinically actionable (routine practice and experimental) biomarkers in 71% of all patients tested. Compared to SOC MolDx, cWGS identified one or more additional clinically actionable biomarkers in 54% (446/832) of patients. Interestingly, in patients who were not tested by SOC MolDx, actionable variants were identified by cWGS in 54% (153/282). **Conclusions:** The WIDE study has shown that cWGS is feasible in routine clinical practice in a comprehensive cancer center setting, using tumor material obtained during routine procedures. Furthermore, cWGS showed added value by identifying one or more additional clinically actionable biomarkers in 54% of patients including patients who had not received SOC MolDx. These outcomes have led to the successful adoption of cWGS at the Netherlands Cancer Institute as part of routine care, which will further facilitate precision medicine for cancer patients. 3014 **Poster Discussion Session**

Racial and ethnic disparities among participants in precision oncology clinical studies. *First Author: Christopher M. Aldrighetti, Department of Radiation Oncology, Massachusetts General Hospital, Boston, MA*

Background: Precision medicine has revolutionized oncologic care in the United States (US) in the past two decades. While the US cancer population is rapidly diversifying, enrollment of a diverse patient population into clinical trials lags behind. In particular, it is unclear whether minority patients are adequately represented in precision oncology trials. Herein, we report racial/ethnic representation in precision oncology studies spanning four common cancer types (breast, lung, prostate, colorectal cancers). **Methods:** Completed US clinical studies incorporating precision medicine objectives based on a set of 12 precision oncology search terms (including tumor biomarker, whole exome sequencing, tumor mutation testing, gene expression signatures, tumor microarray, tumor genomics, et cetera) were identified from Clinicaltrials.gov. Studies were reviewed for reporting race/ethnicity for inclusion in the analysis. The Surveillance, Epidemiology, and End Results (SEER) database was used to determine incidence of race/ethnicity in the US cancer population, correlated with disease site and median year of enrollment for each trial. The difference in incidence (D-I) was defined as the median absolute difference in study racial enrollment and SEER incidence, with a negative value corresponding to underrepresentation. Wilcoxon signed-rank test was used to compare median D-I to a value of 0 by racial/ethnic subgroups. **Results:** Overall, 156 studies were identified; 40.3 and 27.5% studies enrolling from 2000 through 2020 met the inclusion criteria for racial and ethnic subgroups reporting, respectively. Of 4,418 total enrollees, 82.5% were White, 10.5% Black, 3.8% Asian, and 0.4% American Indian/Alaskan Native (AIAN). Ethnically, 6.4% were Hispanic. The D-I was +2.2% for Whites (interquartile range (IQR) = -43.7% to 25.4%; $P < 0.013$), -0.74% AIAN (IQR = -0.8% to +5.9%; $P < 0.001$), -2.5% Asians (IQR = -4.1% to 30.4%; $P < 0.152$), -4.6% Blacks (IQR = -20.1% to +45.0%; $P < 0.001$), and -8.1% Hispanics (IQR = -14.8% to + 29.6%; $P < 0.001$). By disease site, Blacks were significantly underrepresented proportional to their cancer incidence among prostate (D-I of -11.8%, $p = 0.009$) and lung studies (D-I of -5.9%, $p = 0.013$), while prostate studies significantly overrepresented Whites (D-I +14.0%, $p = 0.005$). Lung studies overrepresented Asians (D-I +0.49%) consistent with the prominent role of targetable oncogene drivers in this population. **Conclusions:** Results demonstrate an underrepresentation of minority racial groups and an overrepresentation of Whites in precision oncology studies. Increased emphasis on equitable enrollment onto these studies is critical, as resulting precision Omic conclusions are used to stratify populations and personalize treatments. A continued lack of diversity among enrollees may further leave behind vulnerable minority populations in the era of precision oncology. Research Sponsor: None.

3015 **Poster Discussion Session**

A first-in-human study of mirzotamab clezutoclax as monotherapy and in combination with taxane therapy in relapsed/refractory solid tumors: Dose escalation results. *First Author: Anthony W. Tolcher, Next Oncology, San Antonio, TX*

Background: Mirzotamab clezutoclax (ABBV-155) is a first-in-class antibody drug conjugate comprised of a BCL-X_L (B-cell lymphoma - extra long) inhibitor, solubilizing linker, and a monoclonal anti-B7H3 antibody. **Methods:** Patients (pts) with relapsed and/or refractory (R/R) solid tumors were administered mirzotamab clezutoclax with or without paclitaxel. Dose escalation of mirzotamab clezutoclax was guided by Bayesian continual reassessment. Primary outcomes were to determine the maximum tolerated dose (MTD) and the recommended phase 2 dose (RP2D). Secondary outcomes: safety, pharmacokinetics, and overall response rate per RECIST v1.1. **Results:** As of November 6, 2020, 31 pts received mirzotamab clezutoclax monotherapy (monoTx) and 28 pts received combination therapy with paclitaxel (comboTx). Overall demographics: median age 62 years (range 25–79); 61% female; 86% white; 24% ECOG 0, 76% ECOG 1; 51% had > 3 prior systemic therapies. The median duration of mirzotamab clezutoclax exposure was 3 cycles (range 1–14) for monoTx and 5 cycles (range 1–14) for comboTx. There were no dose limiting toxicities (DLT) reported with monoTx. In comboTx, 2 pts experienced a DLT: Grade 4 neutrophil count decreased and Grade 3 lymphocyte count decreased considered related to paclitaxel. 97% of all pts had adverse events (AEs). The most common AEs (in $\geq$20% of pts) overall were fatigue (39%), nausea (25%), diarrhea and arthralgia (22% each), vomiting and hypokalemia (20% each). AEs in $\geq$5 pts related to mirzotamab cleuzutoclax were fatigue (27%), diarrhea (12%), and nausea (9%). Related Grade 3/4 AEs overall (in > 1 patient) included anemia, lymphocyte count decreased, fatigue, and diarrhea (3% each). One patient on monoTx experienced a fatal cardiac arrest. No fatal AEs occurred on comboTx. Responses were observed with comboTx as shown in the Table. **Conclusions:** Mirzotamab clezutoclax as monotherapy and with paclitaxel demonstrates a tolerable safety profile (MTD not reached) with anti-tumor activity in R/R solid tumors. Further investigation in prospectively-selected B7H3 positive tumors as monoTx in pts with R/R small cell lung cancer and with paclitaxel in pts with R/R breast cancer and docetaxel in pts with R/R non-small cell lung cancer in the dose expansion phase is ongoing. Clinical trial information: NCT03595059. Research Sponsor: AbbVie.

Efficacy, n (%)	MonoTx N = 31	ComboTx N = 28
Objective response (confirmed CR or PR) [95% CI]	0	4 (14%) [4–33%]
Clinical benefit rate (CR + PR + SD) [95% CI]	16 (52%) [33–70%]	19 (68%) [48–84%]
Best Response*:		
Partial response	0	6 (21%)
Stable disease	16 (52%)	13 (46%)
Progressive disease	12 (39%)	3 (11%)
Missing post-baseline assessment	3 (10%)	6 (21%)

3016 **Poster Discussion Session**

A phase I dose-escalation study of the MDM2-p53 antagonist BI 907828 in patients (pts) with advanced solid tumors. *First Author: Patricia LoRusso, Yale University School of Medicine, Yale Cancer Center, New Haven, CT*

Background: BI 907828, a highly potent and orally administered MDM2-p53 antagonist, showed antitumor efficacy *in vivo*, especially in *TP53* wild-type MDM2-amplified de-differentiated liposarcoma (DDLPS) patient-derived xenografts and syngeneic models. **Methods:** NCT03449381 is a phase I study of BI 907828 in pts with solid tumors. The objectives of the dose-escalation part were to determine the maximum tolerated dose (MTD) based on the frequency of pts with dose-limiting toxicities (DLTs) during cycle 1, determine the recommended dose for expansion, and evaluate the safety and tolerability of two dosing schedules: BI 907828 given on day 1 of 21-day cycles (Arm A) or days 1 and 8 of 28-day cycles (Arm B). Dose escalation was guided by a Bayesian logistic regression model. The secondary objectives include pharmacokinetics (PK), pharmacodynamics and antitumor activity. **Results:** At January 15, 2021, 54 pts with advanced solid tumors (median of 2 lines of prior systemic therapies; range 0–11) were treated with BI 907828 (Arm A, 29 pts, dose range 10–80 mg; Arm B, 25 pts, dose range 5–60 mg). In Arm A, 5 pts experienced DLTs in cycle 1, including one Grade (Gr) 3 Nausea and one Gr 3 Thrombocytopenia at 45 mg, one Gr 3 Enterocolitis at 60 mg, and one Gr 4 Neutropenia and one Gr 4 Thrombocytopenia at 80 mg. In Arm B, 3 DLTs were reported: one Gr 4 Thrombocytopenia at 45 mg, one Gr 4 Neutropenia associated with Gr 4 Thrombocytopenia, and one Gr 3 Neutropenia at 60 mg. The most common Gr 3/4 treatment-related adverse events (AEs) were Thrombocytopenia (28.6%), Neutropenia (10.7%) and Nausea (10.7%) in Arm A, and Thrombocytopenia (16.6%) and Neutropenia (12.5%) in Arm B. Preliminary PK data indicate that BI 907828 reaches T_{max} at 4–6 h. Mean plasma exposures (C_{max} and $AUC_{0\text{-}inf}$) increased with dose. The geometric mean (gMean) Clearance/F was 5–19 mL/min and the gMean apparent volume of distribution was 23–57 L. The gMean half-lives estimated after the 1st dose were 26–55 h. Inter-patient variability in exposure was moderate. An increase in the target engagement biomarker GDF-15 in plasma was observed. The mean fold-change from baseline ranged from 8 to 49. Antitumor activity was seen in both schedules. In Arm A, a confirmed PR was seen in 2 pts with MDM2-amplified LPS (one PR lasted $>$ 2 years) and SD in 17 pts. In Arm B, 2 pts had PR (one confirmed in MDM2-amplified LPS and one not yet confirmed in MDM2-amplified pancreatic adenocarcinoma) and 14 had SD. Of note, 5 of 10 pts with DDLPS were progression-free for $\geq$9 months. **Conclusions:** BI 907828 showed a manageable safety profile, favorable PK properties and early signs of efficacy, especially in MDM2-amplified tumors. With both dosing regimens, DLTs were Neutropenia and Thrombocytopenia. Non-hematologic AEs, mainly gastrointestinal, were mostly low-grade and not dose-limiting. The MTD of 60 mg in Arm A (day 1 of 21-day cycles) and 45 mg in Arm B (days 1 and 8 of 28-day cycles) are awaiting confirmation. Clinical trial information: NCT03449381. Research Sponsor: Boehringer Ingelheim.

3017 **Poster Discussion Session**

Phase I study of mTORC1/2 inhibitor sapanisertib (TAK-228) in combination with metformin in patients (pts) with *mTOR/AKT/PI3K* pathway alterations and advanced solid malignancies. *First Author: Niamh Coleman, The University of Texas MD Anderson Cancer Center, Houston*

Background: Sapanisertib (TAK-228) is a potent, selective ATP-competitive, dual inhibitor of mTORC1/2. Metformin is thought to inhibit the mTOR pathway through upstream activation of AMPK suggesting combination therapy may enhance anti-tumor activity of TAK-228. We report preliminary safety, tolerability and efficacy from the dose escalation study of sapanisertib in combination with metformin in patients with advanced solid tumors. **Methods:** Pts with advanced metastatic solid tumors resistant or refractory to standard treatment, with and without *mTOR/AKT/PI3K*pathway alterations, received sapanisertib 3mg or 4mg daily together with metformin once to three times daily(500mg - 1500mg). All patients underwent 14-day titration period for metformin in cycle 1. Tumor measurements were performed following cycle 2 and subsequently every 8 weeks. Data cut-off date was December 31 2020. **Results:** 30 pts were enrolled across 4 cohorts (3mg/500mg; 3mg/1000mg, 4mg/1000mg; 4mg/1500mg). 19 were female (63%), median age was 57 (range: 30–77), all were ECOG PS 1. Tumor types included sarcoma (6), breast (4), ovarian (4), head and neck (3), colorectal (2), lung (2), renal cell (2), endometrial (2), gastro-esophageal junction (1), prostate (1), stomach (1), urachus (1) and cervical cancer (1). Median number of prior lines of therapy was 4. Most common genomic alterations included *PIK3CA* (27%), *PTEN*(17%), *AKT1/2* (10%), *mTOR* (10%). Of 30 pts evaluable for response, 4 pts achieved partial response (PR); 14pts achieved stable disease (SD) as best response. Disease control rate (CR+PR+SD) was 60%. Of the responders in PR, 3/4pts had documented*PTEN*mutations (3/5 pts enrolled with*PTEN*mutation had PR); 2/4 of pts in PR had co-mutations (pt with leiomyosarcoma had both *PTEN*and *TSC*;pt with breast cancer had both *PTEN*and *STK11*); 1/4 pts in PR had *AKT*and *mTOR*mutation; tumor types included leiomyosarcoma (n = 2), breast (n = 1) and endometrial cancer (n = 1).Most common treatment-emergent adverse events included nausea, anorexia, diarrhea, and rash. Grade (G) 3-5 treatment-related adverse events included hyperglycemia (4/30; 13%) fatigue (2/30; 7%) hypertriglyceridemia (1/30; 3%) rash (2/20; 7%), diarrhea (2/30; 7%), creatinine increase (1/30; 3%), acidosis (1/30; 3%). No dose-limiting toxicities (DLTs) were reported in the 3mg/500mg cohort. 1/6 pt had DLT in the 3mg/ 1000mg cohort (G3 diarrhea) and 2/11pts had DLTs in the 4 mg/1500mg cohort (G3 fatigue, G3 rash). 4mg/1000mg was defined as the maximum tolerated dose. **Conclusions:** The safety profile of mTORC1/2 inhibitor sapanisertib in combination with metformin was generally tolerable, with anti-tumor activity observed in patients with advanced malignancies harboring *PTEN* mutations and *AKT/mTOR* pathway alterations. Clinical trial information: NCT03017833. Research Sponsor: None.

3018 **Poster Discussion Session**

Phase 1b/2a study of PLX2853, a small molecule BET inhibitor, in subjects with advanced solid tumors and lymphoma. *First Author: Michael S. Gordon, HonorHealth Research Institute, Scottsdale, AZ*

Background: PLX2853 is a potent, orally active small molecule BET inhibitor. Its unique pharmacokinetic (PK) profile is associated with less thrombocytopenia and improved tolerability by allowing transient target engagement with a prolonged pharmacodynamic (PD) response and time for recovery after dosing. **Methods:** We conducted a first-in-human 3+3 Ph1b/2a study of PLX2853 in adults with relapsed or refractory solid tumors and lymphoma to determine the safety, PK and recommended phase II dose (RP2D) (NCT03297424). Secondary endpoints included efficacy and PD. **Results:** As of 2 February 2021, 44 subjects (median age 65, range 39 - 84) received PLX2853 in escalating doses from 5mg to 120mg QD and 40mg to 60mg BID. Ovarian cancer (n = 11), uveal melanoma, colorectal, and prostate (n = 5 each) were the most represented tumor types. Adverse events (AE) occurring in $\geq$15% of subjects included nausea (41%), decrease appetite (39%), fatigue (27%), vomiting (25%), diarrhea (25%), dysgeusia (25%), dehydration (23%), anemia (20%), dry mouth (18%), dizziness (16%), abdominal pain (16%), and pyrexia (16%). Thrombocytopenia occurred in 11% of subjects. Most AEs ($>$ 85%) were grades (G) 1-2. Of all AEs, 40% were related. There were 5 treatment-related serious AEs in 2 subjects (n = 1 G4 thrombocytopenia, G4 ischemic stroke, G3 subarachnoid hemorrhage [SAH], and G3 thromboembolic event; n = 1 G3 vomiting). Dose-limiting toxicities were observed at 120mg QD (G4 thrombocytopenia, G4 ischemic stroke, G3 thromboembolic event, and G3 SAH; asymptomatic G4 thrombocytopenia), 60mg BID (G3 thrombocytopenia with recovery $>$ 7 days), and 40mg BID (dose reduction for transient G3 fatigue). PLX2853 systemic exposure was dose-proportional up to 120mg with a short terminal half-life ($<$ 3.5 hr). Plasma concentrations were above the IC_{90} in the MYC-responsive reporter assay for 9 hr at 80mg or higher doses. RNA-seq analyses of peripheral blood mononuclear cells showed a dose-dependent modulation of BET target gene expression. One complete response (ongoing 9+ months) was seen in a patient with DLBCL, two patients had partial responses (1 uveal melanoma, 1 primary peritoneal cancer), and 14 patients had stable disease. The median PFS was 82.5 days (range: 51 – 209 days). **Conclusions:** PLX2853 shows encouraging signs of clinical activity and is well tolerated at the anticipated RP2D of 80 mg/day. PLX2853 is being evaluated as monotherapy and in combination. Clinical trial information: NCT03297424. Research Sponsor: Plexxikon.

3019 **Poster Discussion Session**

PF-06939999, a potent and selective PRMT5 inhibitor, in patients with advanced or metastatic solid tumors: A phase 1 dose escalation study. *First Author: Jordi Rodon Ahnert, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Protein arginine methyltransferase 5 (PRMT5) methylates multiple substrates known to be dysregulated in cancer, including components of the spliceosome machinery. PF-06939999 is a selective small-molecule inhibitor of PRMT5. Here we report the safety, PK, PD, and preliminary activity of PF-06939999 in patients (pts) with selected advanced/metastatic solid tumors. **Methods:** This phase 1 dose escalation trial (NCT03854227) enrolled pts with solid tumor types marked by potential frequent splicing factor mutations, including advanced/metastatic endometrial cancer, head and neck squamous cell carcinoma (HNSCC), non-small cell lung cancer (NSCLC), urothelial cancer, cervical cancer, or esophageal cancer. PF-06939999 monotherapy was continuously administered orally QD or BID in 28-day cycles. A Bayesian Logistic Regression Model was used to inform dose level decisions. Primary objectives were to assess dose limiting toxicities (DLTs), AEs and laboratory abnormalities. Tumor response was assessed using RECIST v1.1. PK and PD were assessed by determining PF-06939999 plasma concentration after dosing and changes in plasma levels of symmetric di-methyl arginine (SDMA), the product of PRMT5 enzymatic activity. **Results:** 28 pts received PF-06939999 at doses from 0.5-12 mg daily (QD or BID) during dose escalation. Median number of cycles was 2 (range, 1-13) . Most were female (54%) with a median age of 61.5 (range, 32-84) y. Median number of prior therapies was 4. Overall, 4/24 (17%) pts reported DLTs: thrombocytopenia (n=2, 6 mg BID); anemia (n=1, 8 mg QD); and neutropenia (n=1, 6 mg QD). Treatment-related AEs occurred in 24 (86%) pts. Most common ($\geq$20%) treatment-related AEs across all cycles were anemia (43%), thrombocytopenia (32%), dysgeusia, fatigue and nausea (29% each). Grade $\geq$3 treatment-related AEs included anemia (25%), thrombocytopenia (21%), fatigue, neutropenia and lymphocyte count decreased (4% each). One pt (6mg BID) had Grade 4 treatment-related thrombocytopenia. All cytopenias were dose-dependent and reversible with dose modification. No pts discontinued treatment for treatment-related toxicity. There were no treatment-related deaths. Exposure to PF-06939999 increased with doses in the dose range tested. Plasma SDMA was reduced at steady state (58.4-87.5%), indicating robust PD target inhibition. Two pts had confirmed partial response (HNSCC and NSCLC). 6 mg QD was identified as the recommended monotherapy dose for expansion. **Conclusions:** PF-06939999 showed dose-dependent and manageable toxicities in this phase 1 dose escalation study. Objective tumor responses were observed in pts with HNSCC and NSCLC. Analysis of archival tissue for the presence of splicing factor mutations and other potential predictive biomarkers is ongoing. Enrollment to part 2 dose expansion is ongoing in pts with NSCLC, HNSCC and urothelial cancer. Clinical trial information: NCT03854227. Research Sponsor: Pfizer.

3020 **Poster Discussion Session**

Phase 1 study of CB-103, a novel first-in-class inhibitor of the CSL-NICD gene transcription factor complex in human cancers. *First Author: Elena Lopez Miranda, Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: CB-103 selectively inhibits the CSL-NICD interaction leading to down-regulation of CSL-NICD mediated oncogenic pathway activation downstream of NOTCH receptor/ligand signaling, and has shown potent anti-cancer activity as single agent and in combination with targeted/chemotherapies in preclinical models. The aim of this dose escalation/expansion phase 1/2a study is to assess safety, maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D), preliminary activity, pharmacokinetics and pharmacodynamics of CB-103. **Methods:** Eligible were adult patients (pts) with advanced or recurrent selected solid tumors. Tumor tissue, where available, was retrospectively tested for NOTCH pathway activating mutations and surrogate tissues were evaluated for gene expression of related target genes. CB-103 was given orally in 28 days cycles at escalating doses until disease progression or toxicity. In a dose confirmatory cohort, NOTCH activation will be prospectively assessed to determine eligibility. **Results:** Forty-one pts (19 adenoid cystic carcinoma (ACC), 16 colorectal and 4 breast cancer, 2 prostate cancer) were assigned to increasing dose levels starting from 15mg once daily (OD). Median age was 55 years (range 25-76). Median number of prior lines of therapy was 2 (range 0-7). Thirty-two pts in 8 escalation groups completed the 28-day DLT window. One DLT (asymptomatic grade (G) 3 GGT increase) was observed at the highest dose (600mg). Related treatment emergent adverse events (AE) occurring in >10% of pts were nausea (24%), diarrhea (20%), dyspepsia (15%), fatigue (12%) and vision blurred (12%), all G 1/2. No discontinuations occurred due to treatment-related AEs. The MTD has not been reached. Several pts reported vision changes that improved over time and were fully reversible after stopping the drug. Median time on treatment for all pts was 52 days (range 5-249). Best response was stable disease (SD). For ACC pts, preliminary median PFS was 21.7 weeks (95% confidence interval (CI) 13.7-22.4 weeks) and disease control rate (DCR) was 79% at week 8 and 58 % at week 20. Three pts with ACC harboring activating NOTCH alterations had radiologically confirmed stable disease (SD) > 6 months. Importantly, in 3 pts with NOTCH positive disease a temporary stop of tumor growth was observed. One pt showed a reduction in size of a liver lesion up to 25% before progression due to new lesions. Mechanistically, strong on-treatment downregulation of NOTCH target genes was observed. The dose of 600mg CB-103 OD was declared the RP2D. **Conclusions:** CB-103 is the first drug to effectively control the CSL-NICD transcription complex. CB-103 is well tolerated in pts with advanced tumors and, as expected on the basis of mechanistic studies, in the absence of the typical toxicities associated with Notch targeting GSIs or mABs. The RP2D has been established for advancing clinical development into phase 2. Clinical trial information: NCT03422679. Research Sponsor: Cellestia Biotech AG.

3021 **Poster Session**

A phase 1 trial of FID-007, a novel nanoparticle paclitaxel formulation, in patients with solid tumors. *First Author: Jacob Stephen Thomas, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: FID-007 (FID) consists of paclitaxel encapsulated in a polyethyloxazoline (PEOX) polymer excipient designed to enhance PK, biodistribution, and tolerability. In addition to allowing the drug to remain in solution until it can enter a cancer cell, the PEOX nanoparticle preferentially delivers paclitaxel to the tumor through the leaky hyperpermeable vasculature. In xenograft studies, FID reduced or limited tumor growth in multiple tumor types including lung, gastric, breast, pancreatic, and ovarian cancer. FID was more effective at lower or comparable taxane doses with fewer side effects. We present the first-in-human trial of FID. **Methods:** The study is evaluating the safety, PK, and efficacy of FID in pts with advanced solid tumors. The primary objective is to determine the MTD and RP2D. Pts received FID in doses between 15mg/m^2 and 125mg/m^2 using a standard 3+3 dose escalation design. FID was given IV on Days 1, 8, and 15 of a 28-day cycle. Eligibility included ECOG 0-2, adequate organ function, and no more than 3 prior lines of cytotoxic therapy for advanced disease. **Results:** Twenty-five pts were treated across 6 dose levels. Median age was 62 (44-76). ECOG PS was 2 in 1 pt and 1 in 64%. Median number of cycles was 2 (1-16). There were 2 DLTs of grade 3 rash at 100 mg/m^2. Given the transient nature of the rash and response to topical therapy, DLT definition was modified to exclude grade 3 rash that lasts $\leq$ 7 days and additional patients were treated at 100 mg/m^2 which was deemed tolerable. There was 1 DLT of grade 3 neutropenia at 125 mg/m^2. All grade treatment related adverse events (TRAEs) in $\geq$ 25% of pts were rash (64%), alopecia (52%), pruritus (44%), anemia (44%) leukopenia, fatigue (40% each), dysgeusia, anorexia, nausea (32% each), and neutropenia (28%). Grade 3/4 TRAEs occurring in > 1 pt were anemia (20%), neutropenia, leukopenia, and maculopapular rash (16%). There were no treatment discontinuations due to toxicity. Twenty-two pts were evaluable for response by RECIST 1.1 with a PR rate of 14% (PR in pancreatic, biliary tract and NSCLC) and disease control rate of 59%. PK is linear and dose proportional. There is no paclitaxel accumulation after weekly dosing, and the $t_{1/2}$ is between 18-26 hours. **Conclusions:** FID has a manageable safety profile with MTD not reached. Accrual is continuing at 125 mg/m^2. PK is linear, dose proportional and comparable to that of nab-paclitaxel. There is preliminary evidence of anti-tumor activity in heavily pre-treated pts across different tumor types. Enrollment in dose escalation continues. Combination studies with immunotherapeutic agents are planned. Clinical trial information: NCT03537690. Research Sponsor: Fulgent.

3022 **Poster Session**

Bosutinib in combination with pemetrexed in patients with selected metastatic solid tumors: A phase I study (NCT03023319). *First Author: Nagla Fawzy Abdel Karim, Augusta University-Georgia Cancer Center, Augusta, GA*

Background: Activation of the *Src* kinase pathway has been observed in about 50% of cancers of the colon, liver, lung, breast and pancreas. Ceppi, *et al*, explored that *Src* inhibitors *might* be synergistic in combination with pemetrexed. Bosutinib is an approved oral ATP-competitive *Bcr-Abl* tyrosine-kinase inhibitor with an inhibitory effect on *Src* kinases. **Methods:** In this phase 1, dose-escalation study, we enrolled 10 patients with advanced metastatic solid tumors who progressed on standard of care chemotherapy, 9 of whom were evaluable, to receive bosutinib and pemetrexed. Bosutinib was administered once daily in a 3 + 3 dose-escalation study design where the first cohort started at an oral dose of 200 mg daily with I.V. pemetrexed 500 mg/m2 on a three weekly schedule. The primary objective was to determine the dose-limiting toxicity (DLT), and maximum tolerated dose (MTD) of bosutinib with pemetrexed, and the type and frequency of adverse events. Secondary objective(s) were to estimate tumor response rate (RR), progression-free survival (PFS), and overall survival (OS). **Results:** All patients had progressed on prior chemotherapy and included 9 patients with adenocarcinoma of the lung, and 1 patient with metastatic adenocarcinoma of the appendix. Two patients (22%) had prior pemetrexed exposure. Median age was 62 years (range, 58-44). The median number of bosutinib and pemetrexed cycles received was 2 (range, 1-4). Nine patients were evaluable. The MTD of bosutinib was 300 mg daily in this combination as 2 out of the 3 patients who received 400 mg experienced elevated liver transaminases (>CTCAE Grade 3) and one patient experienced grade 3 fatigue. Two patients (22%) had a partial response, and 6 patients (67%) had stable disease, including 2 patients with prior pemetrexed exposure, and 1 patient had disease progression. The two responders and the subject with the longest stable disease duration demonstrated Src overexpression on immunohistochemical staining of their tumor. Two patients died of sepsis; both had stable disease. Median PFS was 4.1 months (range, 1.2-11.6), and the median OS was 11.9 months (range, 4-36.7). Adverse events included pneumonia/sepsis, diarrhea, fatigue, rash, weakness, transaminitis, hypertension, and thrombocytopenia. **Conclusions:** The MTD of oral bosutinib was 300 mg daily in combination with pemetrexed 500 mg/m2 every 3 weeks. Despite the limitations of this phase I study there appears potential efficacy of this combination in pretreated patients. We are currently enrolling patients in the expansion cohort. Clinical trial information: NCT03023319. Research Sponsor: Pfizer.

3023 **Poster Session**

Profiling 523 cancer associated genes in circulating tumor DNA of children with CNS tumors. *First Author: Erin R. Bonner, Children's National Health System, Washington, DC*

Background: Pediatric central nervous system (CNS) cancers often pose unique challenges including tumor 'invisibility', where surgical resection is restricted due to the sensitive tumor location and tissue biopsy is not always feasible. Detecting cancer associated mutations and copy number variations (CNV) at diagnosis is increasingly important, as the WHO classification of pediatric CNS cancers has incorporated molecular signatures with tumor grade. To achieve CNS tumor molecular 'visibility', we previously established a liquid biopsy platform for detecting single nucleotide variants in circulating tumor DNA (ctDNA). However, our method was limited by the restricted number of genes that can be monitored and the inability to detect genomic events including CNVs. To address this, we developed a deep sequencing liquid biopsy approach to profile alterations across selected genes. Our platform provides an opportunity for multi-gene monitoring, to assess tumor subclonal evolution and response to treatment in the absence of repeat tissue biopsies. **Methods:** We tested the performance of our platform using paired tissue, CSF, and plasma/serum from 10 children with diffuse midline glioma (DMG). ctDNA was analyzed using the TruSight Oncology 500 (TSO500) ctDNA targeted panel covering 523 genes. Matched tumor, CSF, and blood were assessed for concordance and sequencing results were compared to digital droplet PCR (ddPCR) detection of H3K27M mutation. **Results:** The median exons with ^{3}500X coverage was 96% for 7 CSF samples with optimal input (^{3}60ng), 0.01% for 3 CSF samples with < 5ng input, and 74.5% for plasma/serum samples. ctDNA was more readily detectable in CSF, yet concordance between paired tumor, CSF and plasma/serum was observed. DMG associated mutations in genes including *H3F3A, HIST1H3B, TP53,* and *ACVR1* were detected in ctDNA. Of 9 H3K27M mutations identified in tumor, 8 were present in CSF and 3 in plasma/serum, for a positive percent agreement of 89% and 33%, respectively, with the tumor results. Among CSF samples, H3.3K27M was detected in 6/6 cases, and H3.1K27M in 2/3 cases, with variant allele frequencies comparable to ddPCR results. CNVs including *PDGFRA/B* and *MDM4* amplifications were present in CSF and confirmed by analysis of paired tumor. Additional events, including *PIK3CA* p.E545Q, *PPM1D* truncation, and *KRAS* amplification, were detected in CSF but absent from paired tumor, indicating tissue heterogeneity. Strategies to optimize ctDNA detection, including optimization of ctDNA isolation and adjustment of library QC metrics, were identified. **Conclusions:** This proof-of-concept study demonstrates the feasibility of our high depth, targeted sequencing approach for detecting clinically relevant mutations in ctDNA from children with CNS tumors. This approach may aid in diagnosis of CNS tumor molecular subtype, and monitoring of tumor evolution and response to therapy in serially collected ctDNA. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Other Government Agency.

3024 **Poster Session**

Interleukin-1-beta concentration and neutrophil-lymphocyte ratio as possible predicting biomarkers of response to therapy with checkpoint inhibitors. *First Author: Rashida Orlova, Saint-Petersburg State University, Saint-Petersburg, Russian Federation*

Background: One of the discussed predictive markers of the immune therapy efficacy is the index of neutrophils to lymphocytes ratio in peripheral blood (NLr), which reflects the activity of adaptive immunity and correlates with the level of tumor-infiltrating lymphocytes (TILs). High NLr and low TILs are associated with disease progression. Interleukin-1-beta (IL-1β) is one of the main cytokines produced by the tumor microenvironment (TMO). Overexpression of the cytokine leads to a local immunosuppression. For some tumors, elevated serum IL-1β levels have been associated with a poor prognosis. The aim of this work is to analyze the serum IL-1β level as a marker of TMO activity and the NLr as a marker of adaptive immunity activity in relation to the response to therapy with checkpoint inhibitors in patients with various solid tumors. **Methods:** The study involved 63 patients with various solid tumors who were treated at the City Oncological Dispensary and were prescribed checkpoint inhibitors (nivolumab (n = 33), pembrolizumab (n = 23), ipilimumab + nivolumab (n = 7)). The determination of the level of IL-1β was performed using the ELISA method ("Interleukin-1-beta, ELISA-best", Novosibirsk), a clinical blood test was performed in a dispensary. The response to treatment was assessed 3-6 months after the start of therapy. Statistical analysis was carried out in GraphPad Prism. **Results:** Among the examined patients 49.21% (31/63) achieved partial regression or stabilization of the process (group I), and 50.79% (32/63) progressed (group II). The mean concentration of IL-1β before treatment in group I was 2.21±0.3 pg/ml, in group II - 0.98±0.2 pg/ml. NLr was increased in 7 patients from group I and in 9 patients from group II, with the mean index level being 2.9±0.39 and 3.2±0.5, respectively. There was no statistically significant difference in the concentration of IL-1β and the NLr between the studied groups. In group II, the number of patients undergoing systemic anticancer therapy before immune therapy (n = 18) was statistically significantly higher than in group I (n = 8), p = 0.033. There was no statistically significant difference in IL-1β concentration and NLr relative to previous treatment. **Conclusions:** Our study showed that the level of IL-1β corresponds to that of healthy donors and its isolated determination has no prognostic value. The NLr in most patients from the progression group was higher than normal, in contrast to group I, which is confirmed in the literature. The presence of previous systemic anticancer therapy was found to be associated with disease progression. The described feature can be explained by the fact that patients who received therapy before, already have a longer period of illness, a more severe clinical condition. The presence of systemic anticancer therapy does not affect the level of IL-1β and NLr. Research Sponsor: RFBR, project number 20-015-00498.

3025 **Poster Session**

Genes copy number as a marker of low-invasive assessment of rectal tumors radiotherapy effectiveness. *First Author: Marina A. Gusareva, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Radiotherapy (RT) is a key component of rectal cancer (RC) treatment, however, nonresponsiveness in patients to preoperative RT is very common, usually due to the tumor cells radioresistance, mediated by their molecular characteristics, such as gene expression. The features of mRNA rapid degradation in extracellular environment make this indicator unsuitable for low invasive diagnostics. The solution to this problem is possible by switching to a more stable marker - the copy number variation (CNV), which can be determined in the extracellular DNA (cfDNA) circulating in the blood plasma. Therefore, the aim of the study was to identify the relationship between the level of genes CNV in the cfDNA of blood plasma with the effectiveness of rectal tumors RT. **Methods:** We used cfDNA preparations from blood plasma obtained before RT from 200 patients with RC, as well as from blood plasma of 50 apparently healthy donors (AHD, without cancer). RT was carried out on a linear accelerator Novalis TX (SFD = 2.4 Gy, TFD = 54.0 Gy). Blood samples were separated into plasma and cell fraction by centrifugation. Isolation of cfDNA from blood plasma was performed using the phenol-chloroform method. Determination CNV of 5 genes (BRCA2, H2AX, CASP9, RBBP8 and BCL2) was performed using Real-Time qPCR method. Differences were assessed using Mann-Whitney test; the Bonferroni correction was used to correct multiple comparisons. **Results:** RT results for 200 patients allowed them to be divided into 2 groups. After RT, 120 patients showed complete tumor regression (group 1), 50 patients showed insignificant tumor regression and 30 patients did not regress (group 2). In cfDNA of group 1 patients was found CNV decrease ($p < 0.05$) of H2AX and RBBP8 genes by 2.5 and 2.0 times, respectively, relative to AHD group. In the cfDNA of group 2patients an increase ($p < 0.05$) of BRCA2, H2AX, RBBP8 and BCL2 genes CNV was found by 2.0, 2.2, 2.0 and 2.0 times, respectively, relative to AHD group. Only 2 genes CNV differed in group 1 from group 2: the CNV of H2AX and RBBP8 was 5.4 and 4.0 times less respectively ($p < 0.005$). **Conclusions:** Thus, it has been found that increased CNV of genes BRCA2, H2AX, BCL2, RBBP8 in blood plasma cfDNA is associated with low efficiency of RT. At the same time, the CNV of H2AX and RBBP8 genes in cfDNA of patients with RC has the greatest potential as a marker of the RT effectiveness. Liquid biopsy testing: Impact on treatment assignment and survival in a community-based oncology practice—A real-world experience. *First Author: Khalil Choucair, Kansas University School of Medicine, Wichita, KS*

Background: Liquid biopsy is a promising, rapid and minimally invasive genetic test examining circulating tumor DNA. It offers a significant potential in selecting signal-matched therapeutic options. **Methods:** A retrospective chart review was conducted on adult patients with advanced solid cancer whose tumors were tested with the Guardant 360® (Guardant Health) assay between December 2018 and 2019. A follow-up analysis (censor date: 01/06/2021) was carried to assess the actual impact of testing results on treatment assignment and survival. **Results:** A total of 178 patients underwent testing. Mean age at diagnosis was 65 years. Median (m) Karnofsky Performance Scale was 90% and the majority of patients (89.9%) had ≥ stage III-B disease. Lung (LCa; 50.56%), breast (BCa; 17.42%) and colorectal (CRCa; 7.87%) cancers were the most common cancer types. A positive test was reported in 140/178 patients (78.7%); of those, 105/140 (75%) had an actionable mutation, either with an FDA-approved target-matched therapy (n = 32/105; 30.5%) or with a therapy outside current FDA indication (n = 73/105; 69.5%). In patients with no actionable mutation (n = 35/140; 25%), 85.7% (n = 30/35) had a signal-based clinical trial opportunity. The actual overall signal-based matching rate was 17.8% (24/135; vs. 82.2% no-match rate). Within candidates for FDA-approved treatment, 50% (16/32) received targeted therapy while only 6.9% (5/73) were treated with targeted agents outside current FDA indication: mean matching score (number of matched drugs/number of actionable mutations) was 0.6 (range: 0.33-2) and 0.8 (range: 0.17-2), respectively. Only 10% (3/30) were referred to signal-based clinical trials. Survival analysis of LCa, BCa and CRCa patients with actionable mutations who actually received any therapy (n = 66) revealed post-testing survival advantage for target-matched therapy (n = 22) compared to unmatched therapy (n = 44): overall survival (OS) was longer in the matched cohort (mOS: 13.3 months; 95% CI: 11.8-14.8 vs. 10.7 months; 95% CI: 9-12.4 in unmatched) but did not reach statistical significance ($P = 0.09$). Progression free survival (PFS) was significantly longer in patients who received matched therapy (mPFS: 11.3 months; 95% CI: 9.9-12.7 vs. mPFS: 6.8 months; 95% CI: 5.1-8.5 in unmatched; $P < 0.05$). **Conclusions:** Implementation of liquid biopsy testing is feasible in community practice and impacts therapeutic choices in patients with advanced malignancies. Receipt of liquid biopsy-generated signal-matched precision therapies conferred added survival benefit compared to unmatched therapy. Larger sample size studies are needed to validate these findings. Research Sponsor: None.

Circulating tumor DNA as markers of dynamic recurrence risk and adjuvant chemotherapy benefit in resected non-small cell lung cancer. *First Author: Wei Guo, Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: A significant proportion of non-small cell lung cancer (NSCLC) patients relapse after surgical resection with or without adjuvant therapy. The detection of molecular residual disease (MRD) has great potentials to stratify postoperative risk and facilitate early recurrence diagnosis. Here, we aim to evaluate the clinical utility of serial plasma circulating tumor DNA (ctDNA) in MRD detection, adjuvant therapy guidance, and recurrence risk prediction in resected NSCLC patients. **Methods:** This prospective cohort study recruited 116 patients with NSCLC following surgery and/or adjuvant therapy. Thirteen patients discontinued, leaving 103 patients for analysis. Tumor samples were obtained at surgery. Plasma samples were collected at baseline, after surgery, after adjuvant therapy and every 3 months thereafter and were analyzed by ultradeep (30000×) next-generation sequencing with molecular barcode and in-silico error correction. **Results:** Pretreatment ctDNA was detected in 69.8% of patients. ctDNA positivity after surgery and after completion of adjuvant chemotherapy (ACT) were significantly associated with worse recurrence-free survival (RFS) (HR: 4.0; 95% CI: 2.0-8.0; $P < .001$ and HR:3.2; 95% CI: 1.3-8.2; $P < .05$, respectively). In stage II-III patients who were positive for ctDNA after surgery, ACT-treated patients had a better RFS than those without ACT ($P < .05$), whereas ACT did not confer significant clinical benefits in patients with negative postsurgical ctDNA. During surveillance after definitive therapy, ctDNA positivity was associated with worse RFS (HR: 8.5, 95% CI: 3.7-20, $P < .001$) and preceded radiological recurrence by a median of 88 days. Using joint modeling of serial ctDNA and time-to-recurrence, we accurately predicted patients' 12-month and 15-month recurrence status, with areas under receiver-operating characteristics curves (AUROC) of 0.88 and 0.84, respectively. **Conclusions:** These results indicate that ultradeep ctDNA sequencing could sensitively detect MRD, thus identifying patients with high recurrence risk and guiding the adjuvant therapy decision in resected NSCLC. We also demonstrate that joint modeling of serial ctDNA levels and time to recurrent can provide an accurate dynamic risk prediction for NSCLC patients during surveillance. Plasma hPG_{80} circulating prograstin levels in cancer patients in Nigeria: Prolevcan study. *First Author: Omolara A. Fatiregun, Lagos State University Teaching Hospital, Ikeja, Nigeria*

Background: Progastrin is a tumor-promoting peptide which is detectable in the blood of patients with different cancers. hPG_{80} (circulating progastrin) is produced by cancer cells. Recently it was reported that hPG_{80} is detected in the blood of cancer patients, suggesting its potential utility for cancer detection. In this Nigerian study, we assessed the performance of hPG80 in diagnosed cancer patients versus healthy volunteers. **Methods:** Plasma samples of 50 patients with breast (n = 41) and colorectal (n = 9) cancer, aged from 26 to 70 years, were assayed for hPG_{80} levels with the DxPG80 kit from ECS-Progastrin. The diagnostic performance (ROC AUC) of hPG_{80} was assessed compared to 50 healthy volunteers aged from 21 to 38 years. **Results:** Plasma hPG_{80} levels were significantly higher in cancer patients compared to controls (median values: 4.59 pM (IQR: 2.02-8.27 pM) vs 1.37 pM (IQR: 0-3.11 pM), $p < 0.0001$). The median value of hPG_{80}level was 3.96 pM (IQR: 1.61-7.89 pM) for breast cancers and 6.43 pM (IQR: 2.80-15.86 pM) for colorectal cancer patients. ROC AUC for all cancers, breast cancer and colorectal cancer were 0.75, 0.74 and 0.82 respectively. There was no correlation between hPG_{80} blood levels with age or CA15.3 levels. **Conclusions:** Plasma hPG_{80} is a simple and relatively affordable blood test, it shows potential utility as a biomarker for cancer detection, monitoring and treatment assessment. Further prospective studies are needed to explore and confirm its potential. Research Sponsor: None.

Genetic predictor of severe sorafenib-induced diarrhea and hand-foot syndrome (HFS). *First Author: Julia C. F. Quintanilha, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Diarrhea, HFS, and hypertension are common toxicities of sorafenib. No markers are validated to predict patients at risk of these toxicities. This study aimed to identify genetic predictors of sorafenib-induced toxicities. **Methods:** A two-step, discovery-validation approach was used. The discovery set included 140 renal cell carcinoma patients from the TARGET study treated with sorafenib (400 mg twice daily) and genotyped for 1040 single-nucleotide polymorphisms (SNPs) in 56 genes. The three most statistically significant SNPs associated with grade ≥2 composite toxicity (either hypertension, diarrhea, HFS, or other skin toxicities, CTCAE v.3.0) were tested for association with grade 3 composite toxicity (either hypertension, diarrhea, or HFS, CTCAE v.4.0) in a validation set of 240 hepatocellular carcinoma patients from Alliance/CALGB 80802 treated with sorafenib (400 mg twice daily) alone or with doxorubicin. Associations between SNPs and composite toxicity was performed by logistic regression, with adjusting covariates (age, gender, race, and treatment arm, the latter two covariates for the validation set only). A meta-analysis odds ratio (OR) of each SNP-grade 3 toxicity association between the discovery and validation sets was obtained by inverse variance to point toward effects specific to a type of toxicity. **Results:** In the discovery set, the top three SNPs associated with grade ≥2 composite toxicity were rs12366035 (C>T, minor allele frequency, MAF 0.34) in *VEGFB* (p 0.0007), rs4035887 (G>A, MAF 0.49) in *EPAS1* (p 0.0021), and rs4864950 (T>A, MAF 0.23) in *KDR* (p 0.0058). These SNPs were genotyped in the validation set and only rs4864950 in *KDR* was replicated. No grade 4 toxicities were reported. Similar to the discovery set (OR 2.41, 95% CI 1.29-4.51), the A allele of rs4864950 increased the risk of grade 3 composite toxicity (p 0.032, OR 2.12, 95% CI 1.70-4.27) in the validation set. Grade 3 toxicity prevalence in the discovery and validation sets were 3.6% and 7.4% diarrhea, 8.6% and 12.3% HFS, 3.6% and 8.8% hypertension, respectively. The meta-analysis of the two datasets showed that the A allele of rs4864950 increased the risk of grade 3 diarrhea (p 0.045, OR 3.09, 95% CI 1.03-9.29), grade 3 HFS (p 0.012, OR 2.57, 95% CI 1.24-5.37), but not grade 3 hypertension (p 0.207, OR 0.51, 95% CI 0.18-1.45). **Conclusions:** We provide the first evidence of clinical validity of a marker of sorafenib-induced diarrhea and HFS. Sorafenib inhibits VEGFR2 (coded by *KDR*), leading to epithelial hypoxia and causing diarrhea and HFS. Variant rs4864950 might affect the function VEGFR2, which, during VEGFR2 inhibition, increases the risk of diarrhea and HFS. This SNP is common and can be genotyped in patients before receiving sorafenib for a better risk assessment. Tumor-educated platelets for breast cancer detection: Biological and technical insights. *First Author: Marte C. Liefaard, Department of Molecular Pathology, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Mammographic screening has enabled early detection of breast cancer, both in a general population and in women with increased risk of breast cancer. However, mammography yields many false positive results, leading to unnecessary invasive diagnostic procedures, and has limited sensitivity, particularly in women with high breast density. Blood-based markers may improve breast cancer screening, but no marker has proven sufficiently sensitive and specific for this purpose thus far. The mRNA repertoire in blood platelets (tumor educated platelets, TEPs) differs between patients with cancer and healthy controls. In this study, we aimed to train a classification algorithm on TEP mRNA profiles to distinguish patients with breast cancer from healthy controls. **Methods:** Platelet mRNA was sequenced from 266 women with stage I-IV breast cancer and 214 female asymptomatic controls from six different hospitals. First, a particle-swarm optimized support vector machine (PSO-SVM) classifier was trained (Best et al., Nature Protocols, 2019). To this end, 71% of the dataset was randomly allocated to train the algorithm, while the remaining 29% was used for internal validation. Second, an alternative classifier was trained on the same samples as in the PSO-SVM using elastic net (EN) regression. Reproducibility of classifier performance was evaluated in a single-center, independent, blinded set, consisting of cases (n = 37) and age-matched controls (n = 36). Post-hoc analyses were performed to assess the influence of hospital of origin and other factors on TEP gene expression and classifier performance. **Results:** Performance of both classifiers in the internal validation set was adequate with an area under the curve (AUC) of 0.86 for the PSO-SVM and 0.87 for the EN classifier. A strong correlation was observed between case control status and hospital of origin (Fisher's exact test, $p < 0.001$). Performance in the single-center, independent set was poor with an AUC of 0.57 and 0.60 for the PSO-SVM and EN, respectively. Post-hoc analyses indicated that 25% of the variance in gene expression was associated with hospital of origin, 6% with case control status, whereas 69% remained unexplained. Gene expression related to platelet activity was significantly different between the two hospitals that contributed most samples, and between cases and controls. **Conclusions:** We were unable to successfully validate two TEP RNA based classifiers for breast cancer detection in a single-center, independent, blinded set, regardless of the algorithm employed. Gene expression was severely influenced by hospital of origin and other factors unrelated to case-control status, suggesting that the wet lab protocol is highly sensitive to within-protocol variations in execution. Therefore, we suggest that thorough revision of the protocol is necessary before TEP RNA based classifiers can be reconsidered for breast cancer detection in the future. Detection of prognostic cancer-specific circular RNA in plasma. *First Author: Jason Brown, Department of Internal Medicine, University of Michigan, Ann Arbor, MI*

Background: Earlier detection of cancer could lead to improved outcomes. Non-invasive biomarkers are integral for early detection, and protein and DNA-based assays have been previously described for this purpose. Evaluation of highly expressed circulating RNA would improve upon existing methods by allowing for quantitation, however RNA expression in plasma is low. Circular RNA (circRNA) is formed by alternative backsplicing and provide resistance to exoribonclease-mediated degradation. Therefore, circRNA is more stable in plasma and could potentially be more easily detected non-invasively. Here, we report results from a novel assay that identifies and quantitates expression of circRNA in cancer plasma. **Methods:** Cancer-specific circRNA targets were identified by analyzing differential expression and abundance based on capture RNA sequencing in tissues. CircRNA-specific probes were designed and validated by stable expression with RNAse R incubation. Expression of selected circRNA isoforms were measured using a quantitative PCR-based assay. For breast cancer specimens, plasma was collected from a cohort of 36 patients and 12 normal female controls without known cancer diagnosis. Expression was determined by normalizing signal to two averaged universally expressed circRNAs. Differential expression for each target was determined for cancer vs. normal and stratified based on ER and HER2 positivity as well as stage. **Results:** Normalized expression of seven proposed breast cancer-specific circRNA targets was determined for all patients in the cohort. All targets demonstrated resistance to RNAse R-mediated degradation in breast cancer cell lines. In the breast cancer cohort, CircTRPS1 expression was higher in cancer plasma than normal, trending toward significance. Expression of circTRPS1 was significantly more common in ER-negative than ER-positive breast cancer ($p = 0.02$). CircPDHX expression was elevated in normal plasma compared to cancer and relatively higher in ER-positive than ER-negative cancer ($p = 0.05$). Median expression in plasma was elevated in cancer specimens compared to normal for CircVAV3, circDNAH14, and circCDYL. CircERBB2 expression was also relatively higher in HER2-positive cancer when compared to other targets. Higher expression significantly positively correlated with metastatic disease for circERBB2 ($p = 0.01$) and circCDYL ($p = 0.005$) and negatively correlated with metastasis for circWDR78 ($p = 0.02$). **Conclusions:** CircRNA are promising biomarkers for early non-invasive detection of cancer. We identified seven circRNA biomarkers in breast cancer plasma which correlated with clinical characteristics. Three circRNAs were significantly prognostic for metastatic breast cancer. Identification of additional cancer-specific targets and multiplexing markers is underway. This assay is generalizable to other cancers, and similar studies in prostate and bladder cancer are in progress. Research Sponsor: Early Detection Research Network (EDRN).

Prognostic value of plasma hPG_{80} (circulating progastrin), alone or in combination with Alpha-fetoprotein (AFP) in patients with hepatocellular carcinoma. *First Author: Alexandre Prieur, ECS-Progastrin, Prilly, Switzerland*

Background: Alpha-fetoprotein (AFP) is the most widely used biomarker for hepatocellular carcinoma (HCC) prognosis since it is expressed in the advanced stages of the disease. Consequently, AFP is not useful in establishing a prognosis for patients with a tumor in the early stages of the disease. hPG_{80} (circulating progastrin), a new drug target for cancer treatment which plays a pivotal role in tumorigenesis, is present in the blood of multiple types of cancers at early stages including HCC. The purpose of this study was to evaluate the prognostic value of plasma hPG_{80} in patients with HCC, in combination or not with AFP. **Methods:** A total of 168 HCC patients (BCLC from 0 to D) managed with local or systemic treatments, ("Liverpool" biobank) were enrolled prospectively and analyzed retrospectively. hPG_{80} was quantified using $DxPG_{80}$ Lab kit (ECS-Progastrin) and AFP was quantified using Cobas E411 in the blood of HCC patients. An optimal cutoff value of hPG_{80} was identified at 4.5 pM by calculating the minimal p-value based on the log-rank method. For AFP, a cutoff of 100 ng/mL was used as for liver transplantation (Notarpaolo, 2016). The prognostic impact of hPG_{80} and AFP levels on patient survival was assessed using Kaplan-Meier curves and log-rank tests. **Results:** The median overall survival (OS) of the full cohort is 20.9 months. HCC patients with high hPG_{80} levels (hPG_{80}+: >4.5 pM, 105/168) had significantly lower median OS compared to patients with low hPG_{80} levels (hPG_{80}-: <4.5 pM, 63/168) (12.4 months versus undefined respectively, $p < 0.0001$). Patients with high AFP (AFP+: >100 ng/mL, 69/165) had significantly lower median OS compared to patients with low AFP (AFP: <100 ng/mL 96/165) (7.2 months versus undefined, $p < 0.0001$). To improve the stratification, the patients were further categorized into four groups: hPG_{80}-/AFP- (n = 42), hPG_{80}+/AFP- (n = 54), hPG_{80}-/AFP+ (n = 21) and hPG_{80}+/AFP+ (n = 48). In the AFP- group, hPG_{80}+ patients exhibited a significantly worse prognosis than those with hPG_{80}- (26.3 months versus undefined, p=0.0087). Similarly, in the AFP+ group, patients with hPG_{80}+ had a significantly worse survival compared to hPG_{80}- patients (5.7 months versus 13.4 months, p = 0.0391). Finally, we evaluated the median OS of AFP+ patients according to BCLC staging. Interestingly, in the group BCLC 0 to B, hPG80+ had a significantly worse prognosis than those with hPG_{80}- (15.8 months versus 40.25 months, p=0.0317). **Conclusions:** Our findings show that hPG_{80} could serve as a new prognostic biomarker in HCC. Used in combination with AFP, it improves the stratification of the patients in good and worst prognosis, especially for those patients with negative AFP and early-stage HCC. Research Sponsor: None.

Detection of any-stage cancer using plasma and urine glycosaminoglycans. *First Author: Francesco Gatto, Chalmers University of Technology, Gothenburg, Sweden*

Background: Non-invasive liquid biopsies promise to enable early cancer detection and improve patient outcomes. However, virtually all liquid biopsies rely on genomic biomarkers, with limited sensitivity to early-stage tumors and poor detection of cancers shedding little cell-free DNA, like genitourinary or brain tumors. Here, we explored the use of plasma and urine glycosaminoglycan (GAGs) profiles, or GAGomes, as biomarkers reflective of tumor metabolism to serve as an alternative pan-cancer liquid biopsy. **Methods:** In this case-control study, we enrolled retrospective and prospective cohorts from Sweden and Italy. Included cases were treatment-naïve early-stage/low-grade cancers or metastatic/high-grade cancers across 14 histological types. Included controls were healthy 22-78 y/o adults with no history of cancer. We measured GAGomes – encompassing 17 chondroitin sulfate (CS), heparan sulfate (HS), and hyaluronate (HA) disaccharides - using a standardized UHPLC-MS/MS-based kit in a central blind laboratory. We tested the top GAGome features different in cancer using Bayesian estimation. These were used to design one plasma and one urine GAG score for the binary classification of cancer vs. control in a discovery set. We computed the area-under-the-curve (AUC), and sensitivity at 98% specificity of each GAG score in the validation set. A subset analysis was performed in early-stage/low-grade cancers only. In the subset of cases with survival records, we used multivariable Cox regression to estimate the hazard ratio (HR) for overall survival (OS) on each GAG score adjusted for cancer type, age, and gender. **Results:** GAGomes were measured in 753 plasma samples (460 cancers across 14 types, median age = 66 y/o, 51% female vs. 293 healthy adults, median age = 58 y/o, 57% female) and 559 urine samples (219 cancers across 5 types, median age = 69 y/o, 23% female vs. 340 healthy adults, median age = 56 y/o, 60% female). In the discovery set, the urine GAG score had an AUC = 0.80 (95% CI: 0.74-0.85, 124 cancers across 5 types vs. 184 controls) while the plasma GAG score had an AUC = 0.82 (95% CI: 0.78-0.86, 153 cancers across 14 types vs. 282 controls). In the validation set, the urine GAG score had an AUC = 0.78 (95% CI: 0.71-0.84, 95 cancers across 5 types vs. 156 controls) with 35% sensitivity at 98% specificity. The plasma GAG score had an AUC = 0.84 (95% CI: 0.79-0.88, 178 cancers across 14 types vs. 140 controls) with 41% sensitivity at 98% specificity. In the subset of early-stage/low-grade cancers, the AUC was 0.78 and 0.72 in plasma and urine, respectively. The plasma and urine GAG scores were independent predictors of OS regardless of cancer type (HR = 1.39, $p = 0.005$ in plasma [$N = 283$, 11 types, 67 deaths, median follow-up 17 months] and HR = 1.53, $p = 0.016$ in urine [$N = 161$, 4 types, 32 deaths, median follow-up 15 months]). **Conclusions:** GAGomes were sensitive non-invasive metabolic biomarkers for any-stage cancer, including genitourinary and brain tumors. Research Sponsor: Knut and Alice Wallenberg and Cancerfonden.

Dynamics of circulating tumor DNA in patients with advanced solid tumors treated with cediranib and olaparib. *First Author: Yiduo Hu, Yale New Haven Hospital, New Haven, CT*

Background: Circulating tumor DNA (ctDNA) has emerged as a potential biomarker to monitor treatment response in solid tumors. Our group previously showed that changes in ctDNA levels were predictive of radiographic response and survival in NSCLC patients receiving immunotherapy. Here we evaluated whether ctDNA dynamics could similarly be used to assess response in a PARP inhibitor-based therapy. **Methods:** A total of 122 patients with NSCLC, TNBC, PDAC or SCLC received cediranib (C) 30mg daily and Olaparib (O) 200mg twice daily in a phase II study NCI9881. Using a multigene NGS assay, ctDNA was measured longitudinally at baseline (T_0), after 3 to 7 days of C monotherapy (T_1), after 1 week of C+O combination (T_2), after 4 weeks of C+O (T_3), and every 4 weeks (T_{4+}) thereafter. The first radiographic assessment was done after 8 weeks of C+O and every 8-12 weeks thereafter. CtDNA was quantified by determining the allele fraction of cancer-associated somatic mutations in plasma. We defined an early ctDNA response *(e-ctDNA-R)* as a >10% decrease in mutant allele fraction from T_0 to T_2, and an early ctDNA progression *(e-ctDNA-P)* as a > 10% increase; otherwise, it was stable ctDNA *(e-ctDNA-S)*. **Results:** In total, 493 samples were analyzed from 94 patients, and 40 unique patients had both T_0 and T_2 ctDNA measurements, as well as corresponding radiographic assessments. These included 10 NSCLC, 17 TNBC, 3 SCLC and 10 PDAC. Of these patients, 4, 21, and 15 patients had PR, SD, and PD as best overall radiographic response respectively. Twenty-three (57.5%) patients had either *e-ctDNA-R* (17, 42.5%) or *e-ctDNA-S* (6, 15.0%), 18 (78.3%) of whom subsequently had either radiographic partial response (PR) or stable disease (SD). Seventeen (42.5%) patients had *e-ctDNA-P*, 10 (58.8%) of whom then had PD. A fair agreement was observed between *e-ctDNA-R/S* or *e-ctDNA-P* and radiographic PR/SD or PD with Cohen's k 0.38 (70% agreement). The correlation between early ctDNA changes and PFS/OS are summarized in the table. All 25 patients with PR/SD eventually progressed. Of these, 17 (68%) had >10% increase in ctDNA from the nadir prior to disease progression (median 94.6%, 95%CI 38.2%-389.1%). The time between ctDNA progression and ctDNA nadir was significantly shorter (median 21 days, 95%CI 21-28) than the time between radiographic/clinical progression and initial PR/SD (median 107 days, 95%CI 56-204, P=0.0015). **Conclusions:** Longitudinal ctDNA measurements could enable early assessment of treatment response, resistance, and disease progression in patients treated with PARP inhibitor-based therapy. However, in this study, tumor responses and ctDNA changes were generally not as robust as have been observed with other classes of therapy. Research Sponsor: U.S. National Institutes of Health.

Correlation between different levels of HER2 expression in circulating tumor cells (cHER2 ratio) and metastatic behavior in $stageIV_{aggressive}$ breast cancer. *First Author: Paolo D'Amico, Northwestern University, Feinberg School of Medicine, Chicago, IL*

Background: The presence of HER2 expressing (HER2+) circulating tumor cells (CTCs) occurs often in metastatic breast cancer (MBC) patients (pts). We have previously showed that the ratio among CTCs expressing high level of HER2 and the total number of HER2+ CTCs (circulating HER2 ratio, cHer2 ratio) has a prognostic role in MBC patients. Here we further investigate the role of the cHER2 ratio in the process of metastatic spread. **Methods:** Under IRB-approved study we prospectively analyzed blood samples of patients with MBC enrolled before starting a new line of therapy. Samples were collected from pts treated at Northwestern University (Chicago, IL) between 2016 and 2020. CTCs were enumerated through CellSearch (Menarini Silicon Biosystems, Bologna, Italy) and characterized for HER2 expression using the CellSearch CXC Kit. HER2+ CTCs were divided in 3 different categories (1+,2+,3+) leaning on fluorescence intensity. Pts with <5 CTCs (stage $IV_{indolent}$) were excluded from the analysis. The cHER2 ratio, defined as the sum of 2+ CTCs and 3+ CTCs divided by the total number of HER2+ CTCs, was used to split the remaining pts in 2 different cohorts: cHER2 ratio high (> 0.75) ($cHER2_{high}$) and cHER2 ratio low (≤0.75) ($cHER2_{low}$). The frequency of each metastatic site (i.e. liver, lung, central nervous system, bone, lymph nodes, skin/soft tissue, serosa) and the total number of different sites involved (1-7, ≤2 and >2 sites) were compared among the two sub-populations and analyzed through Fisher exact test. **Results:** Out of 98 pts enrolled, 77 were classified as $cHER2_{low}$ and 21 as $cHER2_{high}$. We observed a higher frequency of oligometastatic pts (≤2 sites involved) in the $cHER2_{high}$ cohort (16, 76%), compared to only 29 (37%) in the $cHER2_{low}$ ($p<0.005$). Moreover, the cHER2 ratio was associated with a tropism toward specific sites of disease spread with higher incidence of liver, lung and lymph nodes metastases in the $cHER2_{low}$ cohort ($p<0.05$). No other statistical associations were observed in respect of specific organ tropism. The frequency of involvement for each metastatic site among the two cohorts are reported in the table. **Conclusions:** Measuring CTCs enumeration and HER2 expression we identified two cohorts, $cHER2_{high}$ and $cHER2_{low}$, associated with distinct patterns of metastatic spread. The $cHER2_{low}$ pts were correlated to multiple sites of metastatic involvement, with particular tropism toward liver, lung and lymph nodes. These results confirm the prognostic role of the cHER2 ratio, suggesting a peculiar biological meaning of the HER2+ 1+ CTCs. Research Sponsor: None.

Machine learning-based multiple cancer detections with circulating miRNA profiles in the blood. *First Author: Juntaro Matsuzaki, Division of Pharmacotherapeutics, Keio University Faculty of Pharmacy, Tokyo, Japan*

Background: Early detection of cancer is one of the most important unmet clinical demands. A wide variety of circulating microRNAs (miRNAs) that specifically indicate many types of cancer have been identified, and their miRNA expression profiles are considered as potential biomarkers. Therefore, circulating miRNAs may serve as a non-invasive liquid biopsy diagnostic tool for early detection of many types of cancer. Here, a novel blood-based diagnostic method combined with machine learning techniques is developed using the entire circulating miRNA expression repertoire in serum without prior selection of miRNA marker sets. **Methods:** To validate this diagnostic method, clinical serum samples from cancer patients with five types of cancer (breast cancer(272), colorectal cancer(239), lung cancer(223), stomach cancer(221) and pancreatic cancer(100)) and 289 non-cancer volunteers were collected. Serum samples were immediately processed and their small RNAs were extracted. The entire miRNA expression profile is analyzed via next generation sequencers. The resulting total miRNA expression profile was used to train machine learning models, including deep learning techniques, without prior selection of miRNAs by human intervention. The machine learning model was trained with a training set to test set ratio of 4:1 and was carefully monitored by 5-fold cross-validation to avoid overfitting. **Results:** The diagnostic model provided 88% accuracy for all five cancer types (mean). The overall average AUROC was 0.954. Especially for breast cancer, the machine learning model provided 90% accuracy and 91 % sensitivity at 90% specificity. The overall AUROC was 0.966. High sensitivity was obtained regardless of the stage of the cancers, indicating that the possibility of early detection of cancer is kept high. **Conclusions:** Circulating miRNAs can be informative biomarkers for the earliest cancer detection in combination with machine learning. Unlike other cancer diagnostic methods where only a handful number of biomarkers are considered, this novel miRNA diagnostic platform method that uses machine learning reads a large set of miRNA expression profiles and automatically extracts the specific patterns of miRNA expression for early detection of multiple cancer types. In addition, the main advantage of miRNA-based cancer diagnosis is that they are more sensitive even in the early stages of cancer, compared to other diagnostic methods, such as cell-free DNA diagnostics, where the sensitivity of many types of cancer in the early stages still remains low. This approach could be easily expanded to other cancer types. Given the potential value of early detection in fatal malignancies, further validation studies are justified in future population-based studies. Many cancer research institutes are currently conducting further clinical trials to validate this early cancer diagnosis based on miRNA expression profiles. A single institution experience with droplet digital polymerase chain reaction (dd-PCR) liquid biopsy (LB) for therapeutic decision in advanced solid tumors. *First Author: Andre Marcio Murad, Personal. Oncologia de Precisao e Personalizada, Belo Horizonte, Brazil*

Background: Droplet digital polymerase chain reaction (ddPCR) is a promising method for analyzing minor amounts of cell-free circulating free nucleic acid (DNA and RNA) due to its high sensitivity, low cost, and fast reading, since it dispenses bioinformatics, making it an appropriate alternative to new generation sequencing (NGS) for the detection of biomarkers to guide molecularly targeted cancer therapy. The assay covers main actionable hotspot alterations across many actionable genes: EGFR(mutations), ALK (fusion, mutations), ROS1(fusion), BRAF(mutations), KRAS (mutations), NRAS(mutations), PIK3CA (mutations), ERBB2(CNV- copy number variation), ESR1(mutations), KIT(CNV) and PDGFRA(CNV). Therefore, our genes can be used in panels, both in therapeutically applied genotyping and in detecting molecular responses as well as in secondary resistance to tumors such as NSCLC, breast, cervix. rectal, GIST, melanoma and pancreas. **Methods:** dd-PCR was performed using the QX200 system (BIO-RAD, Hercules). The extraction of DNA and RNA was done using the magnetic beads technique of Thermofisher's MagMAX Kit. All samples were tested in duplicate. Up to now, 108 metastatic cancer patients were tested: NSCLC - 28 (26%), breast - 22 (20%), colorectal - 22(20%), melanoma - 18(17%), pancreas - 8(7%), ovarian - 6(6%), salivary glands - 2 (4%) and GIST 2(4%). **Results:** Significant genomic alterations were detected in 38(35%) patients: 10 (9%) mutations in the KRAS G12V gene (all in colorectal cancer), 10 (9%) ERBB2 amplification (breast cancer), 4 (3.65%) EGFR L858R mutations (NSCLC), 4 (3.5%) EGFR del19 mutations (NSLC), 4 (3.5%) EGFR T790M mutations (NSCLC), 4 (3.5%) BRAF-V600E mutations (colon and melanoma), 2 (1.8%) ALK-EML4 fusion (NSCLC). The MAF (Mutant Allele Fraction) ranged from 0.9% to 24%. In all cases, the results were decisive for the indication or change of a targeted therapy. Median turnaround time was 36 hours and the average cost of the panels was around 500 USD (median of 4 genes per panel). **Conclusions:** Our results suggest that dd-PCR is a highly sensitive method and could be used for a routine laboratory detection of the important genomic variations to determine the targeted therapy in patients with varied advanced solid tumors. Hyper engorged cancer associated macrophage-like cells in circulation predict for multi-organ metastatic disease in solid tumors. *First Author: Daniel J Gironda, Rutgers, the State University of New Jersey, New Brunswick, NJ*

Background: Patients with multiple organ metastases have poorer prognoses than those with a single organ metastasis, are frequently associated with drug resistance, and have higher tumor burden. Engorged (≥50um) Cancer Associated Macrophage-Like Cells (CAMLs) are a circulating stromal cell subtype detected in the blood of patients with solid tumors at high risk for recurrence or progression. While numerous studies have shown that ≥50um CAMLs predict poor clinical outcomes, meta-analysis of these studies have also suggested that hyper engorged CAMLs ≥100um (heCAMLs) may be associated with multifocal metastatic disease and even worse outcomes. In this prospective study, we evaluated the presence of heCAMLs in patients with metastatic disease and demonstrated a strong relationship with multi organ spread, which also correlated with shorter Progression Free Survival (PFS) and Overall Survival (OS). **Methods:** We prospectively recruited 151 patients with metastatic (m) mbreast (n = 58), mlung (n = 34), mprostate (n = 39), and mrenal (n = 20) cancers. Peripheral blood was collected prior to the induction of new treatment for metastatic cancer. Cells were isolated following standard CellSieve techniques, then imaged and measured in ZenBlue. Multi organ metastasis was defined as spread to ≥2 distant organ sites, or any spread to the brain. Single factor ANOVA was conducted to compare heCAML presence in multi organ metastatic patients versus patients with single organ site metastasis. Univariate and multivariate analysis was run to evaluate for PFS and OS against heCAMLs, and all known clinical parameters. **Results:** 150 viable samples (excluding 1 failed sample) were obtained. Multi organ metastases were present in 55% (n = 83/150) of patients. heCAMLs were found in 59% (n = 49/83) of the multi organ metastatic population, but only in 16% (n = 11/67) of the single site metastatic cohort ($p < 0.001$). heCAML presence appeared to differentiate multi organ vs single organ metastases in mbreast (85% vs. 52%, p = 0.006), mlung (71% vs. 26%, p = 0.025), mprostate (75% vs. 37%, p = 0.029), and mRCC (88% vs. 36%, p = 0.025). Further, in all n = 150 patients, heCAML presence predicted a significantly shorter median PFS of 4.5 versus 7.2 months, 24 month PFS (HR = 1.67, 95%CI = 1.13-2.45, p = 0.013), and significantly shorter median OS of 13.1 versus 20.4 months, 24 month OS (HR = 2.05, 95%CI = 1.24-3.39, p = 0.008). **Conclusions:** We examined a non-invasive prognostic blood based assay to determine its relationship to multi organ metastatic spread as well as its prognostic value in several solid cancers. These results showed patients with heCAMLs had higher rates of multi organ metastases, and appear to predict for shorter PFS and OS. Studies of larger cohorts are needed for prospective validation of these initial findings. Research Sponsor: Department of Defense (DARPA), U.S. National Institutes of Health.

Blood-based tumor mutational burden from circulating tumor DNA (ctDNA) across advanced solid malignancies using a commercially available liquid biopsy assay. *First Author: Leylah Drusbosky, Guardant Health, Inc., Redwood City, CA*

Background: Pembrolizumab was recently FDA approved across solid tumors for TMB scores ≥ 10mut/Mb as assessed by next-generation sequencing (NGS) of tissue (tTMB). A prior study of advanced cancer patients treated with immunotherapy found that higher somatic TMB, as defined by the 80th percentile in each histology, was associated with better overall survival. Previously, bTMB assessed by ctDNA from patients with newly diagnosed advanced NSCLC at a score of 16 mut/MB correlated with a tTMB score of 10 mut/MB. TMB levels vary by cancer type, line of treatment, and therapy received; the distribution of bTMB scores across solid tumor types has not been well characterized. Here we report the distribution of bTMB scores in patients with advanced malignancies. **Methods:** We queried 5,610 samples from patients with different cancer types undergoing clinical cell-free DNA testing (Guardant360; Redwood City, CA) and assessed bTMB scores from October 2020 - January 2021. bTMB score was derived via a previously described computational algorithm examining the total number of synonymous and non-synonymous SNVs and indels across a 1.0MB genomic footprint. We assessed the success rate of bTMB evaluation, overlap with microsatellite instability (MSI) status, and defined the distribution of bTMB levels across indications in this dataset. **Results:** bTMB score was successfully assessed in 4,275/5,610 (76.3%) samples (Table). The majority of samples (58%) were tested at disease progression as compared to initial diagnosis (42%). The median turnaround time from sample receipt to clinical reporting was 11 days and decreased to 9 days over the course of the study. For the majority of cancer types the 80th percentile TMB was ≥ 16 mut/MB tissue equivalency. **Conclusions:** Our analysis demonstrates the feasibility of measuring bTMB using a commercially available liquid biopsy assay. bTMB scores trended higher than tTMB previously reported in these cancer types, reflecting the ability of ctDNA to better capture tumor heterogeneity. cfDNA may allow for exploration of bTMB evolution throughout treatment. TMB should be interpreted in the context of disease, treatment, and method; these data establish a pan-cancer benchmark for bTMB which will serve as a resource for further studies. Research Sponsor: None.

Tumor Type	Male %	Mean age	ctDNA tested at diagnosis	ctDNA tested at disease progression	80th %ile (mut/MB)	MSI-H and TMB ≥ 80th %ile	bTMB Success Rate

Single cell RNA-sequence analysis to identify transcriptomic differences associated with treatment outcome and ethnicity in circulating tumor cells (CTCs) from patients (pts) with metastatic colorectal cancer (mCRC). *First Author: Francesca Battaglin, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: CTCs are a promising diagnostic and prognostic biomarker in colorectal cancer. The analysis of CTCs at the single-cell level may allow to capture tumor heterogeneity and identify novel prognostic and predictive markers in mCRC. Our aim was to evaluate whether the transcriptome profile of CTCs was associated with progression-free survival (PFS) in pts receiving treatment for mCRC and whether we could identify significant differences based on pts' ethnicity. **Methods:** Single CTCs were prospectively collected from 25 pts undergoing treatment for mCRC at the USC/Norris Comprehensive Cancer Center between April and October 2019. Pre-treatment peripheral blood was processed using CTC-FIND comprised filter separation and immunomagnetic depletion of CD45/50-expressing cells to collect ultra-pure CTCs samples. After isolation to single cell, CTCs were processed by single cell RNA-sequence (scRNAseq). Principal component analysis was used for clustering expression data. DESeq2 was used to identify differentially expressed genes between pts with short ($<$ 150 days) and long term ($>$ 150 days) PFS, as well as between Hispanic and non-Hispanic ethnicity with control for FDR ($Q < 0.1$). Ingenuity pathway analyses (IPA) of enriched pathway networks were performed. **Results:** Main pts characteristics were as follow: median age = 52 years; M/F = 18/7; Hispanics/non-Hispanics = 7/18; treatment line (n pts) = 1st (5), 2nd (11), $\geq$ 3rd (9). We identified 59 single CTC and CTC cluster from 22/25 pts (range 1-9, median = 2/pt). scRNAseq analysis identified two separate clusters of pts based on PFS (short term vs long term). Hispanic pts were mainly distributed within the short term PFS cluster. The IPA of the network of top 40 enriched pathways showed several pathways related with metabolism, such as Sirtuin signaling, mitochondrial dysfunction and oxidative phosphorylation, and IL6/JAK/STAT signaling pathways in pts with short term PFS ($Q < 0.05$). When comparing Hispanic vs non-Hispanic pts, we detected enrichment of neuroinflammation signaling pathway in Hispanics, including *CXCL8* (fold change, FC: 11.04), *GAD2* (FC: 4.77), *IRAK3* (FC: 17.06), *PLCG2* (FC: 4.65) and *TYROBP* (FC: 8.43) (all $Q < 0.05$). **Conclusions:** In our study CTCs transcriptome profiles showed an association with PFS in pts receiving treatment for mCRC, with an enrichment in mitochondria-related pathways and IL6/JAK/STAT signaling in the CTCs of pts with shorter PFS. Additionally, CTCs scRNAseq identified differentially expressed genes in Hispanic pts, displaying enrichment in neuroinflammation signaling. These results highlight the potential of CTCs molecular profiling as a tool to identify novel prognostic and predictive biomarkers in mCRC and actionable molecular pathways which may impact tumor spread and treatment response Research Sponsor: NCI P30CA014089, Gloria Borges WunderGlo Foundation, Dhont Family Foundation, Victoria and Philip Wilson Research Fund, San Pedro Peninsula Cancer Guild, Daniel Butler Research Fund.

Targeted ctDNA sequencing analysis reveals concurrent genomic alterations and its impact on TKI and immune checkpoint inhibitor therapy in advanced NSCLC from Asian population. *First Author: Wei Wu, University of California, San Francisco, San Francisco, CA*

Background: For advanced non-small cell lung cancer (NSCLC), liquid biopsy followed by targeted DNA sequencing is used in the clinical setting for driver-gene identification in circulating tumor DNA (ctDNA), tumor evolution and treatment monitoring. To understand the complexity and diversity of genetic alterations in advanced NSCLC, we examined the genetic landscape of late-stage NSCLC from an Asian population and its association with tyrosine kinase inhibitor (TKI) or immune checkpoint inhibitor (ICI) treatment. **Methods:** Plasma cell-free DNA (cfDNA) from 142 Asian patients with advanced NSCLC underwent real-world testing in a CAP-accredited and CLIA-certified central laboratory. We analyzed genetic alterations in cfDNA using an amplicon-based next-generation sequencing assay that covers 61 NSCLC related genes. 88 patients (62%) had received one or more lines of treatment. A similar cohort from Caucasian NSCLC was used for comparison (Blakely et al. *Nat Genet* 2017). Systematic co-mutation analysis, functional annotation and pathway enrichment analysis were performed. **Results:** The top 10 mutated genes in the Asian cohort were *EGFR* (66.2%), *TP53* (48.6%), *KRAS* (11.3%), *BRCA2* (7%), *CTNNB1* (6.3%), *PIK3CA* (6.3%), *SMAD4* (5.6%), *BRCA1* (4.9%), *MET* (3.5%) and *RB1* (3.5%). *EGFR* mutations occurred at hotspots in exons 18 – 21, with exon19 deletion, L858R, T790M, C797S, and G719A being the top-ranking alleles, similar to the Caucasian NSCLC cohort. Concurrent *KRAS* and *EGFR* mutations were higher in Asian cohort (8.5%) than in Caucasian cohort (0.56%). A rare PD-L1 structural variant (1.1%), reported to be related to immune evasion in other cancers (Kataoka et al. *Nature* 2016), was detected in the *EGFR*-mutated subgroup. Within the first line TKI-treated group, responders (CR+PR) harbored more alterations than non-responders ($p < 0.017$). Among ICI-treated NSCLC patients (anti-PD-1/PD-L1 mono- or polytherapy), responders from 1st line or 2nd line ICI treatment harbored fewer mutations than non-responders, but the distribution of mutational allele frequency (MAF) in responders was shifted to the right (more clonal than subclonal mutations). Functional annotation suggests that concurrent mutated genes and copy number alterations in advanced *EGFR*-mutant NSCLC were enriched in cell cycle, DNA repair, PI3K-AKT signaling pathways. **Conclusions:** We characterized the ctDNA-derived genetic landscape of advanced NSCLC from an Asian population and dissected mutated genes with the outcome of TKI or ICI treatment. We also report a rare PD-L1 structural variant in the *EGFR* mutated subgroup, which could be associated with immune evasion. Our analyses support the occurrence of clonal and subclonal driver co-alterations in *EGFR*-driven NSCLC, underlining the clinical utility of ctDNA detection for NSCLC diagnosis and treatment selection. A dual target sequencing solution to assess genomic and epigenomic alterations in cell-free DNA with no sample splitting. *First Author: Grace Q. Zhao, Avida Biomed Inc., Fremont, CA*

Background: Assessing the genomic and epigenomic changes on plasma cell-free DNA (cfDNA) using next-generation sequencing (NGS) has become increasingly important for cancer detection and treatment selection guidance. However, two major hurdles of existing targeted NGS methods make them impractical for the clinical setting. First, there is no comprehensive, end to end, kit solution available for targeted methylation sequencing (TMS), let alone one that analyzes both mutation and methylation information in one assay. Second, the low yield of cfDNA from clinical blood samples presents a major challenge for conducting multi-omic analysis. Thus, an assay that is capable of both genomic and epigenomic analysis would be advantageous for clinical research and future diagnostic assays. **Methods:** Here, we report the performance of Point-n-SeqTM dual analysis, a kit solution that can provide in-depth DNA analysis with highly flexible and customizable focused panels to enable both genomic and epigenomic analysis without sample splitting. With custom panels of tens to thousands of markers designed with $>$ 99% first-pass success rate, we conducted both performance validation and multi-center, multi-operator, reproducibility studies. Using spike-in titration of cancer cell-line gDNA with known mutation and methylation profiles, Point-n-Seq assay achieved a reliable detection level down to 0.003% of tumor DNA with a linear relationship between the measured and expected fractions. Benchmarked with conventional targeted sequencing and methylation sequencing, Point-n-Seq solution also demonstrated improved performance, speed and shortened hands-on time. **Results:** In a pilot clinical study, a colorectal cancer (CRC) TMS panel covering 560 methylation markers and a mutation panel with $>$ 350 hotspot mutations in 22 genes were used in the dual assay. Using 1ml of plasma from late-stage CRC patients, cancer-specific methylation signals were detected in all samples tested, and oncogenic mutations. In an early-stage cohort (33 stage I/II CRC patient), comparison of the analysis between tumor-informed, personalized-mutation panels (~100 private SNVs) for each patient and the tumor-independent CRC methylation panels were conducted. The initial results showed that tumor-independent TMS assay achieved a comparable detection compared to the personalized tumor-informed approach. Moreover, cfDNA size information (fragmentome) is also integrated into the analysis of the same Point-n-Seq workflow to improve the assay sensitivity. **Conclusions:** Point-n-Seq dual analysis is poised to advance both research and clinical applications of early cancer detection, minimal residual disease (MRD), and monitoring. Genome-wide 5hmC profiles to enable cancer detection and tissue of origin classification in breast, colorectal, lung, ovarian, and pancreatic cancers. *First Author: David Haan, Bluestar Genomics, San Diego, CA*

Background: Epigenomics assays have recently become popular tools for identification of molecular biomarkers, both in tissue and in plasma. In particular 5-hydroxymethyl-cytosine (5hmC) method, has been shown to enable the epigenomic regulation of gene expression and subsequent gene activity, with different patterns, across several tumor and normal tissues types. In this study we show that 5hmC profiles enable discrete classification of tumor and normal tissue for breast, colorectal, lung ovary and pancreas. Such classification was also recapitulated in cfDNA from patient with breast, colorectal, lung, ovarian and pancreatic cancers. **Methods:** DNA was isolated from 176 fresh frozen tissues from breast, colorectal, lung, ovary and pancreas (44 per tumor per tissue type and up to 11 tumor tissues for each stage (I-IV)) and up to 10 normal tissues per tissue type. cfDNA was isolated from plasma from 783 non-cancer individuals and 569 cancer patients. Plasma-isolated cfDNA and tumor genomic DNA, were enriched for the 5hmC fraction using chemical labelling, sequenced, and aligned to a reference genome to construct features sets of 5hmC patterns. **Results:** 5hmC multinomial logistic regression analysis was employed across tumor and normal tissues and identified a set of specific and discrete tumor and normal tissue gene-based features. This indicates that we can classify samples regardless of source, with a high degree of accuracy, based on tissue of origin and also distinguish between normal and tumor status.Next, we employed a stacked ensemble machine learning algorithm combining multiple logistic regression models across diverse feature sets to the cfDNA dataset composed of 783 non cancers and 569 cancers comprising 67 breast, 118 colorectal, 210 Lung, 71 ovarian and 100 pancreatic cancers. We identified a genomic signature that enable the classification of non-cancer versus cancers with an outer fold cross validation sensitivity of 49% (CI 45%-53%) at 99% specificity. Further, individual cancer outer fold cross validation sensitivity at 99% specificity, was measured as follows: breast 30% (CI 119% -42%); colorectal 41% (CI 32%-50%); lung 49% (CI 42%-56%); ovarian 72% (CI 60-82%); pancreatic 56% (CI 46%-66%). **Conclusions:** This study demonstrates that 5hmC profiles can distinguish cancer and normal tissues based on their origin. Further, 5hmC changes in cfDNA enables detection of the several cancer types: breast, colorectal, lung, ovarian and pancreatic cancers. Our technology provides a non-invasive tool for cancer detection with low risk sample collection enabling improved compliance than current screening methods. Among other utilities, we believe our technology could be applied to asymptomatic high-risk individuals thus enabling enrichment for those subjects that most need a diagnostic imaging follow up. Multiomic, plasma-only ctDNA NGS assay for minimal residual disease (MRD) detection in solid tumors. *First Author: Jessica Kurata, Guardant Health, Redwood City, CA*

Background: Detection of minimal residual disease (MRD) by circulating tumor DNA (ctDNA) post-curative intent treatment is predictive of recurrence in many solid tumors. Due to biological challenges with low ctDNA shed in early-stage disease and potential to detect non-tumor derived alterations in plasma (e.g. CHIP), most ctDNA MRD assays are dependent on *apriori* knowledge of genomic alterations from tumor tissue to achieve high sensitivity and specificity. Tissue-dependent methods limit the clinical application of a MRD assay, especially in cancer types where tissue biopsy is challenging, neoadjuvant therapy (NAT) is standard of care, and/or rapid turnaround times are needed for clinical decision making. We previously validated an assay (Guardant Reveal) that combines somatic and epigenomic analysis to detect ctDNA from early-stage colorectal tumors without tumor tissue or peripheral blood cells. Here we describe the expansion of this assay to detect MRD across multiple tumor types. **Methods:** Cell-free DNA (cfDNA) fragments are extracted from patient plasma, partitioned based on methylation fraction, enriched using a panel to target informative genomic and epigenomic regions, barcoded, and pooled for sequencing. Methylation status is determined non-destructively and with minimal loss of molecules, allowing sensitive genomic and epigenomic analysis of the same cfDNA fragments. A single assay with a total panel size of 5.3 Mb was developed for MRD analysis in multiple cancer types, including CRC, Lung and Bladder. A "ctDNA detected" result is defined by the de novo identification of tumor-derived somatic variants and/or the observation of a tumor-specific methylation profile exceeding predefined thresholds. **Results:** The assay performance was tested using 163 pre-treatment clinical samples from patients with early-stage non small cell lung cancer (NSCLC) and bladder cancer and 133 self-declared healthy donors. Sensitivity for pre-treatment detection in NSCLC was 68.9% at 95% specificity (20/42 Stage I: 47.6%, 25/30 Stage II: 83.3%, 19/21 Stage III: 90.5%). Sensitivity for bladder cancer was 44.2% at 95% specificity (13/43 NMIBC: 30.2%, 18/27 MIBC: 66.7%). Additional development from larger cohorts and other tumor types is ongoing and data will be presented as available. **Conclusions:** Using cancer-specific genomic and epigenomic signals combined with learning-based classifiers, we developed a highly specific method for detecting the presence of ctDNA in early-stage NSCLC and bladder cancer patients from plasma without the need for tumor tissue but with comparable sensitivities to tissue-dependent approaches. A plasma-only MRD assay will allow for greater clinical impact by overcoming the challenges of tissue procurement, particularly following NAT, and enabling faster time to results. Research Sponsor: Guardant Health.

Addition of selpercatinib to overcome osimertinib resistance in non-small cell lung cancer (NSCLC) with acquired RET fusion detected in ctDNA at very low allele frequency. *First Author: Leeseul Kim, Developmental Therapeutics Institute, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Osimertinib, a highly selective third generation EGFR tyrosine kinase inhibitor (TKI) became the standard front-line therapy for EGFR-mutant NSCLC. However, therapeutic options are limited for TKI resistance which commonly occurs. Therefore, overcoming acquired resistance to osimertinib remains an important high unmet need in the field of precision oncology. Herein, we present the first case of advanced adenocarcinoma of the lung that showed notable response with the addition of selpercatinib after acquired resistance to osimertinib monotherapy. **Methods:** Case presentation. **Results:** A 37-year-old woman with stage IVB adenocarcinoma of lung with osseous, hepatic and brain metastases initially received one cycle of carboplatin, pemetrexed and pembrolizumab. Based on the EGFR exon19 deletion detected from ctDNA NGS assay (Guardant 360) [variant allele frequency (VAF) 62.7%], the treatment regimen was changed to osimertinib monotherapy (80mg PO daily). Bevacizumab was empirically added given CNS involvement. She maintained overall stable disease for 10 months before subsequent CT showed disease progression. The treatment regimen was switched to atezolizumab, bevacizumab, paclitaxel and carboplatin combination therapy. She tolerated 6 cycles of the regimen in 4 month before a subsequent brain MRI revealed progression of the metastatic brain disease with new leptomeningeal disease. Whole brain radiotherapy was performed and decision was made to start combination TKI treatment of selpercatinib (120mg BID) added to the osimertinib (80mg daily) monotherapy based on her repeat ctDNA NGS assay result showing concurrent acquired CCDC6RET fusion (VAF 0.05%) and EGFR exon 19 deletion (VAF 10.0%). The 6 week follow-up CT demonstrated significant decrease in the largest lung mass (33.95*24.22mm->32.50*16.07mm). Repeat ctDNA NGS assay at one week after selpercatinib use showed disappearance of RET fusion and significant decrease in EGFR clone (VAF 10.0% to 0.05%). **Conclusions:** It has been reported that co-occurring RET fusions in NSCLC patients with EGFR mutations may contribute to acquired resistance to EGFR inhibitors. Several successful cases of cabozantinib, a non-selective RET inhibitor, or pralsetinib, a selective RET inhibitor combined with EGFR inhibitor, have been reported to aid in overcoming the acquired resistance to EGFR inhibitors. To date, there has been no report of clinical benefit in adding a RET inhibitor based on ctDNA detection of RET fusion with minute variant allele frequency. We for the first time report the case of overcoming acquired resistance to osimertinib by adding selpercatinib, a selective RET inhibitor in NSCLC patients with acquired RET fusion detected in ctDNA at VAF of 0.05%. Research Sponsor: None.

Concordancy of immunocytochemistry profiling of circulating tumor cells with immunohistochemistry for analysis of therapeutically relevant biomarkers. *First Author: Dadasaheb B Akolkar, Datar Cancer Genetics, Nasik, India*

Background: Immunohistochemistry (IHC) profiling of tumor tissue is the present standard for evaluation of therapeutically relevant biomarkers such as ER, PR, HER2, AR, ARv7, PD-L1 and MMR for selection of targeted, endocrine and checkpoint inhibitor therapy selection. However, this critical analysis is dependent on availability of tumor tissue obtained by an invasive biopsy. Challenges to this analysis include insufficient tumor tissue and inability to perform a repeat biopsy to obtain fresh tumor tissue. We have previously described an approach for negative enrichment of Circulating Tumor Cells (CTCs) from peripheral blood and for Immunocytochemistry (ICC) profiling of these CTCs for detection of diagnostically relevant tissue of origin and subtype specific markers, concordant with tumor tissue analysis. **Methods:** In the present study, we determined concordance between tumor tissue (HPE) and CTCs (ICC) for ascertaining the status of therapeutically relevant markers ER, PR, HER2, AR, ARv7 PD-L1 and MMR. We evaluated 201 matched pairs of tumor tissue (FFPE blocks) and CTCs obtained from peripheral blood. **Results:** Among the 743 paired assays on matched tumor tissue and CTCs, concordance (positive or negative) was observed in 651 matched pairs (87.6%). The concordance was 82.9% for ER, 100% for PR, 90.2 % for Her2, 93.8% for AR, 90% for Arv7, 85.1% and 87.6% for PD-L1 clones 22c3 and 28-8, and 85.6% for MMR (MLH1, MSH2, MSH6, and PMS2). **Conclusions:** The study findings indicate that ICC analysis of CTCs may be able to substitute IHC analysis of tumor tissue for profiling of therapeutically relevant markers. This approach may have application in cases where tumor tissue may be limiting and / or where an invasive biopsy to obtain tumor tissue may be unviable. Research Sponsor: None.

Development of extracellular vesicles-based classifier for detection of early-stage bladder, ovarian, and pancreatic cancer. *First Author: Juan Pablo Hinestrosa, Biological Dynamics, San Diego, CA*

Background: Many cancers are lethal because they present with metastatic disease. Because localized/resectable tumors produce vague symptoms, diagnosis is delayed. In pancreatic cancer, only ~10% of patients survive five years, and it will soon become the second leading cause of cancer-related deaths in the USA. For patients with metastatic disease, the 2- and 5-year survival is $< 10\%$ and ~3%, respectively. For the few patients with local disease, 5-year survival is ~40%. Many other cancers have comparable differences between early- and late-stage disease. It is apparent a diagnostic assay for early-stage cancers would transform the field by minimizing the need for aggressive surgeries and other harsh interventions, and by its potential to increase survival. Identifying cancer-specific aberrations in blood-based "liquid" biopsies offers a prospect for a non-invasive cancer detection tool. In the bloodstream, there are extracellular vesicles (EVs) with cargoes including membrane and cytosolic proteins, as well as RNA and lipids derived from their parent cells. **Methods:** We used an alternating current electrokinetics (ACE) microarray to isolate EVs from the plasma of stage I and II bladder (N = 48), ovarian (N = 42), and pancreatic cancer patients (N = 44), and healthy volunteers (N = 110). EVs were analyzed using multiplex protein immunoassays for 54 cancer-related proteins. EV protein expression patterns were analyzed using stepwise logistic regression followed by a split between training and test sets (67%/33% respectively). This process enabled biomarker selection and generation of a classifier to discriminate between cancer and healthy donors. **Results:** The EV protein-based classifier had an overall area under curve (AUC) of 0.95 with a sensitivity of 71.2% (69.4% – 73.0%, at 95% confidence interval) at $> 99\%$ specificity. The classifier's performance for the pancreatic cancer cohort was very strong, with overall sensitivity of 95.7% (94.6% – 96.9%, at 95% confidence interval) at $> 99\%$ specificity. **Conclusions:** EV-associated proteins may enable early cancer detection where surgical resection is most likely to improve outcomes. The classifier's performance for the initial three cancers studied showed encouraging results. Future efforts will include examining additional cancer types and evaluating the classifier performance using samples from donors with related benign conditions with the aim of a pan-cancer early detection assay. Research Sponsor: Biological Dynamics.

Dermatologic adverse events of brentuximab vedotin: Characteristics, management, and their relationship with dose regimen. *First Author: Yuna Oh, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Owing to its high efficacy and tolerability, brentuximab vedotin (BV) is increasingly being favored over other aggressive systemic therapies for the treatment of various CD30+ Hodgkin and non-Hodgkin lymphomas, including peripheral T-cell lymphoma and cutaneous T-cell lymphomas. Dermatologic adverse events (dAE) are one of the most common toxicities associated with BV but data regarding their characteristics including correlation to dose, time to occurrence, and management is scarce. We aim to describe the clinical and pathologic characteristics of dAEs associated with BV, their relationship with administered dose regimen, and available management strategies. **Methods:** An IRB-approved retrospective analysis was conducted for all patients who had received at least one cycle of BV from Memorial Sloan Kettering Cancer Center in 2009-2020. Logistic regression, χ^2, student's t-test were performed for univariate analyses. Kaplan-Meier survival and multivariate Cox proportional hazard model evaluated dAE occurrence stratified by 5 major dose regimens (single cycle, 1.2mg q1w, 1.2mg q2w, 1.2mg q3w, 1.8mg q3w). **Results:** Of 611 patients, 201 experienced dAE with median time-to-event of 24 days and 29% experiencing $>$ 1 dAEs. Rash was the most common (62%; 142/230), followed by alopecia (20%) and xerosis (13%). For rash, 50% reported involvement of only the extremities and/or acral sites compared to 25% who had generalized rash. Of those reported (111), 68 patients had grade 1 dAE (61%), 38 grade 2 (34%), and 5 grade 3 (5%)-all grade 3 were rash (maculopapular/morbilliform). 14 cases (7%) resulted in treatment interruptions and 6 in discontinuations due to dAEs (3%). Pathology were often nonspecific consistent with a hypersensitivity reaction: spongiotic/psoriasiform dermatitis with perivascular lymphocytic infiltrates. Patients undergoing weekly regimen were at a statistically and clinically significantly higher risk of dAE during the first 100 days of BV treatment (p = 0.001). Between the two most frequently administered dose regimens (1.8mg vs. 1.2mg, q3w), the higher dose carried 105% higher risk for dAE (HR: 2.047, p = 0.053). Those who had received a single cycle of BV had the lowest risk compared to all other regimen (1/42, p = 0.001). Topical and/or systemic steroids were most frequently prescribed (43%) with 12% of patients requiring systemic steroids. Other treatments varied ranging from antihistamines to moisturizers. **Conclusions:** Understanding of the detailed characteristics, management strategies, dose-dependent effects associated with BV is critical to provide clinical guidance for primary providers and minimize treatment interruptions or discontinuations. The results overall suggest that the risk for dAEs is dose-dependent with those undergoing frequent dosing regimens having a greater risk, although most dAEs remain mild or low-grade. A phase 1 study of TAK-164, an anti-guanylyl cyclase C (GCC) antibody-drug conjugate (ADC), in patients (pts) with advanced gastrointestinal (GI) cancers expressing GCC. *First Author: Richard D. Kim, Moffitt Cancer Center, Tampa, FL*

Background: TAK-164 is a second-generation ADC comprising a human IgG1 monoclonal antibody targeting GCC conjugated to a DNA-damaging alkylating agent by a peptide linker. TAK-164 demonstrated cytotoxic and antitumor activity in GCC-expressing cells and xenograft mouse models. This first-in-human study investigated the safety, pharmacokinetics (PK), and preliminary efficacy of TAK-164. **Methods:** Adult pts with GCC-positive, advanced/metastatic GI cancers received TAK-164 intravenously on day 1 of a 21-day cycle (Q3W). Dose escalation proceeded based on cycle 1 safety data via a Bayesian model of modified toxicity probability interval starting at 0.004 mg/kg. **Results:** Thirty-one pts were enrolled. Median age was 58 years (range 32–72), 58.1% of pts were female and 64.5% had colon carcinoma. The median number of prior lines of therapy was 4 (range 2–9). TAK-164 was given at 0.004 (n = 1), 0.008 (n = 1), 0.016 (n = 1), 0.032 (n = 5), 0.064 (n = 7), 0.12 (n = 7), 0.16 (n = 2), 0.19 (n = 3), 0.25 (n = 3) and 0.32 mg/kg (n = 1). No pts had dose-limiting toxicities (DLT) in cycle 1 up to 0.32 mg/kg. Three pts had adverse events (AEs) after cycle 1 considered to be DLTs: 1 pt receiving 0.19 mg/kg (grade 3 pyrexia and grade 5 hepatic failure) and 2 pts receiving 0.25 mg/kg (1 pt had grade 3 nausea, and grade 4 platelet count decrease and neutrophil count decrease; 1 pt had grade 4 hepatic failure and grade 4 platelet count decrease). Dosing was capped at 0.19 mg/kg due to hepatic toxicity and the recommended phase 2 dose (RP2D) was determined as 0.064 mg/kg based on safety and tolerability beyond cycle 1. Overall, pts received a median of 2 (range 1–8) treatment cycles. TAK-164-related treatment-emergent AEs (TEAEs) reported in 77.4% of pts included platelet count decrease (58.1%), fatigue (38.7%), and anemia (32.3%). TAK-164-related grade $\geq$3 TEAEs reported in 32.3% of pts included platelet count decrease (12.9%), alanine aminotransferase increase, aspartate aminotransferase increase, fatigue, and anemia (all 9.7%). Three pts discontinued due to TAK-164-related TEAEs. There was a dose-dependent increase in TAK-164 maximum plasma concentration and exposure over the range 0.016–0.32 mg/kg, with no meaningful accumulation in PK with repeat Q3W dosing. One pt receiving TAK-164 0.19 mg/kg showed γH2AX induction via immunohistochemistry in a post-treatment biopsy, demonstrating target engagement. One pt with low baseline GCC expression who received 5 cycles of TAK-164 0.008 mg/kg had an unconfirmed partial response at cycle 4; 11 of 25 (44.0%) evaluable pts had a best overall response of stable disease. **Conclusions:** TAK-164 appeared to have a manageable safety profile up to 0.064 mg/kg in pts with advanced GI cancers; hepatic toxicity was identified as a potential risk. The RP2D was determined as 0.064 mg/kg but was considered insufficient to derive significant clinical benefit. Clinical trial information: NCT03449030. Research Sponsor: Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

Phase I study of mesothelin-targeted immunotoxin LMB-100 in combination with tofacitinib in patients with advanced pancreatobiliary cancer. *First Author: Nebojsa Skorupan, National Cancer Insititute, Bethesda, MD*

Background: LMB-100 recombinant immunotoxin consists of a mesothelin-binding Fab for targeting a modified *Pseudomonas* exotoxin A payload to tumors. Previous clinical trials demonstrated that almost all patients formed anti-drug-antibodies (ADAs) to LMB-100 that made administration beyond cycle 2 ineffective. Tofacitinib is an oral JAK inhibitor that prevented formation of ADAs against a closely related immunotoxin in pre-clinical studies. The primary objective of the dose escalation cohort was assessment of safety and tolerability of LMB-100 given with tofacitinib to patients with mesothelin-expressing solid tumors. The primary objective of the expansion cohort was to determine whether co-administration of tofacitinib delays formation of neutralizing LMB-100 ADAs. **Methods:** Patients (n = 13) with pancreatic adenocarcinoma and other mesothelin-expressing solid tumors (n = 3; cholangiocarcinoma, appendix, cystadenocarcinoma) were treated for up to 3 cycles with LMB-100 as a 30-minute infusion on days 4, 6, and 8 at two dose levels (100 and 140 mcg/kg) and co-treated with oral tofacitinib for the first 10 days of the cycle (10 mg BID). **Results:** Dose level 1 of LMB-100 was started at 100 mcg/kg one dose level below the single agent MTD. Dose escalation to 140 mcg/kg (dose level 2) resulted in DLTs in 2 of the 3 patients treated: grade 3 cardiac toxicity and grade 4 hyponatremia, both attributed to capillary leak syndrome. Ultimately, 7 patients were treated at dose level 1 without DLTs and 100 mcg/kg was chosen as the LMB-100 dose for the expansion cohort. The last of 6 patients treated in the expansion cohort developed grade 4 pericardial effusion leading to early closure of the study for toxicity. No objective responses were seen. Of the 8 patients who received two cycles of treatment at MTD, 4 met prespecified criteria for ADA prevention, and 2 patients who went on to receive cycle 3 had detectable LMB-100 plasma drug levels after administration. **Conclusions:** LMB-100 was unable to be co-administered safely with tofacitinib. ADA formation was prevented in 2 patients through 3 cycles, a rare occurrence. Clinical trial information: NCT04034238. Research Sponsor: U.S. National Institutes of Health.

RNA sequencing effectively identifies gene fusions undetected by DNA sequencing in lung adenocarcinomas. *First Author: Ruiying Zhao, Department of Pathology, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China*

Background: Next-generation sequencing of DNA, which can provide valid information for clinical therapeutic decision-making, has been widely used in the management of lung cancer especially adenocarcinoma. However, due to its technical limitations for detecting certain alterations such as gene rearrangement, the DNA-based sequencing (DNA-seq) may miss the actionable alteration in some cases, who would have benefited from targeted therapy. The study aimed to evaluate the capability of RNA sequencing (RNA-seq) in identifying DNA-seq undetectable gene alterations in lung adenocarcinomas. **Methods:** A total of 219 lung adenocarcinomas, which had no driver alteration detected by DNA-seq (OncoScreen Plus, Burning Rock Biotech) and had a max AF $\geq$5%, underwent capture-based RNA-seq using a custom panel (OncoRNA, Burning Rock Biotech) spanning full transcripts of 115 genes commonly involved in cancer genomic rearrangements. Furthermore, an independent cohort of 100 DNA-seq driver–negative lung adenocarcinomas were also subjected to RNA-seq with the same panel. **Results:** In the discovery cohort, 166/219 samples (75.8%) generated qualified RNA-seq data for subsequent analyses. RNA-seq identified 44 previously undetected alterations (26.5%), including 40 gene fusions (24.1%), 1 *MET* exon14 skipping variant (*MET*ex14, 0.6%) and 3 other alternative splicing variants (1.8%). Among them, 14 (8.4%) were potential actionable alterations, consisting of *MET*ex14 and in-frame fusions containing functional domain of the driver gene (4 *ROS1* fusions, 3 *BRAF* fusions, 2 *NRG1* fusions, 2 *EGFR* fusions, 1 *ALK* fusion and 1 *MET* fusion). In the validation cohort, 69/100 samples (69.0%) generated qualified data. RNA-seq identified 22 DNA-seq undetected alterations (31.9%), with 7 of them being potential actionable fusions (10.1%). *ROS1* fusion remained as the most common actionable alteration (n = 3), followed by *ALK* fusion (n = 2), *EGFR* fusion (n = 1) and *MET* fusion (n = 1). Further analyses of the two datasets revealed that lacking sufficient coverage spanning the rearrangement breakpoint in the DNA-seq panel mainly accounted for the failure of DNA-seq on detecting these fusions. This can be improved by increasing the corresponding probe coverage in the DNA-seq panel. In addition, complex genomic rearrangement at DNA level and the presence of repetitive sequence in the intronic region spanning or adjacent to the breakpoint might lead to missed calling of canonical fusions by DNA-seq. **Conclusions:** Targeted RNA-seq can effectively identify genomic rearrangements that are undetectable by DNA-seq and provide lung adenocarcinoma patients with more opportunities for targeted therapy. Therefore, it should be recommended for all patients, in whom DNA-seq fails to detect driver alteration. Research Sponsor: None.

Sputum supernatant as a viable alternative for liquid biopsy in advanced non-small cell lung cancer. *First Author: Chengzhi Zhou, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China*

Background: Sputum has previously attracted attention as a potential medium for detecting genetic and epigenetic alterations in early-stage lung cancer. Recent progress in advanced non-small cell lung cancer (aNSCLC) has highlighted plasma as an option in scenarios where tissue specimens are unavailable. In this study, we investigated the feasibility of mutation profiling with sputum from aNSCLC patients. **Methods:** Matched tissue (TIS), whole blood, and either induced or spontaneous sputum were collected from 42 prospectively enrolled, previously untreated patients with stage IIIB-IV NSCLC. Eight and two milliliters of whole blood and sputum were respectively used for preparation of plasma (PLA) and sputum supernatant (SPU). Capture-based targeted sequencing of TIS, PLA and SPU samples was performed with a panel of 520 cancer-related genes. **Results:** The cohort had a median age of 59 (range 26-79) with a majority of men (31/42). Thirty-five patients were diagnosed with lung adenocarcinoma (LUAD) and the remaining seven with squamous cell carcinoma (LUSC). There were more non-smokers (26/42) than smokers. Most patients (34/42) had metastatic disease. First, we assessed the performance of three sample types in terms of key quality control indices. PLA and SPU showed maximum allelic fraction that were both significantly smaller than that of TIS. Subsequently compared was positive detection rate, TIS, PLA, and SPU achieved respective rates of 92.9%, 71.4%, and 59.5%, revealing comparable levels between PLA and SPU samples ($p = 0.36$). Rates of detection were highly similar between induced (54.6%) and spontaneous sputum (61.3%), but were higher in LUSC (85.7%) than in LUAD patients (54.3%) although this difference was not statistically significant ($p = 0.21$). Furthermore, detection rates rose in smokers (81.3% for PLA and SPU, 100% for TIS). Next, using TIS as the gold standard, we compared the sensitivity of detecting eight established driver alterations in NSCLC with the two liquid biopsies. SPU and TIS achieved respective levels of 50.0% and 70.0%, which, similar to detection rate, improved to 88.9% (8/9) and 77.8% (7/9) in the smokers subgroup. Importantly, detection of altered *KRAS* and *ALK* was more sensitive with SPU (6/6, 2/3, entire cohort) than with PLA (5/6, 1/3). For *EGFR* mutation, which occurred mainly in nonsmokers, the sensitivity was considerably lower in SPU (4/14, entire cohort) than in PLA (12/14). Detection of mutant *MET*, however, appeared difficult for both biopsies (0/4). In addition, there was a high level of correlation between estimates of tumor mutational burden based on PLA and on SPU (Pearson $r^2 = 0.58$). **Conclusions:** Our study demonstrated that for aNSCLC patients, sputum supernatant demonstrates comparable performance as plasma. Sputum is therefore a viable alternative for profiling for established driver alterations in aNSCLC, especially in smokers. Research Sponsor: None.

Novel imaging biomarkers predict progression-free survival in stage 3 NSCLC treated with chemoradiation and durvalumab. *First Author: Khalid Jazieh, Cleveland Clinic Foundation, Cleveland, OH*

Background: The current management of stage III non-small cell lung cancer (NSCLC) is chemoradiation followed by durvalumab consolidation. There are no robust biomarkers that predict benefit from this regimen. We evaluated the utility of novel imaging biomarkers (radiomics) to distinguish patients with stage III NSCLC who will benefit from treatment from those likely to progress despite therapy. **Methods:** Patients with stage III NSCLC treated at our center with chemoradiation and durvalumab from July 2017 - July 2019 were identified. We collected patient clinical outcomes, subtype of NSCLC, and PD-L1 expression as well as pre-treatment CT images. Images were split into training and test sets. Lung tumors were contoured on 3D-Slicer software and 1542 radiomic features capturing both intra- and peritumoral texture patterns were extracted. The primary endpoint of this study was progression-free survival (PFS), and the secondary objective was difference in PFS within high PD-L1 ($\geq$50%) and low PDL1 ($<$50%) groups. We used the least absolute shrinkage and selection operator (LASSO) Cox regression model to build the radiomic signature for PFS. A risk score was computed according to a linear combination of selected features and their corresponding coefficients. High- and low-risk groups were defined based on median radiomics risk score. Multivariable Cox regression analysis was performed to evaluate the effect of each factor on PFS. We performed Kaplan–Meier survival analysis and log-rank tests to assess prognostic ability of the features. **Results:** We identified 118 patients who fit our criteria with available CT images and randomly divided them into a training (n=59) and a test set (n=59). The radiomic risk score was calculated using a linear combination of the top six selected features with corresponding coefficients. In a multivariable analysis using clinicopathologic and radiomic signatures, the radiomics risk-score and PD-L1 expression were found to be significantly associated with PFS in training (risk-score: HR = 2.3, 95% CI: [1.46 – 3.63], P = 0.0003; PD-L1: HR = 0.31, 95% CI: [0.081 – 0.96], P = 0.038) and test sets (risk-score: HR= 2.56, 95% CI: [1.75 – 4], P = 8.7e-05; PD-L1: HR = 0.27, 95% CI: [0.048 – 0.58], P = 0.005). Kaplan-Meier analyses showed a significantly shorter PFS in the high-risk radiomics group versus the low-risk group ($P < 0.0001$). The radiomics risk scores were also predictive of significant differences in PFS within both the low (p=0.0005) and high (p=0.0007) PD-L1 groups. **Conclusions:** Radiomic biomarkers from pre-treatment CT images in stage III NSCLC patients were predictive of PFS to chemoradiation followed by durvalumab and could predict outcomes regardless of PD-L1 level. Pre-treatment radiomics may allow early prediction of benefit and expedite more aggressive treatment for high-risk patients. Additional validation of these imaging biomarkers is warranted. Differences of US-FNA BSRTC class, postoperative pathology, and mutation landscape of thyroid nodules between China and other countries. *First Author: Yuntao Song, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Head and Neck Surgery, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Ultrasound and ultrasound-guided fine needle aspiration (US-FNA) are the first choice for judging benign and malignant thyroid nodules. This study will report on the differences of US-FNA BSRTC class, postoperative pathology and mutation landscape of thyroid nodules between China and other countries. **Methods:** We conducted a prospective study containing 383 FNA samples of thyroid nodules. For most of these FNA samples, genomic DNA and RNA were extracted and sequenced with FSZ-Thyroid NGS Panel V1, and postoperative pathology were followed up. Moreover, we also compared results of this study with those of West China Hospital in China, Yamashita Thyroid Hospital in Japan, and Cleveland Clinic in the United States. **Results:** Among the 383 FNA samples, the proportions of BSRTC class I to VI were 10.7%, 6.3%, 18.8%, 3.7%, 12.3%, and 48.3% respectively. Compared with study in other countries, the proportion of class II was significantly lower than that in Japan and the United States. Meanwhile, the proportion of class V and VI were significantly higher than the above two countries. Subsequently, 232 thyroid nodules were surgically removed. Postoperative pathology showed that the proportion of malignant tumors (85.3%) was also significantly higher than reported in Japan and the United States. But compared with other studies in China, there was no significant difference. Most of the malignant tumors were papillary thyroid cancer (PTC, 96%), accompanied with 2 follicular thyroid cancer (FTC), 3 medullary cancer (MTC) and 3 anaplastic thyroid cancer (ATC). Compared with study in the United States, the proportion of PTC and FTC were elevated (96% vs. 85.3%) and reduced (1% vs. 9.3%) respectively. At last, we also analysis the mutation landscape of 180 malignant tumors. Compared with TCGA study, the frequency of BRAF V600E in PTC in our study was significantly higher than that of TCGA (73.3% vs. 58%), and the frequency of RAS mutation was significantly lower (1.2% vs. 12.6%). And compared with an institutional experience of ThyroSeq v3 for Bethesda III and IV at the University of Pittsburgh Medical Center, the frequency of BRAF V600E and RAS mutation in Bethesda III-IV malignant tumors was also significantly higher (45.8% vs. 1.4%) and lower (8.3% vs. 47.1%). **Conclusions:** There were significant differences in BSRTC class and postoperative pathology between China and other countries, such as Japan and the United States. The possible reasons included that the indications for FNA in China were different. For example, most of patients who underwent FNA in this study had suspicious clinical/ultrasound features. So the proportion of BSRTC class V and VI as well as the malignant rate were elevated. On the other hand, more BRAF V600E and less RAS mutations were detected in malignant tumors in this study which might result from racial differentiation and discrepancy in proportion of PTC and FTC. Research Sponsor: genetronhealth.

Circulating genetically abnormal cells combined with artificial intelligence for accurate and non-invasive early detection on NSCLC. *First Author: Han Yang, Department of Respiratory and Critical Care Medicine, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China*

Background: Non-small-cell carcinoma (NCSLC) is the most common type of early lung cancer. Early detection of NSCLC is still a diagnostic challenge. Current clinical management of patients with pulmonary nodule is inefficient and may lead to misclassification, thus increasing healthcare expenses. Further, a few previous studies showed liquid biopsy and artificial intelligence (AI) platform on computed tomography (CT) imaging contributes to early NSCLC detection. Still, there is something lacking in a precise and authorized lung nodule classifier to minimize discomfort of patients. This study aims to evaluate the possibility and effectiveness of combining circulating genetically abnormal cells (CACs) with an AI platform on CT imaging to improve the diagnostic route for NSCLC. **Methods:** A prospective cohort of 101 in-patients was enrolled from Sep. 1, 2020 to Jan. 15, 2021, with non-calcified pulmonary nodules, ranging from 0.5 to 3 cm in diameter, indicated by CT. The participants' pulmonary nodules will be assessed by two evaluation tools: CAC detection on full blood and AI platform on CT imaging. The diagnostic performances of the two tools were evaluated in a blinded validation study respectively and combined in an open-label retrospective analysis. **Results:** 68 of enrolled patients were confirmed as NSCLC by pathology. The diagnostic performance of CACs for NSCLC detection was 80.9% for sensitivity and 87.3% for positive predictive value (PPV) while overall accuracy reaches 79.2%. AI platform showed a slight disadvantage as 78.6% for PPV and 73.5% for accuracy. 9 false-negative patients on CAC results could be reversed with a combination of AI platform on CT imaging, while sensitivity rises to 94.1%. However, of 33 benign nodules patients, 8 wrong diagnoses by CAC detection could decrease to 2 when combined with the results from the AI platform, which may avoid unnecessary biopsies. **Conclusions:** Coupling CAC with an AI platform on CT imaging could be a useful strategy to improve the diagnostic route for NSCLC and avoid unnecessary biopsies. Research Sponsor: None.

	Sensitivity (%)	95% CI (%)	PPV (%)	95% CI (%)	+LR (%)	95% CI (%)
CAC	80.9	69.5–89.4	87.3	78.8–92.7	3.34	1.8–6.2
AI-CT	78.6	63.1–89.7	78.6	67.9–86.4	2.25	1.3–3.9
Combined	94.1	85.6–98.4	96.8	89.3–99.2	15.5	4.1–59.6

Prediction of adenocarcinoma among other subtypes of lung cancer from CT using deep learning. *First Author: Noah Waterfield Price, Optellum, Oxford, United Kingdom*

Background: Determination of histological subtype is a crucial step in the management of patients with lung cancer as it informs prognosis and management. The identification of adenocarcinoma (AC) is particularly important with new targeted treatments becoming available. Although the gold standard for diagnosing histological subtype is pathological analysis of tissue samples, interventions can present a risk of complication. Imaging-based, computational approaches to distinguishing malignant from benign lesions have shown promising results. A similar approach may also be applied to determining histological subtype, which could provide an early, non-invasive alternative or complimentary method to biopsy. Here, we investigate an imaging and machine learning method to predict the subtype of a malignant lung lesion. **Methods:** A dataset of 1493 primary lung cancer patients was collected, of which 943 were diagnosed with AC. The histological subtypes of the non-AC patients were, squamous-cell carcinoma (158), large-cell carcinoma (69), small-cell carcinoma (33), other subtypes (27), or unreported non-AC subtype (253). This consists of retrospectively collected CT images and demographic data from both screening and clinical settings, across 41 academic and community centres from the USA (35 centres), and Europe (6 centres). All patients included were aged $\geq$ 18 with no history of cancer in the last 5 years. Each CT was manually curated. Given a CT-image of a lung nodule, a Convolutional Neural Network (CNN) was trained to classify nodules as AC or non-AC, using 8-fold cross-validation. A logistic-regression model based on clinical parameters was also trained using the same data and cross-validation. Classification performance was evaluated using the Area-Under-the-ROC-Curve (AUC), sensitivity, and specificity. Confidence intervals and *P* values were calculated by nonparametric bootstrapping. **Results:** The median age of AC patients was 66 yr (non-AC 67 yr) and 62.3% of them were male (non-AC 57.8%). The median pack years for AC patients was 38.4 p.yr (non-AC 50.0 p.yr). For AC tumours, the median diameter was 14.0 mm (non-AC 14.0 mm) and the mean diameter was 15.0 mm (non-AC 16.4 mm). The AC-classification results are tabulated below. The CNN classification performance is significantly better than the logistic-regression baseline across all three measures of performance $P < .001$. AC classification results. All values are given in % with 95% confidence interval bounds in parentheses. **Conclusions:** We find that the CNN significantly outperforms a logistic model in identifying AC from other histological subtypes. With further development, this algorithm could prove a useful tool to aid management of lung cancer patients. Research Sponsor: None.

	AUC	Sensitivity	Specificity
CNN	74.3 (71.5, 76.3)	66.7 (64.5, 68.8)	67.1 (64.1, 69.8)
Logistic regression with clinical data	59.8 (57.5, 62.0)	52.6 (50.1, 54.8)	62.7 (59.7, 65.9)

Modeling cell-free DNA fragment size densities for non-invasive detection of cancer. *First Author: Jacob Carey, Delfi Diagnostics, Baltimore, MD*

Background: Circulating cell-free DNA (cfDNA) is largely nucleosomal in origin with typical fragment lengths of 167 base-pairs reflecting the length of DNA wrapped around-the histone and H1 linker. Given the nucleosomal origin of cfDNA, we have previously used low coverage whole genome sequencing to evaluate DNA fragmentation profiles to sensitively and specifically detect tumor-derived DNA with altered fragment lengths or coverage. **Methods:** Here we evaluate the use of Bayesian finite mixtures to model the fragment length distribution and demonstrate how the parameters from these models can be useful to distinguish between individuals with and without cancer. We examined the number of cfDNA fragments by size ranging from 100-220bp and approximated the mixture component location, scale, and weight using Markov Chain Monte Carlo. The performance of the method was determined using a ten-fold, ten repeat cross-validation of Gradient Boosted Machine model using 1) our previously described genome-wide fragmentation profile approach, 2) the parameters from the mixture model and 3) a combination of approaches 1) and 2) as features. **Results:** In this study of 215 cancer patients and 208 cancer-free individuals, we observed cross-validated AUCs of 1) 0.94, 2) 0.95, and 3) 0.97 among the three approaches. **Conclusions:** Our findings indicate that parsimonious mixture models may improve detection of cancer in conjunction with fragmentation profile analyses across the genome. Research Sponsor: Nicholas Dracopoli.

Advanced imaging to assess longitudinal vascular changes in brain metastases treated with checkpoint inhibition. *First Author: Albert Eusik Kim, Massachusetts General Hospital, Boston, MA*

Background: Immune checkpoint inhibitors (ICI) have recently been shown to be effective for brain metastases (BM) in melanoma and lung cancer. Several studies demonstrate that 20-50% of BM patients respond to ICI. The reasons behind this wide variability in treatment response is not clear. Therefore, using physiologic imaging, we seek to identify the longitudinal biological changes exerted on BM as a result of ICI administration. **Methods:** Given the importance of aberrant tumor vasculature in cancer proliferation, we have focused on assessing changes in vascular physiology. We analyzed standard post-contrast and dynamic susceptibility contrast (DSC) MRI to identify characteristic vascular signatures as part of an ongoing Phase 2 study of pembrolizumab for patients with untreated or progressive, previously treated BM from any histology. Tumor volume measurements were calculated by summating all enhancing voxels. As per modified RECIST and RANO criteria for immunotherapy, volumetric increase of $>$ 40% was defined as progressive disease (PD), a decrease of $>$ 60% as partial response (PR), and stable disease (SD) as between -60% and +40%. **Results:** 35 patients, out of the total cohort of 60, have undergone DSC-MRI analysis. Histologies include 15 with breast cancer, 6 with non-small cell lung cancer, 4 with melanoma, and 10 with other cancers. At baseline, the total number of BM was 1-50+ per patient. Based on summing the entire enhancing intracranial disease burden, best volumetric responses for the 35 evaluable patients include 4 PR, 12 SD, and 19 PD. Thus far, we found that ICI-resistant BM had a 50% increase in cerebral blood flow (CBF), 105% increase in cerebral blood volume (CBV), a 15% increase in mean transit time (MTT), and an 80% increase in vessel caliber at 6 weeks post-treatment. On the other hand, ICI-responsive BM had no change in CBF, a 33% increase in CBV, a 10% decrease in MTT, and no change in vessel caliber. Ongoing analysis to uncover additional vascular changes (e.g. tumor oxygenation, vessel size index) within BM to ICI are pending. **Conclusions:** Our data provides evidence that effective ICI for BM is associated with unique intra-tumoral vascular physiology. With final analysis, we will uncover other facets of vascular physiology that correlate with ICI response, and may reveal mechanisms of response/resistance within tumors to ICI. Genetic profiling across multiple cancer types using molecular prescreening comprehensive gene panels offered by clinical trials (CT). *First Author: Iván Victoria, Hospital Clínic de Barcelona, Barcelona, Spain*

Background: Genetic profiling (GP) is essential not only for understanding tumor biology but also helps to identify potential genes for targeted therapies. At the same time, selected CT provide an individual genomic profile panel during the pre-screening phase. Here, we demonstrate our experience using these panels. **Methods:** We selected 14 CT from our Early Drug Development Clinical Trial Unit at Hospital Clinic of Barcelona that included analysis of gene panels in tumor (Foundation One, ArcherDX, Therascreen and Sophia Genetics) or plasma (Resolution Bioscience ctDx). These panels analyzed mutations, fusions, amplifications, microsatellite instability (MSI) and tumor mutational burden (TMB), among others. We collected information about types of cancers, molecular alterations and therapies chosen according to the results of GP. The platform OncoKB (Chakravarty JCO PO, 2017) was used to define genes with potential target therapies and levels of evidence (LE) for those targets (from LE 1 –FDA-recognized biomarker predictive of response to an FDA-approved drug- to LE 4 –Compelling biological evidence supports the biomarker as being predictive of response to a drug). Descriptive statistics were used. **Results:** From March 2017 to January 2021 we analyzed samples from 410 patients (pts) with CNS (19.3%), urothelial (18.3%), prostate (17.6%), breast (15.4%), ovarian (9.3%), esophageal and gastric (5.4%), colorectal (4.4%), pancreas (2.7%), endometrial (2.4%), cholangiocarcinoma (1.2%), cervix (1%), HNSCC (1%), renal (1%), lung (0.5%), liver (0.2%) fallopian tube (0.2%) and paraganglioma (0.2%). 352 pts (85.8%) had at least 1 genetic alteration. The most frequently altered genes were TP53 (153 pts, 46.2%), INSR (19 pts, 22.8%), TERT (76 pts, 22%), CDKN2A (65 pts, 19.9%), FAM175A (11 pts, 19.3%), CDKN2B (54 pts, 18.1%), MLL2 (53 pts, 17.7%), PTEN (52 pts, 16%), MTAP (45 pts, 15.7%), PIK3CA (52 pts, 15%) and ATM (55 pts, 14.4%). TMB ranged from 0 to 76.9 mut/Mb (median 2.5 mut/Mb). MSI was found in 3 pts (1.5%). 196 pts (47.1%) had an OncoKB LE 1 alteration, 105 pts (25.6%) if we restrict the options to their specific cancer type. 16 pts (3.9%) received a matched therapy: 6 pts received an off-label drug, 6 pts were included in the same CT for which the pre-screening was performed and 4 pts were included in a different CT. Additionally, 13 pts (3.2%) received a matched therapy either with OncoKB LE 4 (5 pts received an off-label drug and 3 were included in a different CT) or not included in OncoKB (8 pts included in the same CT of the pre-screening). As a whole, 29 pts (7.1%) received a matched drug according to their genomic results. **Conclusions:** Comprehensive gene panel testing offered through CT allows the identification of targets to enroll pts, although the recruitment was 1.5%. However, 7.1% of the pts received a matched therapy due to the molecular information of these gene panels. Research Sponsor: None.

Machine learning models to quantify HER2 for real-time tissue image analysis in prospective clinical trials. *First Author: Benjamin Glass, PathAI, Inc, Boston, MA*

Background: Patient eligibility for HER2-targeting treatments is commonly informed by testing tumor HER2 expression using immunohistochemistry. As HER2 expression is visually assessed by pathologists, inter- and intra-rater variability might affect treatment decisions. Here, we report the development of an automated machine learning (ML)-based algorithm to quantify HER2 cell membrane expression across a diversity of breast cancer phenotypes as a clinical tool for monitoring HER2 testing quality. **Methods:** A total of 689 breast cancer tissue samples were either procured (Avaden Biosciences) or were anonymized samples from the AstraZeneca biobank comprising tissues from primary and metastatic tumors, core needle biopsies and surgical resections, lobular and ductal carcinomas, across tumor grades and HER2 expression levels. Samples were stained for HER2 detection (Ventana HER2 (4B5) Assay) and digitized (Leica Biosystems) across 5 laboratories in the US. Whole-slide images (WSIs) were stratified into training (n = 407), validation (n = 110), and test sets (n = 172). Multiple convolutional neural network based ML models (PathAI, Boston, MA) were trained using 190,000 manual annotations provided by 30 board-certified pathologists to identify artifacts, invasive tumor, identify individual cancer cells and measure tumor cell membrane HER2 expression as partial or complete, and negative, weak-or-moderate, or intense. Cell-level scores were validated against a consensus of manual cell counts from 5 independent pathologists in 320 representative regions of test set WSIs. HER2 scores were generated by automatically applying rules derived from 2018 ASCO/CAP guidelines and then compared in the test set with consensus scores from 3 independent pathologists. **Results:** Cell counts provided by the ML model were strongly consistent with cell counts obtained by pathologist consensus in all cell-types except for faintly positive HER2 cells where ML-based quantification identified more cells on average. Automatically generated ML-ASCO/CAP HER2 scores using WSI showed substantial consistency across IHC categories with the consensus of pathologists (ICC 0.88, 95%CI 0.82-0.92) in the test set and improved further when ML models were trained to agree with pathologists by adjusting cut offs (ICC 0.91, 95%CI 0.89-0.94). The ML-based model was deployed through the PathAI cloud platform to calculate HER2 testing quality control metrics in real-time in multicentric clinical trials. **Conclusions:** Automated image analysis of HER2-stained breast cancer tissues using ML-based models is consistent with pathologist consensus across breast cancer tissue types. The results support evidence that ML-based algorithms can help pathologists assess HER2 testing reproducibility in clinical trials. Research Sponsor: AstraZeneca R&D.

Comprehensive molecular profiling of advanced cancers in a real-world setting using an ultrasensitive amplicon-based next-generation sequencing (NGS) liquid biopsy assay. *First Author: Jonathan Poh, Lucence Diagnostics, Singapore, Singapore*

Background: Molecular profiling of circulating tumor DNA (ctDNA) by NGS has demonstrated the value of liquid biopsy in informing treatment decisions and monitoring disease progression in cancer patients. Here we report results from the real-world clinical application of an ultrasensitive amplicon-based NGS liquid biopsy assay for advanced cancers. **Methods:** Plasma cell-free DNA (cfDNA) from 1,338 consecutive samples (51.3% lung, 15.6% breast, 8.4% colorectal, 26.8% from 18 other cancer types; 86.3% of cancer samples were metastatic) underwent real-world testing in a Singapore-based, CAP-accredited, CLIA-certified laboratory from Jan 2018 – Nov 2020. Genomic alterations were analyzed using an amplicon-based NGS assay that detects alterations in 80 cancer-related genes, microsatellite instability (MSI) and cancer-causing viruses, with previously validated cfDNA detection limits of 0.1% variant allele frequency (VAF) for SNPs and indels, 5% tumor fraction, and 2 IU/mL plasma, respectively. **Results:** ctDNA was successfully detected in 70.0% of cancer samples (76.3% from metastatic and 24.7% from localized tumors) for a total of 977 unique variants. Across ctDNA-positive samples the median VAF was 1.4%, and 8.5% of all reported variants had VAFs between 0.01 – 0.09%. The most frequently altered genes were *TP53* (48.8%), *EGFR* (36.9%), *KRAS* (17.4%), *PIK3CA* (15.3%), and *APC* (9.5%). In ctDNA-positive lung cancer, 74.6% of samples (66.5% *EGFR*+) harbored ≥1 actionable target, with 29.9% of patients treated with a first- or second-generation EGFR tyrosine kinase inhibitor harboring an EGFR T790M resistance mutation. Among breast cancers, *ESR1* or *PIK3CA* alterations predicting drug resistance/response were detected in 44.2% of HR+ cases. In colorectal cancer, alterations implicated in anti-EGFR resistance (*NRAS*, *KRAS*, *BRAF*, *ERBB2*) were found in 50.0% of samples. Profiling of cfDNA also enabled cancer monitoring, even among cancers with low genetic biomarker prevalence. 50% of nasopharyngeal cancer samples were Epstein-Barr virus-positive while 35.7% of liver cancer samples were Hepatitis B virus-positive, enabling an additional yield of 14.3% and 7.1% respectively, over ctDNA detection. cfDNA profiling of cancers of unknown primary origins informed potential tumor origins via the detection of tumor type-specific alterations such as mutations in *AR*, *ESR1*, *GNAS*,*EGFR* genes, viral biomarkers, and MSI. **Conclusions:** The use of a comprehensive pan-cancer liquid biopsy panel with rational inclusion of actionable and driver genes resulted in detection of ctDNA in the vast majority of clinical cases processed routinely. These findings support the utility of ultrasensitive amplicon-based NGS liquid biopsy assays in probing cancer drug sensitivity/resistance, tumor burden monitoring, and molecular characterization of tumors. Feasibility and clinical utility of cancer whole genome and transcriptome sequencing for pediatric and young adult solid tumors. *First Author: Neerav Shukla, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Next generation sequencing (NGS) assays have accelerated the identification of mutations and potential matched targeted therapies for patients with cancer. However, a significant proportion of patients do not derive clinical benefit from targeted panel sequencing approaches. Cancer whole genome and transcriptome sequencing (cWGTS) offers the opportunity to fully characterize tumors, but are challenged by significant cost and computational resource requirements, concerns of assay sensitivity, and the need to deliver curated results within clinically relevant time frames. We performed a prospective study to evaluate the feasibility and utility of cWGTS in pediatric and young adults with solid tumors. **Methods:** We developed an automated analytical workflow (Isabl) for the QC and processing of cWGTS data to include ensembl variant calling for germline and somatic substitutions, indels, and structural variants; fusion genes; gene expression; and mutation signatures. Treatment biomarkers were annotated using OncoKB with generation of a clinical prototype report. We tested the feasibility of cWGTS implementation, evaluated its analytical validity compared to standard diagnostic assays, and characterized the clinical utility of incremental findings in a prospective study of children and young adults treated at Memorial Sloan Kettering Cancer Center. **Results:** A total of 114 patients were enrolled. Standard NGS assays (MSK-IMPACT, MSK-Fusion) identified clinically relevant biomarkers in 22% of cases. The cWGTS process was completed, from sample acquisition to summary report, in less than 12 days. Comparison against clinically reported NGS results demonstrated high precision and recall for reported mutations (98.8%) with high concordance across variant allele representations ($r^2 > 0.73$). cWGTS identified additional oncogenic mutations not captured by targeted sequencing in 49% of patients. Furthermore, incremental findings, beyond those identified by NGS assays, of direct clinical relevance (diagnostic, prognostic, therapy guiding) were identified in 26% of patients. Importantly, < 5% of the incremental findings would have been captured by whole exome or transcriptome sequencing alone. Of possible therapeutic relevance, cWGTS analyses revealed a significantly higher tumor mutation burden than previously reported (range: 0 - 11.23). **Conclusions:** We demonstrate feasibility, analytical validity and clinical utility of cWGTS approaches in pediatric and young adult cancer patients, with nearly half of all patients having incremental findings that were not captured by standard targeted NGS approaches. Improving differential diagnosis of pulmonary large cell neuroendocrine carcinoma (LCNEC) and small cell lung cancer via a transcriptomic, biological pathway-based ridge regression model. *First Author: Jun Hong, Department of Pathology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China*

Background: In clinics, it can be challenging to make correct diagnosis of LCNEC, Small cell lung cancer (SCLC), if tissues, like needle biopsies, are insufficient or morphology was poorly preserved. In this study, a reliable classifier was constructed based on transcriptome data and machine learning (Ridge regression) to improve the diagnostic accuracy for LCNEC and SCLC. **Methods:** RNA-Seq data obtained from 3 public cohorts were collected as training set, including 60 NSCLC cases from The Cancer Genome Atlas (TCGA), 66 LCNEC cases from Julie George et al., Nature Communications 2018, and 33 SCLC cases from Julie George et al., Nature 2015. Another 80 NSCLC, 30 LCNEC and 15 SCLC cases published by Martin Peifer et al., Nature Genetics 2012 were used as validation set. Additionally, RNA-Seq data of 27 borderline samples which were hard to make diagnosis based on histology and Immunohistochemistry were used to test the accuracy of the prediction model. **Results:** 13,959 genes mapped to 186 Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways were included. Gene Set Variation Analysis (GSVA) algorithm was used to enrich and score each KEGG pathway. A prediction model based on GSVA score of each pathway was constructed via Ridge regression. This GSVA Score Model achieved ROC-AUC 0.949 and concordant rate of 0.75 for the entire prediction efficiency. Of the 27 borderline samples which were hard to make confirmed diagnosis, 17/27 (63.0%) were predicted as LCNEC, 7/27 were predicted as SCLC, and the remainder were predicted as NSCLC. While only 8 (29.6%) cases with LCNEC were diagnosed by pathologists, which was significantly lower than the results predicted by the model. Furthermore, cases with model predicted LCNEC had a significant longer disease-free survival than that with model predicted SCLC (median DFS,59 months for LCNEC vs 5 months for SCLC, $p = 0.0043$), which was in parallel with currently known prognostic difference of these two types of neuroendocrine tumors. **Conclusions:** This GSVA algorithm-based prediction model was able to make accurate diagnosis of LCNEC and SCLC. And it may provide valuable information for clinics to choose optimal therapeutic approach for patients with pulmonary neuroendocrine tumors. Research Sponsor: Shanghai Municipal Commission of Health and Family Planning (No. 20184Y0222), "Dream Mentor" training program of Shanghai Pulmonary Hospital (No. fkxr1903).

Validation of FAPi PET biodistribution by immunohistochemistry in patients with solid cancers: A prospective exploratory study. *First Author: Christine Mona, UCLA Ahmanson Translational Theranostics Division, Los Angeles, CA*

Background: Fibroblast activation protein (FAP)-expressing cancer-associated fibroblasts (CAF), a major component of tumor stroma, confer treatment resistance, promote local progression, metastasis and immunosuppression. Because FAP is selectively expressed in the tumor stroma of many cancers, radiolabeled small molecule ligands targeting FAP are being explored for their use as pan-cancer theranostic agents. The objective was to establish the spectrum of FAP expression across various cancers by immunohistochemistry (IHC) and to explore whether 68Ga-FAPi-46 PET image biodistribution faithfully reflects tumor FAP expression from resected tumor and non-tumor specimens. **Methods:** This study was a prospective, exploratory, imaging trial in cancer patients. Referred volunteer patients scheduled to undergo surgical resection of the primary tumor and/or metastases were eligible. Patients underwent one whole body 68Ga-FAPi-46 PET/CT scan. Subsequently, patients underwent surgical resection of the primary tumor and/or metastasis. The outcome measure was the correlation of 68Ga-FAPi-46 PET maximum standardized uptake value (SUVmax) with FAP IHC score in patient-matched cancer and non-cancer tissue. **Results:** The frequency of FAP expression across 14 cancers on tissue microarrays ranged from 25 to 100% (mean 76.6±25.3%). For imaging and IHC correlation, fifteen patients with the following cancer types were prospectively included: colorectal (n = 4), head and neck (n = 3), pancreas (n = 2), breast (n = 2),stomach (n = 1), esophagus (n = 2) and uterus (n = 1). All 15 patients underwent surgery following their 68Ga-FAPi-46 PET scan within a mean time interval of 16.1±14.4 days (range 1 – 50 days). For two patients the tumor was deemed unresectable. 68Ga-FAPi-46 SUVmax and IHC scores were higher in cancer tissue than in normal tissue: mean 68Ga-FAPi-46 SUVmax 7.4±4.6 (range 1.5-15.9) vs 1.6±1.2 (range 0.4-5.1), ($p < 0.001$) and mean FAP IHC score 2.38±0.65 vs 0.54±0.66 ($p < 0.001$), respectively. The FAP IHC scores strongly correlated with 68Ga-FAPi-46 SUVmax ($p = 0.001$, repeated measures correlation $r = 0.85$ (95% CI 0.53-0.95), $p < 0.001$). **Conclusions:** 68Ga-FAPi-46 PET biodistribution across multiple cancers strongly correlates with FAP tissue expression as measured by IHC. This translational validation paves the way for large scale prospective trials on the use of 68Ga-FAPi-46 PET/CT as a biomarker and stratification tool for FAP-targeted therapies. Clinical trial information: NCT04147494. Safety profile and disease stabilization in late stage, heavily pretreated, solid tumor patients in a first-in-human (FIH) study of ATX-101, a drug targeting proliferating cell nuclear antigen (PCNA). *First Author: Charlotte Rose Lemech, Scientia Clinical Research, Randwick, Australia*

Background: PCNA is a conserved scaffold protein orchestrating DNA replication, repair or bypass pathways as well as cellular signaling and apoptosis. More than 500 protein-PCNA interactions have been identified which are mediated via two binding motifs, the PIP-box and APIM. Cellular stress, to which cancer cells and cells of tumor microenvironment are exposed, increases the affinity of the APIM motif. APIM-containing proteins bind to PCNA and mediate processes of escape mechanisms and survival of cancer cells. ATX-101 is a cell penetrating peptide containing APIM. It inhibits protein binding via APIM, resulting in cancer cell death and altered cellular signaling. Anticancer effects of ATX-101 have been demonstrated *in vitro* and *in vivo*. **Methods:** A FIH study using a 3+3 dose escalation design was conducted. Patients with late-stage solid tumors received weekly infusions of 20, 30, 45 and 60 mg/m^2 over 6 weeks. Primary objective was safety, secondary objectives were PK and efficacy. Patients with stable disease (SD) after 6 weeks could continue treatment in a long-term follow-up (LTFU) study. **Results:** As of January 2021, 22 patients have been treated. All patients received in average 3.8 [1-9] prior treatment lines, all but one had progressive disease at study entry and 80% were refractory to the last therapy. No dose limiting toxicity or death and no treatment related Grade 3/4 or serious adverse events were reported. The maximum tolerated dose was not reached. Mild to moderate infusion related reactions (IRR) were observed in 73% of patients. They were not dose dependent and resolved completely after treatment interruption and/or symptomatic treatment. IRRs occurred despite premedication and could cause infusion interruptions with extended infusion duration. Experiments in dogs indicate that transiently increased histamine levels may cause IRRs. However, elevated histamine and tryptase levels could not be measured in patients so far. ATX-101 exposure was dose-dependent. Cmax was reached either at the middle or at the end of infusion. ATX-101 disappeared quickly from plasma and was not detectable 5 - 60 minutes post infusion. 13 patients finished the FIH study, 10 had SD after 6 weeks. 9 of 10 patients moved into the LTFU study. The treatment duration in the LTFU study varied from 2.1 to 15.6 months (median 4.2 months). **Conclusions:** ATX-101 is well tolerated at all dose levels with IRRs being the most frequent AEs. Drug exposure is dose dependent with rapid plasma clearance, which confirms *in vivo* data demonstrating the quick uptake by cells of all organs. The observed duration of SD may be attributed to ATX-101 activity. Proof of concept combination studies are being initiated. Clinical trial information: 375262. Research Sponsor: Therapim PTY LTD.

3068 **Poster Session**

Association of low RKIP expression with poor prognosis in non-small cell lung cancer. *First Author: Lingbin Meng, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Raf1 kinase inhibitor protein (RKIP) is able to bind Raf1 to inhibit Ras-Raf-MEK-ERK signaling, a major oncogenic pathway. It has been reported that reduced RKIP expression associates with poor prognosis in many cancers, including gastric adenocarcinoma, gliomas and bladder cancer. However, there are only several studies on its role in non-small cell lung cancer (NSCLC) and the conclusion is still controversial. Hence, we performed this study to assess the prognostic significance of RKIP in our NSCLC population. **Methods:** Between June 2017 and June 2020, 156 NSCLC patients treated at our hospital were included for the present study. None of the patients had received chemotherapy, radiotherapy or surgery before. Their tumor tissues and surrounding normal lung tissues were collected for immunostain and western blot analysis of RKIP expression and ERK signaling. We collected information about gender, age, histological differentiation, tumor size, TNM stage, and lymph node status. Survival curves were analyzed using the Kaplan-Meier method. Cox proportional hazards model was used to determine the prognostic value of various variables in a univariate and multivariate setting. **Results:** Immunostain and western blot results showed a lower RKIP expression and a higher p-ERK level in cancer tissues compared with the surrounding normal tissues. A reduced RKIP expression with high level of p-ERK was also observed in TNM stages III and IV as compared with I and II. Pearson's chi-squared test confirmed low RKIP expression associated with poorer TNM stage ($p< 0.001$) and N-stage ($p< 0.05$). No significant correlation was observed between RKIP expression level and gender, age, histological type or tumor size. Kaplan-Meier survival analysis revealed that patients with low RKIP expression had significantly worse overall survival than patients with high RKIP expression ($p= 0.019$, log-rank). This conclusion was consistent in the stage I&II patients ($p= 0.011$, log-rank) but not in the stage III&IV patients ($p= 0.711$, log-rank). Univariate Cox proportional hazards regression analysis indicated Tumor size, TNM stage and RKIP expression significantly affected overall survival of the NSCLC patients. Multivariate Cox proportional hazards regression analysis confirmed RKIP expression remained a significant predictor of survival after correcting for the effects of Tumor size and TNM stage (hazard ratio = 1.730, 95% confidence interval = 1.017 – 2.942, $p = 0.043$). **Conclusions:** In this study, low RKIP expression was a poor prognostic indicator in NSCLC as it significantly correlated with poorer TNM stage, N-status, and overall survival. Our findings suggest that by inhibiting Ras-Raf-MEK-ERK pathway RKIP may play an anti-tumor role in NSCLC. Research Sponsor: Natural Science Foundation of Anhui Province.

Mutational analysis of rare insertions and deletions in exon 18 and 19 of HER2 in Chinese patients with different cancer types. *First Author: Jianwen Qin, Tianjin Chest Hospital, Tianjin, China*

Background: *HER2* belongs to the same family with *EGFR* and is known as an important cancer driver gene. Kinase domain insertions and deletions (KD indels) are frequent driver mutations in both *EGFR* and *HER2*. The most common *HER2* KD indels are the exon 20 insertions while others are rarely reported. Our study aimed to investigate the role of less common *HER2* KD indels in solid tumors. **Methods:** This study was performed in 63,267 Chinese patients including 53,591 patients with lung cancer, 5,888 patients with colorectal cancer, 3,774 patients with breast cancer and 14 patients with renal pelvis cancer. Tissue or plasma samples from the patients were subjected to capture-based targeted sequencing covering *HER2* and other cancer related genes. The sequencing data of each patient were retrospectively collected and analyzed. The *HER2* exon 18/19 indels identified in our study were compared with data from COSMIC and MSKCC. In vitro analysis in Ba/F3 cell lines was performed to assess drug response of different *HER2* exon 18/19 indels. **Results:** We identified recurrent *HER2* KD indels in exon 18 and 19, with a frequency of 0.04% (25/63,267). The data from COSMIC and MSKCC reported the prevalence of *HER2* exon 18/19 indels ranging from 0.04% to 0.23% among breast, cervical, and pancreatic cancers. In our study, *HER2* exon 18/19 indels were identified in 20 patients with lung cancer (0.037%), two with colorectal cancer (0.034%), two with breast cancer (0.053%) and one with renal pelvis cancer (7.143%). Only two patients (8%) harbored concurrent actionable driver mutations including *EGFR* mutation and *MET* amplification. Meanwhile, high level of normalized allelic frequency of *HER2* exon 18/19 indels was presented in most patients (22/25, 88%). In lung cancer, the presence of *EGFR* driver mutation was less common in patients with *HER2* exon 18/19 indels than wild type *HER2* (5% vs. 47.4%, $p < 0.01$). The rates of concurrent driver mutations in lung cancer were comparable between *HER2* exon 18/19 indels and the two established *HER2* drivers, exon 20 insertions and S310 mutations. The in vitro proliferation assay demonstrated that E698_P699insLL mutation in *HER2* exon 18 and L755_E757delinsPQ mutation in *HER2* exon 19 both conferred a survival advantage to Ba/F3 cells. Dose-response curves showed inhibitory effects on cell viability of several HER2 tyrosine kinase inhibitors including neratinib, lapatinib, poziotinib and afatinib. In particular, lapatinib, poziotinib and afatinib demonstrated comparable or stronger inhibitory ability toward the two *HER2* mutants than wild type *HER2* in terms of IC50. **Conclusions:** Our study revealed a novel class of *HER2* KD indels in exon 18/19 that may act as driver mutations in several cancer types. The drug response observed in vitro indicated the potential to use anti-*HER2* targeted therapies for *HER2* exon 18/19 indels. Further studies on this rare type of *HER2* mutation are warranted. Research Sponsor: None.

A prespecified interim analysis of the PATHFINDER study: Performance of a multicancer early detection test in support of clinical implementation. *First Author: Tomasz M. Beer, Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: A multi-cancer early detection (MCED) test that uses targeted methylation-based cfDNA technology to detect cancer and predict cancer signal origin (CSO) has potential to efficiently identify malignancies for which effective screening modalities do not exist. A previous version of a blood-based MCED test demonstrated favorable classification and test characteristics. Samples from the ongoing PATHFINDER study were reanalyzed in a prespecified interim analysis to evaluate performance of a more recent version of the test with an updated classifier (eg, updated CSO localization, hematological signal threshold) that is planned for clinical implementation as a general multi-cancer screening tool. **Methods:** PATHFINDER (NCT04241796) is an interventional, prospective study in which results (cancer signal detected/not detected and predicted CSO) using a previous version of the MCED test are returned to investigators, and those with a signal detected undergo further diagnostic testing. In this prespecified interim analysis, samples from those enrolled as of October 6, 2020 were reanalyzed with the more recent version of the MCED test (these results were not returned to investigators). The positive predictive value (PPV) for cancer detection, overall CSO accuracy, and concordance between the two test versions were assessed. **Results:** A total of 4011/4047 (99%) participants (pts) were analyzable (mean [SD] age 63.9 [8.7] years, 62% female, 92% white, 24% with prior cancer history, 39% ever smoker [4% current], 6% with genetic cancer predisposition). Cancer signal was detected in 0.95% (38/4011). A total of 27/38 also had signal detected by the previous version of the MCED test, including 19 who reached diagnostic resolution (13 with cancer diagnosis and 6 without); 11/38 were discordant positives. Nine different cancer types were detected in the 13 pts (2 stage I, 3 stage II, 2 stage III, and 3 stage IV); 1 had no AJCC stage expected, 1 metastatic recurrence and 1 stage evaluation underway. A conservative minimal PPV assuming all discordant positives are false positives, was 43.3% (13/30, 95% CI 27.4-60.8%) based on 19 pts with diagnostic resolution and 11 discordant positives. High negative percent agreement (PA) 99.7% (99.5-99.8%) between the two test versions was observed. Positive PA of 43.5% (95% CI, 31.9-55.9%) was consistent with the more stringent threshold for hematologic signal in the recent MCED version, as most discrepant cases had hematologic CSO with the previous MCED test. Among 13 detected cancers, accuracy of the top CSO prediction was 92.3% (12/13, 95% CI 66.7-99.6%). **Conclusions:** In this prespecified interim analysis, the more recent version of the MCED test detected cancers with high PPV and high accuracy of CSO prediction, supporting readiness for use in clinical practice. Full enrollment cohort data will be available at the meeting. Clinical trial information: NCT04241796. Research Sponsor: GRAIL, Inc.

Performance of a targeted methylation-based multi-cancer early detection test by race/ethnicity. *First Author: Wai Hong Wilson Tang, Cleveland Clinic, Cleveland, OH*

Background: Disparities in cancer screening and outcomes based on factors such as gender, socioeconomic status, and race/ethnicity are well documented.[1] The Circulating Cell-free Genome Atlas study (CCGA; NCT02889978) was designed to develop and validate a blood-based multi-cancer early detection (MCED) test analyzing plasma cell-free DNA (cfDNA) to detect cancer signals across multiple cancer types and simultaneously predict cancer signal origin. Findings stratified by race/ethnicity from the third and final CCGA validation sub-study are reported. **Methods:** CCGA is a prospective, multicenter, case-control, observational study with longitudinal follow-up (overall N = 15,254). In this pre-specified exploratory analysis from the third substudy, key objectives were to evaluate test performance for cancer signal detection (specificity, overall sensitivity, and sensitivity by clinical stage) among racial/ethnic groups. Plasma cfDNA from evaluable samples was analyzed using a targeted methylation bisulfite sequencing assay and a machine learning approach. Overall, 4077 participants comprised the independent validation set with confirmed status (cancer: n = 2823; non-cancer: n = 1254). The groups stratified by race/ethnicity were White Non-Hispanic, Black Non-Hispanic, Other Non-Hispanic (including but not limited to Asian, Native Hawaiian, Pacific Islander, American Indian, Alaska Native), Hispanic (all races), and Other/unknown. The study was not powered to detect statistical differences between groups. **Results:** Cancer and non-cancer groups were predominantly White (2316/2823, 82.0% and 996/1254, 79.4%, respectively). Across racial/ethnic groups, specificity for cancer signal detection was 99.6% (White Non-Hispanic: 992/996, 95% confidence interval [99.0-99.8%]), 100.0% (Black Non-Hispanic: 85/85 [95.7-100.0%]), 100.0% (Other Non-Hispanic: 33/33 [89.6-100.0%]), 98.1% (Hispanic: 101/103 [93.2-99.5%]), and 100% (Other/unknown: 37/37 [90.6-100.0%]). Despite slight differences in cancer type and staging across racial/ethnic groups, overall sensitivity for cancer signal detection among groups ranged from 43.9% to 63.0% (White Non-Hispanic: 50.5%, 1169/2316 [48.4-52.5%], Black Non-Hispanic: 53.9%, 104/193 [46.8-60.8%], Other Non-Hispanic: 43.9%, 25/57 [31.8-56.7%], Hispanic: 63.0%, 121/192 [56.0-69.5%], and Other/unknown: 52.3%, 34/65 [40.4-64.0%]). For all racial/ethnic groups, sensitivity generally increased with clinical stage (with limited exceptions at Stage IV in some groups with small sample sizes). **Conclusions:** The MCED test demonstrated consistent specificity and sensitivity across racial/ethnic groups, though results are limited by sample size for some groups. These findings indicate broad applicability and support clinical implementation of this MCED test on a population scale. 1. Zavela et al. Brit J Cancer 2021. Clinical trial information: NCT02889978. Detection of cancer signal for over 50 AJCC cancer types with a multi-cancer early-detection test. *First Author: Habte Aragaw Yimer, The U.S. Oncology Network, Tyler, TX*

Background: The Circulating Cell-free Genome Atlas study (CCGA; NCT02889978) previously demonstrated that a blood-based multi-cancer early detection (MCED) test utilizing cell-free DNA (cfDNA) sequencing in combination with machine learning could detect cancer signals across multiple cancer types and predict cancer signal origin. Cancer classes were defined within the CCGA study for sensitivity reporting. Separately, cancer types defined by the American Joint Committee on Cancer (AJCC) criteria, which outline unique staging requirements and reflect a distinct combination of anatomic site, histology and other biologic features, were assigned to each cancer participant using the same source data for primary site of origin and histologic type. Here, we report CCGA 'cancer class' designation and AJCC 'cancer type' assignment within the third and final CCGA3 validation substudy to better characterize the diversity of tumors across which a cancer signal could be detected with the MCED test that is nearing clinical availability. **Methods:** CCGA is a prospective, multicenter, case-control, observational study with longitudinal follow-up (overall population N = 15,254). Plasma cfDNA from evaluable samples was analyzed using a targeted methylation bisulfite sequencing assay and a machine learning approach, and test performance, including sensitivity, was assessed. For sensitivity reporting, CCGA cancer classes were assigned to cancer participants using a combination of the type of primary cancer reported by the site and tumor characteristics abstracted from the site pathology reports by GRAIL pathologists. Each cancer participant also was separately assigned an AJCC cancer type based on the same source data using AJCC staging manual (8th edition) classifications. **Results:** A total of 4077 participants comprised the independent validation set with confirmed status (cancer: n = 2823; non-cancer: n = 1254 with non-cancer status confirmed at year-one follow-up). Sensitivity was reported for 24 cancer classes (sample sizes ranged from 10 to 524 participants), as well as an "other" cancer class (59 participants). According to AJCC classification, the MCED test was found to detect cancer signals across 50+ AJCC cancer types, including some types not present in the training set; some cancer types had limited representation. **Conclusions:** This MCED test that is nearing clinical availability and was evaluated in the third CCGA substudy detected cancer signals across 50+ AJCC cancer types. Reporting CCGA cancer classes and AJCC cancer types demonstrates the ability of the MCED test to detect cancer signals across a set of diverse cancer types representing a wide range of biologic characteristics, including cancer types that the classifier has not been trained on, and supports its use on a population-wide scale. Clinical trial information: NCT02889978. Research Sponsor: GRAIL, Inc.

3073 **Poster Session**

Preliminary efficacy from an ongoing phase 1 dose escalation study of seclidemstat (SP-2577) in patients (pts) with advanced solid tumors (AST). *First Author: Sant P. Chawla, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Lysine-specific demethylase 1 (LSD1) is an epigenetic enzyme that is aberrantly expressed in many solid tumors. High levels of LSD1 expression are often correlated with poor patient prognosis due to LSD1's role in cancer cell proliferation, metastasis, and chemoresistance. Seclidemstat is a novel, selective, reversible and oral LSD1 inhibitor capable of inhibiting both LSD1's catalytic and scaffolding functions. We report preliminary efficacy in AST from an ongoing phase 1 trial. **Methods:** SALA-003-AC19 (NCT03895684) is a phase 1 trial of single agent SP-2577 in pts with AST. All pts had progressive disease (PD) at time of study entry. Pts received oral SP-2577 twice a day under fasting condition, in 28-day cycles (C). The primary objective is safety and tolerability. Secondary objectives are to determine maximum-tolerated dose, preliminary efficacy, pharmacokinetics, and pharmacodynamics. **Results:** As of December 30, 2020, 19 pts with AST (10 sarcoma, 2 prostate, 2 ovarian, 2 pancreatic, 1 renal, 1 cervical, 1 breast) were enrolled. Pts received escalating doses of SP-2577 from 150 to 600 mg BID and the dose escalation is ongoing. The median age was 63 years (range, 21–79). 42% were male, and pts had received a median of 4 (range, 1–8) prior systemic therapies. The most common (>5%) grade 3 treatment-related adverse events were GI related including diarrhea (5.3%) and abdominal pain (5.3%). No grade 4 events were reported and there were no treatment-related deaths. Safety data will be presented after completion of phase 1. Three pts had at least one dose reduction. Among the 13 pts who were evaluable for response at end of C2, 7 pts (54%) had best response of stable disease (SD) with median time to progression (TTP) of 4.3 months (range, 2.1–11.5). Four of the 7 pts had genetic abnormalities that may demonstrate increased sensitization to SP-2577 according to preclinical studies. Characteristics of 7 pts with SD at C2 and beyond are shown in the table. **Conclusions:** Seclidemstat has shown activity among advanced sarcoma pts with a manageable safety profile. The dose escalation is ongoing and preliminary clinical data supports further exploration in FET-translocated sarcoma as single agent and in combination therapy. Clinical trial information: NCT03895684. Research Sponsor: Salarius Pharmaceuticals Inc.

Diagnosis	Genetic Abnormality	# prior systemic treatments	Dose level (mg BID)	Best overall response	TTP (months)
Myxoid liposarcoma	FET-translocation: FUS-DDIT3	7	300	SD	7.2
Desmoplastic small round cell tumor	FET-translocation: EWSR1-WT1	5	600	SD	4.3
Extra-skeletal myxoid chondrosarcoma	FET-translocation: TAF15-CHN	1	600	SD	NA - not progressed at 5.7
Ovarian	Mutation in SMARCA4	5	600	SD	3.9
Leiomyosarcoma[1]	–	2	300	SD	11.5
Pleomorphic sarcoma[2]	–	1	600	SD	2.1
Prostate	–	5	300	SD	2.6

[1]Underwent wedge resection of target lung lesion after C2 and other residual lung lesions did not progress until 11.5 months.
[2]No PD, discontinued SP-2577 due to adverse events.

3074 **Poster Session**

First-in-human phase I study of the bifunctional EGFR/TGFβ fusion protein BCA101 in patients with EGFR-driven advanced solid cancers. *First Author: Filip Janku, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Therapeutic targeting of EGFR has demonstrated efficacy in common advanced malignancies such as colorectal cancer (CRC), squamous cell of the head and neck (SCCHN), and non-small cell lung cancer (NSCLC). TGFβ has protumorigenic effects on migration, invasion and tumor-specific immunosuppression, which may enhance the oncogenic effects of activated EGFR. Inhibition of EGFR signaling can lead to TGFβ upregulation as a resistance mechanism. BCA101 is a bifunctional recombinant fusion protein consisting of a chimeric anti-EGFR antibody and an extracellular domain (ECD) of human TGFβRII which demonstrated anti-tumor activity in several preclinical models. **Methods:** Patients with EGFR-driven advanced solid cancers refractory to standard therapies received BCA101 at escalating doses from 64 mg to 1000 mg intravenously (IV) weekly across 6 dose levels using a 3+3 design to determine dose limiting toxicities (DLT, established within 21 days of initial dosing), maximum tolerated dose (MTD) and/or recommended dose (RD). Secondary endpoints include detailed pharmacokinetic (PK), pharmacodynamic (PD) studies in serial tumor and/or blood samples and assessment of anti-tumor activity. **Results:** As of 2/11/2021, 21 patients received single agent BCA101 at 64 (n = 3), 240 (n = 7), 500 (n = 2), 750 (n = 3), 800 (n = 3) or 1000 (n = 3) mg IV weekly, including patients with CRC (n = 6), SCCHN (n = 5) uveal melanoma (n = 2), ovarian cancer (n = 2), glioblastoma multiforme (n = 2), conjunctival melanoma, chordoma, pancreatic cancer and anal squamous cell carcinoma (all n = 1). These patients had 1-7 prior lines of antineoplastic therapy (median 4), including 3 patients with prior EGFR inhibitor exposure. Adverse events (AE) related to BCA101 observed in >1 patient included grade (G) 1-2 rash (n = 9), G 1-2 lipase elevation (n = 2). G3 vitreous hemorrhage at the 240 mg dose level has been the only DLT. The MTD has not been reached and the RD will be based on safety, exposure and pending PD data. Saturation of the clearance was observed at doses above 500mg. Dose proportional increase in Cmax and AUC were observed with doses of 750-1000mg. Best RECISTv1.1 response was stable disease (SD) in 3/10 evaluable patients, with 1 patient on drug $\geq$4 months. **Conclusions:** BCA101 is well tolerated at biologically active doses. BCA101 is now being tested in combination with the PD-1 antibody pembrolizumab in patients with SCCHN and anal carcinoma. Clinical trial information: NCT04429542. Research Sponsor: Bicara Therapeutics.

3075 **Poster Session**

Phase 1 study of OKI-179, an oral class 1-selective depsipeptide HDAC inhibitor, in patients with advanced solid tumors: Final results. *First Author: Jodi A. Kagihara, University of Colorado, Aurora, CO*

Background: OKI-179 is a novel, oral pro-drug analog of largazole, a compound in the romidepsin-depsipeptide class of natural products. OKI-006, the active metabolite of OKI-179, inhibits HDAC 1,2,3 (IC_{50} = 1.2, 2.4, 2.0 nM, respectively), with no significant inhibition of Class IIa HDACs and has shown promising activity in preclinical models of solid tumors. We conducted a first-in-human dose escalation study of OKI-179 in patients with advanced solid tumors. **Methods:** Patients with advanced solid tumors, ECOG $\leq$1, normal QTc, and disease refractory to or with no available standard therapy options were treated with OKI-179 with either intermittent dosing (once daily for 4 days on 3 days off) or continuous dosing (once daily). Dose escalation was conducted using a standard 3+3 design. Pharmacokinetic (PK) and pharmacodynamic (PD) testing was performed at various time points after dosing. **Results:** As of Feb 4, 2021, 26 patients (19 female, 7 male) were enrolled with mean age of 63 (range 41-83). Patients received a median of 5 (range 1-11) prior lines of therapy and most common tumor types included pancreatic (N = 5), breast (N = 4), lung (N = 4), and ovarian cancer (N = 4). Twenty patients were treated in intermittent dosing cohorts from 30-450 mg. One DLT (Grade 2 [G2] thrombocytopenia) occurred in the 450 mg cohort which was expanded to 6 patients without subsequent DLTs. Six patients were treated in 2 continuous dosing cohorts of 200 mg and 300 mg. Two of 3 patients in the 300 mg cohort had DLTs of G3-4 thrombocytopenia and no DLTs were observed in 3 patients treated at 200 mg PO daily. The most common adverse events (AEs) were nausea (62%), fatigue (42%), anemia (39%), anorexia (27%), and vomiting (23%). These AE's were G1-2 except for G3 anemia (12%), G3 fatigue (12%), and G3 anorexia (4%). No other G4-5 treatment-related AEs occurred. Median time on study was 79 days and best response was stable disease (SD) in 10 of 24 patients evaluable for efficacy (42%). Prolonged SD was observed in patients with platinum-resistant serous ovarian cancer (446 days) and adenoid cystic nasopharyngeal carcinoma (256 days). OKI-006 achieved consistent exposure with $C_{max} > 2{,}000$ ng/ml and AUC $>$ 8,000 hr*ng/ml, well above the targeted exposure for efficacy based on pre-clinical studies in murine models. T_{max} was 2 hours and $T_{1/2}$ was 6-8 hours. OKI-179 treatment resulted in $>$ 3X increased T cell histone H3K9 and H3K27 acetylation within circulating PBMCs at doses of 180 - 450 mg. **Conclusions:** OKI-179 has a manageable safety profile, with thrombocytopenia being the on-target DLT. It has a favorable PK profile and demonstrated on-target PD effects at tolerable doses. The MTD and RP2D for OKI-179 was 450 mg daily for intermittent dosing and 200 mg daily for continuous dosing. Phase 2 studies are being designed, with a focus on combination with endocrine therapy in ER+ breast cancer and in NRAS-mutant melanoma. Clinical trial information: NCT03931681. Research Sponsor: OnKure, Inc, CU Cancer Center.

Patient-derived micro-organospheres recapitulate tumor microenvironment and heterogeneity for precision oncology. *First Author: Shengli Ding, Duke University, Durham, NC*

Background: Preclinical models that can recapitulate patients' intra-tumoral heterogeneity and microenvironment are crucial for tumor biology research and drug discovery. In particular, the ability to retain immune and other stromal cells in the microenvironment is vital for the development of immuno-oncology assays. However, current patient-derived organoid (PDO) models are largely devoid of immune components. **Methods:** We first developed an automated microfluidic and membrane platform that can generate tens of thousands of micro-organospheres from resected or biopsied clinical tumor specimens within an hour. We next characterized growth rate and drug response of micro-organospheres. Finally, extensive single-cell RNA-seq profiling were performed on both micro-organospheres and original tumor samples from lung, ovarian, kidney, and breast cancer patients. **Results:** Micro-organospheres derived from clinical tumor samples preserved all original tumor and stromal cells, including fibroblasts and all immune cell types. Single-cell analysis revealed that unsupervised clustering of tumor and non-tumor cells were identical between original tumors and the derived micro-organospheres. Quantification showed similar cell composition and percentages for all cell types and also preserved functional intra-tumoral heterogeneity.. An automated, end-to-end, high-throughput drug screening pipeline demonstrated that matched peripheral blood mononuclear cells (PBMCs) from the same patient added to micro-organospheres can be used to assess the efficacy of immunotherapy moieties. **Conclusions:** Micro-organospheres are a rapid and scalable platform to preserve patient tumor microenvironment and heterogeneity. This platform will be useful for precision oncology, drug discovery, and immunotherapy development. Funding sources: NIH U01 CA217514, U01 CA214300, Duke Woo Center for Big Data and Precision Health Research Sponsor: U.S. National Institutes of Health, Duke Woo Center.

Phase Ia study of CBP-1008, a bi-specific ligand drug conjugate targeting FRα and TRPV6, in patients with advanced solid tumors. *First Author: Jifang Gong, Peking University School of Oncology, Beijing, China*

Background: CBP-1008 is a first-in-class bi-specific ligand drug conjugate targeting folate receptor α (FRα) and vanilloid subfamily member 6 of transient receptor potential channels (TRPV6) with a high potency tublin inhibitor payload, monomethyl auristatin E (MMAE). A first-in-human, multicenter, phase I study of CBP-1008 (NCT 04740398) is ongoing, and we herein report the preliminary result of part A which is to evaluate the safety, tolerability, pharmacokinetics, and antitumor activity of CBP-1008 in solid tumors. **Methods:** Dose escalation commenced in single-patient cohorts for the first 2 planned dose levels and then followed by a standard 3 + 3 scheme. CBP-1008 was administered as intravenous infusion at escalating doses (0.015, 0.03, 0.12, 0.15, and 0.18 mg/kg). The primary endpoints were to determine the safety and maximum tolerated dose (MTD). Adverse events (AEs) and dose-limiting toxicities (DLTs) were evaluated. **Results:** Eighteen patients with advanced solid tumors who had failed multiple systemic treatment regimens were enrolled. The diseases include colorectal cancer (n = 7), breast cancer (n = 5), non-small cell lung cancer (n = 2), ovarian cancer (n = 2), adrenocortical carcinoma (n = 1), and follicular dendritic cell sarcoma (n = 1). The DLTs observed included grade 4 hypophosphatemia (0.15 mg/kg), grade 4 neutropenia (0.12, 0.15, and 0.18 mg/kg), grade 4 febrile neutropenia (FN) (0.18 mg/kg), grade 3 hyperglycemia (0.15 mg/kg), and grade 3 alanine aminotransferase (ALT) elevation (0.18 mg/kg). The most common all grade AEs suspected to be drug-related were fever (83.3%, totally limited to grade 1-2), aspartate aminotransferase (AST) elevation (72.2%, 5.6% evaluated as grade 3-4), leukopenia (66.7%, 27.8% as grade 3-4), neutropenia (66.7%, 38.9% as grade 3-4) and hypohemoglobinemia (55.6%, 5.6% as grade 3-4), with no drug-related deaths. MTD is estimated between 0.15 mg/kg and 0.18 mg/kg Q2W. Best overall response was partial response (PR) in 1 patient at 0.18 mg/kg and 4 patients (22.2%) achieved stable disease (SD). Responses occurred in patients with FRα and/or TRPV6 -positive expression advanced solid tumors. **Conclusions:** CBP-1008 has demonstrated acceptable safety profile. Tumor response correlating with dosing and FRα/TRPV6 receptor expression levels has been well observed. Clinical trial information: 04740398. Research Sponsor: Coherent Biopharma (Suzhou) Co., Ltd.

3078 **Poster Session**

First-in-human study of PM14 in patients with advanced solid tumors. *First Author: Maria Vieito, Hospital Vall d'Hebron, Barcelona, Spain*

Background: PM14 is a new chemical entity that forms DNA adducts which specifically inhibit RNA synthesis and block active transcription of protein-coding genes. Antitumor activity has been demonstrated *in vitro* in several cell lines (e.g. lung, kidney, prostate), and *in vivo* in mice bearing xenografted human-derived tumors (soft tissue sarcoma, small cell lung cancer, ovarian, gastric, breast and renal cancer). **Methods:** Open-label, dose-escalating, phase I trial of PM14 administered as a 3-hour infusion i.v. every 3 weeks (q3wk) in patients (pts) with advanced solid tumors, adequate organ function and ECOG PS score of 0-1. Two schedules were explored: Schedule A (Day 1 [D1], Day 8 [D8]) and Schedule B (D1). **Results:** 37 pts were treated (Schedule A/B: 28/9 pts). Baseline characteristics of pts (A/B): median age 56/47 years; male 57%/56%; ECOG PS 0: 57%/56%; median of prior lines (range): 3 (1-8)/4 (1-10). Most common tumor types (A + B): STS (n=7 pts), ovarian (n=6), pancreatic (n=4), prostate cancer (n=3). The maximum tolerated dose was 4.5 mg/m^2 for A (dose-limiting toxicities [DLTs]: D8 omission due to lack of recovery of lab parameters for re-treatment [n=2 pts]) and 5.6 mg/m^2 (DLTs: G4 febrile neutropenia [n=1], G4 transaminase increase [n=1]) for B. The recommended dose (RD) was 3.0 mg/m^2 on D1,D8 (A), and 4.5 mg/m^2 on D1 (B). No DLTs were present at the RDs. Most common toxicities were hematological abnormalities and transaminase increase. Main toxicities at the RDs are shown below. Antitumor activity comprised stable disease ≥4 months in 7 heavily pretreated pts (6 in A; 1 in B) at all dose levels. Linear pharmacokinetics were observed for PM14 at tested doses (0.25-5.6 mg/m^2), with geometric mean (CV%) total plasma clearance 5.9 L/h (88%), volume of distribution 128 L (81%) and median (range) terminal half-life 15.9 h (7.5-34.3 h). Less than 1.6% of administered dose was recovered in urine. **Conclusions:** RDs were determined for two PM14 schedules in pts with advanced solid tumors. At the RDs, PM14 is well tolerated and has a manageable safety profile. An expansion phase in specific tumor types, with an optional Bayesian continual reassessment method for RD fine-tuning, is ongoing with both schedules. Research Sponsor: PharmaMar SA, CDTI.

Clinical activity and safety of the RET inhibitor pralsetinib in patients with *RET* fusion-positive solid tumors: Update from the ARROW trial. *First Author: Vivek Subbiah, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *RET* fusions are targetable oncogenic drivers in multiple solid tumor types. ARROW study (NCT03037385) data supported the US FDA approval of pralsetinib, a once-daily (QD) oral highly potent and selective RET inhibitor, for *RET*-altered metastatic non-small cell lung cancer (NSCLC) and advanced/metastatic thyroid cancer. Here we provide an update on the clinical activity of pralsetinib in patients (pts) with advanced *RET* fusion-positive solid tumors other than NSCLC and thyroid cancer ("other" *RET* fusion–positive solid tumors). **Methods:** The global ongoing ARROW study (84 sites in 13 countries) includes phase 1 dose-escalation (30–600 mg [QD or twice daily]) and phase 2 expansion cohorts (400 mg QD) defined by tumor type and *RET* alteration status. Primary objectives are overall response rate (ORR; blinded independent central review per RECIST v1.1) and safety. **Results:** Updated analyses were completed as of Nov 6, 2020 (data cut-off) for 21 pts with other *RET* fusion–positive solid tumors enrolled by May 22, 2020 (enrollment cut-off) (lung other than NSCLC, n = 4; pancreatic, n = 3; colon, n = 3; cholangiocarcinoma, n = 3; unknown primary [UP], n = 2; other, n = 6). Overall, 11 (52%) pts received ≥2 prior lines of therapy for metastatic disease. The most common *RET* fusion partners were *CCDC6 and KIF5B* (24% each), *NCOA4* (19%), other (10%), and unknown (24%). Two pts with colon cancer were excluded from efficacy analyses due to other driver mutations (*KRAS*, *PIK3CB*). In 19 evaluable pts, ORR was 53% (95% CI, 29–76) with 2 (11%) complete responses (CR) and 8 (42%) partial responses (PR). Responses occurred across multiple tumor types including 3/3 pts with pancreatic cancer (including a CR ongoing at 20.8 months on treatment), 2/2 pts with UP, 2/3 pts with cholangiocarcinoma, and in pts with mesenchymal, salivary duct, and lung carcinoid tumors. Median duration of response was 19.0 months (95% CI, 5.5–not estimable). Clinical benefit rate (proportion with CR, PR, or stable disease persisting ≥16 weeks) was 68% (95% CI, 43–87). Tumor shrinkage was observed in 89% of 18 evaluable pts with post-baseline tumor assessment. In all pts enrolled in ARROW who received pralsetinib 400 mg QD irrespective of tumor type (n = 471) the most common (≥25%) treatment-related adverse events (TRAEs) were increased aspartate aminotransferase (39%), anemia (35%), increased alanine aminotransferase (28%), constipation (26%), and hypertension (25%). Overall, 6% of pts discontinued treatment due to TRAEs. **Conclusions:** Pralsetinib showed robust, durable antitumor activity in patients with multiple RET fusion–positive, heavily pre-treated, advanced solid tumors, and was well tolerated. These data highlight the need for broad *RET* testing to identify candidates who could benefit from treatment with pralsetinib. Enrollment of patients with other *RET* fusion–positive solid tumors in ARROW is ongoing. Clinical trial information: NCT03037385. Research Sponsor: Blueprint Medicines Corporation.

3080 **Poster Session**

A phase 1/2 trial of ORIN1001, a first-in-class IRE1 inhibitor, in patients with advanced solid tumors. *First Author: Nashat Y. Gabrail, Gabrail Cancer Center Research LLC, Canton, OH*

Background: ORIN1001 is a first-in-class small molecule with a novel, unique enzyme and mode of inhibition that selectively inhibits Inositol Requiring Enzyme 1α (IRE1) RNAse and blocks X-Box Binding Protein 1 (XBP1) activation in the endoplasmic reticulum (ER). IRE1α/XBP1 has been implicated in a host of pathologies, and molecules that modulate it are under intense investigation for the treatment of oncologic, metabolic, neurodegenerative and other diseases. ORIN1001 has demonstrated preclinical anti-tumor activity alone and in combination with standard of care across multiple animal models including breast, prostate, lung, liver, pancreatic, brain, colon, ovarian, esophageal, and hematologic cancers and is now undergoing first-in-human testing. **Methods:** A phase 1, open label, 3+3 dose escalation trial is testing ORIN1001 administered PO daily to patients (pts) with advanced solid tumors (single agent) or relapsed refractory breast cancer (in combination with Abraxane). The phase 1 dose escalation part of the trial evaluates the safety, tolerability, pharmacokinetics and preliminary efficacy of ORIN1001. After identification of the maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D) for the single agent, the dose expansion part of the trial will test ORIN1001 in combination with Abraxane. **Results:** As of Jan 25, 2021, 22 patients with advanced cancer have received ORIN1001 dosed at 100mg, 200mg or 300mg per day in 21-day continuous cycles with a median age of 61 (range 42-77). The pts had received a median of 4 prior line of treatments. Two DLTs were observed at 200 mg with thrombocytopenia and rash. MTD has not been reached. Common (>15%) treatment-emergent adverse events (TEAEs) included nausea, vomiting, rash, fatigue, and hypokalaemia. The vast majority of these events were Grade 1-2 in severity. Seven (32%) pts had at least 1 TRAE grade≥ 3, the most frequent of which were thrombocytopenia (N=3) and rash (N=3). Preliminary pharmacokinetic analysis showed ORIN1001 exposure to increase in a dose proportional manner. Mean $t_{1/2}$ at steady state was 18 hrs. Thirteen pts were evaluated for preliminary efficacy. Best response, per RECIST 1.1, was stable disease (SD) in 8 pts while 5 pts had progressive disease (PD). For 2 ongoing patients with advanced liver or colorectal cancer, duration of treatment has exceeded 300 days and 570 days, respectively. **Conclusions:** To date, the phase 1 part of the first-in-human trial has demonstrated a reasonable safety and pharmacokinetic profile for ORIN1001 at 100mg and 200mg dose levels. While efficacy data have yet to mature, chronic dosing achieved in pts with heavily treated advanced solid tumors, suggests clinical potential for in the setting of advanced solid cancers. The phase 2 part of the trial testing ORIN1001 in combination with Abraxane is currently enrolling pts with advanced breast cancer. Clinical trial information: NCT03950570. Research Sponsor: Shanghai Fosun Pharmaceutical Industrial Development Co., Ltd.
